Chapter 1	What's New in Flame Premium 2014	1
Chapter 2	Getting Started with the New Workflow	15
Chapter 3	Flame Premium Interface Overview	17
	About the Media Panel	18
	Media Icons and Selection Reference	19
Chapter 4	Managing Projects and Users	23
	Working with Projects	23
	Working with Users	30
Chapter 5	Organizing Media in the Workspace	33
	Changing Your View of the Flame Premium Workspace	38
	Generating Clips	38
	Displaying Media Metadata	39
	Managing Sequences	40
	Working in Thumbnails View	41
	Working with Reels	43
	Undo and Redo	47
Chapter 6	Setting Up a Flare Workflow	49
	About Flare	49
	Flare Workflow	49
	Considerations for Working in a Collaborative Environment	50
	Starting Flare	52
	Changing Projects and Users	52

Chapter 7	Importing and Exporting Media	55
	Importing File-Based Media	55
	Exporting Clips and Sequences to Files	56
	Supported Media File Formats	69
	Importing a Final Cut Pro XML Sequence	80
	Importing an AAF Sequence	101
	Importing an EDL Sequence	110
	MediaHub Reference: Browsing for Files	113
	Modifying Import Options After Import	153
	Working with Others	154
	Using Subtitles Files	157
	Conform Tab Overview	165
	Clip Input/Output Using a VTR	196
	Clip Output Using Real-Time Deliverables	230
Chapter 8	Archiving in Flame Premium	243
	Archiving a Project to a File-based Archive	244
	Restoring a Project from a File-based Archive	245
	Archiving Clips to a File-based Archive	246
	Restoring Material from a File-based Archive	247
	Tips for Using Archives	247
	Managing the Size of an Archive	249
	Configuring a Data Tape Device	249
	About VTR Archives	254
	Archiving to Multiple Volumes	259
	Supplementing Archives with System Drive Backups	259
	Restoring Legacy Archives	263
	Deleting Content from an Archive	265
	MediaHub Reference: Browsing for Archives	265
Chapter 9	Playing Back Media	267
	Playback	267
	Cue Marks	271
	Playback Options	272
	Color and Light Levels	275
	Preview options	276
	Changing Playback Scan Mode Options	276
	Enabling the Aspect Ratio Display	277
	Setting up the Image Display Viewer in the Tools	277
	Displaying the Reference Area	277
	Displaying Multiple Views	279
	Viewing Settings tab	282
Chapter 10	Editing Clips and Sequences	285
	Inserting a Clip on the Timeline	286
	Overwriting a Clip on the Timeline	288
	Replacing a Clip on the Timeline	289
	Other Editing Operations	289
	Timeline Editing Settings	292
	Trimming Clips	298
	About Timeline Tracks and Versions	305
	About Timeline Patching	307
	Navigating and Searching the Timeline	308
	Using Markers on the Timeline	310
	About Timeline Containers	310
	About Timeline Gaps	311
	Playing the Timeline	311

	Cutting Clips on the Timeline	312
	Swapping Timeline Elements	313
	Removing Elements From the Timeline	314
	Matching Clips with Their Sources	315
	Grouping and Syncing Elements on the Timeline	316
	Timeline Reference	318
Chapter 11	Editing on the Desktop	325
	About Editing on the Desktop	325
	Gestural Editing on the Desktop	325
	Ganging Clips on the Desktop	327
	Cutting Clips	327
	Splicing Clips	329
	Inserting Frames and Clips	330
	Replacing Frames and Clips	331
	Matching Clips with Their Sources	332
	Swapping Segments	333
	Hard Committing from the Desktop	334
	Rendering from the Desktop	335
Chapter 12	Audio	337
	Accessing the Audio Desk	337
	Importing Audio Files	338
	Monitoring Audio in Batch or Batch FX	338
	Adding an Audio Effect on a Segment	338
	Adjusting the Audio Levels on Part of an Audio Segment	339
	Cross-fading Two Audio Segments Together	339
	Fading Audio Into or Out of a Clip	339
	Scaling the Size of the Waveform	340
	Displaying Audio Waveforms	340
	Muting Audio Tracks	340
	Mapping Audio Tracks to Audio Desk Input Strips	340
	Converting Audio from Stereo to Mono or Mono to Stereo	341
Chapter 13	Timeline FX and Transitions	343
	Working with Timeline FX	343
	Working with Timeline Transitions	348
	Working with Timeline FX and Transition Presets	349
	Navigating Timeline FX and Transitions	349
	Adding Timeline FX to Gaps	350
	Working With Clip Format and Import Options on the Timeline	350
	2D Compositing on the Timeline	351
	Adding Matte Containers	351
	Working with Mattes and Masks on the Timeline	352
	Compositing in 3D Space on the Timeline Using Action	355
	Keying on the Timeline	356
Chapter 14	Creating New Sources Using Tools from the Tools Tab	359
	Accessing Tools	359
Chapter 15	Procedural Compositing with Batch and Batch FX	361
	Accessing Batch	361
	Creating Batch FX	362
	About the Batch and Batch FX Process Tree	364
	Adding Clips to the Process Tree	366
	Adding and Connecting Nodes to the Process Tree	380

	Selecting Nodes in the Schematic	386
	Adding Media to an Action Node	387
	Viewing Nodes in Context	390
	About Batch Rendering	391
	About BFX Output Nodes	399
	Saving and Loading Batch or Batch FX Setups	400
	Saving Sources with Batch Snapshots	401
	Using a Create BFX Clip for Caching or Versioning	402
	Using the Timing View to Offset Clips	402
	Caching Frames	404
	Grouping Nodes	406
	Mimicking, Copying, and Duplicating Nodes	410
	Customizing the Tools Bin	413
	Creating Custom Nodes	417
	Batch and Batch FX Preferences	418
Chapter 16	Compositing in 3D Space with Action	421
	About Action	421
	About Media	456
	About Axes	466
	About Surfaces	473
	About Stereoscopic Workflow in Action	501
	About the Perspective Grid	507
	About Lights and Lighting Effects	511
	About 3D Geometry	544
	About 3D Text	563
	About Shading and Textures	591
	About Atomize	647
	About 3D Paths	648
	About the Camera	654
	About the 3D Camera	671
	About the Analyzer	688
	About Source Nodes	711
	About Action GMasks	718
	About Action's Particle System	726
Chapter 17	Chroma Keying and Working with Green Screens	801
	Setting Up the Nodes and Media to Pull a Key	802
	Setting Up Viewports for Keying	804
	About the 3D Keyer	805
	Creating a Precise Key in the 3D Keyer	805
	Animating Key Elements	817
	Mastering the RGB Viewer	819
	More Keying Techniques	835
	Setting 3D Keyer Preferences	837
	Creating and Refining a Key in the Master Keyer	838
	Creating a Key by Extracting a Single Colour with the Channel Keyer	847
	Creating a Key by Extracting a Range of Colours with the HLS, YUV, RGB and RGBCMYL Keyers	848
	Creating a Key by Setting the Luminance	852
	Refining Your Key	852
	Resetting Your Key	866
	Rendering Your Key	866

What's New in Flame Premium 2014

1

Welcome to Autodesk Flame Premium 2014.

This release has many new creative features, performance enhancements, expanded media support, and many other improvements that come from your requests.

Here is a quick summary:

- [Timeline FX are now GPU accelerated](#) (page 1). There are also a number of [new and updated Timeline FX and transitions](#) (page 2) as well as [new and updated effects and tools in Batch and Batch FX](#) (page 3).
- There are [new surface tools](#) (page 4) and [surface tracking enhancements](#) (page 5) in Action, including the perspective surface type, which can now be tracked along with extended bicubic surfaces.
- [Tracking has been enhanced in the Stabilizer](#) (page 5) with, among other things, the ability to track an offset reference.
- Many media management features have been added, including:
 - [Expanded functionality, and improved performance and feedback in the MediaHub](#) (page 6).
 - [Support for new codecs](#) (page 6).
 - [Conform enhancements](#) (page 7), including [FCP X XML improvements](#) (page 7) and [improved EDL support](#) (page 7).
 - [Archive enhancements](#) (page 8).
- There are a number of [Player enhancements](#) (page 9) and [long-GOP format optimizations](#) (page 10).
- The [Media panel has been enhanced](#) (page 10) with new functionality, including the ability to apply colours to reels, determine the sorting order of media in the Media panel, and the ability to move and copy all open sequences to a new reel or folder.
- There are many [additions to colour grading in Lustre](#) (page 11), including [Lustre ShotReactor](#) (page 11) background rendering.

Read the following for complete details.

NOTE This topic and the entire online documentation are written for Flame Premium, which has all available features. For information on what features are specific to Autodesk Flare™, go to <http://www.autodesk.com/compare-flare/>. For all the other Linux products, see <http://www.autodesk.com/flame/compare/>.

Timeline FX Are Now GPU Accelerated

Reactor 2.0, the GPU-accelerated Batch pipeline, now supports the timeline (replacing the Soft Effects pipeline), improving both interactivity and the effects workflow, and bringing the performance of Timeline FX on par with the performance of associated nodes in Batch. Gone is the need to render a segment, a transition, anything, before being able to view and playback the applied effects. You still need to render before output.

Reactor 2.0 also provides 16-bit floating point precision throughout the application and has the added benefit of allowing you to rearrange the order in which the effects are applied to a segment.

New and Updated Timeline FX and Transitions

Image courtesy of The House

The reworked Timeline FX pipeline also means new effects, and familiar effects reworked and optimized to better match their more efficient Batch or Batch FX equivalent.

All Timeline FX are now consistent with their Batch or Batch FX node equivalents. This means their menus, functions, performances, and outputs are identical between the Timeline and Batch or Batch FX.

New and Updated Timeline FX

Timeline FX	Comments	Reactor-Enabled
2D Transform	New on the timeline.	yes
Action	This is a one-media-layer Action, with media and objects. Replaces Axis and Blend.	yes
Blur	New on the timeline.	yes
Colour Corrector and Colour Warper	Now stand-alone effects.	yes
Comp	New tool. Always found at the end of the segment pipeline, which allows quick compositing between tracks. Replaces Axis and Blend.	yes
Flip	New on the timeline.	yes
GMask	New on the timeline.	no
Timewarp	Updated for use from within the timeline.	yes
Resize		yes
Text	Timeline FX is now the same as the Text node in Batch.	no
Sparks		no

Timeline FX	Comments	Reactor-Enabled
Stereo Toolbox	New tool. Use this tool to edit the horizontal distance between content in the left and right input, mask out unwanted elements, and edit the position of Stereo3D content along the Z-axis.	yes

New and Updated Timeline Transitions

Pre-2014 Timeline Transition	New 2014 Timeline Transition
Dissolve	Dissolve
Wipe	Wipe
Axis	Action

See:

- [Timeline FX and Transitions](#) (page 343)
- [Compositing in 3D Space on the Timeline using Action](#) (page 355)

Presets Are Now Available for Timeline FX

A library of presets is available for certain Timeline FX and transitions. A preset can be applied as is to achieve a particular effect, or it can be tweaked as needed, also speeding up the process compared to customizing a Timeline FX from its default settings in the Editor.

All Timeline FX quick menus display a Presets box to the right of the Editor button. If the Presets button is enabled, then presets can be applied from the quick menu or in the Editor.

See [Working With Timeline FX Presets](#) (page 349).

New and Updated Effects and Tools

Effects and tools in Batch and Batch FX that have equivalents in the timeline are now RGBA.

New and Updated Effects and Tools

Timeline FX	Comments
2D Transform (page 1238)	Matte offset axis controls are now available in the Matte Offset menu tab.

Timeline FX	Comments
Comp (page 1287)	Use the Comp node to blend two inputs and their mattes, to create a result and output matte. The Comp node replaces Logic Ops and Quick Comp.
Matchbox (page 1402)	<p>The Variables shader allows you to set numeric and position values which can then be linked to one or more variables in the expressions of animation channels of other nodes. You can customize the Variables tab menu interface to add additional variables and edit variable names. The Display Name parameter in the shader's XML file controls variable names as they appear in the user interface.</p> <p>TIP It is recommended that you copy the original <i>Variables.xml</i>, <i>Variables.glsl</i> and <i>Variables.glsl.p</i> files, rename them and work in the renamed files.</p>
MUX (page 1422)	As many RGBA inputs as needed can be set, and the selection of the active input can be animated over time. You can think of the MUX node as an animated switcher.
Stereo Toolbox (page 1453)	Same as the Timeline FX.
Timewarp (page 1481)	Same as the Timeline FX, with small differences based on where it is accessed from (timeline versus Batch).

New Surface Tools and Enhancements in Action

- New Perspective surface type in Action, in Flame Premium 2014.
The Perspective surface type is similar to the Bilinear surface, except that it plots a perspective transform that does not introduce distortion at the four corners.
- New surface tools in the Object menu in Action enhance your ability to create and refine 3D warping effects, providing you the ability to:
 - Map UV textures to surfaces.
 - Use the Object View in the Surfaces menu to view UV points. Display this view with the F8 keyboard shortcut.
 - Slide a texture under vertices, without moving the vertices, effectively moving the UV points behind the scene.
 - Move UV points and vertices simultaneously without any deformation.
 - Extrapolate a texture beyond the geometry, in X and Y. You can assign negative extrapolation values and effectively crop the texture.
 - Crop the parts of the image that are outside of the geometry, or let the texture go beyond the surface wireframe. Available for perspective and bilinear surfaces only.

- You can also now merge the subdivisions back in the Extended Bicubic surface, without having to undo and lose all operations applied to the surface.
- See:
 - [Modifying Surfaces](#) (page 474)
 - [UV Points Settings](#) (page 480)
 - [Surface Settings](#) (page 474)

Surface Tracking Enhancements in Action

Image courtesy of P. Fua, CVLab, EPFL, Switzerland

- Perspective and extended bicubic surface tracking is now available in Action. Use perspective tracking to straighten out elements captured at an angle in the scene, to insert surface elements with camera motion and to replace logos. Use extended bicubic tracking to track complex surfaces that move in 3D space. Extended bicubic tracking is particularly useful for tracking non-rigid objects, like faces and bodies, because the vertices and the UV points can be tracked individually. Extended bicubic surface tracking is available in Flame Premium only.
- There is a new Shape channel that you can use to control surface transformations, without changing the tracking data that is generated by analysis.
- An Axis transformation selection (position, rotation, scale) is now available for tracking of selected surface UV points and vertices.
- See:
 - [Perspective Surface Tracking](#) (page 890)
 - [Extended Bicubic Surface Tracking](#) (page 886)
 - [Adjusting the Surface with the User Shape Channel](#) (page 896)

Enhanced Tracking in the Stabilizer

There is a new offset reference mode in the Stabilizer to help track challenging elements that do not have adequate tracking anchor points, such as those that go off screen or are occluded during the analyze process. When tracking using the Offset Reference, you apply the tracking information from one point to another point in the image. A dotted line is displayed between the tracker and the offset target.

Other Stabilizer enhancements include:

- The ability to reposition a reference point to another location during an analyze process for greater accuracy.
- Forward and backward tracking.
- Start tracking at any frame of a clip.
- Resetting the trackers now switches back to Select mode.
- The current time keyframe of the motion path is now highlighted with a different colour than the rest of the keyframes in the motion path.

See [Offsetting the Tracking Motion of the Reference](#) (page 894).

MediaHub Enhancements

- The MediaHub now provides additional contextual information to help you understand what is happening in the background. In addition to the existing read-only status of the displayed folder, the MediaHub status bar now displays:
 - The name of the folder being scanned by the MediaHub.
 - The names of the compatible media files found in the scanned folder.
- You can now delete EDL, AAF, and XML files from the filesystem from the MediaHub.
- In the List view of the MediaHub, the File Location column is now larger and displays longer media locations.
- Faster AVCHD media browsing

Long AVCHD media files can take a long time before being seen in MediaHub. MediaHub now stores an index file at the same location of the media file (if file system is writeable by the application) so the next time any users browse to this location, the clip listing in MediaHub will be faster.

Index files are created as a non listed file (<filename>.MTS.index). If the file system is read-only, these files are created in /var/tmp as <full original media file path>/<filename>.MTS.index)

NOTE For file management purposes, the index files are very small (a few KB at the most) and it is safe to remove these files. MediaHub regenerates them as needed when browsing AVCHD files without an index file.

Media Import Improvements

- The following codecs are now supported:
 - Sony XAVC in HD and 4K.
 - Sony XDCAM HD, XDCAM EX and XDCAM 422 format in QuickTime files.
 - 1080/60p timing in Panasonic AVC-Intra Class 100 clips.
 - Panasonic AVC-Intra Class 200.
 - OpenEXR 2.0.
- Decoding and playback optimization. The multi-part and deep pixel features are not supported: only the first part of a multi-part file can be accessed, and deep pixel channels are ignored.
- The Film Keycode database has been updated with the latest film stocks codes used with DPX.

See:

- [Supported Media File Formats](#) (page 69)

- [About Supported XDCAM Formats](#) (page 79)
- [About Keycode](#) (page 126)

Conform Enhancements

FCP X XML Improvements

The following effects are now supported when conforming XML sequence from FCP X (10.0.4 and later).

- Position (translated as 2D Transform with X and Y positioning).
- Scaling (translated as 2D Transform with X and Y scaling).
- Rotation (translated as 2D Transform with Z scaling).
- Transparency (translated as Comp transparency).
- Compositing mode (translated as Comp with corresponding Blend mode).
- Text (only the text string is translated as Text with RGBA option and Comp with premultiplied option).

See [FCP X Sequence Import: Supported Transitions and Effects](#) (page 98).

Improved EDL Support

You can now import Edit Decision Lists through MediaHub just as you would an Avid AAF or an Apple Final Cut pro XML, to conform a sequence.

- In MediaHub, there is a new EDL Options tab where you can define various EDL import options such as frame rate and resolution.
- You can now import multiple EDLs and get these EDLs assembled within the same sequence, using the Multi-Assemble option. The selected EDLs will be assembled on video tracks based on the selection order.
- It is now possible to import a folder that contains multiple EDLs based on the Multi-Assemble option. The EDLs create either a single video track sequence, or a single sequence with multiple video tracks. Alphabetical order is used to determine the destination video track when Multi-Assemble option is enabled.
- The user interface of the EDL Editor Import Options has been slightly modified to match the MediaHub EDL Options.
- Through the MediaHub, Flame Premium can automatically relink an imported EDL to its media files, if the file paths are stored in the DLEDL comments. These DLEDL comments are part of any EDL Publish generated by an **Export...** ➤ **Sequence Publish** from Flame Premium.

See [Importing an EDL Sequence](#) (page 110).

Other Notable Conform Improvements

- Improved feedback when loading an EDL, AAF, or FCP XML.
Loading a sequence window now has more feedback, which should help you see what is happening in the background. When you import a sequence, a progress message provides you with the name of the media files being scanned, in addition to the existing progress bar.
- Improved relink.
In the Conform tab, you can now easily relink unlinked sequences, if the segments store the path to the media.
- A File Location column can now be found in the Conform event list.
- The selected Match Criteria is now saved per user.

See [Relinking Media](#) (page 167).

Export Format Improvements

- Extended OpenEXR Export.

OpenEXR exports now support RLE (Run-Length Encoding) compression.

- Apple Final Cut Pro X XML Export.

It is now possible to Publish a sequence as a Final Cut Pro X XML with a corresponding QuickTime movie. The export results in a flattened, committed sequence published as an FCP X XML file, with a 10-bit YUV QuickTime file with 48kHz audio reference file (audio tracks are exported as-is, without any mixdown). These two files are created in a new folder named after the sequence. Media Export Presets are available.

When you open the XML in FCP X, the media automatically relinks if exported to a file location available on the FCP X workstation. You might have to use the FCP X Relink tool to link the XML sequence back to the YUV QuickTime if the media file path is different.

NOTE If you export to a Mac Wiretap Gateway server, you have the added option of exporting the reference file as a ProRes QuickTime.

- EDL Sequence Publish with References to the Original Media Files.

When you export a sequence as a Sequence Publish with EDL, and if you disable both Export Video Media and Export Audio Media, the resulting EDL will contain the paths to the original media files. Such paths are stored in the resulting EDL as DLEDL comments.

See [Exporting Clips and Sequences to Files](#) (page 56).

Other Notable Export Improvements

- Improved File Padding.

It is now possible to export a single file clip without any file numbering. Set the Frame Padding field to zero.

You can also create an export preset with padding set to 0. And to avoid overwriting media files, when padding is set 0, file sequences for clips that have more than one frame are named using a padding of 8 digits.

- Preserved Export Preset Edits.

Flame Premium can now temporarily store the edits you made to a preset in a *_custom* preset: just edit a preset in Show Advanced Options, and it is temporarily appended the *_custom* flag. These temporary settings remain between exports, and last until you change preset or quit Flame Premium.

Saving the edited preset is still the option if you need a more persistent solution.

- Larger Export Preset Description Field.

In the Media Export window, the Preset Description field can now contain up to four lines of text.

Archive Enhancements

- Improved Cached Media and Timeline FX Renders Management.

When archiving, you can now enable Cache Media on Archive to force the archiving of all the clips as cached media. This means that all media is cached in the archive using an uncompressed format. Use the new Archive Renders box to decide whether or not to archive Timeline FX renders.

When you disable Cache Media on Archive, already cached source media is archived. Clips with uncached source media are archived, but their source media is not. And if Cache Media on Archive is disabled, you can go one step further in your archive size management by using the new Archive Renders box to discard or keep Timeline FX renders and already cached media.

- Improved Archive Queue Management.

You can now remove any not-yet-archived clip from the pending archive folder. Use this new feature to remove superfluous clips from a folder you drag-and-dropped to the archive: just right-click the item to remove and select Clear Pending Selection.

Removing a clip from the pending archive folder does not delete material from the archive, it only removes clips from the list of things yet to be archived: nothing greyed out is committed to the archive until you click Archive.

- Multiple users can open a file archive as read-only. Only the first user to open the archive can write to it.

See:

- [Archiving a Project to a File-based Archive](#) (page 244)
- [Archiving Clips to a File-based Archive](#) (page 246)
- [Restoring Material from a File-based Archive](#) (page 247)
- [Tips for Using Archives](#) (page 247)
- [Managing the Size of an Archive](#) (page 249)

Other Notable Timeline Enhancements

- New methods are now available to help you quickly patch tracks on the timeline. See [About Timeline Patching](#) (page 307).
- The broadcast monitor is now enabled for Trim View. In Screen Grab mode, the UI is displayed; while in Show Selected Item mode, the selected trim viewport is displayed, or if both sides of the trim are selected, you can hover over the desired viewport to display it in the broadcast monitor.
- Performing a Lift or Ripple Delete (Extract) operation on the timeline does not delete a segment between marks if another explicit selection is made.
- New options are now available to you when you enter Batch FX. See [Creating Batch FX](#) (page 362).

Other Notable Action Enhancements

- The Analyzer node is now available in Autodesk Smoke[®] Advanced and Autodesk Flint[®]. Use Action's Analyzer to compute the path of live-action camera and object motion in 3D space. Using the calculated position and motion of the virtual camera, you can match image sequences perfectly, placing any element in the scene. See [About the Analyzer](#) (page 688).
- Projection is now available as a Texture Mapping type for Parallax and Hardware Displacement maps, along with the other maps where it was previously supported.
- When working with a Perspective Grid node in Action, you are now able to adjust the width and height settings in the menu (they were previously non-editable fields). When adjusting the grid directly in the image window, you can use the new Grid Mode box to choose whether to adjust only the width, only the height, or to apply no size adjustment (in this case, only the Z Offset is updated).
- When tracking or stabilizing an Action Axis node, you now have access to an Adjust Offset button, that allows you to set a reference frame that has no transformation data.
- Background media is now supported when working with Surface, GMask, and Analyzer mono nodes in Action. In the schematic, a zero (0) indicates Back media next to the name of the node.

Player Enhancements

- Triptych view is now available from all editors with multiview capabilities. Coloured positioners help you identify clips in Triptych view, and new Positioner options allow you to set the behaviour of the viewports (such as All Synced or All Free).
- In Timeline FX editors and Batch FX, you are now able to choose which range to display on the timebar (Segment, Media, or Timeline).

NOTE The triptych and range settings can be found in the new Options box (next to the playback controls) in the effects editors and Batch or Batch FX. This new Options menu also has options to display audio waveforms and cue marks.

Long-GOP Format Optimizations

The decoding of long-GOP codecs has been optimized to improve performances during:

- Forward & backward playback.
- Scrubbing, jogging, and shuttling.

This applies to all QuickTime, MXF, and MTS media containers with long-GOP codecs, including H.264 and AVCHD.

Media Panel Enhancements

- You can now assign colours to selected reels, folders, and Libraries in the Media Panel, from the contextual menu.

NOTE Does not apply to Batch Sources, Snapshots or Shared Libraries.

- You can now determine the sorting order of media in the Media panel. Right-click on the Media panel header and select the sorting order. You can choose between Ascending, Descending, and Clear Sort, which enables custom sort.
- You can now move or copy all open sequences to a new reel or a new folder, by placing the cursor over an open sequence tab and selecting the appropriate option from the contextual menu.

NOTE This can also be achieved by dragging the sequence handle to the left of the tabs in the timeline and dropping it in the Desktop section of the Media panel or the Media Library. You are prompted to select whether to move or copy the sequences to the new location.

Other Notable Enhancements

- Stereo 3D updates.

When grading Stereo 3D content, it may happen that certain elements of the scene are present in one eye but not the other. It is now possible to apply a Floating Window that crops part of Stereo 3D content that is only displayed in one eye, preserving the 3D illusion.

The Floating Window tool is located in the Stereo Toolbox menu. See [Stereo Toolbox](#) (page 1455).

- Colour Management updates.

New transforms are available to support version 0.2 of the ACES system. The corresponding CTF files include "v0.2" in their names.

- New Preferences.

- **Storage tab ► Temporary Libraries ► Clear All button**

Click to delete temporary libraries from the current project. Do not use if background operations are running. Use the Background Tasks monitor to ensure all tasks are done before using.

Temporary libraries are used by background tasks, and are usually automatically deleted by Flame Premium. But if they are not deleted correctly, they can build up over time and tax your storage. Clearing these libraries recovers that lost space. This is a safe operation unless background operations are running: wait for them to complete before clearing the temporary libraries.

- **General tab ► Default Rendering Options ► Rendering Display box**

Improvements were made to rendering in the application. You can select between a normal rendering display that synchronizes the new image display with the refresh rate of the monitor. Alternatively, select to display a rendered image before the refresh cycle is completed, resulting in a reduced total rendering time for the clip. During rendering, this may result in tearing of the image.

Select whether to display all frames as they are rendered or to allow the display of all frames with potential tearing.

- Updates to Project Management.

From the Startup screen, you can now copy a project from a previous version instead of just converting it. This allows you to have a copy of the project that remains compatible with the previous version while being able to use the converted project in the current version.

The converted project keeps the original name. The copy gets appended with the version of Flame Premium with which it is compatible.

Lustre project settings are also updated to reflect the changes.

- New graphical installer and Setup Application.
- UHDTV resolutions New frame size presets for the UHDTV standard (7680x4320 & 3840x2160) have been added in tools and dialog boxes where a resolution can be defined such as Resize, Colour Source, Project Management.

What's New in Flame Premium Grading - Lustre 2014

Lustre ShotReactor

Lustre ShotReactor is a background rendering service that automatically renders grading decisions when you navigate away from the last shot you graded. Lustre automatically detects any changes to the grade and only sends those changes to the ShotReactor.

ShotReactor can be configured in two ways.

- On your local Workstation (this is the default configuration).
- On a remote server.

NOTE Running a rendering service such as ShotReactor on the creative workstation as a background task may impact interaction and playback performance, based on the resolution of your project, the configuration of the workstation, etc.

See [Rendering Shots as You Work](#) (page 2274).

Stereo 3D

- Floating Window.

When grading Stereo 3D content, it may happen that certain elements of the scene are present in one eye but not the other. It is now possible to apply a Floating Window that crops part of Stereo 3D content that is only displayed in one eye, preserving the 3D illusion.

See [Using the Floating Window](#) (page 2252).

- Floating Window Lock.

Floating Window parameters can be locked using the Tool Locking feature.

- Support for 2048x1080 rasters.

Stereo mode now supports for 2048x1080 rasters at various rates.

ASC Color Decision List (ASC CDL)

- Cut-based CDL Data.

When you import an EDL with CDL comments, or a sequence with CDL data from Smoke or Flame, the CDL data is stored in the Cut file. If you modify that CDL data, it gets saved with the Grade. This means that you can revert back to the original CDL data, by reloading the original Cut.

NOTE If you create the CDL data in Lustre, from scratch, it is only stored in the Grade, not the Cut.

- EDL Export with CDL Data.

It is now possible to export an EDL from Lustre with CDL data. The CDL data is either stored in the Cut or the Grade (see above).

- Lock CDL Tool.

The Use CDL button can now be locked, using the Tools Locking feature.

See:

- [Colour Decision List \(CDL\)](#) (page 1949)
- [Importing an EDL, ALE, or Cutlist File](#) (page 1939)
- [Exporting Shots to an EDL](#) (page 1945)

Interoperability with Smoke and Flame

ASC CDL comments from a sequence conformed in Smoke or Flame are now supported in Lustre.

Animation Editor

- Curves Copy & Paste to/from any channel.
You can now copy and paste animation curves to and from any channel in the Animation Editor.
- New Curves Functions.
Lustre now supports all of the same curves functions as Flame and Smoke.
- Secondaries Master Axis.
In the Animation Editor, it is now possible to control the following parameters for all shapes on all secondaries for a shot:
 - Center X
 - Center Y
 - Offset X
 - Offset Y
 - Rotate Z
 - Scale X
 - Scale Y

See:

- [Copying and Pasting Keyframes](#) (page 2235)
- [Animation Controls](#) (page 2217)
- [Transforming All Geometries With the Secondaries Master Axis](#) (page 2144)

Editing

- Support for Flags, Notes, and Group in Change Cut.
Flags, notes and Group settings are now carried over when you perform a Change Cut.
- Match Cut flags for Change Cut.
It is now easier to see to which shots in the sequence grading decisions were applied from a previous version of the sequence when performing a Change Cut:
 - Thumbnails of shots to which grading decision were applied from a Change Cut are updated with the new grade.
 - Thumbnails of shots to which grading decision were applied from a Change Cut, based on partial matching are updated with the new grade and display the Partial Match Flag (orange flag).
 - Thumbnail of shots to which grading decision were not applied from a Change Cut are shown with the Failed Match (red flag). This is due to non-matching criteria or to new shots having been added to the sequence that require grading.
- Partial Matching for Change Cut.

When performing a Change Cut, Lustre uses the various Match options to transfer grading decisions from one cut to another. By default, Strict Matching is enabled and the criteria have to match exactly. In some visual effects workflows however, it happens that file names differ between editorial versions even though they are comprised of the same shots. For these cases, you can now perform partial matching using the Custom Match option and disabling Strict matching. In the following examples, a match can be made based on partial criteria:

- The original sequence name is seq1_shot1_version1, while the updated sequence name is seq1_shot1_version2.
- The Change Cut is performed based on a Custom/DLEDL Clip name.

When a match is based on partial criteria, the partial match flag is displayed in the Storyboard.

- Storyboard content re-ordering when working with a Collapsed Group.

You can now reorder shots in Storyboard view when working with a Collapsed Group.

- Gang/Solo new colour.

When enabling the Solo mode while working with grouped shots, the storyboard thumbnails outline for the shots that are not soloed is now grey, making it easy to identify the currently soloed shot.

See:

- [Partial Matching for Change Cut](#) (page 1827)
- [Reordering Shots in a Collapsed Group](#) (page 1860)

Media Import and Export

- The following codecs are now supported on import:

- Sony XAVC in HD and 4K.
- Sony XDCAM HD, XDCAM EX and XDCAM 422 format in QuickTime files.
- 1080/60p timing in Panasonic AVC-Intra Class 100 clips.
- Panasonic AVC-Intra Class 200
- RGBA OpenEXR.

NOTE Lustre does not render RGBA OpenEXR files. Do not use the Same As Scans rendering option. Use the OpenEXR RGB rendering option if you want to render 16-bit half float media files.

- OpenEXR 2.0.

Decoding and playback optimization. The multi-part and deep pixel features are not supported: only the first part of a multi-part file can be accessed, and deep pixel channels are ignored.

NOTE The resolution of the matte channels has to be identical to the one of the beauty pass that will be used for secondary color grading.

- The Film Keycode database has been updated with the latest film stocks codes used with DPX.
- Lustre now supports exporting OpenEXR with RLE (Run-Length Encoding) compression.

See [Wiretap Gateway Supported Media File Formats](#) (page 1902).

Project Management

- Grade Loading Option at Startup.

You now have a preference, in the Project Settings, to load a grade at startup. Options are:

- Project Based: Loads the last grade used in the project.
- User Based: Loads the last grade used by the current user.

- **Never Load:** Does not load a grade at startup.
- **Copy Project Locations for Burn and ShotReactor.**
You can now copy the project location paths from the project settings to the Network Rendering settings menu, by clicking the From Project button.
- **Show Notes on On-Screen View.**
When activating the On-Screen View mode (`Ctrl+W`), the notes you added to the shot are displayed alongside the shot name.
- **ShotReactor Job Priority.**
You can define whether jobs sent to ShotReactor are placed at the start or the end of the background rendering queue.

See:

- [Project Settings](#) (page 1784)
- [Network Rendering Settings](#) (page 1799)

User Interface

- **Select All keyboard shortcut in text fields.**
You can now use the `Ctrl+A` keyboard shortcut to select all the text displayed in the application's text fields.
- **`Ctrl-Delete` (Delete without confirmation).**
You can now delete saved grades from the Grade Bin without needing to confirm, by using the `Ctrl+Delete` keyboard shortcut.
- **Message when loading & saving Grade Bin and Preset.**
A confirmation message is now displayed in the user interface when loading and saving grades in the Grade Bin, as well as Presets.
- **Grade Bin cursor issue with Grade Bin containing a lot of content.**
The Grade Bin scroll bar now remains large enough to select, even when the Grade Bin contains a lot of content.

Getting Started with the New Workflow

2

Welcome to the New Unified Creative Workflow

In this topic, we provide:

- An explanation of the changes we made to the interface
- Discussion of the benefits you can get in the new workflow
- Videos demonstrating the enhancements in the interface
- Tips for navigating the interface
- Answers to common questions

We hope this help you speed up your transition to the new workflow.

Why did you change the UI so drastically? The old one worked fine, and now I have to retrain my muscle memory!

Unifying the Desktop, Batch and Timeline into one workspace allows us to treat your data more efficiently and provide you with centralized access to functions that were once limited to modules.

Think of the Desktop, the Timeline, and Batch as 3-different views of your media. Each of these views provides unique ways of visualizing and interacting with your media.

Now that these views have been surfaced to the same level, you will get significant gains in productivity and creativity.

Talk to me about the creative benefits. What benefit is there to having the Timeline and Desktop together?

Together, the Timeline and the Desktop are a very powerful editorial and visualization tool. With the two, you get detailed editorial information, with powerful Desktop visualization and visual editing tools.

What creative benefit is there to having Batch in a tab?

By promoting Batch to the same level in the interface, we have made it possible for you to use Batch more powerfully for creative tasks.

You have talked about some of the creative benefits, what about productivity benefits?

These are some of the productivity benefits you will see:

- You can unlink and reformat clips right from the Desktop.
- Iterating in Batch is even more efficient than it was with the old Desktop tools because of its integration with the workspace.

- It's more efficient to save your Batch flowgraph and media for future edits with BFX clips than saving and reloading setups.
- It is easier to manage iterations of media from the Media panel. Dragging clips from the Media Library to any location creates a copy automatically. Media in the Media Library is protected from editing by default.

How do I protect my clips from being edited? I used to use the Clip Library as my safety backup. How do I do that now?

The Media Library in the Media panel provides a similar workflow as the previous Clip Library. In addition, there are a number of ways that you can save and version your work in the 20th Anniversary Edition.

Where has the Record Area gone?

Although we no longer have the concept of a Record Area in the application, you can replicate some of the Record Area functionality using features in the 20th Anniversary Edition.

How do I navigate quickly between the different areas of the interface?

- Shift + ESC = Show/Hide the Media panel
- Spacebar + F1 = MediaHub tab
- Spacebar + F2 = Conform tab
- Spacebar + F3 = Timeline tab
- Spacebar + F4 = Batch tab
- Spacebar + F5 = Tools tab
- Open the timeline of a clip: double-click the clip.
- Go to the Batch schematic: double-click the Batch label in the Media Library.
- Go to the Desktop: double-click the Desktop label in the Media library.

Flame Premium Interface Overview

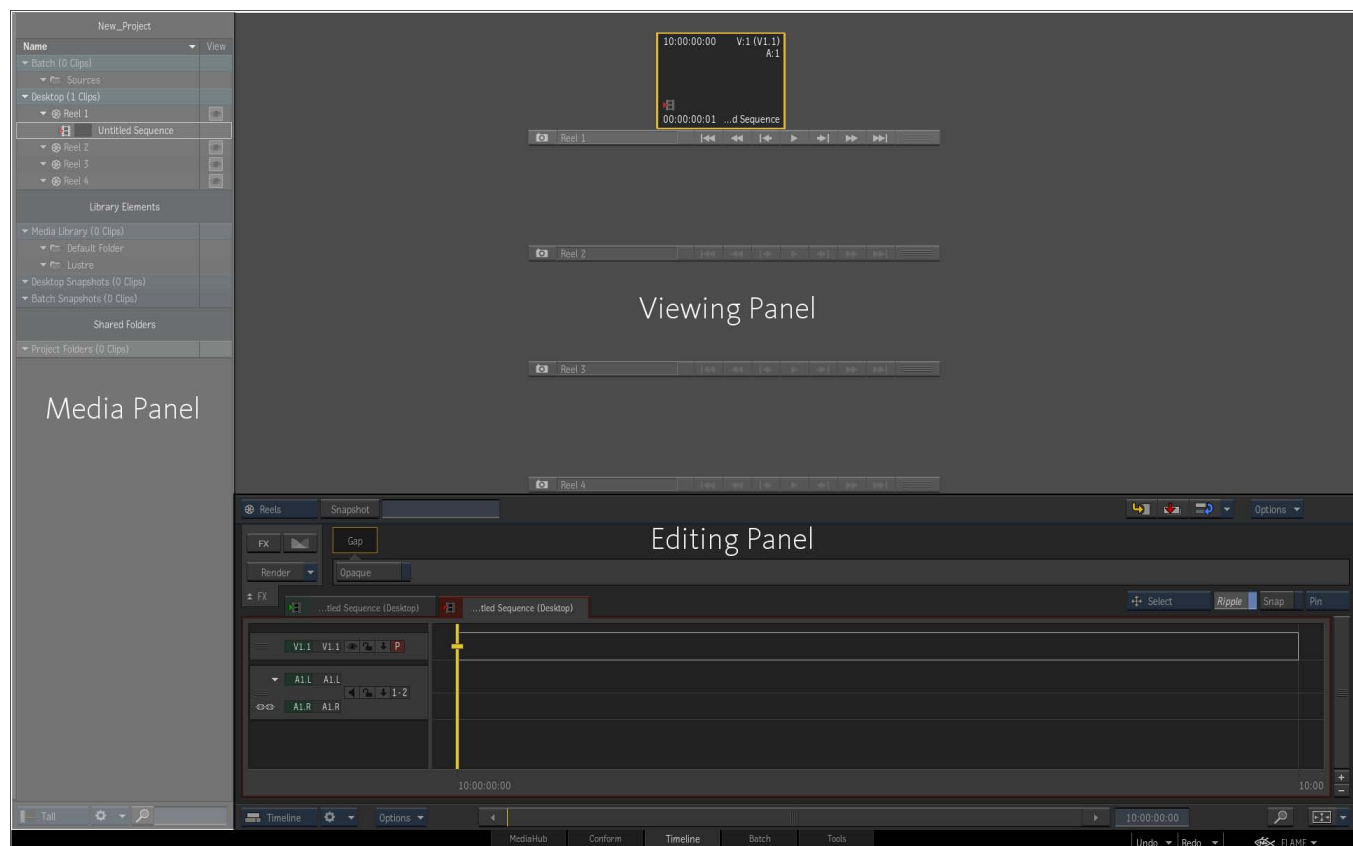

3

The workspace is where you accomplish all of your project tasks. The workspace consists of three main panels:

- The Media panel
- The Viewing panel
- The Editing panel

Each panel has its own menu bar with commands specific to the tasks you can perform in that space.

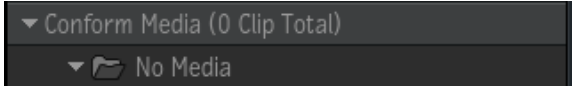

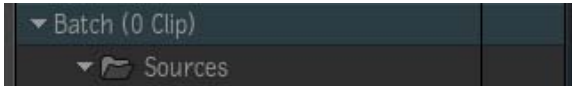

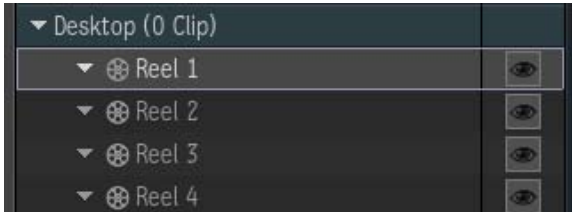

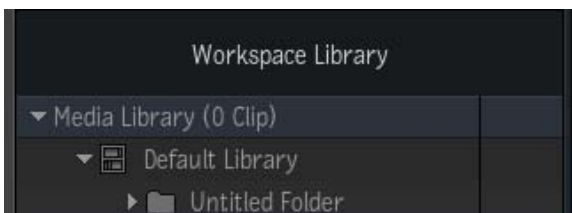

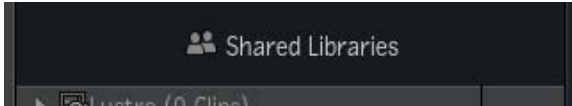

At the bottom of the user interface is a series of five tabs. Each tab gives you access to different views within the application. Regardless of which view you are in, you remain in the same environment.

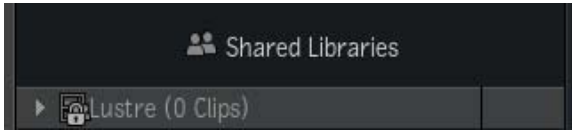

About the Media Panel

The Media panel is the centralized location where you organize all of your project media.

NOTE When you launch Flame for the first time, the Media panel is not displayed. To display it, from the Media panel View Mode box, deselect Hidden.

Section:	Description:
	Project Name: The name of your current project is displayed at the top.
	Workspace Name: The name of your current workspace is displayed under the project name, if there are multiple workspaces available for that project.
	Conform Media: Any conform media imported in the application is displayed in the Conform Media section. This section is only displayed while in Conform view.
	Batch Sources: Any media used in Batch is displayed in the Batch Sources section.
	Desktop Reels: All of the reels and their media are displayed in the Desktop section.
	Workspace Library: All media and folders reside in a Library. Within Libraries, you can create folders to organize your media.
	Desktop Snapshots: Save Desktop Snapshots to this section of the Media panel and restore them. Desktop Snapshots include all the settings and media associated with the Desktop.
	Batch Snapshots: Save Batch snapshots to this section and restore them. Batch snapshots include all the nodes, settings and media associated with the Batch schematic.

Section:	Description:
	
	Shared Libraries: Drag clips and folders from the Media Library to this section to make the content available to other Creative Finishing applications running on your network.
	Search Field: Perform name based searches for media in the Media panel. Search results are displayed in alphabetical order. The search results list is always the last entry in the panel.

Media Icons and Selection Reference

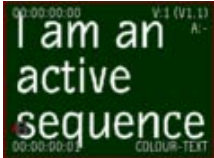

Media Thumbnail Icons

The Media panel displays icons next to the media so you can assess its contents at a glance.

Icon:	Media:
No Icon	Clip
	Sequence
	Effects Clip
	Opened Sequence (Timeline)
	Selected Clip
	Selected Sequence
	Selected Effects Clip

Media Selection Colour Coding

Clips on the Desktop or the Viewing panel are displayed with a coloured border based on the type of selection and the media type.

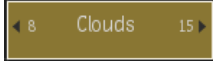

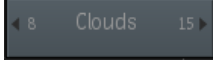

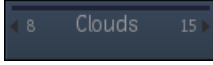

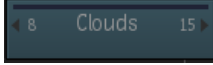

Border:	Selection:
	Unselected clip. No border.
	Primary/secondary selection. A yellow border is displayed on the primary selection and a grey border on the secondary selection(s). The last selected clip becomes the primary selection.
	Active sequence. A red border is displayed when an active sequence is selected.
	Active source. A green border is displayed on the currently open source when an active sequence is selected.
	Last rendered clip. A blue border is displayed on the last rendered clip.

Border:	Selection:
	<p>Ganged clips. The clip information displayed on the thumbnails of ganged clips turns green when selected. Otherwise, the clip information on ganged clips is yellow.</p>

NOTE When the selection is made from the Media panel, the yellow border appears in the Media panel selection and the clip on the Desktop or the Viewing panel is bordered in grey, regardless of the media type.

Timeline Colour Coding

On the timeline, different colours indicate different states of elements:

Element:	State:
	A selected video segment.
	An unselected video segment.
	An audio segment.
	A container.
	A segment with a BFX applied.
	A segment with unlinked video.

Managing Projects and Users

4

Projects and users define your working environment.

Projects:

- Define the display environment
- Control values for resolution, aspect ratio, bit depth, scan mode, etc.

You typically create a project for each job you work on.

For each person working on your system, you can also create a user.

A user is a profile that maintains the following preferences:

- User interface settings
- Pen and tablet preferences
- Keyboard shortcuts

Working with Projects

To create a project:

- 1 To create a project on start-up, click New from the Project panel.
- 2 To create a project in the middle of a session, from the Flame menu, select Project and User Settings.
 - The Project and User Settings dialog box appears.
 - From the Project panel, click New.
 - The Create New Project dialog box appears.
- 3 In the Name field, enter a name for the new project. Names can be up to 120 characters long.
- 4 If you have multiple volumes on your system, you can select the volume you want to work with from the Volume field. If you only have one volume, the volume name is displayed.

NOTE Projects are tied to the volume they were created on and cannot be accessed from a different volume. To access the content from a project on a different volume, you can wire the clips and sequences from that project to a project on the current volume.

- 5 Set the setup directory for the project.
- 6 Set the setup mode for the project.

- 7 Set the default resolution for the project.
The default project configuration template is automatically loaded. You can manually select a different project configuration template if you like. This can be useful if your monitor does not natively support the resolution of your project. See [About the Project Configuration Template](#) (page 26).
- 8 Set the aspect ratio for the project.
- 9 Select the bit depth for the project.
- 10 Set the scan mode for the project.
- 11 Select the graphics rendering bit depth for the project. For best results, leave the default option of 16-bit FP Graphics.
- 12 Select Flame Reactor or Classic Engine for rendering.
 - **Flame Reactor:** This is the default option when creating a new project. Use this option to enable rendering optimization. However, when working with content created in a previous releases, final renders may look different. This option may not be available on some configurations.
- 13 Set the Cache and Renders settings.
- 14 Set the Proxy Settings.
- 15 When you are satisfied with project settings, click Create.

NOTE

- Flame Reactor is not supported on configurations using NVidia Quadro FX4500 and FX5500.
- It is recommended that you use Burn nodes with GPU processing capabilities when sending remote rendering jobs from a project that has the Render option set to Flame Reactor, to avoid discrepancies.
- **Classic Engine:** Use this option when working with content generated in pre-2013 Extension 1 releases that need to have the same look.

TIP

- Projects have an autosave feature. The project is automatically saved at the interval set in the preferences. You can manually save your project with the **Alt+S** keyboard shortcut or by selecting Save Project from the Flame menu.
- If you create a project in the middle of a session, you must load it by clicking Load in the Project panel.
- To reset project settings, click Reset. You can edit a project's settings at any time.
- You can exit the Create Project dialog box at any time without creating a project, by clicking Cancel.

To edit a project:

- 1 From the Flame menu, select Project Management. The Project and User Settings dialog box appears.
 - 2 From the Project box, select the project you want to edit.
 - 3 Click Edit. The Edit Project dialog box appears.
 - 4 Modify the settings.
 - 5 Click Done and then Confirm.
- The modifications are applied to your project.

To delete a project:

- 1 From the Flame menu, select Project And User Settings. The Project and User Settings dialog box appears.
- 2 From the Project box, select the project you want to delete.

NOTE You cannot delete the current project.

- 3 Click Edit. The Edit Project dialog box appears.
- 4 Click the Project Edit box and select Delete Project.
- 5 Click Done and then Confirm.

You are prompted to confirm the deletion of the clips contained in the project.

- 6 Click Confirm.

You are prompted to confirm the deletion of the setups contained in the project.

- 7 Click Confirm.

The project is deleted.

NOTE When you delete a project, all its associated clips and setups are deleted with the project.

NOTE You cannot open a project created in Flame 2013 20th Anniversary Edition Flame Premium without first converting it.

To open a project created in Flame 2013 20th Anniversary Edition or later:

- 1 From the Startup screen, in the Projects section, set the Versions filter to All Versions.
- 2 Select the project to convert from the Project box.
The version of Flame Premium used to create it appears in brackets.
- 3 Click Start.
- 4 From the Convert Project dialog box, select one of the following:
 - **Keep Copy:** Flame Premium converts the project (keeping the original name) and also duplicates it. This copy gets appended the version of Flame Premium with which it is compatible.
The Lustre project settings are also updated to reflect the changes.
 - **Convert:** Flame Premium converts and opens the project.

IMPORTANT The conversion is one way: once you convert the project, you cannot open it again in an older version of Flame Premium.

To open a project created in Flame Premium before Flame 2013 20th Anniversary Edition, use one of the following options.

- Create an archive in that older version of Flame Premium and restore that archive in the newer version.
- Open **MediaHub > Browse for Projects** and browse to project to restore. You can then import those files in the new Flame Premium.

About the Project Setup Directory

Setups are file-based resources such as effects settings, EDLs, and LUTs and are managed in a set of subdirectories in the project's setup directory.

When you create a project, the project's setup directory appears in the Setup Directory box.

You are not restricted to these directories when you load or save setups. You can use the file browser to locate a different directory, or use project shortcuts to browse the setup directories of other projects on the same system.

Sharing a Setup Directory with an Existing Project

You can share the project home directory with an existing project, allowing you to share setups between the two projects.

To share the project home directory with an existing project:

- 1 From the Setup Directory box, select the existing project's home directory that you want to share. Any setups already saved to the existing project are made available to the new project.

Copying Setups from an Existing Project:

To copy setups from an existing project:

- 1 From the Setup Mode box, select Copy From.
- 2 From the Projects box that appears to the right of the Setup Mode box, select the existing project from which you want to copy the setups.

About the Graphics Rendering Bit Depth

Depending on your system, you can specify the bit depth for images rendered by the graphics card. The bit depth affects the quality of the resulting clip. The images can be rendered with 8-bit or 16-bit FP precision.

As a rule, if you are working with mixed resolutions and some clips are higher than 8-bit, you should select 16-bit FP graphics display. Even if you work only with 8-bit images, you can get better rendered results with 16-bit FP graphics rendering when transparencies, blending, and gradients are part of your effect. 16-bit FP graphics rendering produces better results but takes longer.

Also, if your output is ultimately an 8-bit format, having the best possible quality immediately prior to output produces the best results.

About the Project Configuration Template

Each project has a project configuration file. When you load a project, its project configuration file is read. Information in the project configuration file determines settings such as graphics monitor refresh rate, default timecode, and default frame rate for playback.

A project's configuration file is created based on a project configuration file template. The template specifies project settings typically associated with the project's default resolution.

When you select a resolution, a project configuration template appears in the Configuration Template box. The project configuration file primarily defines the display environment, and in no way restricts you from working with clips of another resolution.

Setting the Proxy Management Options

Proxies are low-resolution copies of high-resolution clips. Using proxies enables you to get a higher level of playback performance and responsiveness, especially when working with large files. Set proxy management options to specify how and when proxies are generated for clips used in the project. The default setting is Proxies Off.

To set proxy management options:

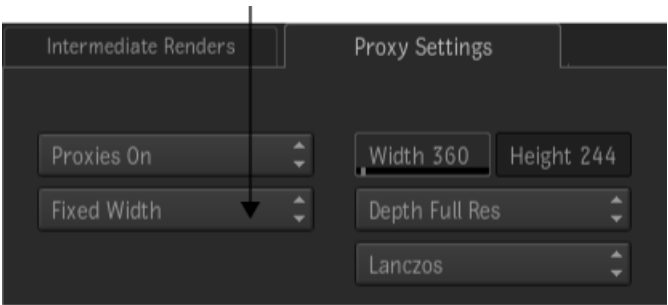

- 1 From the Proxy Management option box, select an option.

TIP To change proxy management options for a current project, you must access the Project and User Settings dialog box.

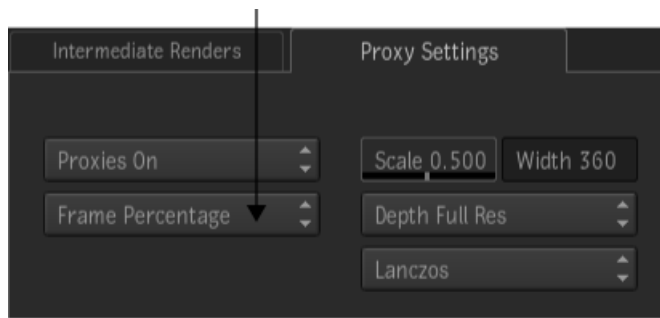

Select:	To display:
Proxies On	Proxies for all clips larger than the proxy width you set for all proxies.
Conditional	Proxies only for clips that meet conditional criteria, for example, clips that exceed a width of 4000 pixels.

- 2 Specify the proxy size by doing one of the following:
- Select Fixed Width from the Proxy Size box and then enter a value in the Proxy Width field beside the Proxy Size box. For example, enter 720 to create and store proxies 720 pixels wide. Proxy height is determined by the clip's aspect ratio.

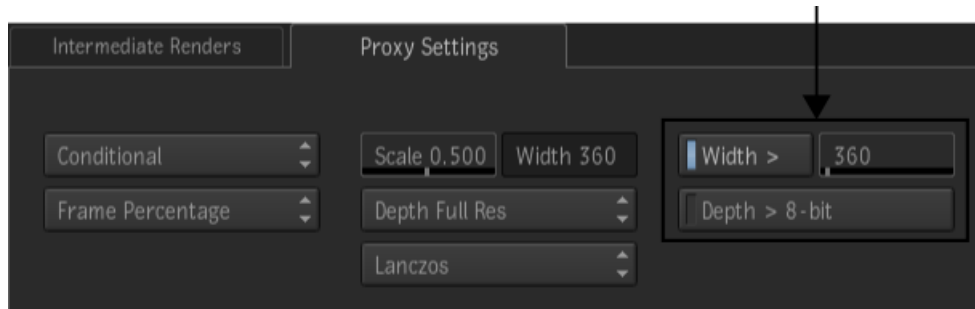

NOTE

- If the proxy resolution and bit depth settings are the same as the as the full resolution clip, proxies are not generated.
- If the proxy resolution is the same as the full resolution clip, but their bit depth is different, proxies are generated.
- Select Frame Percentage from the Proxy Size box and then enter a value in the Scale field. For example, enter 0.50 to create and store proxies that are 50% of the clip resolution.

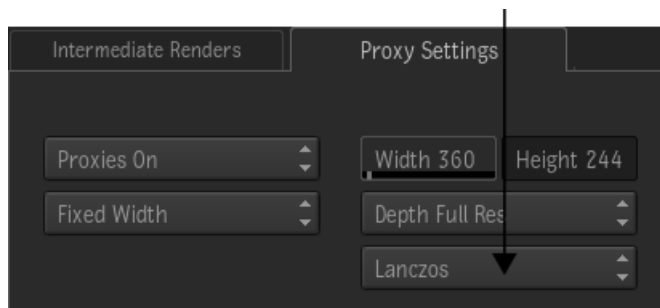

Proxies always have the same aspect ratio as the full-resolution clip. The width of proxies for clips with the default resolution corresponding to the scale value you set is displayed in the Width field.

- 3 If you selected Proxies Conditional, set your conditional criteria.

- To store proxies for all clips of a certain width and greater, enable Frame Width > and then enter a value in the adjacent field. For example, enter 4000 to store proxies for all clips wider than 4000 pixels.
 - To store proxies only for 10-bit, 12-bit, or 12-bit unpacked clips, enable Depth > 8-bit.
- 4 From the Proxy Quality box, set the quality of the proxy image for viewing purposes.

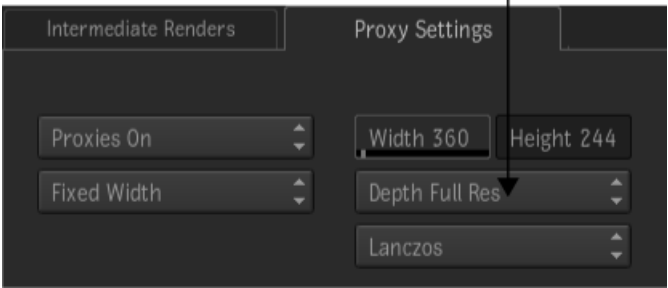

Proxy quality affects rendering and proxy generation duration since lower qualities are faster to calculate. However, the quality does not affect the amount disk space required for proxies.

Select:	To specify:
Lanczos	Excellent and sharp results. Recommended for upscale and downscale. Expensive to compute.
Shannon	Excellent and sharp results. Results are sharper than Lanczos in small details. Recommended for upscale and downscale. Expensive to compute.
Gaussian	Medium quality and softer results.

Select:	To specify:
Quadratic	Medium quality and softer results.
Bicubic	High-quality results, but not as sharp as Shannon. Use for both upscale and downscale.
Mitchell	High-quality results, but not as sharp as Shannon. Use for both upscale and downscale.
Triangle	Low quality results that are fast to compute. Use for downscale.
Impulse	Very low quality results that are fast to compute. Use for downscale.
Draft	The lowest possible quality. This is the quality used when proxies are generated automatically following video I/O.

5 From the Proxy Bit Depth box, select the bit depth for proxies.

Select:	To set:
Depth: 8-bit	The proxy bit depth to 8 bits.
Depth: Full Res	The proxy bit depth to be the same bit depth as that of the clip.

Setting Cache and Renders Format

Set the default media format for your project under the Cache and Renders tab.

When rendering, media is rendered to the format specified in the Cache and Renders tab.

When importing media with Cache Source Media enabled, the media is transcoded to the format specified in the Cache and Renders tab. Media imported with Cache Source Media disabled is not transcoded and keeps its original format.

To set the Cache and Renders format:

- 1 Click the Cache and Renders tab.
- 2 Select the media format from the Cache and Renders Preferred Format box.

NOTE Preferred formats are all available in RAW and non-RAW flavours. The difference between the two flavours is the presence or absence of OpenEXR as an alternate format: RAW flavours have only DPX and RAW, non-RAW ones have DPX, OpenEXR, and RAW.

As a rule of thumb, use RAW Preferred Format flavours in most cases, and the non-RAW ones if you plan on exporting OpenEXR in linked publish.

Format Restriction:	Description:
Maximum Width	Displays the maximum width of a frame for it to use the Preferred Format. A frame wider than this is written using one of the Alternate Formats.
Maximum Height	Displays the maximum height of a frame for it to use the Preferred Format. Any frame bigger than this is written using one of the Alternate Formats.
Depths	Displays the maximum bit depth of a frame for it to use the Preferred Format. Any frame at a bit depth higher than this is written using one of the Alternate Formats.
Alternate Formats	<p>Displays the fallback formats used to write frames that do not fit within the parameters defined by Maximum Width, Maximum Height, and Maximum Bit Depth. The application follows a specific fallback strategy, based on the bit depth of the frame and the displayed formats:</p> <ul style="list-style-type: none">■ DPX, OpenEXR, RAW: DPX for 8-, 10-, and 12-bit frames. OpenEXR for 16-bit floating point frames, RAW for 12-bit packed ones.■ DPX, RAW: DPX for 8-, 10-, and 12-bit frames. RAW for 12-bit packed, 16-bit floating point, and higher.

Working with Users

Creating a User

You can create a user:

- On start-up from the Project panel.
- During a session, by selecting Project and User Settings from the Flame menu.

When you create a user, you have the option of copying preferences from an existing user. If the user whose preferences you want to copy was created on the same version of the application, you can copy all preferences. If the user was created on an older version of the application, you can only copy shortcut preferences.

To create a user:

- 1 If you are creating a user on start-up, select New under User on the startup screen. (If you are starting Flame Premium for the first time, New is the only option).
- 2 If you are creating a user in the middle of a session, from the Flame menu, select Project And User Settings.
The Project and User Settings dialog box appears.
- 3 Under User, click New.
The Create New User Profile dialogue box appears.
- 4 Under User, click New.

- 5 In the Name field, enter a name for the new user.
 - 6 Set your Preferences Directory.

If you are connected to a network with multiple hosts, you can select a remote host to store your user preferences. The default option is Local Host.
 - 7 Select your Keyboard Shortcuts scheme. Options are:
 - Smoke (FCP 7)
 - Flame
 - Smoke Classic
 - 8 If you do not want to copy user preferences from an existing user, select New Prefs and click Create. The user is created. The dialog box closes and you can begin working.
 - 9 If you want to copy user preferences from an existing user, select Copy From.
 - 10 From the Files box, select the type of files to copy. Options are:
 - All
 - Shortcuts
- NOTE** If the user you want to copy the settings from was created on an older version of the application, you can only copy shortcut preferences.
- 11 From the Host box, select the host on which the user is saved.
 - 12 From the Version box, select the software version used to create the user.
 - 13 From the User box, select the user from which you want to copy the preferences.
 - 14 Click Create.

The user is created. The dialog box closes and you can begin working.
- NOTE** If you create a user in the middle of a session, you must load it by clicking Load in the User panel.

Editing a User

You can edit a user after it has been created.

To edit a user:

- 1 From the Flame menu, select Project And User Settings. The Project and User Settings dialog box appears.
- 2 From the User box, select the user you want to edit.
- 3 Click Edit. The Edit User Profile dialogue box appears.
- 4 Modify the appropriate settings.
- 5 Click Done and Confirm.

Deleting a User

To delete a user:

- 1 From the Flame menu, select Project And User Settings. The Project and User Settings dialog box appears.
- 2 From the User box, select the user you want to delete.
- 3 Click Edit. The Edit User Profile dialogue box appears.
- 4 Click the User Edit box and select Delete User.
- 5 Click Done and Confirm.

Organizing Media in the Workspace

5

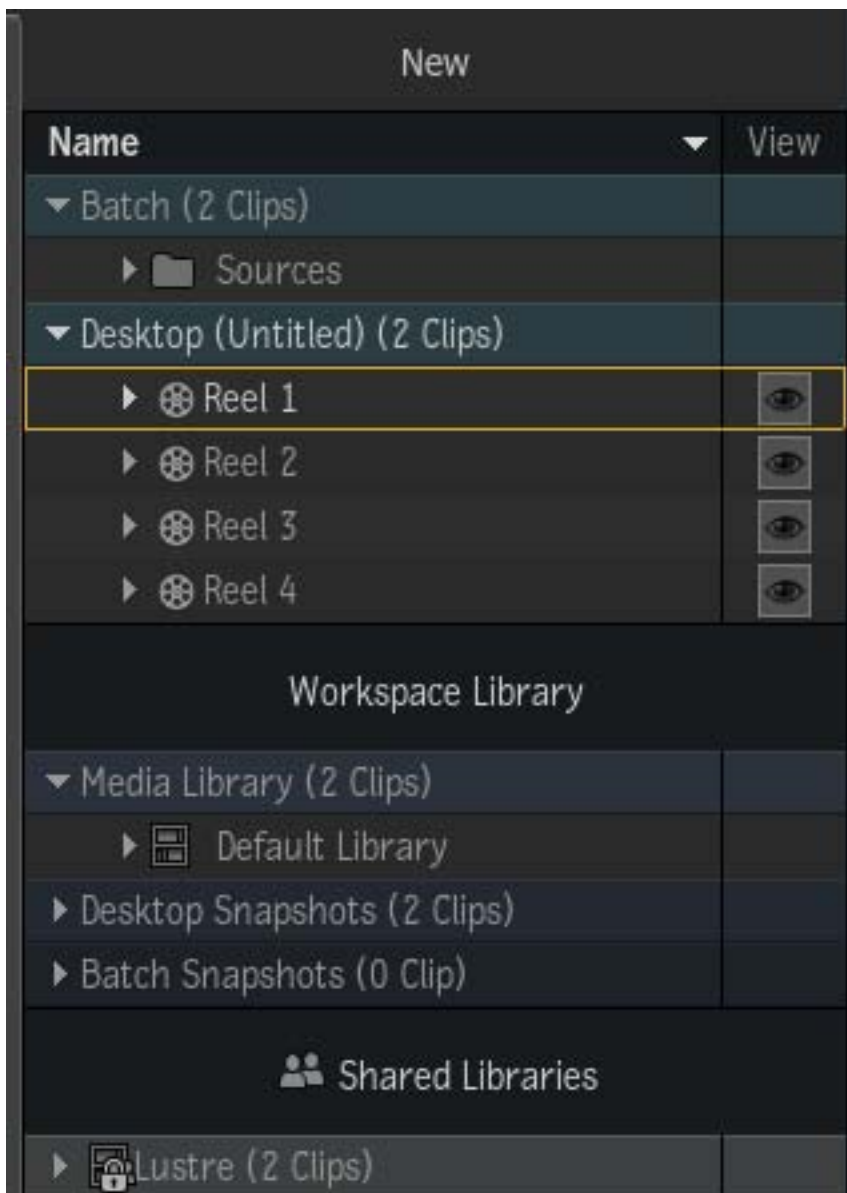

Displaying and Hiding the Media Panel

The first time you run the application, the Media panel is hidden. To display it, from the Media panel View Mode box, deselect Hidden.

The Media Library is the centralized location to which you import all of your media. The Media Library organizes your media into Libraries which contain your clips. Within a Library, you can create as many folder as you like to organize your clips. Libraries can be opened and closed. Closing the Libraries releases them from memory and makes their content inaccessible. You open and close Libraries from the contextual menu.

The Media panel is persistent throughout the application. You can toggle the display of the Media panel by using the `Shift + Esc` keyboard shortcut.

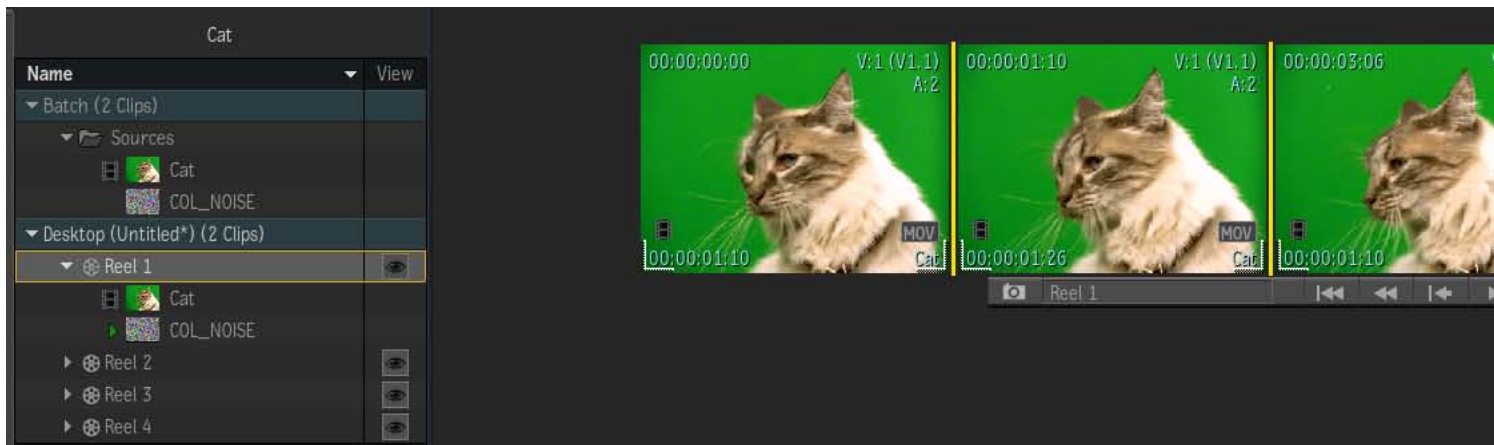

TIP You can view the clips in the Media panel as large thumbnails by `Alt + clicking` them.

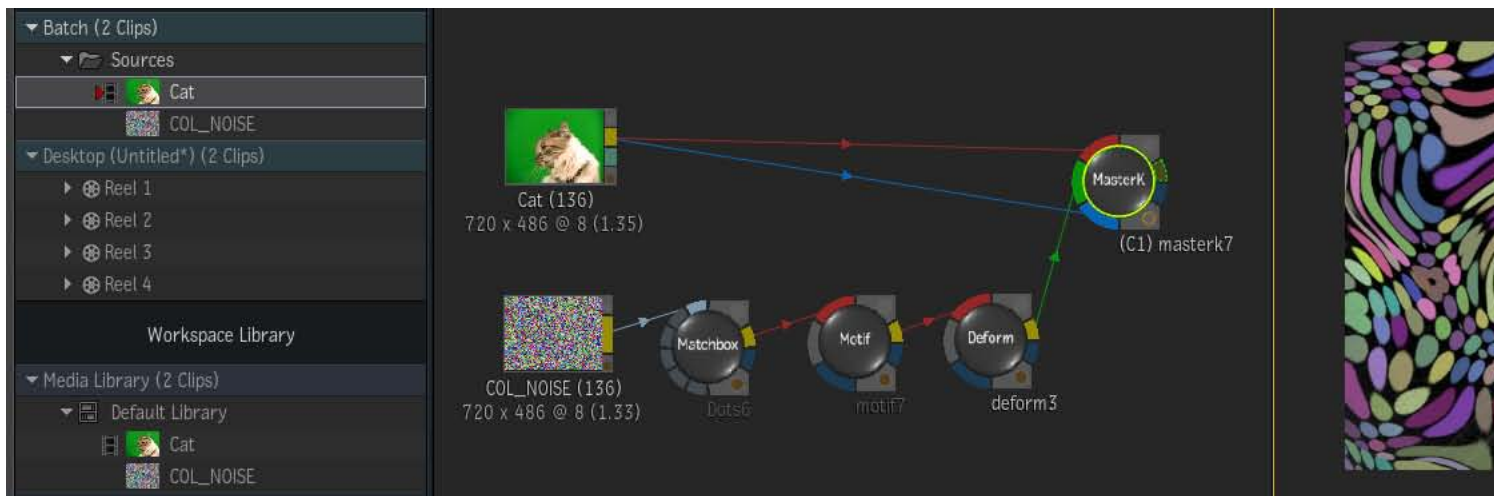

Dragging and Dropping media in the Media Panel

From the Media Library you can drag and drop your clips to the different sections of the Media panel, creating copies of the clips for you to work on, leaving the originals intact in the Media Library.

Drag and drop the media from the Workspace Library to the Desktop section of the Media panel to perform gestural edits to the copies on the Desktop Reels.

Drag and drop the media from the Workspace Library to the Batch Sources section of the Media panel to apply procedural effects to the copies in the Batch Sources folder.

Drag and drop the media from the Workspace Library to the Shared Libraries to make the copies of the clips available to other workstations on your local network.

Sorting Clips and Sequences in the Media Panel

You can determine the sorting order of media in the Media panel.

To select a sorting order, right-click on the Media panel header and select the sorting order. Options are:

- **Sort Ascending:** Sorts the media by name in ascending alphabetical order.
- **Sort Descending:** Sorts the media by name in descending alphabetical order.
- **Clear Sort:** Enables custom sort. You can drag and drop the clips and sequences in the Media panel, to sort them in the order you want. This does not apply to the Desktop Snapshots and the Batch Snapshots sections of the Media panel.

Assigning Colours to Reels, Folders and Libraries

You can assign colours to selected reels, folders and Libraries in the Media panel, from the contextual menu.

NOTE Does not apply to Batch Sources, Snapshots or Shared Libraries.

Name	View
▼ Batch (1 Clip)	
▶ Sources	
▼ Desktop (0 Clip)	
▼ Reel 1	
▼ Reel 2	
▼ Reel 3	
▼ Reel 4	
Workspace Library	
▼ Media Library (0 Clip)	
▼ Default Library	
▶ Folder 1	
▶ Folder 2	
▶ Desktop Snapshots (15 Clips)	
▶ Batch Snapshots (0 Clip)	

Tips for Working with the Media Panel

Dragging a clip from the Workspace Library to the Batch section header (above the Sources folder) adds the clip to the Batch schematic and automatically opens Batch view.

Dragging a Library or a folder from the Media Library to the Desktop section header (above the Reels list) automatically creates a new Reel named after the Library or folder.

Dragging a Reel from the Desktop section of the Media panel or from the Desktop itself to the Media Library automatically creates a Library named after the Reel.

When in Desktop view, you can display the contents of Libraries and folders in the Media Library by double clicking the Library or folder or by enabling the eye icon to the right of the Library or folder. The view automatically switches to Thumbnail and displays the contents of the Library or folder. You can then drag the clips you want to work with to a Reel in the Media panel and set the view back to Desktop.

Protecting Media from Editing in the Media Library

You can protect clips in the Media Library from editing, by enabling the Protect from Editing button under the General tab in the Preferences (it is enabled by default). When this preference is enabled, the following operations cannot be performed on clips in the Media Library:

- Editing of a source clip (Trim, Slip, Cut, etc.)
- Timeline FX operations (Add, Delete, Modify, etc.)

- Batch FX operations
- Opening a clip as a sequence

Clips on the Desktop and in the Batch Sources area can still be edited with the Protect from Editing preference enabled.

Changing Your View of the Flame Premium Workspace

The Viewing panel gives you different visual representations of the clips in the Media panel.

From the View mode box, you can select from the following views:

- **Desktop Reels:** Displays reels onto which you place clips and sequences. Clips and sequences can be edited and played back from the reels. The contents of reels can also be displayed in Thumbnails view, by enabling the View icon next to reel when in Thumbnails view.
- **Thumbnails:** Displays the clips within the selected Media panel folder or reel as thumbnails.
- **Player:** Displays and plays back the selected clip in a Player.
- **Source - Sequence:** Displays and plays back the selected source clip and sequence in two side-by-side players.
- **Triptych Player:** Displays and plays back one or multiple clips in three side by side players. This can be useful for colour matching, for example.
- **Trim View:** Displays the last (outgoing) and first (incoming) frame above the Timeline from the two clips you are trimming.

TIP Double-clicking a clip in the Media panel, displays it in the Player.

Generating Clips

You can generate the following generic video and audio clips and use them as would any other media:

- Colour Source
- Colour Bars
- Noise
- Gradient
- Audio Tone

To generate a clip:

- 1 In the Viewing panel, right-click and select New.
- 2 Select the type of clip you want to generate.
- 3 Set the options in the dialog box that appears.
- 4 Click Create.

Once created, a clip is displayed as a source in the timeline, the Media panel and the Viewing panel.

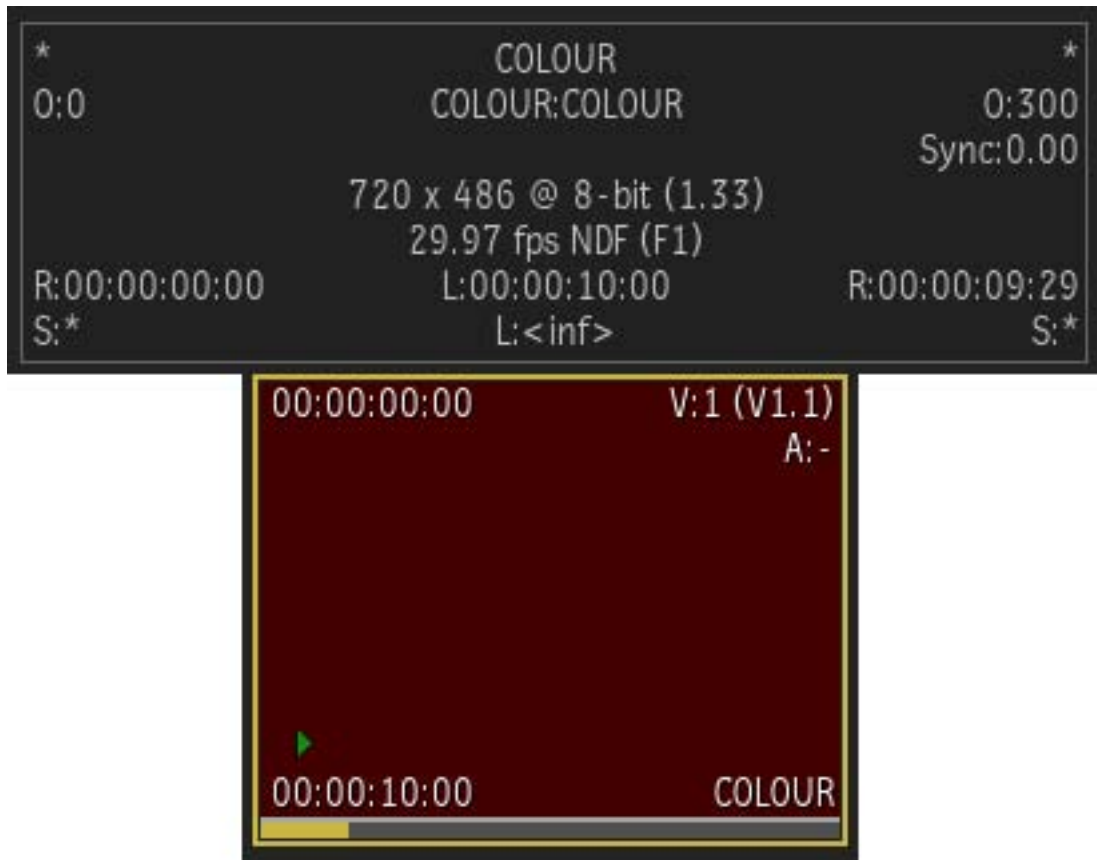

Displaying Media Metadata

By default, basic metadata is displayed on each corner of a thumbnail, such as current timecode, video and audio tracks, duration and clip or sequence name. You can also view detailed metadata for each clip or sequence in the Viewing panel.

There are two ways you can display detailed clip information:

To display clip information on a thumbnail:

- 1 Make sure you are in Thumbnail view.
- 2 Press the **Alt** key and click a thumbnail.

To display detailed clip information in the Media panel:

- 1 From the View mode box, select Details.

New_Project_1														
Name	View	S-I	D	H	TC In	TC Out	Duration	Clip Length	Take	Versions	Audio	E	Width	Height
Media Library (2 Clips)														
Default Folder														
COLOUR					00:00:00:00	00:00:09:29	00:00:10:00	00:00:10:00	COLOUR	1	0	1	720	486
Sequence					10:00:00:00	10:00:00:00	00:00:00:01	00:00:00:01	N/A	1	1	3	720	486

Managing Sequences

A sequence is an edited clip that can contain multiple sources. When you edit a clip, it becomes a sequence. When you create a new project, an empty sequence is created within the project. You can create new sequences from the Media panel.

Creating an Empty Sequence

- 1 From the Media Panel Gear menu, select **New ► Sequence**.

The New Sequence dialog appears.

- 2 Specify the settings for your sequence.
- 3 Press Create.

An empty sequence is created. It is displayed in the Timeline, the Media panel, and the Viewing panel.

Opening a Source as a Sequence

- 1 Select a source from the Viewing panel or the Media panel.
- 2 From the contextual menu, select Open as Sequence.

A new sequence is created from the selected source. It is displayed in the Timeline, the Media panel, and the Viewing panel.

NOTE When opening a source as a sequence, the sequence is created using the original media. When you add a source to an existing sequence, a copy of that source is added to the sequence, leaving the original source intact.

Opening Multiple Sequences Simultaneously

- 1 Select reels, folders or Libraries in the Viewing panel or the Media panel.
- 2 From the contextual menu, select Open All as Sequences.

All the clips and sequences within the reel, folder or Library are opened as individual sequences.

TIP This can also be achieved by dragging the reel, folder or Library to the timeline.

Opening Multiple Clips as One Sequence

- 1 Create an empty sequence.
- 2 Select the clips to load and join as one sequence from the Media panel or the Viewing panel.
- 3 Drag the selected clips to the empty sequence at the desired timecode.

The selected clips are inserted in the sequence, in the order in which they were selected.

Closing all Sequences Simultaneously

- 1 Mouse over an open sequence tab in the Editing panel.
- 2 From the contextual menu, select Close All Sequences.

TIP This can also be achieved with the `Shift + C` keyboard shortcut.

Moving all Open Sequences to a New Reel or a New Folder

- 1 Do one of the following:
 - To move all open sequences to a new reel, in the Media panel, select the reel **above** which you want to create the new reel.
 - To move all open sequences to a new folder, in the Media panel, select the Library or folder **under** which you want to create the new folder. If you select a folder, a sub folder is created.
- 2 Mouse over an open sequence tab in the Editing panel.
- 3 From the contextual menu, select Move All Sequences.

The open sequences are moved from their original location to the new reel or folder.

TIP This can also be achieved by dragging the sequence handle to the left of the left-most tab in the timeline and dropping it to the Desktop section of the Media panel or the Media Library. You are prompted to select whether to move or copy the sequences to the new location.

Copying all Open Sequences to a New Reel or a New Folder

- 1 Do one of the following:
 - To copy all open sequences to a new reel, in the Media panel, select the reel **above** which you want to create the new reel.
 - To copy all open sequences to a new folder, in the Media panel, select the Library or folder **under** which you want to create the new folder. If you select a folder, a sub folder is created.
- 2 Mouse over an open sequence tab in the Editing panel.
- 3 From the contextual menu, select Copy All Sequences.

The open sequences are copied to the new reel or folder.

TIP This can also be achieved by dragging the sequence handle to the left of the left-most tab in the timeline and dropping it to the Desktop section of the Media panel or the Media Library. You are prompted to select whether to move or copy the sequences to the new location.

Working in Thumbnails View

Organizing the Thumbnails in the Viewing Panel

The Thumbnails view displays the clips in the selected folder or reel as thumbnails.

Arranging the Thumbnails

When in Thumbnails view, you can arrange the displayed thumbnails in a number of ways. To arrange the thumbnails, do one of the following:

From the contextual menu, select:	To:
Arrange ► Clean Up All	Tile the thumbnails across the Viewing panel.
Arrange ► Fit All	Tile the thumbnails across the Viewing panel at the highest possible resolution while fitting all the thumbnails within the Viewing panel.
Arrange ► Cascade Selection	Arrange the selected thumbnails as cascading stacks.

Displaying a Snap Grid

Use the grid to snap thumbnails into position when moved.

To display a snap grid in the Thumbnails view:

- 1 Make sure the Viewing panel is set to Thumbnail view.
- 2 Access the Preferences dialog box by clicking the Flame button at the bottom of the window.
- 3 Under the User Interface tab, in the Thumbnails view section, enable Snap To Grid.
- 4 Set your preferred grid size.
- 5 Set your preferred proxy height.
- 6 Click Close to close the Preferences dialog box.

The Viewing panel displays a grid of the specified size.

Gangng Clips in the Viewing Panel

You can gang clips and sequences together in the Viewing panel so that when you jog one, they are all jogged. This is useful for multicam setups. When you play a clip that is part of a gang, the current frame of all other ganged clips is updated once playback has stopped.

To gang clips in the Viewing panel:

- 1 From the View Mode box, select Thumbnail view.
- 2 In the Viewing panel, locate all the clips or sequences you want to gang, and move their positioners to the timecode you want to lock.

TIP Each clip or sequence can have its own timecode offset, but if you are working with a multicam setup, make sure all positioners are parked at the same location.

- 3 Hold the **Ctrl** key and select the clips or sequences you want to gang.
- 4 While the cursor is over one of the clips to be ganged, from the contextual menu, select Gang. All selected clips are ganged and the clip information turns green.

NOTE The clip information of ganged clips turns yellow when a non-ganged clip is selected.

- 5 Jog the positioner of one of the ganged clips. All ganged clips or sequences are jogged.

To select all clips in a gang:

- 1 Select any clip or sequence that is part of a gang.
- 2 From the contextual menu, select **Gang > Select Gang**.
All ganged clips or sequences are selected.

To remove a clip from a gang:

- 1 Select the clip(s) or sequence(s) you want to remove from the group.
- 2 From the contextual menu, select **Gang > Ungang**.
All selected clips or sequences are unganged.

Working with Reels

Organizing the Desktop Reels

A Desktop can contain as many reels as you like. The reels can be displayed in any order within the Desktop. However, a maximum of six reels can be displayed on a Desktop at a time.

To add a reel to a Desktop:

- 1 From the Media panel, select the current Desktop.
- 2 From the contextual menu, select New Reel.

The new reel, labeled Untitled Reel, is added to the Desktop. You can rename it by highlighting it and clicking the name field, in the Media panel or by clicking the name field on the reel itself and clicking the camera icon to the left of the reel name to save the change.

NOTE Saving two reels with the same name triggers a prompt to either Cancel, Bump or Replace the snapshot. Selecting Bump creates a new version of the reel and appends a version suffix to the reel name.

To display active reels:

- 1 From the Media panel, click in the View field to show or hide the selected reel.
An eye icon appears in the View field next to the active reels.

NOTE A maximum of six reels can be displayed on the Desktop at a time.

To change the order of the reels on the Desktop:

- 1 Click the Move button to the right of the reel you want to move.

- 2 Drag and drop the reel to its new position on the Desktop.

Saving and Restoring Desktops with Snapshots

You can save multiple Desktop snapshots to the Media panel and restore them. When you restore a Desktop Snapshot, you restore settings and media associated with the Desktop.

When you make a change to a saved Desktop (for example, deleting a clip from a reel), an asterisk appears next to the Desktop section in the Media panel. This lets you know at a glance that changes have been made to the Desktop since you last saved it.

To save a Desktop Snapshot:

- 1 From the Viewing panel menu bar, enter a name in the Desktop Name field.
- 2 Click the Desktop Snapshot button.

A closed snapshot folder is created and can be seen in the Desktop Snapshots area in the Workspace Media panel. If you right-click, and select Open Snapshot, you can expand the reels under the Desktop Snapshot to view the sources saved with the snapshot.

NOTE Saving two snapshots with the same name triggers a prompt to either Cancel, Bump or Replace the snapshot. Selecting Bump creates a new version of the snapshot and appends a version suffix to the snapshot name.

To restore a Desktop:

- 1 In the Media panel, right-click the Desktop snapshot you want to restore and do one of the following:
 - **Replace Desktop** : Clears the current Desktop and replaces it with the Desktop you restored.
 - **Append Desktop** : Appends the restored Desktop to the current Desktop.

The selected Desktop is loaded and appears under Desktop, in the Media panel.

You can also drag and drop the Desktop Snapshot to be restored, from the Media panel to the Desktop or simply double-click the Desktop Snapshot to restore it. A prompt pops up asking you to select between the Replace and Append options. Once you make your selection, the selected Desktop is loaded and appears under Desktop, in the Media panel.

Dragging and dropping multiple Desktop Snapshots is also possible. In this case, all of the selected Desktop Snapshots are appended together and all of the media contained in the multiple snapshots are displayed on the Desktop, on the appropriate reels.

Scrubbing Clips, Sequences and Reels

Scrubbing a Clip or Sequence

You can scrub a clip or sequence by using the transport section under the reel or by dragging left or right on the lower third of a frame.

Scrubbing a Reel

Click:	To:
	Go to the previous clip or sequence on the reel.
	Go to the first frame of the clip or sequence currently over the reel's playback controls.
	Scrub the reel backward.
	Load the clip currently above the playback controls into the Player for full-resolution playback.
	Scrub the reel forward.
	Go to the last frame of the clip or sequence currently over the reel's playback controls.
	Go to the next clip or sequence on the reel.

To scrub a reel using the cursor:

- 1 Click the grey area on top of the reel to be scrubbed.
- 2 Place the cursor in the top third of the reel.
The cursor displays two white arrows on each side.
- 3 While holding the left mouse button, drag the cursor left or right.

NOTE The closer you are to the edges of the screen, the faster the scrubbing speed. The closer you are to the centre of the screen, the slower the scrubbing speed.

Displaying Collapsed, Frames and Storyboard Views

There are three ways to view clips on Desktop reels: collapsed view, frames view, and storyboard view.

In collapsed view, clips or sequences are displayed as a stack of frames.

In frames view, clips or sequences are displayed as a strip of contiguous frames.

In storyboard view, each segment within your sequence is represented as a frame. Any transitions or cuts between segments are represented as dotted green lines and full yellow lines respectively.

To toggle the view for one clip or sequence:

- 1 Move the cursor over any frame of an expanded clip or sequence.
- 2 Do one of the following:
 - To toggle between collapsed view and frames view, press C repeatedly to cycle the two views.
 - To toggle between collapsed view and storyboard view, press Space + C repeatedly to cycle the two views.

To toggle the view for all clips or sequences on a reel:

- 1 Position the cursor over a grey area between clips or sequences on a reel.
- 2 Do one of the following:
 - To toggle between collapsed view and frames view, press C repeatedly to cycle the two views.
 - To toggle between collapsed view and storyboard view, press Space + C repeatedly to cycle the two views.

To toggle the view for all clips or sequences on the Desktop:

- 1 Position the cursor outside the Desktop.

2 Do one of the following:

- To toggle between collapsed view and frames view, press **C** repeatedly to cycle the two views.
- To toggle between collapsed view and storyboard view, press **Space + C** repeatedly to cycle the two views.

Revealing a Clip in a Reel

If you have a lot of clips on a reel, it can be difficult to quickly locate a specific clip. To facilitate this, you can perform a Reveal in Reels operation. Reveal in Reels automatically centers the selected clip on its reel, eliminating the need to scroll through the reel to locate your clip.

To reveal a clip in a reel:

- 1 Select the clip you want to reveal from the Desktop section of the Media panel.
- 2 From the contextual menu, select Reveal in Reels.

The selected clip is centered on its reel.

Syncing Reels

You can sync clips and sequences on different reels together on the Desktop so that when you jog one, they are all jogged. This is useful for multicam setups. When you play a clip that is synced, all other synced clips are played.

To sync reels:

- 1 Align the frames of the clips you want to sync.
- 2 Click the Sync button on each reel with a clip to sync.

The selected reels are synced.

Undo and Redo

To the right of the tabs are the Undo and Redo combo boxes.

- **Undo combo box:** Click to undo the last operation. You can also click the white arrow to list the last 10 operations performed. Selecting an operation from the list undoes all operations performed after the selected operation (including the selected operation). The undo operations are specific to each tab.

TIP You can set the Undo levels anywhere between 2 and 50, under the General tab in the Preferences. It is set to 10 by default.

NOTE While in Batch FX, you have access to all of your undo levels. Once you exit Batch FX and return to the timeline, all operations performed in Batch FX are considered one undo level. This means that even if you performed 7 different operations in Batch FX, when you return to the timeline you can only undo all the Batch FX operations at once, not each individual operation.

- **Redo combo box:** Click to redo the last operation. You can also click the white arrow to list the last 10 undone operations. Selecting one reapplies all undone operations performed before the selected operation. The redo operations are specific to each tab.

Setting Up a Flare Workflow

6

About Flare

Flare is a fully compatible assistant to Flame Premium, featuring the same creative toolset as Batch. All Batch nodes found in Flame Premium are fully supported in Flare. You can extend the capabilities of Flame Premium by performing any Batch task on a Flare system. You can also offload time-consuming tasks such as rotoscoping and particle creation to Flare.

Because the focus of Flare is on the Batch toolset, there are some tasks performed by Flame Premium that cannot be performed by Flare. For example, Flare does not support video I/O or conforming. In addition, Flare supports archiving, but only to or from file archives.

You can use Flare in an independent system workflow or in a remote connection workflow. In a remote connection workflow, the same (Flame Premium) storage is used by both Flare and Flame Premium so there is no duplication of media. Multiple Flare systems can connect to the same Flame Premium system. Each can be used to work on the same project at the same time, speeding up the production pipeline workflow. Overwriting work on a Flame Premium system from Flare is not a concern. Precautions have been put in place to ensure efficient collaboration between systems. You can even perform project management tasks of Flare folders without leaving the Flame Premium station.

If being able to work on projects collaboratively with Flame Premium is not your main objective, you can still take advantage of the assistant capabilities of Flare in an independent system workflow. There will be duplication of media since you need Wire to transfer media to/from a Flare system. However, there are fewer workflow considerations than in a collaborative environment since Flare work is done on its own storage volume.

The rest of this chapter discusses Flare in the context of a remote connection workflow.

Flare Workflow

The following workflow provides one example of working in a remote connection collaborative environment. In the example, Flare remote connects to a Flame Premium system and loads the media it will work on directly from a Flame Premium project. Flame Premium has direct access to the Flare media at all times since Flare uses the Flame Premium storage volume.

In the following workflow, steps without cross references are specific to Flare and are detailed in this chapter. Steps with cross references are covered in other chapters of the user's guide and may contain some Flame

Premium functionality that does not apply to Flare. Any Flare-specific considerations are outside the scope of the other chapters.

Flare with Flame Premium workflow:

- 1 Start the application and connect to a remote host computer. See [Starting Flare](#) (page 52)
- 2 Load the media from the Flame project's shared folder by either dragging it directly to the schematic area or by dragging it to the Flare Workspace Library to make a copy of the media and dragging the copy to the schematic area.

NOTE Make sure the media was saved to a shared folder in Flame Premium to make them accessible to Flare.

See [Shared Libraries](#) (page 51)

- 3 Work with the Batch toolset. See [Using Batch and Batch FX](#) (page 361).
- 4 Save your Batch branches as BFX clips by selecting the last node in a branch and selecting Create BFX from the contextual menu.

A BFX clip contains all of the media and Setup information of the Batch branch it was created from. It is essentially a Batch branch represented as a clip, which can be expanded back into the original branch by selecting Explode BFX Clip from the contextual menu.

- 5 (Optional) Process by doing one of the following:

- Render clips from the contextual menu.
- Render clips using the Render node.

- 6 Place the resulting media (BFX clips) back into the shared folder, making it available to the Flame workstation.

TIP It is recommended to create a sub folder within the Flame shared folder named From_Flare, for example, to be able to easily distinguish the initial media from the result media. In order to create a sub folder, you first must acquire write access (lock).

Considerations for Working in a Collaborative Environment

The ability to work in a collaborative environment is integral to the Flare remote connection workflow. From Flare, you can open a Flame Premium project on a remote storage volume and access all of the media stored in a shared folder. Conversely, Flame Premium systems can also access Flare media.

Workspaces

By default, when Flare connects to a remote Flame workstation, it automatically creates its own Flare workspace, associated to its own workstation, and which has access to all the contents of the shared folders in the Flame project.

If there are multiple Flare stations on your network, there may already be existing Flare workspaces for a given Flame project.

- If there is only one existing workspace and that it **is** associated to the current Flare workstation, Flare selects it automatically.
- If there is only one existing workspace and that it **is not** associated to the current Flare workstation, a Workspace Selection button is displayed next to the project name, enabling you to either use the existing Flare workspace or to create a new one.

- If there are many existing workspaces, a Workspace Selection button is displayed next to the project name, enabling you to either use an existing Flare workspace or to create a new one. If you do not click the Workspace Selection button, Flare automatically creates a new workspace for the current project.

NOTE Workspaces are project specific. You can only access the workspaces of the current project.

Shared Libraries

About Shared Libraries

The Flare workflow is based on shared libraries. Any media placed in the shared libraries becomes accessible to remote workstations that connect to the project. Shared libraries enable Flame and Flare to quickly and conveniently share media, allowing you to spend more time on creative tasks and less time managing your media.

Write Access

Placing media in a shared library automatically grants read access to any remote workstations connected to the project. The Flare operator can access the media and start working immediately after connecting to the Flame project. Once finished, the Flare operator needs to save the resulting media back to the shared library. To do this he must acquire write access.

Write access locks the library so that only the user having acquired write access can modify the library contents (i.e. write to the library). Read access is still available to other remote workstations connected to the project. Once the media is saved, the user can disable write access, enabling other remote workstations to obtain write access and modify the content.

To acquire write access:

- 1 Select the top level shared library you want to acquire write access to in the Media panel.
- 2 From the contextual menu, select Acquire Write Access.

To disable write access:

- 1 Select the top level shared library you want to acquire write access to in the Media panel.
- 2 From the contextual menu, select Release Write Access.

Open / Close

You can open and close shared libraries. Closing shared libraries turns off access to the media within the shared libraries as well as freeing up your system memory.

To open / close shared libraries:

- 1 Select the top level shared library you want to open or close in the Media panel.
- 2 From the contextual menu, select Open Library or Close Library.

Refresh

You can manually refresh the content of shared libraries, to make sure you have access to all the shared media.

To manually refresh the content of shared libraries:

- 1 Select the top level shared library you want to refresh in the Media panel.
- 2 From the contextual menu, select Refresh.
The content of the selected shared library is updated.

Starting Flare

To work in a remote connection environment, open a remote storage volume on start-up.

To start Flare:

- 1 Double-click the application icon on the desktop.
The Project Management menu appears.
- 2 Select a remote host from the Host Computer box. If the remote host has more than one volume, select a volume from the Volume box. Click Open.
- 3 Select a project from the Project box or create one. See [Managing Projects and Users](#) (page 23).
- 4 Select or create a user:
 - To select a user, select the user name from the User box. You can select a local or remote user by first selecting the appropriate option from the List From box.
 - To create a user, select <New> from the User box. In the Create User menu that appears, you can choose to create a user by copying a user profile.

If you copy a user profile, note the following:

- You can copy a user profile from a local or remote system.
- You can copy all preferences from a user profile in the current version of the application.
- You can copy only keyboard shortcuts preferences from a user profile in an older version of the application.

See [Managing Projects and Users](#) (page 23).

- 5 Click Start.
You enter the Batch module. You have access to the same creative toolset as is found in Flame Premium Batch.

To exit Flare:

- 1 Click the Flare button at the bottom right of the user interface.
- 2 Select Exit Flare.

Changing Projects and Users

You can create or load other projects, as well as create, change, and edit user profiles at any time within a Flare session.

You perform these tasks from the Project and User Settings section of the Preferences menu.

You create projects and users in the same way as from the start-up menu.

To access the Project and User Settings:

- 1 Click the Flare button at the bottom right of the user interface.

- 2 Select Project and User Settings
The Project Management dialog box appears.

To change projects in a Flare session:

- 1 Select a project from the Project box.
- 2 Click Load.
The Confirm dialog box pops up.
- 3 Click Confirm.
- 4 Click Close.
The new project is loaded.

To change users in a Flare session:

- 1 Select a user from the User box.
- 2 Click Load.
NOTE You can select a local or remote user by first selecting the appropriate option from the List From box.
- 3 Click Close.
The new user is loaded.

To edit a user profile in a Flare session:

- 1 Select a user from the User box.
NOTE When a remote user profile is selected, the profile is unavailable to other users. This avoids concurrent user profile modifications.
- 2 Click Edit.
- 3 Modify the user.
- 4 Click Done.
The Confirm dialog box pops up.
- 5 Click Confirm.
- 6 Click Close.
The modifications are applied to the user.

Importing and Exporting Media

7

Importing File-Based Media

To import media using the MediaHub:

- 1 Click the MediaHub tab.
- 2 Using the MediaHub file browser, navigate to the file to import.
- 3 Drag and drop the file to the Media Panel.
The file is now imported.

To import media directly from the Linux desktop:

- 1 From Flame Premium, switch to the Linux desktop.
- 2 Open a file browser and navigate to the file to import.
- 3 Drag and drop the file from the browser to the Media Library.
The MediaHub tab need not be opened for this to work.

Importing File-Based Media Tips

- A folder in the Media Library is the same as a bin in Avid Media Composer or Apple Final Cut Pro.
- Drag and drop a folder in the Media Library. Flame Premium imports all the media files and folders contained therein. Note that only supported media files and folders are imported: other files are ignored.
- Drag and drop multiple files in one operation: **Ctrl-click** or **Shift-click** to select multiple files to import before dragging them over to the Media Library.
- Double-click a clip to display it in the Preview panel. Use the Preview panel to display the clip information and additional metadata.
- For large media, use the Previewer to set In and Out points and import only a subclip.
- If the media file to import is located on a network drive, and if you plan on using referenced media instead of cached sources, make sure that the network connection is at least 1 GB ethernet to have decent playback.

- If the media file to import is located on a removable media such as a USB drive, and you plan to remove the drive before the end of your project, import with Cache Source Media enabled. This way Flame Premium creates natively managed media out of the original, removing the need for the connected drive.
- From the Media Library, right-click > Import... to import media to that location.
- To work in a manner similar to offline editing suites, enable **MediaHub > General tab > Cache Source Media**. This creates local, transcoded, and managed versions of your media. To work online, disable Cache Source Media: the clips remain linked to the original media, and are not transcoded.
- The first time you browse a folder containing long-GOP based codecs (.mts- and .m2ts-structures for AVCHD), Flame Premium creates invisible index files in that folder. These index files will speed up browsing the next time you open that folder.

NOTE Technically, the index files are created with the suffix *.index* in the folder being browsed and can be removed if needed: this will only impact AVCHD browsing performances in that folder, not reading nor writing performances. If that folder is write-protected, Flame Premium creates the index files in the local */var/tmp/*.

Exporting Clips and Sequences to Files

To export a clip or a sequence:

- 1 Do one of the following:
 - From the Media Panel, right-click the clip to export and select Export. And then, using the Media Export window, navigate to the clip's destination.
 - From the MediaHub, drag-and-drop the file from the Media panel to the location displayed in the browser.
- 2 Select an Export type and a Format Preset.
- 3 Click Export.

Flame Premium prepares the export job. Once that preparation is done, the rest of export happens in the background and frees up Flame Premium for your use.

NOTE In the case of the Sequence Publish export type, the presets for EDL Publish, Simple Publish, and Source Media Publish all have Foreground Publish enabled (**Show Advanced Options > Video Options**). Because of this setting, all exports with those presets are done in the foreground. You can always disable Foreground Publish, but the publish operation can take longer.

Tips

To be able to export an RGBA movie file or file sequence, you have to create a Matte Container prior to exporting media files.

- Use the Create Matte Container option in the MediaHub. The resulting clip will be a Matte Container and the Comp effect will be disabled.
- Use the Create Matte Container Tools and select the Contain or the Contain & Add Comp option.
- Use the Add Matte option in the Timeline FX ribbon to create a Matte Container.
To be able to export an RGBA media file, make sure the Comp effect is muted before exporting.
- Use **Ctrl-click** to select multiple clips for export in one operation.
- Select a folder, a reel, or a library from the Media Library to export all of its contents. If that folder contains a folder structure, that structure also gets exported.

- When exporting a single frame, consider setting the Frame Padding field to zero to export that frame without any file numbering. And if you export a multi-frame clip sequence by mistake, Flame Premium detects this and uses a frame padding of 8 digits to correctly export the clip.

- **Apple Final Cut Pro X XML Export**

When you open the XML in FCP X, the media will automatically relink if exported to a file location available on the FCP X workstation. You might have to use the FCP X Relink tool to link the XML sequence back to the YUV QuickTime if the media file path is different.

Note that if you export to a Mac Wiretap Gateway server, you have the added option of exporting the reference file as a ProRes QuickTime.

Not all clip timings are compatible with every codecs. For example, such a 30fps clip cannot be exported as a XDCAM HD 422 (which accepts only 25fps source clips). So when you export multiple clips, Flame Premium exports only the ones with a timing compatible with the codec you selected.

Publishing a Sequence

To publish a sequence as an EDL and export its media:

- 1 Right-click the clip to export and select Export.
In the MediaHub, you can also drag-and-drop the file from the Media panel to a location displayed in the MediaHub browser.
- 2 Navigate to the clip's destination, using the Media Export window.
- 3 Set Export Type to Sequence Publish.
- 4 Set Format Preset to one of the EDL Publish presets.

NOTE Because of the limitations of the format used for the EDL (CMX3600), the published sequence is flattened to 1 video track and 8 audio tracks.
- 5 Click Export.
Flame Premium prepares the export job. Once that preparation is done, Flame Premium performs the export in the background. You are free to use the application as the export happens.

NOTE If you disable both Export Video Media and Export Audio Media in the Sequence Options tab, the resulting EDL contains the paths to the original source media files. Such paths are stored in the resulting EDL as DLEDL comments.

To publish a sequence as an FCP X XML and export its media:

- 1 Right-click the clip to export and select Export.
In the MediaHub, you can also drag-and-drop the file from the Media panel to a location displayed in the MediaHub browser.
- 2 Navigate to the clip's destination, using the Media Export window.
- 3 Set Export Type to Sequence Publish.
- 4 Set Format Preset to one of the XML for Apple Final Cut Pro X.

NOTE The published sequence is a committed QuickTime YUV video, with or without 48 kHz audio file. The XML contains one flattened video track, with or without the audio tracks (there is no audio mixdown).
- 5 Click Export.
Flame Premium prepares the export job. Once that preparation is done, Flame Premium performs the export in the background. You are free to use the application as the export happens.

When you open the XML in Final Cut Pro X, the media will automatically relink if you exported it to a file location accessible to FCP X. You might have to use the FCP X Relink tool to link the XML sequence back to the QuickTime file if the media file path is different.

NOTE Note that if you export using a Mac Wiretap Gateway server, you have the added option of exporting the reference file as a ProRes QuickTime.

Publishing a Sequence as a Customized EDL

The standard EDL published by Flame Premium uses the CMX3600-DLEDL format. But if you require a format other than CMX3600, or need to change how events are combined, use the EDL editor.

NOTE A customized EDL is always published without its media.

To publish a customized EDL:

- 1 Right-click the sequence to export and select Export.
- 2 Set Export Type to Sequence Publish.
- 3 Set Format Preset to one of the EDL presets.
- 4 Click Show Advanced Options.
- 5 Click **Sequence Options > Custom EDL Export**.
The EDL editor appears.
- 6 Set the EDL Save options as required.
- 7 Click Generate, and then click Save Generated EDL.
- 8 In the file browser that appears, browse to the location where you want to export the EDL.
- 9 Click Save. This saves the EDL and returns you to the EDL Editor.
- 10 Exit the EDL Editor.

Custom EDL Export Window Reference

Generate button Generates the new EDL and activates the Save Generated EDL button.

Save Generated EDL button Opens a file browser for you to select a location where to save the EDL.

Specify a file name and path for the saved EDL in the file browser that appears. The filename cannot contain any of the following characters: ` # ~ @ \$ % ^ & * () [] { } < > \ | / ! ? , ; : ' "

EDL Event Combination box Indicates how events with the same source timecodes, record timecodes, and tape ID are combined when the EDL is generated.

Select:	To use:
Combine All Events	A single entry for all video and audio events.
Combine Audio Events	One entry for audio events and a separate entry for video events.
Never Combine Events	A separate entry for each video and audio event.

EDL Format box Select the format of the generated EDL.

You can save EDLs in any of the following formats:

- CMX 340
- CMX 3600
- CMX OMNI
- GVG 4
- GVG 4 Plus (GVG v4.1 or higher)
- SONY 900
- SONY 910
- SONY 5000
- SONY 9000
- SONY 9000 Plus (v2.21 or higher)
- SONY 9100

Segment Comments button Enable to allow comments added to the timeline to be included in the generated EDL.

Clip Name Comments button Enable to allow clip name comments to be included in the generated EDL.

2:3 Insertion Mode button Enable to convert the framerate of a 24p clip from 23.97 fps to 29.97 fps, and maintain 2:3 pulldown information for all in and out points (including cuts, wipes, dissolves, and timewarps). 2:3 pulldown data is important when master tapes are sent out for hardware-based tape-to-tape colour correction.

Frame Code Mode box Select the drop frame mode for the output material: DF (drop frame) or NDF (non-drop frame).

The EDL file will include explicit notification of hybrid splices as punctuation marks in the record in and out data.

A:	Indicates a:
period (.)	Regular splice record-in point for 29.97 fps non-drop frame timecode tapes.
comma (,)	Regular splice record-in point for 29.97 fps drop frame timecode tapes.
colon (:)	Hybrid splice record-in point for 29.97 fps non-drop frame timecode tapes.
semi-colon (;)	Hybrid splice record-in point for 29.97 fps drop frame timecode tapes.

This button is enabled by default when a 24p template is selected at project creation.

Use Delayed Dissolves button Enable to include delayed dissolves in the generated EDL.

Default Tape field Enter a tape name if you want to override the default tape ID when saving an EDL.

Source clips are assigned tape IDs when loaded using the Clip VTR Input or through the Conform tab. For example, an edit that uses a clip created with the Colour Corrector does not have a tape ID. When the EDL is generated, the clip is given the tape ID in the Default Tape field.

Audio Patch Comments button Enable to allow clip audio patching comments to be included in the generated EDL.

Use Tape Name Extension button Enable to correctly support long tape names (more than 8 characters).

This adds a list to the end of the EDL that shows the relationship between a abbreviated tape name (8 characters, maximum) used in the EDL and the actual tape name (52 characters, maximum).

Creating New Export Presets

Flame Premium comes with a number of export presets that should cover most of your needs. But you can also create your own presets.

Whenever you edit an existing preset, it gets appended *_custom*. That new custom preset remains until you change project, exit Flame Premium, or click Reset.

To create a new export preset:

- 1 Select an Export Type.
- 2 Select a Format Preset.
Select the preset that is the closest to what you want, to minimize the amount of required configuration.
- 3 Enable Show Advanced Options.
- 4 Edit the settings as required.
Notice how the Format Preset box has appended the preset you selected with the *_custom* suffix.
- 5 Do one of the following:
 - To cancel your edits, click Reset.
 - If this is essentially a one-off customization that you will not need later, click Export to export your sequence. You can always save that preset at a later time: a customized preset remains until you exit Flame Premium or change project.
 - To keep this new preset, click Save. You now the new preset in Project or Shared sections of the Format Preset drop-down menu, and the original preset back in the Autodesk section.

TIP Consider creating an Export preset with padding set to 0 to export single-frame clips without any file numbering. And to avoid overwriting the media files, Flame Premium will automatically name file sequences of more than one frame with the default padding of 8 digits.

H.264 Codec Export Profiles

When exporting a clip as an H.264 in QuickTime, you can use one of the pre-configured H.264 codec profiles.

NOTE The H.264 codec profiles are xml files stored in */usr/discreet/mediaconverter/2014.../profiles/Quicktime/video/H264*.

The Suggested Clip Resolution guides you in the selection of a target resolution for the output. Using a different resolution can have unexpected results.

Profile	Description	Suggested Clip Resolution	Bit Rate
Baseline_1SEG_384Kbits	H264_CIF, Baseline profile	352x288 or 352x240	384 Kb/s
Baseline_3GP_256Kbits	H264_3GP 3GP, Baseline profile	352x288	256 Kb/s

Profile	Description	Suggested Clip Resolution	Bit Rate
Baseline_600Kbits	H264_BASELINE, Baseline profile	320x240	600 Kb/s
Baseline_Adobe_300Kbits	H264_FLASH_LOWRES, Baseline profile	320x240	300 Kb/s
Baseline_Apple_1_5Mbits	H264_iPOD Apple iPod, Baseline profile	320x240	1.5 Mb/s
Baseline_Apple_400Kbits	H264_iPOD Apple iPod, Baseline profile	320x240	400 Kb/s
Baseline_Apple_600Kbits	H264_iPOD Apple iPod, Baseline profile	320x240	600 Kb/s
Baseline_Apple_970Kbits	H264_iPOD Apple iPod, Baseline profile	320x240	970 Kb/s
Baseline_CIF_600Kbits	H264_CIF at, Baseline profile	352x288 or 352x240	600 Kb/s
Baseline_RIM_12Mbits	H264_BASELINE, Baseline profile	1920x1080	12 Mb/s
Baseline_RIM_20Mbits	H264_BASELINE, Baseline profile	1920x1080	20 Mb/s
Baseline_RIM_4Mbits	H264_BASELINE, Baseline profile	1920x1080	4 Mb/s
HDTV_1080i_10Mbits	H264_HDTV_1080i, High profile, interlaced	1920x1080	10 Mb/s
HDTV_720p_8Mbits	H264_HDTV_720p, High profile	1280x720	8 Mb/s
High_1080i_6Mbits	H264_HIGH, High profile, interlaced	1920x1080	6 Mb/s
High_AVC_HD_20Mbits	H264_AVCHD AVCHD, High profile, interlaced	1920x1080	20 Mb/s
High_AVC_Intra_111Mbits	H264_INTRA_CLASS_100 AVC Intra Class 100, High 10 profile, interlaced	1920x1080	111 Mb/s

Profile	Description	Suggested Clip Resolution	Bit Rate
High_AVC_Intra_54Mbits	H264_INTRA_CLASS_50 AVC Intra Class 50, High 10 profile, interlaced	1440x1080	54 Mb/s
High_Blu_Ray_20Mbits	H264_BD_HDMV Blu-ray HD, High profile, interlaced	1920x1080	20 Mb/s
High_Blu_Ray_8Mbits	H264_BD Blu-ray SD, High profile, interlaced	720x576 or 720x480	8 Mb/s
High_Divx_2Mbits	H264_DIVX DivX+, High profile	1920x1080	2 Mb/s
High_DVD_3Mbits	H264_DVD, High profile, interlaced	720x576 or 720x480	3 Mb/s
High_HD_DVD_20Mbits	H264_HD_DVD, High profile, interlaced	1920x1080	20 Mb/s
High_Microsoft_10Mbits	H264_SILVERLIGHT Microsoft Silverlight, High profile	1920x1080	10 Mb/s
High_Microsoft_500Kbits	H264_SILVERLIGHT Microsoft Silverlight, High profile	640x480	500 Kb/s
Main_3Mbits	H264_MAIN, Main profile	704x576 or 704x480	3 Mb/s
Main_Adobe_670Kbits	H264_FLASH_HIGHRES, Main profile	640x480	670 Kb/s
Main_Apple_1_8Mbits	H264_MAIN, Main profile	1024x576	1.8 Mb/s
Main_Apple_4_5Mbits	H264_MAIN, Main profile	1280x720	4.5 Mb/s
Main_D1_3Mbits	H264_D1, Main profile, interlaced	720x576 or 720x480	3 Mb/s
Main_Sony_2Mbits	H264_PSP_640x480 Sony PSP Level 3, Main profile	640x480	2 Mb/s
Main_Sony_700Kbits	H264_PSP Sony PSP, Main profile	320x240	700 Kb/s

Profile	Description	Suggested Clip Resolution	Bit Rate
Main_Sony_900Kbits	H264_PSP_480x270 Sony PSP Level 2, Main profile	480x272	900 Kb/s
Main_SVCD_1_15Mbits	H264_SVCD, Main profile, interlaced	480x576 or 480x480	1.15 Mb/s

Exporting to QuickTime ProRes Using a Remote Gateway

You use a remote Gateway running on a Mac to export media to QuickTime ProRes files from a Linux-based Flame.

- 1 Set **Preferences ► Backburner ► Backburner Manager box** to a Mac OS X workstation running a Gateway.
This ensures that the exports are done using that workstation's Gateway. This has the side effect of disabling, for your exports, your access to your local volumes. Flame Premium now considers that you are exporting from the Mac OS X workstation. Switching the Backburner Manager box back to your workstation solves this.
- 2 Close the Preferences window.
- 3 Right-click the clip to export and select Export.
Or in the MediaHub, you can drag-and-drop the file from the Media panel to a location displayed in the MediaHub browser.
- 4 Navigate to the clip's destination, using the Media Export window.
Remember, the navigation is from the perspective of the Mac OS X workstation running the Gateway, not from your Flame Premium.
- 5 Select an Export type and a Format Preset.
Since you are exporting from a remote Gateway running on a Mac OS X workstation, you now have access to QuickTime ProRes file formats.
- 6 Click Export.
Flame Premium takes a few instants to prepare the export job. Once that preparation is done, the rest of export happens in the remote Gateway and frees up Flame Premium for your use.

NOTE The Gateway, also known as the Wiretap Gateway, is the component of the Flame Premium application responsible for all import and export operations. You are usually provided with one remote Gateway license with your Flame Premium, allowing you to install one such Gateway on a Mac OS X workstation and thus export to QuickTime ProRes files.

Media Export Window Settings

Basic Options

Export Type box Select the type of export to use with the selected files.

Preset Selection box Select the export preset to apply to the exported files. Autodesk presets are built-in presets that you can still modify using the Advanced Options. An asterisk indicates that the preset's advanced options were modified.

Exported File Name field Displays the name given to the exported file, as defined in the Advanced Options. Editable when exporting a single clip.

Advanced Options button Enable to display the advanced options. You should not have to edit these settings, unless the pre-configured presets do not meet your needs.

Sequence Options Tab

Sequence Format box Select the format of the sequence. Media Only exports the segments of the sequence as individual clips, but does not export the sequence itself.

Include Video button Enable to include in the published sequence the video tracks information. Required to export the video media.

Include Audio button Enable to include in the published sequence the audio tracks information. Required to export the audio media.

Sequence Filename field Displays the sequence filename based on the Pattern field. Each type of exported file has its own filename defined in the relevant tabs. Non-editable.

Sequence Filename Pattern field Displays how to name the exported media files. Build a dynamic naming scheme using Add Token, or characters normally allowed in a file name. Create folder structure using / . The extension for the file format is automatically appended. Frame identifiers are automatically added to image sequence files. Editable.

Add Token box Inserts a token in the Pattern field to build a dynamic filename. Note: date is the current date, formatted as YYYY_MM_DD.

Select:	To insert the token:	Definition:
Clip Name	<name>	The clip's name
Date	<date>	The current date (YYYY_MM_DD)
Workstation	<workstation>	The name of the workstation, as displayed in the Host Computer field in Flame ► Project and User Settings .
Project	<project>	The name of the project, as displayed in Flame ► Project and User Settings .
User	<user>	The user name, as displayed in Flame ► Project and User Settings .
Clip Height	<height>	The clip's height, after resize if applicable.
Clip Width	<width>	The clip's width, after resize if applicable.
Tape/Reel/Source	<tape>	The clip's tape name
Time	<time>	The time, formatted HH:MM:SS.

Export Video button Enable to export the segments of the sequence as files of the type specified in Video Format.

Video Format box Select the type of video file to create. For movie, select the wrapper and codec in the Movie Options tab. For file sequence, select the file type in the Video Options tab.

Media Source box Select Use Original Media to export the original source referred by the exported sequence, without any modifications. Select Use Media with FX to export the rendered media.

Video Tracks and Transitions box Select Keep All Tracks to export a clip for each segment of the sequence. Select Flatten Tracks to export commit every transition and flatten the sequence. Select Flatten with Transitions to flatten the sequence and commit every transition except dissolves, creating a single clip.

Include Video Handles button Enable to add head and tail frames to the exported video segments that do not have a Timeline FX applied.

Video Handles field Displays the amount of head and tail frames. Editable.

Export Audio button Enable to export the audio tracks of the sequence.

Audio Source Selection box Select Use Original Media to export the original source referred by the exported sequence, without any modifications. Select Use Media with FX to export the rendered media.

Audio Track State box Select Flatten Tracks to commit all transitions and create one audio clip per track. Select Flatten Tracks with Transitions to create an audio clip per track but keep live transitions. Select Keep All Tracks to export one audio clip per audio segment.

Include Audio Handles button Enable to add head and tail frames the exported audio segments that do not have a Timeline FX applied.

Audio Handles field Displays the amount of head and tail frames. Editable.

Movie Options tab

Movie Format box Select the container for the exported media.

Compression box Select the codec to apply to the exported movie file. The available codecs depend on the selected Movie Format.

Codec Profile box Select a pre-defined video compression codec profile when exporting QuickTime files using the H.264 or MPEG-4 codecs.

YUV Headroom Disable to export a YUV headroom compliant clip (also known as valid- or legal-range). As a general rule, should be enabled when deliverable is for broadcast. Enable to export a standard, full-range, clip.

Include Audio button Enable to include audio tracks within the exported file. Available only if Export Type set to Movie.

Video Options tab

Video Format field Select the format for the exported media.

Compression box Select the image compression to apply to the exported file sequence. The available compressions depend on the selected Video Format.

Link Original Media button Enable to hard link the published files to the original files if both the original and exported files are located on the same filesystem. If not, the application creates soft links back to the originals. Available for file sequences only.

This option saves disk space on export as files that remain unchanged by the export are not duplicated. Unchanged in this context means they were not rendered not resized in anyway. For example, a file sequence of 20 dpx are imported in Flame Premium. Of those 20, 12 are modified in some fashion. With Link Original Media enabled, of the sequence of 20 dpx, only the modified 12 are actually created at export; the other 8 dpx are just linked to from the export folder.

NOTE You can have Flame Premium copy files instead of creating symbolic links across filesystems by editing the *StandardFSMediaOptions* keyword in the *stone+wire.cfg* configuration file.

Foreground Publish Enable to generate as a foreground process the filesystem links to the original media files, making the export faster. You cannot use the Flame Premium while the export is running. Available when Link Original Media is enabled.

When this option is enabled, Flame Premium bypasses the Backburner background task manager when exporting, preventing the export job from showing up in the Backburner Monitor.

DPX Transfer Characteristics box Select an option to identify the attributes associated with a particular film or video format, such as resolution, frame rate, or colour space. Available when Video Format is set to DPX.

When exporting DPX files, you can choose a DPX Transfer Characteristic. A DPX Transfer Characteristic is information that is stored in the DPX image file header. It identifies the attributes associated with a particular film or video format, such as resolution, frame rate.

Setting a Transfer Characteristic in no way changes the *image* information stored in the DPX file. The Transfer Characteristic simply indicates the attributes of the DPX file read by another device or application. Some devices or applications may take advantage of this information to improve workflow. For example, selecting Logarithmic can allow a film recorder to adjust its parameters to print film-originated DPX files with the correct densities.

Select:	For:
Z depth homogeneous, Z depth linear, PAL, NTSC, CCIR 601 (525), CCIR 601 (625), CCIR 709-4, SMPTE 274M	Images that you want to identify as one of these types. Although the SMPTE 274M standard defines these DPX Transfer Characteristics, it does not provide usage specifications for them. As a result, these Transfer Characteristics are not generally used in the industry.
Unspecified	Images where the format is not specified.
Logarithmic	Negative film scanners recording status M densities.
Linear	Video images which have built-in gamma correction. This refers to images having a true linear quantization scheme (such as CG-originated material).
Printing Density	Negative film scans which use the SMPTE Printing Density settings. SMPTE Printing Densities use status M density measurements with a higher gain in the red component.
Academy Density Exchange (ADX)	Images at 10- and 16-bit film density encoding, in which colour information is encoded using a logarithmic scale. Usually used in the context of an Image Interchange Format workflow.

DPX Colorimetric Specification box Select an option to identify the colorimetric specifications used to encode the DPX files. Available when Video Format is set to DPX.

Setting a Colorimetric Specification in no way changes the *image* information stored in the DPX file. The Colorimetric Specification simply indicates the attributes of the DPX file read by another device or application. Some devices or applications may take advantage of this information to improve workflow. For example, selecting Academy Density Exchange (ADX) can allow a film recorder to adjust its parameters to print film-originated DPX files with the correct densities.

JPEG Quality field Specifies the degree of quality versus compression. A value of 0 gives the lowest quality (and highest compression), while a value of 100 gives the best quality (but applies no compression). Available when File Format is set to JPEG.

LUT Activation button Enable to apply the LUT displayed in Applied LUT to the clip .

LUT Type box Select the type of LUT to apply to the clip.

Applied LUT field Displays the type of conversion LUT applied to the clip, either imported using Import, or edited using Edit.

Import button Use to browse and select a LUT.

LUT Editor Access button Click to open the LUT editor.

Frame Padding field Define the padding of the frame identifiers appended to each file of an image sequence. Only used with image sequences.

For example, a frame pad of 6 indicates that each frames's file name has its frame identifier padded with a number of zeroes required to make it a 6-digit number: frame 1 is written as 000001, frame 22 as 000022, frame 55555 as 055555, and so on.

Use Timecode button Enable to base the start number of the exported sequence of numbered images on the timecode read from the clip file.

Start Frame field Enter the start number to be used in the exported sequence of numbered image files. Disabled when Use Clip TC Names is enabled.

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution.

Fit Method box Select a fit method option to be applied to the exported clip.

Select:	To:
Centre/Crop	Fit the source image, centred, over the destination frame. If the source is larger than the destination, it is cropped. If the source is smaller than the destination, it is surrounded by a black border.
Crop Edges	Fit one edge of the source into the destination frame without stretching or squashing the frame. Excess parts of the source frame after resizing are cropped. If the source—after the one edge is resized—is wider than the destination, its overhanging left and right edges are cropped. If the source is taller than the destination, the upper and lower edges are cropped.
Fill	Fit the source, width, and height, into the destination frame. If the source and destination frames do not have the same aspect ratio, the image can become distorted.
Letterbox	Fit the source to the destination frame without squashing or stretching it, and without cropping the source. If the source is wider than the destination, black bars fill the top and bottom of the destination frame. If the source is narrower than the destination, black bars fill the right and left sides of the frame. In all cases, the entire source frame is contained within the destination frame.

Resize Filter box Select the filter option to determine the quality of the interpolated resize result. The Resize Filter box is active only if Fit Method is set to Crop Edges, Fill, or Letterbox.

Select:	To get:
Impulse	Quick, low-quality results.
Triangle	Moderate results with little processing overhead.
Mitchell	Best results when resizing a clip to a higher resolution.
Bicubic	Very good results for resizing soft-looking images. Use to sharpen the image.
Quadratic	Good results for resizing simple images with straight edges. Similar to Gaussian but with more blurring. Use to soften the image.
Gaussian	Excellent results when resizing a clip with no patterns and numerous straight edges to a lower resolution. Useful for softening some detail.
Shannon	Excellent results when resizing a clip to a lower resolution. Very similar to Lanczos, but results are a little softer.
Lanczos	Best results when resizing a clip containing a variety of patterns and elements to a lower resolution. It is the most complex with the longest processing time.

Frame Width field Displays the frame width of the selected clip. By clicking it you activate the field, allowing you to enter the frame width value that you want to use on export.

Frame Height field Displays the frame height of the selected clip. By clicking it you activate the field, allowing you to enter the frame height value that you want to use on export.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the aspect ratio defined by Aspect Ratio Presets. Editable.

Bit Depth box Select a bit depth to be used on export. Some file formats support multiple bit depths. Bit Depth is active only when Resize is enabled.

Scan Mode box Select an option to set the order in which the fields of interlaced material are scanned.

For interlaced material, you can specify whether the resize needs to be done from both fields or just from one of the two. In the latter case, the result is a progressive clip made from the same two fields.

Select:	To resize:
From Clip	Using the scan mode of the source clip.
Progressive	A frame-based clip to another frame-based clip.
Field 1	A clip by drawing Field 1 followed by Field 2.
Field 2	A clip by drawing Field 2 followed by Field 1.

Audio Options Tab

Audio Format box Select the audio format of the exported audio tracks. If Export Type is Movie, the audio is embedded within the video file. Any other Export Type outputs a separate audio file.

Audio Bit Depth box Select the bit depth of the exported audio file.

Audio Compression field Select the compression for the exported audio file. The available options depends on the Audio Format.

Audio Sample Rate box Select the sample rate of the exported audio.

Audio Mixdown box Select a mixdown to apply to the audio tracks, if any are included with the source clip.

Select:	To mix down:
No Mixdown	Nothing
Mixdown As Is	With the current output strip assignments.
Mixdown To 4 tracks	To four tracks. The output strips are assigned sequentially in fours to the mixed-down channels (where M1 goes to 1, M2 to 2, M3 to 3, M4 to 4, M5 to 1, and so on).
Mixdown To Stereo	To one stereo track. The output strips are assigned sequentially in twos to the mixed-down channels (where M1 goes to 1, M2 to 2, M3 to 1, M4 to 2, and so on).
Mixdown To Mono	To one mono track.

Clip Options Tab

Copy Exported Clip in Media Library button Enable to automatically create a copy of the exported clip in the Media panel, linked to the exported media files. Available when performing a Sequence Publish with a File Sequence, with no resize or bit depth change. This is similar to importing back the exported media with Cache Source Media disabled.

Supported Media File Formats

Tables in this topic:

- [Image Sequence](#) (page 70)
- [QuickTime](#) (page 72)
- [MXF](#) (page 74)
- [MP4](#) (page 76)
- [Other Streaming Codecs](#) (page 76)
- [Audio File Formats](#) (page 76)

NOTE Flame Premium cannot display 16-bit integer media (16i in the tables below). It automatically interprets it as 12-bit unpacked. Because of this, 16-bit integer media appears as 12-bit unpacked in the Preview panel. And when you import that media, Flame Premium converts it to 12-bit unpacked. This process is perceptually negligible, as only the 4-least significant digits are discarded. But you can promote 16i media to 16f in order to maximize the precision available for compositing, by applying a colour transform. See [Converting Images Between 12i or 16i and 16f Encodings](#) (page 1598).

Also, if you use the Link Original Media video option during your export, image files that were not edited are not affected by this conversion.

Image Sequence

Format	Extension	Import	Export	Depth
Alias®	.als	yes (page 130)	yes	8 bits
ARRIRAW	.ari	yes (page 118)	—	12, 16fp bits
	NOTE Always presented as a clip, never as a sequence of RAW images. Supports material shot on camera using ARRI SUP 7 or earlier, and features from version 4.4 of the ARRIRAW SDK.			
Cineon®	.cin	yes (page 130)	yes	10 bits
DPX	.dpx	yes (page 125)	yes	8, 10, 12, 16i bits and ADX encoding.
	NOTE 8, 12, and 16i bits support alpha.			
DPX - Single channel	.dpx	yes (page 125)	—	See Note.
	NOTE Monochromatic DPX files from the following film scanners have been validated: <ul style="list-style-type: none"> ■ FilmLight Northlight (10 & 16-bit) ■ DigitalFilmTechnology SCANITY™ (10 & 16-bit) ■ Imagica (8, 10 & 16-bit) Lustre supports single channel DPX files only when imported through Wiretap Gateway.			
Gateway	.clip	yes (page 128)	—	n/a
HDR	.hdr	yes (page 128)	—	32 bits
JPEG	.jpg	yes (page 130)	yes	8 bits
OpenEXR	.exr	yes (page 135)	yes	8, 10, 12u, 12, 16fp, or 32fp bits RGB, RGBA, and multi-channel
	NOTE On import, 32-bit floating point is downconverted to 16-bit floating point. Export is 16-bit only.			

Format	Extension	Import	Export	Depth
OpenEXR 2.0	.exr	yes (page 135)	—	8, 10, 12u, 12, 16fp, or 32fp bits RGB, RGBA, and multi-channel
				NOTE Multi-part and deep pixel features are not supported: only the first part of a multi-part file can be accessed, and deep pixel channels are ignored. On import, 32-bit floating point is downconverted to 16-bit floating point.
Photoshop	.psd	yes (page 138)	—	8 or 16i bits RGB and RGBA
Pict (Macintosh®)	.pict	yes (page 130)	yes	8 bits
				NOTE Supports alpha.
Pixar	.picio	yes (page 130)	yes	8 bits
				NOTE Supports alpha.
Portable Network Graphics	.png	yes (page 139)	—	8 or 16i bits
				NOTE Supports alpha.
Precomp	.precomp	yes (page 141)	—	8, 10, 12u, 12, 16fp, or 32fp bits
SGI®	.sgi	yes (page 130)	yes	8 or 16i bits
				NOTE Supports alpha.
Softimage®	.pic	yes (page 130)	yes	8 bits
				NOTE Supports alpha.
TARGA®	.tga	yes (page 130)	yes	8 bits
				NOTE Supports alpha.
Tdi/Maya®	.iff	yes (page 130)	—	8 or 16i bits
				NOTE Supports alpha.
Tiff	.tif	yes (page 130)	yes	8 or 16i bits

Format	Extension	Import	Export	Depth
	NOTE Supports alpha.			
Wavefront®	.rla	yes (page 130)	yes	8 or 16i bits
	NOTE Supports alpha.			

QuickTime

Format	Extension	Import	Export	Depth
8-bit Packed YUV 4:2:2	.mov	yes (page 141)	yes	
	NOTE Lossy codec. Avoid using for intermediates.			
10-bit Packed YUV 4:2:2	.mov	yes (page 141)	yes	
	NOTE Lossy codec. Avoid using for intermediates.			
Apple Animation	.mov	yes (page 141)	—	
	NOTE Supports alpha.			
Apple Graphics	.mov	yes (page 141)	—	
Apple® Video	.mov	yes (page 141)	—	
Cinepak	.mov	yes (page 141)	—	
Component Y'Cb-Cr 8-bit 4:4:4	.mov	yes (page 141)	—	8-bit planar

	NOTE There is no essence-mode browsing in a QuickTime XDCAM EX.			

MXF

Format	Extension	Import	Export	Depth
AVC-Intra 50	.mxf	yes (page 133)	yes	

Format	Extension	Import	Export	Depth
	NOTE Panasonic P2			
AVC-Intra 100	.mxf	yes (page 133)	yes	
	NOTE Panasonic P2. Import includes support for 1080/60p.			
AVC-Intra 200	.mxf	yes (page 133)	—	
	NOTE Supports 1080/25p, 1080/30p, 720/50p, and 720/60p.			
DNxHD	.mxf	yes (page 133)	yes	
	<p>NOTE Includes support for the following families: 36, 60, 75, 90, 90x, 110, 110x, 115, 145, 175, 175x, 185, 185x, 220, 220x.</p> <p>DNxHD from ARRI ALEXA cameras (145 and 220x as OP1a) are supported.</p> <p>In MXF Op-Atom files generated by Avid Media Composer, audio tracks appear in the MediaHub as a single audio channel file (A1). But once imported, the tracks display the original channels.</p>			
DV 25	.mxf	yes (page 133)	—	
	NOTE Panasonic P2			
DVCPRO	.mxf	yes (page 133)	yes	
	NOTE Panasonic P2			
DVCPRO 50	.mxf	yes (page 133)	yes	
	NOTE Panasonic P2 (PAL & NTSC)			
DVCPRO HD	.mxf	yes (page 133)	yes	
	NOTE Panasonic P2. Available in 1080p@25/50, 1080p@24/30/60, 720p@25/50, and 720p@24/30/60.			
SonyRAW	.mxf	yes (page 149)	—	
	NOTE Includes support for Sony F65, F55, and F5 camera outputs.			
XAVC	.mxf	yes (page 133)	—	
	NOTE Includes support for Sony F55 and F5 camera outputs, in HD and 4K.			

Format	Extension	Import	Export	Depth
XDCAM	.mxf	yes (page 133)	—	
				NOTE MPEG-2 IMX-30, IMX-40, and IMX-50
XDCAM HD	.mxf	yes (page 133)	yes	
				NOTE MPEG-2 long-GOP. Import supports 4:2:0 and 4:2:2. Export is 4:2:2.

NOTE Flame Premium exports MXF as OP-1a files (including the timecode). The is audio encoded as PCM, 16-Bit or 24-Bit. Avid applications support OP-Atom MXF files: use the AMA MXF plug-in to bring the OP-1a files into an Avid application.

MP4

Format	Extension	Import	Export	Depth
H.264	.mp4	yes (page 131)	—	
XDCAM EX	.mp4	yes (page 151)	—	
	NOTE MPEG-2 long-GOP			

Other Streaming Codecs

Format	Extension	Import	Export	Depth
AVCHD	.mts or .m2ts	yes (page 123)	—	
				NOTE Only linear PCM audio is supported. Some cameras can record AC-3 audio, but this format is not supported: Flame Premium can still access the video portion of the media.
R3D	.r3d	R3D Format Settings - Import (page 143)	—	12, 16fp bits
				Supports REDCODE RAW 2 and 3, RED SDK version 4.4, including MONOCHROME R3D media. Starting with Flame 2013 20th Anniversary Edition Extension Extension 2 Service Pack3, changes to the RED SDK affected how the DRX setting was computed for all R3D clips. If you are using clips imported with a earlier version, review the clips DRX setting. See the DRX setting in R3D Format Settings - Import (page 143).

Audio File Formats

Format	Extension	Import	Export	Depth
AIFF	.aiff	yes	yes	16 or 24 bits

Format	Extension	Import	Export	Depth
AIFF-C	.aifc	yes	yes	16, 24, 32fp bits
Audio Visual Research	.avr	yes	yes	16 bits
Berkeley/IR-CAM/CARL Sound (BISCF)	.bsf	yes	yes	16 bits
MP3	.mp3	yes	yes	16 bits
Nextsnd	.au	yes	yes	16, 24, 32fp bits
WAVE	.wav	yes		16, 24, 32fp bits
WAVE - Broadcast	.wav	yes	yes	16, 24, 32fp bits
	NOTE Includes support for RF64 files (BWF-compatible format that supports files larger than 4 GB).			
WAVE - Extensible	.wav	yes	—	16, 24, 32fp bits
	NOTE Audio tracks are imported as regular audio tracks, without mapping the channels to spatial locations.			

NOTE Files of any sample rate can be imported, but they are all resampled to 48 kHz.

Supported QuickTime Audio

The table below lists the audio codecs supported in .mov files, as audio-video and audio-only files.

Audio CODEC	Import	Export
16-bit PCM	yes	yes
	NOTE Export supports both big and small endian.	
24-bit PCM	—	yes
	NOTE Export supports both big and small endian.	
32-bit floating point PCM	—	yes
	NOTE Export supports both big and small endian.	

Audio CODEC	Import	Export
32-bit float	—	yes
A-law 2:1	yes	yes
ADPCM ima WAV	yes	—
Advanced Audio Codec (AAC)	yes	—
	NOTE Supported in mp4 and m4v files.	
Apple lossless	yes	—
IMA 4:1	yes	yes
Linear PCM (QT 7)	yes	yes
MPEG-2 Layer 2 Audio	yes	yes
MS ADPCM	yes	—
Ogg Vorbis (qt4l compatible)	yes	—
Ogg Vorbis (qtcomponents compatible)	yes	—
QDM2 Audio	yes	—
Raw 8-bit audio	yes	—
Sowt	yes	yes
	NOTE 16-bit PCM (Little Endian)	
Twos	yes	yes
	NOTE 16-bit PCM (Big Endian)	
Ulaw	yes	yes

About QuickTime ProRes Support

On Smoke, which runs on Mac OS X, Apple QuickTime ProRes imports and exports are supported natively. For all Linux-based application, exports using the Quicktime ProRes format requires connecting to a Wiretap Gateway running on a Mac OS X workstation.

Native ProRes import is supported in the following Linux applications:

- Flame
- Flame Premium
- Flame Premium - Grading
- Flare (when working with a Flame or Flame Premium project)

The following services can also decode clips using ProRes media imported by one of the above products:

- Burn
- Lustre Burn and Lustre ShotReactor
- Wiretap Central

Other Linux-based products can import ProRes by connecting to a Wiretap Gateway running on a Mac OS X workstation.

About Supported XDCAM Formats

List of supported data rates and timings for Sony XDCAM HD, XDCAM EX, and XDCAM 422 codecs.

XDCAM 422:

- 50mbit 1080/50i
- 50mbit 1080/60i
- 50mbit 1080/24p
- 50mbit 1080/25p
- 50mbit 1080/30p
- 50mbit 720/24p
- 50mbit 720/25p
- 50mbit 720/30p
- 50mbit 720/50p
- 50mbit 720/60p

XDCAM EX:

- 35mbit 1080/50i
- 35mbit 1080/60i
- 35mbit 1080/24p
- 35mbit 1080/25p
- 35mbit 1080/30p
- 35mbit 720/24p
- 35mbit 720/25p
- 35mbit 720/30p
- 35mbit 720/50p
- 35mbit 720/60p

XDCAM HD:

- 35mbit 1080/50i
- 35mbit 1080/60i
- 35mbit 1080/24p
- 35mbit 1080/25p
- 35mbit 1080/30p

Importing a Final Cut Pro XML Sequence

Flame Premium supports both FCP 7 and FCP X file formats.

NOTE To simplify the conform process, create the FCP XML project on a volume accessible to Flame Premium. And when exporting the FCP XML, save the FCP XML to the root of the media used in that timeline: the media should either be with the FCP XML, or within a folder alongside the FCP XML.

To import a sequence using the MediaHub:

- 1 Click the MediaHub tab.
- 2 Review the AAF & XML Import Options. Pay attention to the following options:
 - Preferred Media: If offline intermediates were used during the offline editing, decide now whether you wish to relink to the original media or to those offline intermediates.
 - Search and Import Files: Enable if you want to import the linked media.
 - Use Filename: For the best results, enable only this option. Disable Use Timecode, Use Tape, Use UMID, Use Resolution, and Use Framerate.
- 3 Using the file browser, navigate to the FCP XML sequence to import.
- 4 Drag the file from the browser to the Media Library.

Flame Premium converts the FCP XML to its timeline format, and imports the linked media using the Search Options as match criteria. The media itself is imported using the option file format options defined in the Format Specific Options tab.

FCP 7 Sequence Import: Supported Transitions and Effects

Sections in this topic:

- [Supported Data](#) (page 81)
- [Animation Interpolation](#) (page 82)
- [Motion](#) (page 82)
- [Video Transitions](#) (page 83)
- [Video Filters](#) (page 89)
- [Video Generators](#) (page 94)
- [Audio](#) (page 96)
- [Composite Modes](#) (page 97)

Supported Data

Flame Premium allows you to import multi-track compositions from Apple Final Cut Pro (FCP). Flame Premium reads XML exported from FCP (up to version 7.x of FCP, exported as XML version 2.0) and recreates a timeline accordingly.

The following tables describe the data that is output from FCP and input into Flame Premium.

General Data

FCP composition(s) data maps to Flame Premium timeline data.

Final Cut Pro	Flame Premium
Name	Name
Framerate	Framerate
Duration	Duration

Editorial Data

FCP Source media data and Record side data maps to Autodesk clip data.

Final Cut Pro	Flame Premium
Source media data: <ul style="list-style-type: none">■ Tape name■ Source TC in/out■ Edge code■ Log notes■ Aspect ratio■ Comments	Source clips: <ul style="list-style-type: none">■ Tape name■ Source TC in/out■ Keycode■ Elements comments■ Aspect ratio■ Elements Comments
Record side data: <ul style="list-style-type: none">■ In/Out■ Transition type■ Number of video tracks■ Number of audio tracks■ Marker■ In/Out marker	Record clip: <ul style="list-style-type: none">■ Segment■ Cut/Dissolve/Wipe/Action■ Video tracks■ Audio tracks■ Track marks■ In/Out marks

Effect Data

FCP transitions map to Flame Premium transitions, while FCP Filter effects and FX Script data map to Flame Premium Timeline FX.

Final Cut Pro	Flame Premium
Filter effects	Timeline FX
Transitions	Transitions

Animation Interpolation

FCP animation interpolation maps to Autodesk interpolation.

Final Cut Pro	Flame Premium
Corner	Linear
Smooth	Hermite

Motion

The following table describes how motion from FCP is mapped to Flame Premium Action Timeline FX parameters.

Final Cut Pro	Flame Premium
Basic Motion	Action (Axis)
Crop	Action (Crop)
Distort	Action (Surface)
Opacity	Action (Surface) (partially supported)
Drop Shadow	Action (Shadow)
Motion Blur	Not supported
Time Remap	Time Warp (see below)

About Time Remap to Timewarp

To make sure the conform is accurate with the creative editorial decisions from Final Cut Pro 7, the conformed timewarp speed value seen in Flame Premium Time Warp editor can be slightly different from the one seen in FCP7. But the actual Time Warp Timeline FX will be visually similar to the expected result, and be frame and keyframe accurate. There are exceptions:

- Frame blending used with this effect is not translated.
- Negative constant timewarp speeds are not applied to the audio tracks of the segment being timewarped.

- Variable time warps are not applied to the audio tracks of the segment being timewarped.

Video Transitions

The names of FCP transitions are preserved in Flame Premium and are visible in the timeline.

3D Simulation

Final Cut Pro	Flame Premium
Cross Zoom	Dissolve (partially supported)

Video Generators

The following tables describe generated effects that are translated into equivalent effects in Flame Premium.

Once imported into Flame Premium, effects created with the FCP video generator use the project's default resolution, regardless of their original resolution in FCP. This matches the behaviour of FCP: XML files with these effects that are reimported into FCP projects with different resolutions similarly inherit the project's resolution.

Video Generator

FCP X Sequence Import: Supported Transitions and Effects

Sections in this topic:

- [Supported Data](#) (page 98)
- [Video Effects](#) (page 99)
- [Retime Effects](#) (page 99)
- [Title Effects](#) (page 99)
- [Audio](#) (page 100)
- [Transitions](#) (page 100)
- [Loading RMD Files from FCP in Flame Premium](#) (page 101)

Supported Data

Flame Premium supports Final Cut Pro X (10.0.8) XML export, including ones referencing directly R3D, MXF, and ARRI Alexa ProRes files.

NOTE MultiCam segments in XML sequences from Final Cut Pro 10.0.4 and 10.0.5 are not imported correctly in Flame Premium. Use FCP 10.0.6 for correct support: MultiCam clips appear as regular segments.

Due to the limited information written to the XML file by Final Cut Pro X, the conform in Flame Premium can look different from the sequence created in Final Cut Pro X: Flame Premium cannot set parameters or recreate effects for which there is no information.

To see how the timeline will look in Flame Premium, export in Final Cut Pro X the timeline to XML, and then import it back in Final Cut Pro X.

The following general limitations apply to Final Cut Pro X XML imports in Flame Premium:

- Compounded (nested) clips are not supported. As a workaround, remove any compound clip before exporting the sequence from FCP.
- All transitions and supported effects are reset to default values.

Video Effects

The following effects are supported when conforming XML sequence from FCP X.

Apple Final Cut Pro X Effect	Translation in Flame Premium
Position	2D Transform with X and Y position
Scaling	2D Transform with X and Y scaling
Rotation	2D Transform with Z scaling
Transparency	Comp with transparency
Compositing mode	Comp with matching Blend mode

Retime Effects

A clip retime is translated to a Soft Timewarp with matching speed up or down.

NOTE To make sure the conform is accurate with the creative editorial decisions from Final Cut Pro X, the conformed timewarp speed value seen in Flame Premium timewarp editor can be slightly different from the one seen in FCPX. But the actual Timewarp effect will be visually similar to the expected result, and be frame and keyframe accurate.

Final Cut Pro X Retime	Translation in Flame Premium
Slow	Slower than real-time linear timewarp, at same speed as in Final Cut Pro X
Fast	Faster than real-time linear timewarp, at same speed as in Final Cut Pro X
Normal 100%	Not Timewarp
Hold	0% Soft Timewarp, using same frame as the one defined in Final Cut Pro X
Reverse	Reverse speed linear timewarp, at same speed as in Final Cut Pro X
Speed Ramp (to 0% / from 0%)	Animated speed ramp timewarp
Rewind (1x / 2x / 4x)	Animated speed ramp timewarp

Title Effects

All text effects are translated to a Text Timeline FX for the text itself, and a Comp Timeline FX for the compositing:

- Text Timeline FX:
 - RGBA mode

- Colour: White
 - Font: Discreet
 - Size: 50
 - Alignment: Centered
- Comp Timeline FX set to premultiplied.

Audio

Only audio fades are supported. Audio keyframes are not supported.
 Flame Premium correctly imports FCP X XML using multi-track audio.

Transitions

In cases where the video and audio are imported and treated as a single entity in the Final Cut Pro X sequence, applying a video transition affects both video and audio and is translated in Flame Premium as follows:

- Dissolve transition: Flame Premium applies a dissolve to video and audio.
- Wipe transition: Flame Premium applies a matching wipe to video, and a dissolve transition to audio.
- DVE transition: Flame Premium applies a dissolve to video and audio.

Apple Final Cut Pro X Transition	Translation in Flame Premium
Blur (any)	Dissolve
Dissolve	Dissolve except: <ul style="list-style-type: none"> ■ Cross Dissolve changes to Dissolve (no keyframes) ■ Fade to Colour changes to Fade To/From Black (no keyframes)
Lights	Dissolve
Movements	Dissolve
Objects	Dissolve
Replicator/Clones	Dissolve
Stylized	Dissolve
Apple Final Cut Pro X Wipes	Translation in Flame Premium

Apple Final Cut Pro X Wipes	Translation in Flame Premium
Circle	Supported
Clock	Supported
Gradient Image	Dissolve + cue mark
Inset Wipe	Supported
Letter X	Supported
Wipe	Supported

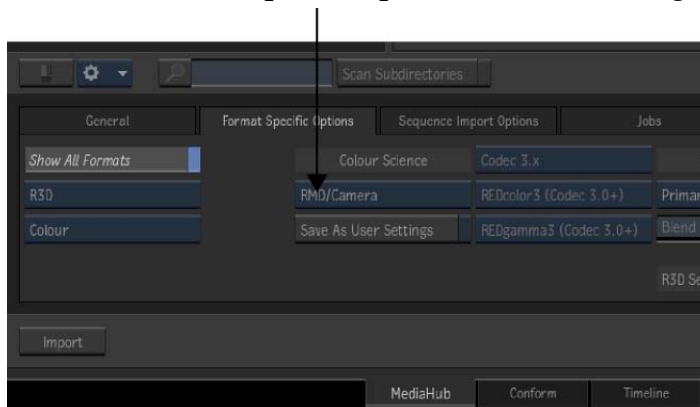

Loading RMD Files from FCP in Flame Premium

NOTE The following only applies when using Final Cut Pro X 10.0.8 (or later).

With Final Cut Pro, you can work directly with R3D files, created by RED cameras, instead of using the QuickTime files. This means that when you import a FCP X XML sequence in Flame Premium, you can relink the sequence to the R3D files, providing you with the best image quality.

Another benefit of using the R3D files is the RAW parameters set in Final Cut Pro X are saved by FCP as an RMD file. This file can be read by Flame Premium on import.

To read FCP X Color settings for R3D files, you have to select an RMD option from **MediaHub ► Browse for Files ► Format Specific Options ► Colour Settings box** for R3D files.

Importing an AAF Sequence

Flame Premium supports AAF files from Avid Media Composer, up to version 7.0.

NOTE To simplify the conform process, save the AAF to the root of the media used in that timeline: the media should either be with the AAF, or within a folder alongside the AAF.

To import a sequence using the MediaHub:

- 1 Click the MediaHub tab.

- 2 Review the AAF & XML Import Options. Pay attention to the following options:
 - Preferred Media: If offline intermediates were used during the offline editing, decide now whether you wish to relink to the original media or to those offline intermediates.
 - Search and Import Files: Enable if you want to import the linked media.
 - Use Filename: For the best results, enable only this option. Disable Use Timecode, Use Tape, Use UMID, Use Resolution, and Use Framerate.
- 3 Using the file browser, navigate to the AAF sequence to import.
- 4 Drag the file from the browser to the Media Library.

Flame Premium converts the AAF to its timeline format, and imports the linked media using the Search Options as match criteria. The media itself is imported using the option file format options defined in the Format Specific Options tab.

Importing an AAF Sequence: Supported Transitions and Effects

Flame Premium supports intermediates encoded with XDCam HD and XDCam EX codecs.

Supported transcoded intermediates generated by Avid Media Composer:

- AVC-Intra 50
- AVC-Intra 100
- DNxHD
- XDCam EX
- XDCam HD

Unsupported transcoded intermediates generated by Avid Media Composer:

- -J2K MXF
- 1:1 MXF
- 1:1p 10b MXF
- Apple ProRes Proxy MXF
- Apple ProRes LT MXF
- Apple ProRes MXF
- Apple ProRes HQ MXF

NOTE In MXF Op-Atom files generated by Avid Media Composer, audio tracks appear in the MediaHub as a single audio channel file (A1). But once imported, the tracks display the original channels.

Pan and Scan	Not supported; replaced by Action FX + Cue mark

Titles

Avid	Flame Premium
Classic Title	Converted to Text FX; only text string is available (white Discreet font, size 50)
Marquee Text	Converted to Text FX; only text string is available (white Discreet font, size 50)

Key

Avid	Flame Premium
Animatte	Not supported; replaced by Cue mark
Luma key	Converted to Action FX (empty) + cue mark
Matte key	Converted to Action FX (empty) + cue mark
RGB keyer	Converted to Action FX (empty) + cue mark
Spectra Matte	Converted to Action FX (empty) + cue mark

Miscellaneous

NOTE To make sure the conform is accurate with the creative editorial decisions from the Avid editor, the conformed timewarp speed value seen in Flame Premium timewarp editor can be slightly different from the one seen in the Avid application. But the actual Timewarp effect will be visually similar to the expected result, and be frame and keyframe accurate.

Avid	Flame Premium
Timewarp	Converted to TW FX; recreate the curve type
Motion Effect	Translated to TW FX (Constant speed, no strobe effect)
3D PIP	Translated to Action FX (Position / Scaling, ISO, Softness / Crop) + cue mark
Peel	Not supported; cue mark
Push	Not supported; cue mark
Spin	Not supported; cue mark
Squeeze	Not supported; cue mark
Video gap	Video gap
Video filler	Video gap
Video match frame edit	Match frame

General Audio

Only audio level keyframes are supported. All other audio keyframes are ignored.

Avid	Flame Premium
Audio level	Audio gain
Audio dissolve	Audio dissolve
Audio fade in	Audio dissolve
Audio fade out	Audio dissolve
Audio gap	Audio gap
Audio filler	Audio gap
Audio match frame edit	Match frame splice

Avid	Flame Premium
Audio warp	Not supported; cue mark

Audio Effects

Flame Premium does not support any of the RTAS Audio Effects. Every RTAS Audio Effect is replaced with a cue mark.

Video and Audio Transitions

The following tables describe how AAF transitions are supported in Flame Premium.

Transitions marked with an * are also supported with the “Inverse” option set.

Blend

Avid	Flame Premium
Dip to colour	Converted to Dissolve (linear animation)
Dissolve	Converted to Dissolve (linear animation)
Fade from colour	Supported; background is black only, reset manually
Fade to colour	Supported; background is black only, reset manually
Picture-in-picture	Converted to Dissolve + cue mark

Film

Avid	Flame Premium
Film dissolve	Converted to Dissolve (bezier animation)
Film fade	Converted to Dissolve (linear animation)

Box wipe

Avid	Flame Premium
Bottom box*	Converted to SMPTE 025; softness not supported
Bottom left to top right*	Converted to SMPTE 006; softness not supported
Bottom right to top left*	Converted to SMPTE 005; softness not supported
Left box*	Converted to SMPTE 026; softness not supported

Avid	Flame Premium
Right box*	Converted to SMPTE 024; softness not supported
Top box*	Converted to SMPTE 023; softness not supported
Top left to bottom right*	Converted to SMPTE 003; softness not supported
Top right to bottom left*	Converted to SMPTE 004; softness not supported

Edge Wipe

Avid	Flame Premium
Horizontal*	Converted to SMPTE 001; softness not supported
Horz open*	Converted to SMPTE 021; softness not supported
Bottom left diagonal*	Converted to SMPTE 042; animation is inverted, softness not supported
Bottom right diagonal*	Converted to SMPTE 041; animation is inverted, softness not supported
Upper left diagonal*	Converted to SMPTE 041; softness not supported
Upper right diagonal*	Converted to SMPTE 042; softness not supported
Vert open*	Converted to SMPTE 022; softness not supported
Vertical*	Converted to SMPTE 002; softness not supported

Shape Wipe

Avid	Flame Premium
4 corners*	Converted to SMPTE 007; softness not supported
Horizontal bands	Converted to Dissolve + cue mark
Horizontal blinds	Converted to Dissolve + cue mark
Vertical blinds	Converted to Dissolve + cue mark
Center box*	Converted to SMPTE 101; softness not supported
Circle*	Converted to SMPTE 119; softness not supported
Ellipse*	Converted to SMPTE 120; softness not supported

Avid	Flame Premium
Clock*	Converted to SMPTE 201; softness not supported
Diamond*	Converted to SMPTE 102; softness not supported

Sawtooth Wipe

Avid	Flame Premium
Horizontal sawtooth*	Converted to SMPTE 071; softness not supported
Horz open sawtooth*	Converted to SMPTE 073; softness not supported
Vert open sawtooth*	Converted to SMPTE 074; softness not supported
Vertical sawtooth*	Converted to SMPTE 072; softness not supported

Matrix Wipe

Avid	Flame Premium
Grid*	Not supported; replaced by SMPTE 008
One-way row	Not supported; replaced by SMPTE 001
Speckle	Not supported; replaced by SMPTE 001
Spiral	Not supported; replaced by SMPTE 001
Zig-zag	Not supported; replaced by SMPTE 001

Xpress 3D Effect

Avid	Flame Premium
3D ball	Converted to Dissolve (linear) + cue mark
3D page fold	Converted to Dissolve (linear) + cue mark
3D slats	Converted to Dissolve (linear) + cue mark
3D PIP	Translated to Action FX (Position / Scaling, ISO, Softness / Crop) + cue mark

Miscellaneous

Avid	Flame Premium
Conceal	Converted to Action FX (bottom left to top right); softness not supported
Illusion FX	Converted to Dissolve + cue mark
L-Conceal	Converted to Action FX (bottom left to top right); softness not supported
Squeeze	Converted to Action FX (bottom centered); softness not supported
Peel	Converted to Dissolve + cue mark
Plasma	Converted to Dissolve + cue mark
Push	Converted to Dissolve + cue mark
Spin	Converted to Dissolve + cue mark
Video gap	Video gap
Video filler	Video gap

About Avid Stereoscopic Sequences

Flame Premium can import Media Composer 6 stereoscopic timelines; an Avid Stereo3D timeline is imported as a stereoscopic timeline with Left and Right tracks, with the following limits.

Avid Stereoscopic Sequence Limitations:

- Segments with multiple nested effects may not be translated as expected.
- The Avid stereoscopic sequence cannot contain S3D master clips with frame compatible contributors (clips with side-by-side or top-bottom stereoscopic media), it can only contain full resolution contributors.

Supported Avid S3D Effects and Transitions:

- S3D Vergence Effect: Translated as a Soft Axis with an equivalent Convergence value.
- S3D Floating Window Effect: Translated as a Soft Axis with a Crop.
- S3D Spatial Alignment Effect: Translated as a Soft Axis with a subset of the original parameters.
- S3D Depth Transition: Not supported.
- Clips with non-stereo effects on top of stereo effects are seen as mono.

Importing an EDL Sequence

To import an EDL from the MediaHub:

- 1 Click the MediaHub tab.
- 2 Review the EDL Import Options.
An EDL has neither frame rate nor resolution. Unless you specify something in the EDL Options, Flame Premium assigns to the EDL the project's resolution and frame rate.
- 3 Using the file browser, navigate to the EDL sequence to import.
- 4 Drag the file from the browser to the Media Library.
Flame Premium converts the EDL to its timeline format.

To assemble multiple EDL into one sequence from the MediaHub:

- 1 Click the MediaHub tab.
- 2 Review the EDL Import Options.
An EDL has neither frame rate nor resolution. Unless you specify something in the EDL Options, Flame Premium assigns to the EDL the project's resolution and frame rate.
- 3 Enable Multi-Assemble in the EDL Options.
- 4 Using the file browser, navigate to the EDL sequences to import.
- 5 **Ctrl**-click to select multiple EDL sequences.
When you assemble multiple EDL, each EDL is imported on a different video track of the new sequence. The order in which you add the EDL to the selection determine their video track: the EDL selected first goes to the first video track, the EDL selected next goes to the second video track, and so on.
If you drag-and-drop a folder with multiple EDL and Multi-Assemble enabled, it still creates a single sequence, but the alphabetical order determines the video track assigned to each EDL.
The created sequence uses the name of the EDL selected last.
- 6 Drag the file from the browser to the Media Library.
Flame Premium converts the EDL to its timeline format.

About EDL Files

An EDL (Edit Decision List) file is a digital list of commands used to describe a series of film or video edits. It consists of an ordered list of reel, keycode, and timecode data, which represents the original location (usually video tapes or sequences of images stored on disk) of each media clip used in the edit. These media clips can later be easily obtained in order to conform the final cut. EDLs are the primary method of transferring information about an edit project between offline and online editing systems.

The most primitive EDL formats are telecine log files. Telecine log files typically describe the most basic edit decisions, which contain only tape name, clip name, source timecode, keycode, and whether 2:3 pulldown was used.

Standard EDL formats, such as CMX3600, support basic functions, such as cuts, dissolves, SMPTE wipes, speed variations (including freeze frames), and direction changes (Forward/Reverse). EDL comments, clip names, and audio patching comments are also supported.

AAF and FCP XML file formats are more modern, enhanced formats of EDLs, supporting multiple layers of video and audio, as well as an expanded set of transitions and effects. Some may include embedded audio.

Collectively, all these formats are known as File Interchange® Formats, but they are still commonly referred to as EDLs.

Supported EDL Formats

The following Standard EDL formats are supported by Flame Premium:

- CMX 340
- CMX 3600
- CMX OMNI (ASCII version)
- GVG 4
- GVG 4 Plus (v4.1 or higher)
- SONY 900
- EDM (edit)
- SONY™ 910
- SONY 5000
- SONY 9000
- SONY 9000 Plus (v2.21 or higher)
- SONY 9100
- ALE (Avid Log Exchange)

NOTE It is recommended that you use EDLs in the CMX 3600 format.

About the DLEDL Format

DLEDL is an EDL file based on the CMX 3600 format supported by most digital nonlinear editing systems. DLEDLs are unique to Autodesk Smoke and Flame applications and contain extra comments that they can interpret, such as media file locations. Using DLEDLs in your post-production workflow allows you to automate the import of media files (video and audio) residing in different locations. Instead of performing media import for each file separately, you can use a DLEDL to import all media files in a single operation.

DLEDL Structure

The following table lists the DLEDL flags used in creating an EDL file. It describes the comments used in creating DLEDLs and provides examples of basic EDLs that you can use in your projects.

Note that the order of flags always remains the same:

- Clip name (EDL comment)
- Start TC
- File path
- Video file name
- Audio 1 file name
- Audio 2 file name
- Audio 3 file name
- Audio 4 file name

DLEDL Flag Example	Description
DLEDL: START TC: 10;00;00;00	The start timecode of the clip that will be created from the media files imported into Flame Premium. This timecode can be different from the source start timecode of the EDL event. Both drop-frame (00:00:00:00) and non-drop-frame (00;00;00;00) timecodes are supported.
DLEDL: PATH /CXFS1/PRODUCTION1/SHOW5	The location of the files on the filesystem. All the files for an event must be in the same directory.

DLEDL Flag Example	Description
DLEDL: EDIT:0 FILENAME: INTRO.(010@240).dpx or DLEDL: EDIT:0 FILENAME: (009@100).dpx	Name of the video file sequence to load. Numbers in parenthesis refer to frames in the sequence. In this example, the following files are referenced: <i>INTRO.010.dpx, INTRO.011.dpx, ..., INTRO.240.dpx</i> or <i>009.dpx, 010.dpx, ..., 100.dpx</i>
DLEDL: EDIT:0 FILENAME: TONE-8TRK-44KHZ.AIFF_CHANNEL_1.AIF	Audio file name to import. The audio files can contain one file per track (_1), one file per stereo pair (_12), or one file per multiple tracks (_1234). Supported formats are wave (.WAV) or AIFF (.AIF).
DLEDL: REEL: 12345678 123456781234556	The CMX EDL format limits the length of the tape name to eight characters. Some editing systems do not impose a tape name length limit. If the tape name exceeds eight characters, Flame Premium generates a short name to be used in the EDL and stores the original name in the Source Table list at the end of the EDL file (one Source Table per EDL).

NOTE File names, tape names, and clip names cannot contain spaces or special characters. For example, TAPE 1 should be set to TAPE_1 (no space) and CLIP\$,12/2 to CLIP_12_2 (no special characters).

Using DLEDLs Examples

The following examples are given to facilitate the creation of edit decision lists for the automatic import of multiple media files into a project. You can simply copy and paste the suitable example into a text editor, modify it accordingly, save the file with an *.edl* extension, and import the resulting file into your application.

Video-only EDL

```
TITLE: SIMPLE EDL VIDEO ONLY
FCM: DROP FRAME
001 TAPENAME V C 10:00:00:00 10:00:05:00 00:00:30:00 00:00:35:00

```

MediaHub Reference: Browsing for Files

The MediaHub consists of two panels: the browser and the MediaHub tabs. Use the browser to locate the files to import, or the location where to export your clips. Use the MediaHub tabs to set you media and sequence import options.

- [MediaHub Browser](#) (page 114)
- [General Tab](#) (page 114)
- [Format Specific Options](#) (page 116)
- [AAF & XML Import Options](#) (page 116)
- [Jobs](#) (page 118)

MediaHub Browser

The MediaHub file browser displays two sections:

- The Autodesk Network lists other Smoke, Flame, or Lustre workstations on the network, and can be used to import files from those workstations.
- The Local Devices displays the hard disks, external disks, and other storage devices that appear under the Devices category in the Finder. Use the Local Devices to access local storage.

TIP Network volumes connected to your workstation appear in Local Device.

General Tab

Cache Source Media button Enable to create a managed copy of the media in the application storage; this copy is a transcoded version of the original media, using the Cached Media Compression Format as the transcode target. Disable to link to the media of the imported clip, without transcoding or copying the media.

Enabling Cache Source Media ensures that the application is the sole owner of the media, preventing the media from being modified by an external source. With Cache Source Media disabled, the application decodes the clip on-the-fly and there is no transcoding.

You can always change your mind after importing a clip: right-click the clip and select **Media ► Cache Source Media** to transcode the media and copy it to your local storage. Right-click and select **Media ► Flush Source Media Cache** to get rid of the transcoded copy and refer back to the original media.

Alpha Channel Processing box Select how alpha channels of RGBA media is processed on import: discard alpha channel information, create a matte container for the clip and its alpha channel, or create an RGB clip and another clip for its matte.

Add Comp on Container button Enable to activate the Comp effect on the matte container and enable matte transparency. Disable to mute the Comp effect.

Cached Media Compression Format field Displays the compression format applied to clips imported with Cache Source Media enabled. Defined for the project, in the Cache and Renders tab of the Project dialogue box.

You access your project's settings in **Flame ► Project and User Settings**.

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution.

Fill box Select a fit method to be applied to the selected clip.

Select:	To fit:
Centre/Crop	The source image, centred, over the destination resolution frame. If the source is larger than the destination, it is cropped. If the source is smaller than the destination, it is surrounded by a black border.
Crop Edges	One edge of the source into the destination resolution frame without stretching or squashing the frame. Excess parts of the source frame after resizing are cropped. If the source—after the one edge is resized—is wider than the destination, its overhanging left and right edges are cropped. If the source is taller than the destination, the upper and lower edges are cropped.
Fill	The source, width, and height, into the destination resolution frame. This process, if the source and destination resolutions do not have the same aspect ratio, can distort the image.

Select:	To fit:
Letterbox	The source to the destination resolution frame without squashing or stretching it, and without cropping the source. If the source is wider than the destination, black bars fill the top and bottom of the destination frame. If the source is narrower than the destination, black bars fill the right and left sides of the frame. In all cases, the entire source frame is fit into the destination frame.

Resize Filter box Select the resize filter to apply to the clip; all but the Impulse filter are rendered using the GPU. This box does not appear if you select the Centre/Crop fit.

Select:	For:
Lanczos	Excellent and sharp results. Recommended for upscale and downscale. Expensive to compute.
Shannon	Excellent and sharp results. Results are sharper than Lanczos in small details. Recommended for upscale and downscale. Expensive to compute.
Gaussian	Medium quality and softer results.
Quadratic	Medium quality and softer results.
Bicubic	High-quality results, but not as sharp as Shannon. Use for both upscale and downscale.
Mitchell	High-quality results, but not as sharp as Shannon. Use for both upscale and downscale.
Triangle	Low quality results that are fast to compute. Use for downscale.
Impulse	Very low quality results that are fast to compute. Use for downscale.

Width field Displays the custom width resolution of the clip. Editable.

Height field Displays the custom width resolution of the clip. Editable.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the custom render/output aspect ratio. Editable

Bit Depth box Select the render/output bit depth of clips.

Scan Mode box Select the scan mode of clips.

Use LUT button Enable to apply the LUT or colour transform displayed in the Applied LUT field to the clip.

LUT Format box Select the type of LUT or colour transform to apply to the clip.

Applied LUT field Displays the type of conversion LUT applied to the clip, either imported using Import, or edited using Edit.

Conversion LUT Type box Select a basic LUT type, EXR Display, PhotoMap, or Gamma correction.

LUT Editor Access button Click to open the LUT editor.

Format Specific Options

Show All Formats button Disable to display only the format of the file selected in the MediaHub browser. Enable to view or edit import options for any of the available file formats.

File Format box With Show All Formats disabled, File Format displays the format of the file selected in the browser; if more than one file is selected, File Format displays the formats of the selected files. With Show All Formats enabled, select the file format to view or edit its import options.

Options Category box Select the set of options to view or edit.

AAF & XML Import Options

Media Options

Link to Files button Enable to create a sequence with track segments that link to the original media. Disable to import an empty shell showing only the structure of the sequence, without references to files.

Preferred Media button Select which, of either offline intermediates or original sources, to import when both are found by the application. Only used when importing AAF sequences.

Consolidate on Import button Enable to import only the segments of the sources used by the imported sequence. Enabled when Use Timecode is enabled.

Maximum Handles field Displays the maximum number of handles (head and tail) allowed for each event in the sequence. If the sequence also sets the amount of handles, the application imports the sources using the lowest number of handles set between Maximum Handles and the sequence. Editable.

Save Sources Separately button Enable to also import each source referred to in the sequence. The application imports the sources in the same folder as the imported sequence, in the Media Library.

Relative Search Options

Search and Import Files button Enable to locate and import the media listed in the sequence, using the selected Search Criteria options but not the file paths the sequence might contain. The media found is imported as segments of the sequence. Enabled if Link to Files is enabled.

Directories Up field Use to expand the search to parent directories. The application searches for media to match by going down any folder structure, starting with the directory from where the sequence file is imported.

NOTE When setting the Directories Up field, keep in mind that the application navigates through the whole directory structure. This means that the higher up you go in the folder structure, the longer the conform takes.

Use Filename button Enable to use the filename specified in the sequence as a match criteria.

Use Timecode button Enable to use the source timecode specified in the sequence as a match criteria. Enables Consolidate on Import.

Use Tape button Enable to use the tape name specified in the sequence as a match criteria.

Use UMID button Enable to use the starting SMPTE UMID in the sequence as a match criteria. This is only used with MXF files and is ignored in all other cases.

Use Resolution button Enable to use the resolution specified in the sequence as a match criteria. If this option is disabled, the Flame Premium applies a Resize FX to the media found to make it match the resolution specified in the imported sequence, if required.

Use Frame Rate button Enable to use the frame rate specified in the sequence as a match criteria. Disable to disregard the frame rate; try slipping the clip and using a timewarp in the timeline after loading the timeline to correct any frame rate discrepancy.

Be careful when using the Use Frame Rate search option with FCP XML files, especially if the FCP sequence is using multiple frame rates. With Use Frame Rate enabled, Flame Premium uses the frame rate of the sequence's *edits* as a match criteria to relink to the correct sources: if the frame rate of the considered source is 24 fps while the edit is at 30 fps, that source is not a potential candidate. Whether or not Flame Premium relinks the considered source to the edit has nothing to do with the frame rate of the *sequence*.

But, if you are importing an FCP sequence, Flame Premium timewarps the *edits* so that they match the frame rate of the imported sequence. For example, an FCP sequence @60fps contains edits @50fps: Flame Premium timewarps the edits to 60 fps as it imports the sequence. Whether or not edits are relinked to their sources has nothing to do with this: if Use Frame Rate is enabled, Flame Premium only relinks the above edits if the sources are matching the *edits' original frame rate*, in this case 50fps.

EDL Import Options

Media Options

Link to Files button Enable to create a sequence with track segments that link to the original media. Disable to import only the structure of the sequence, not linked to the media files.

Consolidate on Import button Enable to import only the segments of the sources used by the imported sequence. Enabled when Use Timecode is enabled.

Maximum Handles field Displays the maximum number of handles (head and tail) allowed for each event in the sequence. If the sequence also sets the amount of handles, the application imports the sources using the lowest number of handles set between Maximum Handles and the sequence. Editable.

Save Sources Separately button Enable to also import each source referred to in the sequence. The application imports the sources in the same folder as the imported sequence, in the Media Library.

EDL Options

EDL Frame Rate box Select the frame rate applied to the imported EDL. Defaults to the project's.

EDL Conversion button Enable to convert the EDL to another frame rate using the settings defined by the Conversion box.

Conversion box Select the option that corresponds to the type of conversion that you want to apply to the EDL. The conversion scripts that appear in this list depend on the frame rate of the EDL you are loading.

Fix Timewarp Match Frames Errors button Enable to fix match frame errors. When you import an EDL that contains dissolves or timewarps, a match frame error may occur. This can cause an unwanted cut at the point where the timewarp begins in your EDL. Match frame errors occur when the in point of the second edit in a dissolve is not the same timecode as the out point of the previous shot.

Pulldown Removal button Enable to remove 2:3 pulldown when loading the EDL. The resulting sequence is @ 23.976 or 24 fps, depending on the setting of the Pulldown Original FCM box.

Pulldown Original FCM box Select the Frame Code Mode that matches the EDL that you are loading. If you are loading multiple EDLs, the same mode is used for all of them.

Multi-Assemble button Enable to assemble into one sequence multi-selected EDLs. Each EDL will appear on a different video track, based on the selection order.

If you drag-and-drop a folder with multiple EDL, it creates either a single video track sequence or a single sequence with multiple video tracks, based on the Multi-Assemble option. With Multi-Assemble enabled, the alphabetical order defines the video track assigned to each EDL.

Varicam button Enable if the EDL is links to material with a Varicam. You must also select a frame rate from the Varicam Frame Rate box.

Jobs

The Jobs tab displays ongoing and completed background processes. Use the Jobs tab to monitor the import and export processes.

Actions box Select from the list an action to perform on the selected job.

When aborting the processing of a file sequence, frames already processed are retained. For example, if the Status column reads 20 of 44 when you click Abort, 20 of the 44 frames of the clip remain. Aborting a streaming file cancels the whole process, there is no partial processing.

Customizing your File Imports Options

Flame Premium includes pre-defined import options for each available file format. While these presets should answer most of your needs, there are times you might want a different debayering settings for .r3d files, or rename a clip on import.

To customize the import options of a selected file:

- 1 In the MediaHub, click the Format Options tab.
- 2 In the file browser, navigate to, and double-click the media file to import.
The Selected Format field displays the format of the selected file.
- 3 From the Options box, select a category of options to edit.
- 4 Edit the options as needed.
The import options are saved automatically; no need for a manual save. Flame Premium will import media of that format using the new options.
- 5 Drag and drop the media file from the browser to the Media Library. A new clip is created, using the new import options.

To customize the import options at any time:

- 1 Click the MediaHub tab.
- 2 In the MediaHub menu, click the Format Options tab.
- 3 Enable Show All Formats.
- 4 From the Selected Format box, select the media format to edit.
- 5 From the Options box, select the category of options to change.
- 6 Edit the options as needed.
The import options are saved automatically; no need for a manual save. From now on, media of that format are imported using the options you have set.

ARRIRAW Format Settings - Import

IMPORTANT The timecode of some ARRIRAW files was not correctly read in versions of Flame Premium prior to Flame 2013 20th Anniversary Edition Extension 2 SP3. This issue is now fixed. But be careful if you use ARRIRAW clips that were imported in a previous release. Loading that material in the fixed version shows the same visual results, but the source timecode is automatically updated. This ensures that both the ProRes and the ARRIRAW files have the same timecode, making it easier to offline in ProRes and relink to the ARRIRAW files.

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

./<tape>/<resolution>/clip.#####.dpx. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (*./<tape>*). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify which of the available timecodes to use as ARRIRAW clips can contain multiple timecodes. If the selected timecode is not available in the selected clip, it displays 00:00:00 for timecode.

Selection:	ARRIRAW Definition
Master TC	Internally generated timecode.
External LTC	Longitudinal Time Code from an external sync.
External VITC	Vertically Integrated Time Code from an external sync.
Time of Day	Internally generated free run timecode starting at time of day.
Free Run	Internally generated free run timecode starting at a time defined by the user.
Edge Code	Internally generated timecode frame count increasing with each new media.
Clip Code	Internally generated timecode frame count increasing with each new take.
Record Run	Internally generated record run timecode starting at a value defined by the user.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.

Resolution Settings

Debayering box Select the resolution of the imported media. ARRIRAW decoding provides for using the original camera image resolution (2880x1620), or the resolution of the ProRes files (2868x1614). SD, HD, and 2K resolutions are not downscaled from the original image, but different debayering resolutions.

NOTE Prior to Flame 2013 20th Anniversary Edition Extension 2 SP3, the debayering options were named Full, Draft, Half... This naming scheme is no longer in use. Additionally, Half and Third cannot be translated into one of the new debayering setting. If you restore material archived at Half or Third debayering, you get a checkerboard (Flame) or a red X (Lustre) upon restore. Open the clip on the Timeline, and use the Format Options from the Timeline to select a valid debayering setting.

Debayering Mode box Select the debayer algorithm to use when importing ARRIRAW files. HW/SW refers to the method ARRI cameras use to decode RAW media. It does not mean that the application is performing hardware optimized debayering. All debayering is done software.

Option:	Description:
ADA-1 HW	Reproduces the hardware optimised debayering that is realised in cameras. Previously named Camera option.
ADA-2 SW	A more efficient debayering algorithm than ADA-1. Previously named AMC-1 option.
ADA-3 HW	Visually matches the hardware optimised debayering realised in cameras with ARRI SUP 7.0: more complex debayering than ADA-1, with extended edge and color handling.
ADA-3 SW	Advanced software debayering provided by the ARRI SDK.
Proxy	A low quality debayering mode designed for performance over quality.

Crispness field Set the cutoff steepness value of the downscaler.

Aspect Ratio box Set the aspect ratio used when importing the clips, or have Flame Premium use the information stored in the file header to set automatically the aspect ratio.

Colour Settings

NOTE Some combinations of Source Camera, Colour Space, and Colour Rendering are not supported.

Colour Settings box Select how Flame Premium uses the colour information stored within an ARRIRAW file.

Select:	To import ARRIRAW clips using:
User	The options you set in the Colour, Processing, and Image menus.
Camera	The look created on the ARRI camera and stored in the ARRIRAW file. This option disables the Processing and Image menus, as well as the Colour Rendering box.

Save as User Settings button Enable to make the Colour, Processing, and Image menus editable in the Import History. Save as User Settings is implicitly enabled when the Colour Settings box is set to User.

Look Selection box Select from where Flame Premium reads the Look information, when available.

Version 4 of the ALEXA Software Update Packet enables a *look* creation workflow. In this workflow, a look is created in the ARRI Look Creator application and either embedded in the source files during the shoot, or saved to a look file. This look information is accessible by Flame Premium.

When working with Look information, set the Colour Rendering to Rec709 or DCI P3 option. If the Colour Rendering is set to LogC, Flame Premium displays a checkerboard instead of the media as ARRI Look Creator does not support images encoded in LogC.

NOTE When used, the Look file must be placed in the folder containing the source material and named *look.xml*.

Select:	To:
Do not apply Look	Not apply any Look information.
From File Header	Apply Look information contained in the ARRIRAW file header.
From Look File	Apply Look information contained in an XML Look file located in the same folder as the media to import.
Header or Look File	Apply Look information from the header of the media to import. If none is present, use the information from an XML Look file located in the same folder as the file to import.
Look File or Header	Apply Look information from an XML Look file located in the same folder as the file to import. If none is present, use the information from the header of the file to import.

Apply Look LUT button Enable to use the LUT stored with the Look information read by Flame Premium from the location determined by the Look Selection box.

Colour Rendering box Select one of the preset combinations of colour spaces and encoding to apply to all imported clips, or select From File Header to read that colour space and encoding information from the file. Select Custom to create your own combination using the Colour Space and Colour Encoding boxes.

ACES (Scene Linear) gives you direct access to 16-bit floating point images, so you do not have to apply a colour transformation to get 16-bit floating point images.

Colour Space box Select the colour space used to read the clips. Available when Colour Rendering is set to Custom. Some combinations of Colour Space and Colour Encoding are invalid and display a checkerboard instead of a clip. Change either settings to display a valid clip.

An invalid combination would be ACES + Encoding Video since ACES colour space requires 16-bit fp Scene Linear encoding.

Colour Encoding box Select the value of the output gamma curve applied to imported clips. Available when Colour Rendering is set to Custom. Some combinations of Colour Space and Colour Encoding are invalid and display a checkerboard instead of a clip. Change either settings to display a valid clip.

Processing Settings

Processing Version box Select the version of the colour science used to process the file, or use From File Header to have Flame Premium read the version of the colour science from the header of the imported file. Use From File Header unless you are trying to recreate a look based on a specific colour science.

Source Camera box Select the camera that created the file, or have Flame Premium read from the file header the camera used. Leave at Camera from File Header unless you are troubleshooting a file.

Image Settings

Exposure box Select how the file's exposure is set. Select Exposure From File to use the camera settings burnt in the clip.

ISO Select the value of the linear gain operation.

White Balance box Select how the white balance is defined. Select White Balance From File to use the camera settings burnt in the clip.

NOTE To determine if white balance information is already present in a clip, look at *White bal burnt in* in the Metadata tab of the Previewer. If it displays *true*, there is white balance camera settings present in the clip.

Kelvin field Set the perceptual colour temperature of the imported clip. Only available if White Balance is set to Set Temperature.

Green/Magenta Tint field Set the green and magenta tint balance. Only available if White Balance is set to Set Temperature.

RGB Gain fields Set the RGB gains of the imported clip. Only available if White Balance is set to Set RGB White Balance.

Audio File Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

AVCHD Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Header	Read the clip name from the header of the imported file.
Clip Name from XML	Use the clip name listed in the XML file accompanying the XDCAM media. (XDCAM only)
Clip Name from Essence	Use the clip name inferred from the directory structure of the P2 or XDCAM clip. (P2 and XDCAM only)

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some mp4 and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

DPX Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from File Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <code>100000.dpx</code>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Sequence Detection box Select how Flame Premium displays image sequences. An image sequence consists of image files, such as .psd, named identically except for a numeric suffix.

- myPhotoshopFile_version_001.psd
- myPhotoshopFile_version_002.psd
- myPhotoshopFile_version_003.psd
- myPhotoshopFile_version_004.psd

Select:	To display and process the related images:
Sequence	As a single clip made of all these related images.
Frames	As independent images.

Keycode Settings

NOTE The keycode supplied here is only used for information purposes. In case of a discrepancy between the information supplied in the Metadata menu and the Keycode menu, the former is used to determine the timecode and frame rate used.

Keycode Scan Mode box Select an option to determine how keycode data is applied to the imported clip.

Select:	To:
File Header Keycode	Use the keycode information embedded in the image file header.
No Keycode	Not use the keycode information.

Keycode Fcm box Select the frame code mode of the tape. Set to File FCM to read the frame code mode from the file.

Film Gauge box Select a film gauge for the keycode.

About Keycode

Keycode (also known as edge code) tracks frames of film from source reels through the post-production pipeline using code. Keycode is a variation of timecode designed to uniquely identify frames in filmstock. Keycode is a valuable tool for any project that originates on film, evolves through digital post production,

and eventually references the original film material for final image capture. Keycode is printed on film in both a human-readable and machine-readable form. It indicates the manufacturer and film emulsion, a unique identification for each reel, as well as the footage and frame number.

Keycode appears in a varying number of increments along the film strip depending on the film gauge. For example, on 35 mm film, keycode appears every foot, which translates to every 16 frames of film.

Keycode Syntax

Keycode in Autodesk Visual Effects and Finishing applications uses the following syntax:

KQ123456 7890+12

Where:

- K is the film manufacturer.
- Q is the film emulsion.
- 123456 (6 digits) is the film reel unique identifier.
- 7890 (4 digits) is the footage number.
- 12 (2 digits) is the frame number.

In 35mm / 3 perf keycode, a reference foot value is also set. The value can be 1, 2, or 3 between parenthesis:

KQ123456 1234+00(1)

Supported Film Emulsions

The available film emulsions are supported in keycode in Flame Premium as follows.

Kodak

Supported Film Gauges

The following film gauges are supported in keycode for Autodesk Visual Effects and Finishing applications:

- 16 mm and Super 16 mm / 1 perf
- 35mm / 8 perf
- 35mm / 3 perf
- 35mm / 4 perf
- 65mm / 5 perf

The increment offset of a particular frame from the keycode dot (which indicates the zero offset point on the film) can be recorded in one of two modes: frame offset and perforation offset. In general, film scanners can write keycode in either of these two modes.

For 35 mm / 3 perf and 35 mm / 4 perf film, both frame and perforation offset keycode are supported when importing files. For all other gauges, only frame offset mode is supported. In these latter cases, set the telecine to use frame offset keycode when you are scanning.

Gateway Clip Format Settings - Import

Gateway clips do not have any available import options.

HDR Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.

Select:	To:
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <code>100000.dpx</code>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Header	Read the clip name from the header of the imported file.
Clip Name from XML	Use the clip name listed in the XML file accompanying the XDCAM media. (XDCAM only)
Clip Name from Essence	Use the clip name inferred from the directory structure of the P2 or XDCAM clip. (P2 and XDCAM only)

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Exposure Adjustment field Set the exposure of the HDR file. In units of stops.

Image Sequences Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <code>100000.dpx</code>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one defined in the Default Resolutions table. Select Select rate to set the framerate using the Framerate box.

The Default Resolutions table determines the aspect ratio, scan mode, and frame rate to apply to an image based on a width and height pair. It is used when you use set the Rate to Auto. **MediaHub ► Browse for Archives ► Default Resolutions**. The table is also used when restoring legacy archives.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Only applies to clips running at 29.97 and 59.94 framerates. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Sequence Detection box Select how Flame Premium displays image sequences. An image sequence consists of image files, such as .psd, named identically except for a numeric suffix.

- myPhotshopFile_version_001.psd
- myPhotshopFile_version_002.psd
- myPhotshopFile_version_003.psd
- myPhotshopFile_version_004.psd

Select:	To display and process the related images:
Sequence	As a single clip made of all these related images.
Frames	As independant images.

MP4 Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from File Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Header	Read the clip name from the header of the imported file.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some mp4 and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediaHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

MXF Format Settings - Import

Material at 1080i sometimes uses a thin raster frame format. It uses an frame size of 1440x1080 (NTSC) or 1280x1080 (PAL). When importing, enable Scale to Full HD in **Format Specific Options ► Image** to scale the material to the full 1920x1080 frames. Disable Scale to Full HD to import the clip using the thin raster frame format.

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from File Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.

Select:	To:
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Header	Read the clip name from the header of the imported file.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Scale to Full HD button Enable Scale to Full HD to have media with a 1280x1080 or 1440x1080 resolution appear in the Player at a standard 1920x1080 resolution. Disable Scale to Full HD to display the media at its native (1280x1080 or 1440x1080) resolution in the Player.

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some mp4 and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediaHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

OpenEXR Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <code>100000.dpx</code>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Names box Channels are imported as clips in Flame Premium. Select how to name, at import, the clips thus created.

Select:	To:
Filename	Use the filename of the container for all the imported channels.

Select:	To:
Channel	Use the channel name as the clip name.
Channel + Filename	Combine the channel name and the filename of the container to form the clip name.
Filename + Channel	Combine the filename of the container and the channel name to form the clip name.

Sequence Detection box Select how Flame Premium displays image sequences. An image sequence consists of image files, such as .exr, named identically except for a numeric suffix.

- myFile_version.001.exr
- myFile_version.002.exr
- myFile_version.003.exr
- myFile_version.004.exr

Select:	To display and process the related images:
Sequence	As a single clip made of all these related images.
Frames	As independent images.

P2 Format Settings - Import

Material at 1080i sometimes uses a thin raster frame format. It uses an frame size of 1440x1080 (NTSC) or 1280x1080 (PAL). When importing, enable Scale to Full HD in **Format Specific Options ► Image** to scale the material to the full 1920x1080 frames. Disable Scale to Full HD to import the clip using the thin raster frame format.

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape Name	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape Name from Filename	Use the name of the imported file as the tape name.
Tape Name from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape Name from Essence	Use the tape name inferred from the directory structure of the P2 clip.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Essence	Use the clip name inferred from the directory structure of the P2 clip.
Clip Name from XML	Use the clip name listed in the XML file accompanying the P2 media.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Scale to Full HD button Enable Scale to Full HD to have media with a 1280x1080 or 1440x1080 resolution appear in the Player at a standard 1920x1080 resolution. Disable Scale to Full HD to display the media at its native (1280x1080 or 1440x1080) resolution in the Player. Available to P2, XDCAM, and MXF.

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some mp4 and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediaHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

Browsing Settings

Essence Mode button Enable to browse the directory structure of P2 media. This option allows you to import specific audio or video files contained within a P2 directory structure.

Photoshop Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from File Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Clip Settings

Clip Names box Layers are imported as clips in Flame Premium. Select how to name, at import, the clips thus created.

Select (PSD):	To:
Filename	Use the filename of the container for all the imported layers.

Select (PSD):	To:
Layer	Use the layer name as the clip name.
Layer + Filename	Combine the layer name and the filename of the container to form the clip name.
Filename + Layer	Combine the filename of the container and the layer name to form the clip name.

Sequence Detection box Select how Flame Premium displays image sequences. An image sequence consists of image files, such as .psd, named identically except for a numeric suffix.

- myFile_version_001.psd
- myFile_version_002.psd
- myFile_version_003.psd
- myFile_version_004.psd

Select:	To display and process the related images:
Sequence	As a single clip made of all these related images.
Frames	As independent images.

Layers Settings

Resolution box Select how Flame Premium sets the resolution of .psd clips.

Select:	To:
Background	Import the layers using the same resolution as the background layer.
Native	Import the layers at their original resolution.

PNG Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Sequence Detection box Select how Flame Premium displays image sequences. An image sequence consists of image files, such as .psd, named identically except for a numeric suffix.

- myFile_version_001.psd
- myFile_version_002.psd
- myFile_version_003.psd
- myFile_version_004.psd

Select:	To display and process the related images:
Sequence	As a single clip made of all these related images.

Select:	To display and process the related images:
Frames	As independent images.

Precomp Format Settings - Import

Precomp clips do not have any available import options.

QuickTime Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from File Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <code>100000.dpx</code>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Header	Read the clip name from the header of the imported file.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some mp4 and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediaHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

R3D Format Settings - Import

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from File Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Orientation box Select to flip (vertical) or flop (horizontal) the media of the imported clip. Camera uses the orientation transformation defined during the shoot; Disable Flip ignores orientation settings defined on the camera or in software.

Timecode box Select which timecode to use as RED camera records both edge code (run record) and time-of-day (free run) timecodes during a shoot. Or Use Primary to use the timecode defined during the shoot.

Debayering Settings

Debayering box Select the level of quality required from the debayering algorithm. Higher resolutions are significantly more processing intensive.

NOTE The debayering setting is the most resource-intensive setting. Try using the level of debayering the most appropriate for your work.

Bit Depth box Set the bit depth of the imported image. If you set Debayering > HDRx box to High Dynamic Range, HDRx footage is always imported as a 16-bit floating point clip, even if Bit Depth is set to 12bit Integer.

Detail box Select the level of detail extraction required.

Denoise box Select the level of noise reduction applied to the debayered clip.

OLPF Compensation box Select the level of Optical Low Pass Filter (OLPF) compensation to use. OLPF is a type of sharpening used to compensate for the optical anti-aliasing filter, which can induce softening of the image during recording.

Colour Settings

Colour Settings box Select how Flame Premium uses the colour information stored within a R3D file.

Select:	To have:
User	Flame Premium import RED clips using the options you set in the Image, Gain, and Curve menus.
Camera	Flame Premium import RED clips using the look created on the RED camera and stored in the RED clip. Disables the Image, Gain, and Curve menu options.
RMD/Camera	Flame Premium import RED clips using the RMD look created in REDCINE-X, or fall back on the camera settings if there is no RMD settings. Disables the Image, Gain, and Curve menu options.
RSX Only	Flame Premium import RED clips using the RSX look created in RED Alert!. The RSX file of a clip must reside in the same directory as the R3D file of that clip. Disables the Image, Gain, and Curve menu options. With this option selected, only clips with an RSX profile can be imported. Clips without an RSX profile appear to be missing media.
RSX or RMD/Camera	Flame Premium import RED clips using the RSX look. If a clip has no RSX file, Flame Premium imports it using the RMD look created in REDCINE-X, or fall back on the camera settings if there is no RMD settings. Disables the Image, Gain, and Curve menu options.
RSX or User	Flame Premium imports RED clips using the RSX look. If a clip has no RSX file, Flame Premium imports it using the options you set in the Image, Gain, and Curve menus. Enables the Image, Gain, and Curve menu options.

Save as User Settings button Enable to make the Colour, Image, Advanced, and Curve menus editable in the Format Options on the Timeline. Save as User Settings is implicitly enabled when the Colour Settings box is set to *User*, or *RSX or User*.

Colour Science box Set the version of the RED codec to use. Using the version 3 of the codec gives you access to the FLUT and the Shadow options in the Image menu, as well as version 3-only colour spaces and gamma curves.

NOTE As a rule, always set Colour Science to Codec 3.x, unless you are working with a footage shot using a RED camera with firmware 30, and that file was imported in Flame Premium prior to version 2011.

Colour Space box Set the colour space of the imported clips.

Gamma Curve box Set the value of the output gamma curve that is applied to the imported clips. If you select Scene Linear, the Bit Depth of imported clips are always set to 16-bit floating point. If you set Debayering > HDRx box to High Dynamic Range, HDRx footage is always imported as Scene Linear, even if Gamma Curve is set to something else.

HDRx Settings box Select which track of a RED HDRx file to import, or how to merge the two tracks together. A RED HDRx media file is made of two tracks, track A (the main exposure) and track X (the highlight protection exposure). Use HDRx Settings to set how you want to use those two tracks.

Select:	To have:
Primary Exposure	Only the main exposure (A track).
Highlight Exposure	Only the highlight protection exposure (X track).
Blend Exposures	A single clip resulting from blending together the Primary and Highlight tracks. Blend Exposures behaves similarly to the option of the same name found in REDCINE-X by RED. Use the Blend field to set the blend value to use.
Magic Motion	A single clip resulting from the merge of the Primary and Highlight tracks using an algorithm provided and developed by RED. This algorithm tries to match and blend together the motion blurs of the two tracks.
High Dynamic Range	A single clip resulting from the merge of the Primary and Highlight tracks using an HDR merging algorithm developed by Autodesk. It converts the two exposures into a single 16-bit float image. Importing an HDRx clip as High Dynamic Range forces the Bit Depth of the imported clip to 16-bit floating point, and the Gamma Curve to Scene Linear. Use the Blend, Highlight Threshold, and Exposure Offset fields to refine the blend.
RMD	A clip using blending options read from the RMD file. If there is no RMD file, the Flame Premium loads the main exposure (A track).

Blend field Set how to blend the two exposures of a RED HDRx clip.

With HDRx Settings set to Blend Exposures, this field behaves like the blend in REDCINE-X; the blend also attenuates the artifacts created by the scene operation, which is a blend of the two exposures: -1 shows only the Highlight (X frame), 1 only the Primary (A Frame), and 0 a 50-50 mix.

With HDRx Settings set to High Dynamic Range, Blend also attenuates the artifacts created by scene motions; set to 1 unless you are troubleshooting motion artifacts.

Highlight Threshold field Set the threshold when pixels from the Highlight exposure are used instead of the over-exposed pixels from the Primary exposure. Only available when HDRx Settings box is set to High Dynamic Range. Set Highlight Threshold last because import options such as ISO or FLUT lighten or darken the image. Too high and you get clipping (often including a magenta-coloured cast), too low and the midtones and shadows have noise leaking in from the Highlight track.

Exposure Offset field Set how much greater the Primary exposure was when compared to the Highlight exposure, in units of stops. Only available when HDRx Settings box is set to High Dynamic Range. The Exposure Offset should be set to match the setting on the camera for how many stops separate the Primary and Highlight tracks. This is typically 2 or 3 stops.

Offset From File button Enable to use the Exposure Offset read from the R3D file. Enabled when HDRx Settings is set to High Dynamic Range.

Image Settings

ISO Select the value of the linear gain operation.

Saturation Set the saturation value.

DRX Set the Dynamix Range Extension, which sets how much pixel data is copied from non-saturated channels into saturated channels.

IMPORTANT In Flame 2013 20th Anniversay Edition Extension Extension 2 Service Pack3, changes to the RED SDK 4.4 affect how the DRX setting is computed for all R3D clips, and can impact clips imported before these changes.

■ Changes to DRX processing

The clips affected are the ones which have a DRX setting different from 0. To check if this is the case for a clip:

- In Flame: Open, from the Timeline, the Pre-Processing Editor, and look for DRX under **Basic > Image**.
- In Lustre: Look for DRX in **Transcode > Colour > Colour Settings**.

If DRX is not 0, then your media is impacted by the change. How much of an impact is hard to predict, but since DRX (Dynamic Range Extension) is used to reconstruct clipped colour channels, watch out especially for clips with dangerous highlights and for HDRx material.

■ Support for DRX processing via RED Rocket

The DRX setting is now processed by the RED Rocket card if one is present on the Mac running the Wiretap Gateway server used to decode R3D files. The following driver and firmwares must be installed on the Mac:

- RED Rocket driver 1.4.32.0
- RED Rocket firmware 1.1.16.11 or later
- RED Rocket Breakout Box firmware 1.0.2.0 or later

Tint Set the tint value.

FLUT Set the FLUT to refine of the ISO level. As FLUT units are in stops, a +1 FLUT value is the same as doubling the ISO.

Exposure Set the exposure value, an equivalent to f-stops.

Brightness Set the brightness value.

Contrast Set the contrast value.

Kelvin Set the perceptual colour temperature of the image, in Kelvin.

Shadow Set the Shadow level.

Advanced Colour Settings

Use the Advanced Colour menu to set the RGB Lift, Gamma, and Gain of RED clips.

Use the Legacy Gain options if you import clips shot with a RED codec that uses a pre-3.0 Colour Science.

NOTE We recommend that you do not change the default settings unless you have prior experience with colour management.

Colour Curves Settings

Use this menu to set the RGB and Luma curves for RED clips.

NOTE We recommend that you do not change the default settings unless you have prior experience with colour management.

Sony Format Settings - Import

The following settings apply to all of XDCAM and XDCAM HD files. It is also used for XAVC footage shot with F5 and F55 cameras.

Material at 1080i sometimes uses a thin raster frame format. It uses an frame size of 1440x1080 (NTSC) or 1280x1080 (PAL). When importing, enable Scale to Full HD in **Format Specific Options > Image** to scale the material to the full 1920x1080 frames. Disable Scale to Full HD to import the clip using the thin raster frame format.

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape Name from Essence	Use the tape name inferred from the directory structure of the XDCAM clip.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.

Select:	To:
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from XML	Use the clip name listed in the XML file accompanying the XDCAM media.
Clip Name from Essence	Use the clip name inferred from the directory structure of the XDCAM clip.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Scale to Full HD button Enable Scale to Full HD to have media with a 1280x1080 or 1440x1080 resolution appear in the Player at a standard 1920x1080 resolution. Disable Scale to Full HD to display the media at its native (1280x1080 or 1440x1080) resolution in the Player.

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some MXF, MP4, and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediaHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

Browsing Settings

Essence Mode button Enable to browse the directory structure of Sony media (XDCAM, XDCAM HD, and XAVC). This allows you to import specific video and audio files contained within the structure.

SonyRAW Format Settings - Import

You can import Sony F5, F55, and F65 RAW MXF files in Flame Premium with a default Scene Linear transformation applied to convert the 16-bit media to 16-bit half-float.

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape from Header	Read the tape name from the header of the imported file.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like: `./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Orientation box Select to flip (vertical) or flop (horizontal) the media of the imported clip. Camera uses the orientation defined on the camera during the shoot. Disable Flip to use the true orientation of the image, as it was shot.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.

Resolution Settings

Debayering box Select the resolution at which the media is imported. Higher resolutions require more processing and impact real-time playback. Other resolutions offer better performance at the cost of lower image resolution.

Only the F65 supports resolutions higher than 4K. Using a higher setting for material shot by other cameras prevents the media from being displayed: an error message also appears in the Previewer (*Cannot initialize codec*). Select 4K or lower to display the media correctly.

Debayering options have been renamed to reflect what is used in other applications. The table below highlights the changes.

Option in Flame 2014:	Deprecated option:
0.25K	Sixteenth
0.5K	Eighth
1K	Quarter
HD (1920)	
2K	Half
QFHD (3480)	
4K	Full
6K	
UHDTV (7680)	
8K	

Quality box Select one of two qualities for the decoding of SonyRAW footage. While debayering resolution result in lower resolution clips, Quality affects the quality of the fully debayered pixels. Depending on your system configuration, Standard provides better decoding performance at the cost of lower image quality compared to High quality. The actual image degradation depends on the footage being decoded, but because of the Bayer pattern, expect to see differences in the red and blue channels. The Quality box is not available for some of the Debayering resolutions.

Colour Settings

Colour Encoding box Select Scene Linear to apply a colour transformation to convert the 16-bit media to 16-bit half-float. Select Native to disable this transformation and work with the RAW media.

NOTE The colour space options —Rec709 primaries, ACES (daylight illuminant), ACES (tungsten illuminant)—were updated in Flame 2013 20th Anniversary Edition Extension 2 SP3 to solve an issue with black levels. This impacts SonyRAW media imported before the update: the black levels will not match SonyRAW media imported after the update. To fix this, view the older clips on the Timeline, and in the Format Options Editor, select **Basic ► Colour**, and then set the correct colour space.

XDCAM EX Format Settings - Import

About XDCAM EX

Support for Sony XDCAM EX media includes support for clips recorded as multiple segments on single SxS card (split clips) or multiple cards (span clips). Flame Premium imports a series of split & span segments as a single clip.

NOTE Clips spanning two card only become available in Flame Premium when browsing the card that contains the last segment.

To ensure that Flame Premium is able to see the clips organisation, copy the full folder structure from the SxS cards to a single folder on your local storage.

For example, with two SxS cards (named Card1 and Card2), create the following structure:

- storage
 - folder
 - Card1
 - Card2

IMPORTANT Do not modify the file structure inside the cards folders. For example, copying only the media files (.mp4) instead of the whole card structure will prevent Flame Premium from recreating the correct clip structure.

AAF Conform

You can conform AAF files referencing XDCAM EX content in Flame Premium. Make sure to import the XDCAM EX clips in Avid products through AMA (the Avid Media Architecture). If you prefer to work with transcoded media in Avid products, but still want to conform with the original media files, enable in Flame Premium the Use Original Media option when importing the AAF file. That way the conform uses the original media, instead of the transcoded MXF generated by the Avid products.

Metadata Settings

Tape Name box Select an option to determine how the tape name is set for the imported clips.

Select:	To:
Enter Tape	Activate the Tape Name field so that you can manually enter the tape name. When selecting multiple files for import, this tape name is used for all imported files.
Tape from Filename	Use the name of the imported file as the tape name.
Tape from Directory	Determine the tape name from the detected directory structure. A Level field appears below the Tape Name box. Use this to configure the relative path to the directory from which the tape name can be determined.
Tape Name from Essence	Use the tape name inferred from the directory structure of the XDCAM EX clip.

Level field Select an option to set the relative file path to the directory from which the tape name can be determined. Although it is available for all file types, the Level field is specifically designed to work with the directory structures that are output by film scanners. A typical file structure would look like:

`./<tape>/<resolution>/clip.#####.dpx`. In this case, selecting Up 2 Levels in the Level field identifies the directory that corresponds to the tape name (`./<tape>`). Enabled if Tape Name is set to Tape From Directory.

Tape Name field Set the name to use as the tape name of the imported clip. Enabled if Tape Name is set to Enter Tape.

Timecode box Select an option to specify how the timecode information for the clip is set.

Select:	To:
Timecode from Header	Set the source timecode of the imported clip based on the timecode information in the image file header.
Timecode from File Name	Use a numerical filename (for instance, <i>100000.dpx</i>) and translate it into timecode for the resulting clip (based on the selected framerate). This is useful when working with files that do not have embedded timecode.

Rate box Select how the framerate is determined. Select Auto to use the framerate specified by the imported clip; if the clip specifies no framerate, it uses the one of the project. Select Select rate to set the framerate using the Framerate box.

Framerate box Select the frame rate of the imported clip. Enabled if the Rate box is set to Select rate.

Drop Frame button Enable to have use a drop frame mode. Disable to use non-drop frame mode. Enabled if the Rate box is set to Select rate.

Clip Settings

Clip Name box Select how the clip is named when the file is imported.

Select:	To:
Enter Clip Name	Activate the Clip Name field so that you can manually enter the clip name. When selecting multiple files for import, this name is used for all imported files.
Clip Name from File Name	Use the name of the imported file as the clip name.
Clip Name from Essence	Use the clip name inferred from the directory structure of the XDCAM EX clip.

Clip Name field Enter the name to use when importing the clip. Enabled if Name is set to Enter Clip Name.

Image Settings

Include YUV Headroom Enable to keep the YUV headroom information during clip import. Only applies to 10-bit YCbCr-material found in some mp4 and QuickTime files. Disabling this option for clips that use the headroom (usually clips from cameras) results in clips with clamped black and whites. Enabling this option for clips that do not use the headroom (usually clips from Final Cut Pro) results in an imported clip with lowered contrast.

Aspect Ratio box Select the aspect ratio of the frames used to import the file and override the aspect ratio stored in the file as specified. You might need to change the aspect ratio as many applications erroneously write a pixel aspect ratio of 1 (a square pixel), even for formats that have non-square pixels (NTSC, PAL).

Viewing the clip in the Player with the specified aspect ratio requires that you enable **Options ► Show Viewing Settings ► Use Ratio**. The Previewer in the MediaHub always displays clips with the specified aspect ratio.

Note that the application internally uses a frame ratio, not a pixel ratio. To specify a pixel ratio, you must select either Square Pixels or Enter Pixel Aspect Ratio; Aspect Ratio from Resolution and Aspect Ratio from Header are interpreted as frame ratios.

Aspect Ratio field Set the ratio used to define the frame or pixel aspect. Affects the frame aspect if the Aspect Ratio box is set to Enter Frame Aspect Ratio. Affects the pixel aspect if it is set to Enter Pixel Aspect Ratio.

Browsing Settings

Essence Mode button Enable to browse the directory structure of XDCAM EX media. This option allows you to import specific audio or video files contained within a XDCAM EX directory structure.

About Pixel Aspect Ratio

Some video and film formats use rectangular instead of square pixels. This explains why NTSC and PAL video formats have a different frame dimension in terms of pixels, but are ultimately broadcast to the same 4:3 aspect ratio screen.

- NTSC pixels are narrower than they are high, which allows for the 720x486 (1.481) aspect ratio frame to fit into a 4:3 (1.333) aspect ratio broadcast screen.
- PAL pixels are wider than they are high, which allows for 720x576 (1.25) aspect ratio frame to fit into a 4:3 (1.333) aspect ratio broadcast screen.

When you capture video or import film frames that use rectangular pixels into Flame Premium, the pixels become square because computer graphics work only with square pixels. This is why the NTSC and PAL frames appear as though they are different size—displayed with square pixels, they are.

You can set the image window to display clips originating from rectangular pixel formats using filters to simulate the use of rectangular pixels. This provides a display that corresponds with the delivery format.

Using the aspect ratio display affects system performance, so if you are using the aspect ratio filter and notice a performance slowdown, you can disable the option and return to square-pixel display.

NOTE Many HD video formats such as 1920x1080 and 1280x720 use square pixels, so enabling this option has no effect. One HD video format that does use “slightly” rectangular pixels is 1920x1035.

Modifying Import Options After Import

- 1 Select the Timeline tab.
- 2 In the timeline, select the segment or clip to edit.
- 3 In the FX Processing Pipeline, select the thumbnail of the clip and click Edit Pre-Processing.

Colour Transforms and Import History

When creating the color transform in the color transform builder at importing the media, the transform selections can be of type Autodesk, Project, Shared, or Import. When editing the import options of the clip, the Color Transform Builder partially reflects the transform list created during the import:

- Muted transforms in the initial builder do not show up.
- Transforms of the Autodesk category are preserved.
- Transforms from the Project and Shared categories are re-branded as Import.

This happens because Flame Premium does not preserve the complete state of the colour transform builder, but rather a reference transform that creates the desired result.

Working with Others

Flame Premium offers you two methods to work in collaboration with other users of Flame or Smoke.

The first one is the Projects browser in the MediaHub. Use it to transfer clips between your project and another one. This other project can be a local, such as a previous project you worked on, or a remote project, such as a sequence being put together in Smoke. Or use Projects to transfer clips from a project created with an older version of the software. But if you want to work on the same shots, clips, sequences, use Shared Folders.

The second method is Shared Folders. Shared folders integrate directly in the MediaHub panel, and are best used when you are working with other users on the same project. [Flare Workflow](#) (page 49) has more about working with Workspaces, and even if it targets mostly a Flame-Flare workflow, it applies to any setup where Shared Folders are used.

Import History and Lustre

When importing media files and using the Cache Source Media, Flame Premium bakes in import options like resize, LUT, and format specific options like R3D settings. Of course, you always have access to the import history, and edit it if need be. Just use the Edit Pre-Processing button in the Timeline FX ribbon.

But Lustre does not have access to the import history for clips imported in Flame Premium with an enabled Cache Source Media option. This means that if you import in Lustre a Flame Premium-created sequence

that uses such clips, you do not have access to their import history. Flushing the media cache prior to importing the clip in Lustre restores access to import history.

To restore access to the import history for Lustre:

- 1 From Flame Premium, right-click the material to grade in Lustre.
- 2 Select **Media ► Flush Source Media Cache**.

You can now edit the import history of the clip from Lustre.

Sharing Clips Between Users

Clips placed in a special folder, called Shared Folder, becomes accessible to remote workstations that connect to the project. Shared folders enable different Creative Finishing workstations to quickly and conveniently share media.

Placing media in a shared folder automatically grants read access to any workstation connected to the project. The remote operator can then access the media and start working immediately after connecting to the project. Once finished, the remote operator needs to save the resulting media back to the shared folder. To do this he must acquire write access.

Write access locks the folder so that only the user having acquired write access can modify the folder contents (i.e. write to the folder). Read access is still available to other remote workstations connected to the project. Once the media is saved, the user can disable write access, enabling other remote workstations to obtain write access and modify the content.

NOTE Clips stored in Shared Folders are archived when you archive a project.

To acquire write access:

- 1 Select the top level shared folder you want to acquire write access to in the Media panel.
- 2 From the contextual menu, select Acquire Write Access.

To disable write access:

- 1 Select the top level shared folder you want to acquire write access to in the Media panel.
- 2 From the contextual menu, select Release Write Access.

To enable or disable shared folders:

- 1 Select the top level shared folder you want to enable or disable in the Media panel.
- 2 From the contextual menu, select Enable or Disable.

To manually refresh the content of shared folders:

- 1 Select the top level shared folder you want to refresh in the Media panel.
- 2 From the contextual menu, select Refresh.
The content of the shared folders is updated.

Transferring Material Between Projects

Elements you can transfer when browsing for Projects:

- Clips
- Folders
- Batch Snapshots
- Reels
- Desktop Snapshots

You can only transfer an item to the same type of location, so a Batch Snapshot to the Batch Snapshots section of the Media panel. One exception is Reels, which can be transferred to the Media Library; this makes it easier to transfer media from a Flame to a Smoke, since Smoke does not have Reels.

To transfer material between your project and one located on another workstation:

- 1 Select **MediaHub ► Browse for Projects**.
- 2 In the Autodesk Network list, double-click the workstation where the project is located.
This displays the list of projects hosted by that workstation.
- 3 Double-click the project to open it.
This opens the project and displays its Workspaces.
- 4 Navigate the project to find what you want to transfer.
- 5 Drag-and-drop from the Projects browser to the Media panel. Or from the Media panel to the Projects browser: you can import or export between projects.

To transfer material between local projects:

- 1 Select **MediaHub ► Browse for Projects**.
- 2 In the Local Projects list, double-click the project to open it.
This opens the project and displays its Workspaces.
- 3 Navigate the project to find what you want to transfer.
- 4 Drag-and-drop from the Projects browser to the Media panel. Or from the Media panel to the Projects browser: you can import or export between projects.

NOTE Proxies are only transferred when both projects have identical proxy settings, as defined in the Projects settings window.

Troubleshooting

Read Only (In use by...)

Appears in one of two cases:

- When the workspace of the project you are browsing is opened and used by the user listed in the Read Only message.
- When someone else is browsing that workspace with the button Exclusive Write Access enabled.

You can still copy items from a Read Only workspace. If you absolutely need to write to the workspace, you will need to locate the user and ask him to switch to another project.

Owned by...

The workspace you are trying to write to is owned by another Flame, Smoke, or Flare. Enable Administrator mode to write to the workspace.

Unmanaged media contained in selection. Cache media on Wire?

When transferring media from a remote project, you can get the following message: "Unmanaged media contained in selection. Cache media on Wire?"

This means that the clip you are importing from the remote project has no media cached. Answer Yes to cache the media during the transfer of the clip. Answer No to only keep a reference to the media.

In fact, answering Yes is identical to importing media with the Cache Source Media enabled, and answering No is identical to importing media without Cache Source Media.

MediaHub Reference: Browsing for Projects

Exclusive Write Access button Enable to get exclusive write permission to the Workspace you are browsing, preventing others from modifying the contents of that Workspace. Other users can still read and copy clips of that Workspace.

Administrator Mode button Enable to modify workspaces created by others. You do not need to enable this option only to read clips from other projects.

This can be used by the Flame artist to clean up workspaces created by Flare collaborators.

Workstation Processing box Select which workstation processes the transferred media using to the Wire options set; has an impact on the overall performance of the selected workstation.

Background Wire button Enable to perform the Wire tasks in the background so that you can continue working in the application. Disable to perform the Wire tasks in the foreground, which is faster but prevents you from using the application.

Using Subtitles Files

With Flame Premium, you can load a subtitle file to quickly add subtitles to a sequence. This is the most effective method as it allows a third party to create subtitles without requiring access to a Flame Premium.

The format of this file is described in [Subtitle XML Elements](#) (page 159), with a sample provided in [Subtitle XML Sample](#) (page 163).

Other methods for subtitling include creating Text Timeline FX on the sequence's segments, or adding a new layer to create the subtitles in Gap effects.

Importing Subtitles to a Timeline Sequence

The procedure below adds subtitles from an imported xml file to an opened sequence.

- 1 From the MediaHub tab, import the subtitle file to the Media Library. There are no Specific Import Options to set.
The subtitle XML file is imported as a single-track clip, where the subtitles are editable Text Timeline FX applied to Gap effects.

NOTE The subtitle clip is renamed to the name defined by the `<name>` element in the file. It also takes the timing and resolution defined for the project.

- 2 From the Timeline tab, right-click the sequence that requires subtitles and select Open or Open as a Sequence.
- 3 Add a track to the opened sequence.
- 4 Drag and drop the subtitle clip to the new top track.
Each text element appears as a editable Text Timeline FX, at the timecode and length specified in the xml file.

TIP You can add multiple subtitle clips to a sequence, then mute all but the track you want to process. With this method you can quickly version a clip with different captions.

Defining Subtitles Looks Using Text Setup Files

A text setup file can be referenced from the subtitle XML file. The text setup file overrides the font style and position parameters indicated in the current `<title>` element.

Using a text setup file allows you to apply your preferred text setup to the subtitles in the file, or even have a different text setup for each subtitle.

To create the text setup file:

- 1 In a Text tool, create a text setup.
- 2 Click Save.
- 3 In the Save menu, select Selected Layers from the Save box.

- 4 Choose the directory into which you want to save the file.
- 5 Type a name for the file and press `Enter` or click the Save button.
The file is saved and you return to the Text tool.

To associate the text setup file to each subtitle element:

- 1 Open the subtitle XML file in a text editor.

TIP Consider using a text editor with syntax coloring for XML elements. It makes for easier navigation of files.

- 2 Within each `<title>` element, indicate the path to the text setup file in the `<setup>` element.

The parameters in the text setup file override the following text parameters within the `<title>` element of the subtitle: font, size, font colour, vertical, and horizontal.

Once you import the subtitle file in Flame Premium, you can see the impact of the text setups on the imported subtitles. Changes to the text setup do not propagate to an imported subtitle file: if you modify the saved text setup after importing a subtitle file, you need to re-import that same file to update the subtitles referencing that setup.

Search for subtitles that are not properly linked to a setup file:

- 1 Place the positioner on the subtitle track.
- 2 Click the magnifying glass icon at the bottom right side of the timeline.
The Find and Select in Timeline window appears.
- 3 Enable
 - Gaps
 - Every Criteria Below
 - Comments. Also enter in the Comments field *Unable* (make sure to enter the asterisk wildcards).
- 4 Click Select on Current Track.
The Find and Select in Timeline windows closes, and subtitles not properly linked to a text setup are highlighted. You need to fix the subtitles file to use the correct text setup path, and then import the file again.

Subtitle XML Elements

Subtitle XML files are text files that use the following elements. Use the following syntax to work with Subtitle XML files external to the Flame Premium workstation.

In Flame Premium-compliant subtitle XML file, the `<!DOCTYPE>` is `subtitle`.

<name></name>

Description	An element that defines the name of the Subtitle XML file. This name appears as the name of the clip created when importing the subtitle XML file.
Attributes	none
Sample	<code><name>French version: Day at the Races</name></code>

<rate></rate>

Description	A format element that describes the framerate of the Subtitle XML clip that appears in Flame Premium after importing the Subtitle XML file. The frame rate must be that of the target sequence or the subtitles might slip timecode.
Attributes	none
Sample	<code><rate>59.94 NDF</rate></code>

<resolution></resolution>

Description	A unique element that wraps around all of the attributes determining the format of the clip when importing a Subtitle XML file. This clip can then be resized within Flame Premium like any other clip, if necessary. If any of these values differ from the target sequence, Flame Premium will apply Resize Timeline FX to the subtitles.
-------------	--

Mandatory children	<p><width></width> The width of the imported Subtitle XML clip. An integer.</p> <p><height></height> The height of the imported Subtitle XML clip. An integer.</p> <p><depth></depth> The bit depth of the imported Subtitle XML clip.</p> <p><aspect></aspect> The aspect ratio of the imported Subtitle XML clip.</p> <p><scanformat></scanformat> The scanformat of the imported Subtitle XML clip.</p>
--------------------	---

Sample	<pre> <resolution> <width>1920</width> <height>1080</height> <depth>8</depth> <aspect>1.778</aspect> <scanformat>default</scanformat> </resolution> </pre>
--------	--

<timecode></timecode>

Description	An element that defines the timecode in and out points during which the subtitles occur. All the titles in the Subtitle XML file will occur during the timecode indicated here, with each title also having its own start and end point indicated within the title elements.
Mandatory children	<p><start></start> The start timecode of the subtitle sequence.</p> <p><end></end> The end timecode of the subtitle sequence.</p>
Sample	<pre> <timecode> <start>01:00:00;00</start> <end>01:00:08;00</end> </timecode> </pre>

<video></video>

Description	The <video> element wraps around all of the <title> elements, which in turn contain the text and attributes of individual subtitles.
Mandatory children	<title></title> The <title> element wraps around each subtitle, with its associated start and end time, text, and font style and position parameters.
Sample	<pre> <video> <title> <start>01:00:01;00</start> <end>01:00:02;00</end> <text>This is a subtitle string</text> Garamond <size>20</size> <fontcolor> <alpha>255</alpha> </pre>

```

        <red>255</red>
        <green>255</green>
        <blue>255</blue>
    </fontcolor>
    <vertical>0</vertical>
    <horizontal>0</horizontal>
    <setup>/usr/discreet/project/test/text/paz.ttg</setup>
</title>
</video>

```

<title></title>

Each <title></title> element defines a single subtitle which will appear as a Text Timeline FX applied to a gap once imported into Flame Premium, and added to a sequence.

The font style, colour, size, and position parameters are overridden if a valid text setup file is referenced within the <title> element.

<start></start>

Description	The start timecode of the current subtitle
Attributes	none
Sample	<start>01:00:01;00</start>

<end></end>

Description	The end timecode of the current subtitle
Attributes	none
Sample	<end>01:00:02;00</end>

<text></text>

Description	The text of the current subtitle To insert a carriage return, add <#13> (without the brackets) to the text.
Attributes	none
Sample	<text>This is a#13; subtitle string</text>

Description	The font of the current subtitle. This value is overridden if a text setup file is referenced in the <setup> element.
-------------	---

Attributes	none
Sample	<code>Garamond</code>

`<size></size>`

Description	The font size of the current subtitle. This value is overridden if a text setup file is referenced in the <code><setup></code> element.
Attributes	none
Sample	<code><size>20</size></code>

`<fontcolor></fontcolor>`

Description	This element wraps around the font colour elements (<code><alpha></code> , <code><red></code> , <code><blue></code> , <code><green></code>) of the current subtitle. These values are overridden if a valid text setup file is referenced in the <code><setup></code> element.
Mandatory children	<p><code><alpha></alpha></code> The <code><alpha></code> colour component of the font of the current subtitle.</p> <p><code><red></red></code> The <code><red></code> colour component of the font of the current subtitle.</p> <p><code><green></green></code> The <code><green></code> colour component of the font of the current subtitle.</p> <p><code><blue></blue></code> The <code><blue></code> colour component of the font of the current subtitle.</p>
Sample	<pre> <fontcolor> <alpha>255</alpha> <red>255</red> <green>255</green> <blue>255</blue> </fontcolor> </pre>

`<vertical></vertical>`

Description	The vertical text position of the current subtitle. This value is overridden if a text setup file is referenced in the <code><setup></code> element.
Attributes	none
Sample	<code><vertical>0</vertical></code>

<horizontal></horizontal>

Description	The horizontal text position of the current subtitle. This value is overridden if a text setup file is referenced in the <setup> element.
Attributes	none
Sample	<horizontal>0</horizontal>

<setup></setup>

Description	The <setup> element can point to a text setup file from which font style and position parameters will be used. The parameters from the text setup file override the formatting elements of the current <title> element. Leave empty when not using a text setup file.
Attributes	none
Sample	<setup>/usr/discreet/project/test/text/paz.ttg</setup>

Subtitle XML Sample

Use the following XML sample as a starting point for your own subtitle XML files.

The following is an example of Subtitle XML which creates three Text soft effects applied to gaps at these timecodes:

- 01:00:01;00 until 01:00:02;00
- 01:00:03;00 until 01:00:04;00
- 01:00:05;00 until 01:00:06;02

```
<?xml version="1.0" encoding="UTF-8"?>

Conform Tab Overview

Use the Conform tab to troubleshoot imported timelines and to link segments to sources.

Event List Displays the events that make up the sequence displayed in the Timeline section. Clicking an event in the list also selects it in the Timeline. You can sort the list using by clicking the column headers. Linked events are usually displayed, but if you are only interested in unlinked events, you can hide the linked events from the Display Options box. If the Event list displays the message All Sources Linked, the selected sequence is already conformed.

Every column, other than Status, Matches, and Media, is a potential match criteria used to find the correct source from the Potential Matches, displayed at the bottom of the Media panel. The data displayed in the Event list is always one of the following colours:

Red This information is used as a match criteria, and the Potential Matches contain no source that matches this criteria.

Yellow This information is used as a match criteria, and the Potential Matches contain more than one source that matches this criteria.

White This information is used as a match criteria, and the Potential Matches contain only once source that matches this criteria.

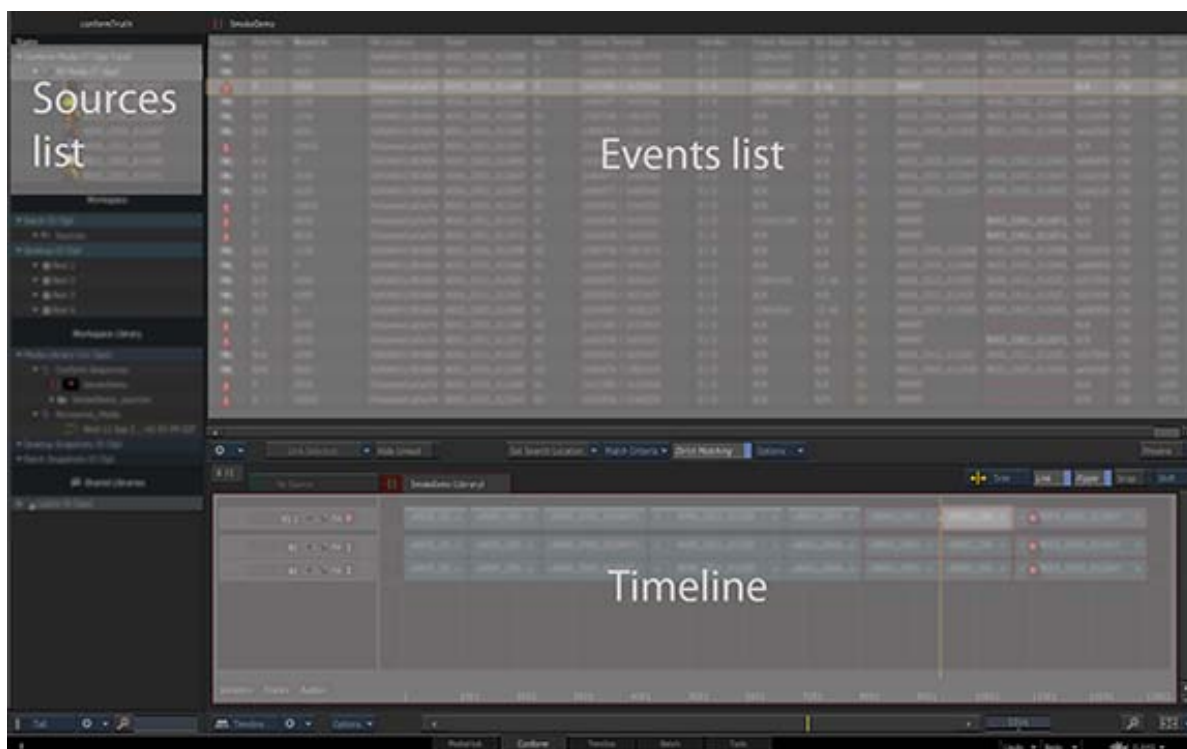

Grey This information is not used as a match criteria.

Potential Matches The Potential Matches display all the information about the sources found when using Set Search Directory or Set as Conform Search Location, from the contextual menu. From all the potential sources, Flame Premium uses the criteria you set using the Match Criteria box to filter in potential matches. From there, you can select the right source and link it to the selected event.

NOTE If you select an event with no matches, it shows the full list, in order to allow for force linking.

Disable Display Options > Filter Potential Matches to show all the sources.

Timeline The Timeline displays an open sequence, with controls similar to the ones found in the Timeline tab. Unlinked events are boxed in red.

Conform Gear menu Use to import an AAF, an XML, or an EDL. If connected to a VTR, select Capture... to send the selected events to the VTR queue and enter the VTR Recapture module.

Linking combo box Select Link Selected to link a selected source to the selected event. Select Link Matched Sources to link every event marked as Match to its found source.

Hide Linked button Enable to filter out, from the Event list, the events that are relinked.

Set Search Location button Use Set Search Location to locate the directory containing the sources, and to load those sources in the Conform Media list. Use Link to Media File to relink event to their sources using the paths stored in the sequence.

Match Criteria box Select from the list the criteria used to match sources to events. In the Event list, grey indicates unused criterion, white is matched criteria, yellow indicates multiple sources match the criteria, and red indicates no match was found in the Conform Media list.

Strict Matching button Enable to force exact matching between source and event. When disabled, matching occurs when source and event have in common a string of at least 7 characters. Only applies to Name and File Name criteria.

Display Options box Select display options for Conform Media and Event lists.

Preview button Enable to display the Preview panel. The Source Player displays the source selected in the Conform Media list, the Record Player displays the event selected in the Timeline.

Adding Sources for Linking to the Conform Media List

Adding sources from an external location:

- 1 In the Conform tab, click Set Search Location.
- 2 Using the Set Directory window, select the directory where the sources are located.

- 3 Click Set.

Flame Premium clears previous sources from the Conform Media folder, and then displays all the media files from the selected location, including any media files located in sub-directories.

Adding sources from a folder, a library, or a reel within Flame Premium:

- 1 In the Conform tab, select a library or a folder from the Workspace or Workspace Library.
- 2 Right-click and select Set as Conform Search Location.

Flame Premium clears previous sources from the Conform Media folder, and then displays all the media files from the selected location, including any media files located in sub-directories.

You can also manually add clips from the Media Panel to the Conform Media folder: drag-and-drop them to the Conform Media folder. This does not clear already present sources.

Notes

- Flame Premium only loads files it can use in a conform, so do not worry about non-media files being loaded to the Conform Media folder.
- Use the options found in the General and Format Specific Options tabs of the Set Directory window to modify the characteristics of the source files found: edit their resolution, bit depth, debayering settings, etc. Keep in mind that this will either facilitate or hamper the linking, depending on the settings and match criteria you set during the conform.
- When you load sources using the Set Search Location button, Flame Premium does not import the media files at that time: it creates only a list of references to the clips. This means that:
 - Even if proxies are enabled for the project, Flame Premium does not create proxies for media files loaded in the Conform Media folder. Proxies are only generated when you link an event to its source.
 - Flame Premium does not cache source media loaded to the Conform Media folder. To cache the source media once relinked, right-click the segment and select **Media ► Cache Source Media**.

Relinking Media

In the Conform tab, you can easily relink an unlinked sequence that stores the path to the media (display the path by **Alt**-clicking the segment). Most AAF, FCP XML, and DLEDL and native sequences do store these paths.

To relink segments of a sequence to their media:

- 1 Display the sequence in the Conform tab.
- 2 Select Link to Media File from the Set Search Location drop-down menu.
- 3 Click Link to Media File.

Flame Premium automatically relinks the segments to their media.

TIP When you import a sequence (AAF, FCP, XML), consolidate the handles on import, and enable Cache Source Media to improve performance. When you need the original full-resolution media, or the media with the discarded handles, unlink the sequence, and then relink using the previous procedure. Every segment is now restored to the full-resolution, not cached, original media.

Conforming an EDL

A regular EDL does not contain the paths to its media. This means that in most cases you will need to perform the following conform operations.

A DLEDL, such as one produced by the Flame Premium when exporting a Sequence as an EDL, does contain the paths to the media. If after having imported a DLEDL some segments are still not linked to their media, use the Conform tab to relink both segments and media.

- 1 Display the EDL to conform in the Conform tab. Do one of the following:
 - If you imported the EDL using the MediaHub: switch to the Conform tab, right-click the EDL and select Open as a Sequence.
 - If you have not already imported the EDL: switch to the Conform tab, right-click the Event list and select Load New FCP XML/AAF/EDL.

From the window that appears, locate and select the EDL to conform, and then click Load.

- 2 Add potential sources to the Conform Media folder.

You now have two lists: the Events list, displaying all the events making up the sequence, and the Conform Media list, displaying the potential sources you selected.

NOTE By default, the Conform Media list displays only the sources matching the currently selected event. Disable **Options > Filter Potential Matches** to view all the possible sources.

- 3 With **Options > Filter Potential Matches** selected, click a event from the event list. The sources matching that event are displayed in the Potential Matches list.

NOTE You can also select a segment directly in the timeline. Both the timeline and the event list update to reflect the current selection.

- 4 What you do next depends on the Status column of each event.

Match Select Link Matched Sources from the Linking combo box. Link Matched Sources links all events with the Match status to their unique sources. Match indicates that Flame Premium found only one source from the Sources list that fit the selected Match Criteria.

Multiple Matches Do one of the following:

- Select the event, the source to relink, and then select Link Selected from the Linking combo box.
- Select the event from the event list, right-click the source to relink, and then select Link.

If there are too many sources to choose from, set additional criteria using the Match Criteria drop-down menu; by trial and error you can reduce the number of matching sources.

No Match Found Either add more sources to the Media folder or modify the criteria selected in the Match Criteria drop-down box. Not Found indicates that either the criteria are too restrictive for Flame Premium to find a match, or that the source is simply not there.

Unlinked Add sources to the Media folder. Unlinked indicates that the event is not linked to any source. It appears only when no sources are available in the Media folder, and the Conform section of the Media panel displays 0 clip total.

Linked Nothing to do: the event is already linked to source. Linked events appear in the Events list only if **Options ► Hide Linked** is not enabled.

- 5 Once there all the events are linked to sources, you are done with the conform. You can leave the Conform tab.

About the Load and Edit New EDL Menu

Use the menu to load an EDL and edit it before conforming it.

EDL Type box Select an EDL type to load. Available options are: ALE, FLX, ATN, TLC, EDM, R23, ETL, and OMF.

File Extension field Displays the file extension for the associated file type. Editable.

EDL Frame Rate box Displays the framerate of the current EDL. Editable.

EDL Conversion button Enable to convert the EDL to another frame rate.

Conversion Option box Select the option that corresponds to the type of conversion that you want to apply to the EDL. The conversion scripts that appear in this list depend on the frame rate of the EDL you are loading.

Fix TW Match Frames button Enable to fix match frame errors. When you import an EDL that contains dissolves or timewarps, a match frame error may occur. This can cause an unwanted cut at the point where the timewarp begins in your EDL. Match frame errors occur when the in point of the second edit in a dissolve is not the same timecode as the out point of the previous shot. This feature is enabled by default.

Frame Code Mode box Select the option that corresponds to the EDLs you are loading. If you are loading multiple EDLs, the same Frame Code Mode is used for all of them.

2:3 Removal Mode button Enable to remove pulldown when loading the EDL.

Varicam button Enable if the EDL is used to capture material shot with Varicam.

Varicam Frame Rate box Select the Varicam frame rate.

Editing an EDL

Once you import an EDL, you can edit any value except the event number. This includes:

- The tape name for single or multiple events
- The audio patching information
- The transition duration and speed value of dissolves
- A cut to a dissolve or wipe
- The source and record timecodes of events

These tasks are described in the following sections. You can open multiple EDLs and copy and paste events between them. You can also use Auto Edit mode to quickly make changes to the entries you specify.

About the Import EDL Menu

Use the Import EDL menu to create, import, edit, auto-capture, assemble, and save EDLs.

EDL List

The EDL list is divided into 12 columns.

Event # The event number, followed by a capture indicator.

Tape The name of the tape containing the source clip.

A. Patch The Audio Patch information.

Tracks The track for the edit (shown as a combination of: V, 1, 2, 3, 4, 5, 6, 7, 8).

Transition The type of transition between the clips: C for cuts, D <duration> for dissolves, and W <wipe code> <duration> for SMPTE wipes.

Source In The starting timecode of the element in the source clip.

Source Out The ending timecode of the element in the source clip. (Ctrl-click the heading to view Source duration.)

Keycode In The starting keycode of the element in the source clip.

Keycode Out The ending keycode of the element in the source clip.

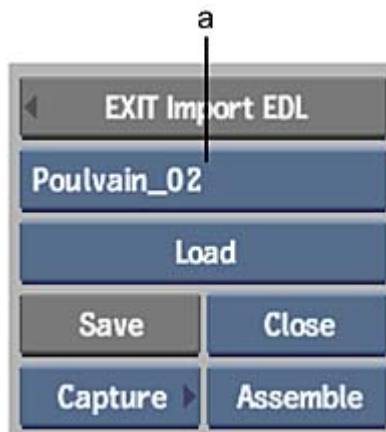

Speed The speed at which the source clip is timewarped in the edit. The value is preceded by a negative sign if the effect is a reverse. The column is blank if the speed value is 100% (no timewarp).

Record In The starting timecode of the element in the result clip.

Record Out The ending timecode of the element in the result clip. (Ctrl-click the heading to view Record duration.)

Operations Group

The Operations group contains the commands that allow you to import an EDL.

(a) File Name field

File Name box Select a previously loaded EDL file to display in the EDL work area.

Load button Opens the Load EDL menu where you set options for loading EDLs.

Save button Opens the Save EDL menu where you set options for saving EDLs.

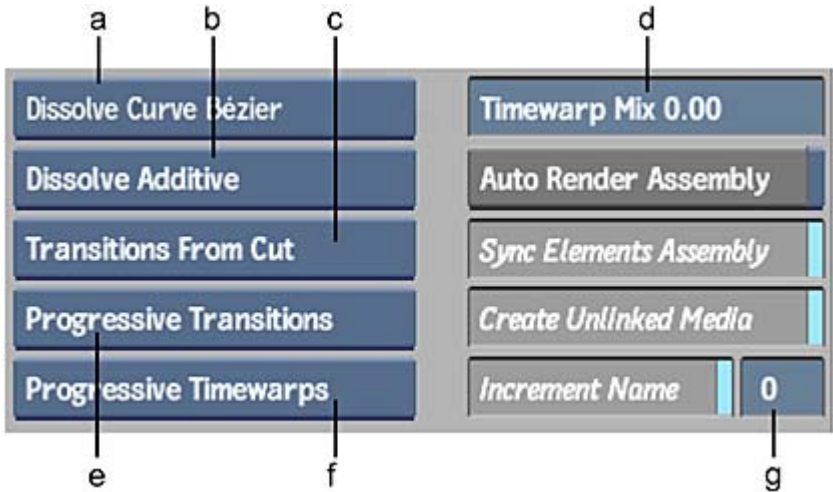

Capture button Opens the Auto-Capture menu where you capture media from a VTR using an EDL.

Close box Select Close to close the currently displayed EDL file, or Close All to close all EDL files.

Assemble box Select Assemble to combine the captured or imported material into a clip on a destination library reel. Select M-Assemble to combine multiple EDLs into a multitrack clip.

Assembly Options Menu

The Assembly Options menu contains options that you can set that affect EDL assembly.

(a) Dissolve Curves box (b) Dissolve Type box (c) Transitions Alignment box (d) Timewarp Mix field (e) Transition Render Option box (f) Timewarp Render Option box (g) Increment field

Dissolve Curves box Select the type of interpolation to use for all dissolves.

Select:	To:
Dissolve Curves Linear	Create dissolves with linear interpolation curves.
Dissolve Curves Bézier	Create dissolves with Bézier interpolation curves.

Dissolve Type box Select a rendering option for dissolves during EDL assembly.

Select:	To:
Dissolve Additive	Render dissolves as additive.
Dissolve Non Additive	Render dissolves as non additive.
Dissolve Inv Non Additive	Render dissolves as inverse non additive.

Transitions Alignment box Select an option for the placement of transitions in assembled EDLs.

Select:	To:
Transitions From Cut	Align transitions after the cut.
Transitions Centred	Centre transitions on the cut.

Select:	To:
Transitions Up To Cut	Align transitions before the cut.

Transition Render Option box Select the rendering mode for transitions in assembled EDLs.

Select:	To:
Interlaced Transitions	Override the Preferences settings and render transitions in Interlaced mode.
Progressive Transitions	Override the Preferences settings and render transitions in Progressive mode.

Timewarp Render Option box Select an option for the rendering mode for timewarps in assembled EDL.

Select:	To:
Progressive TW	Render timewarps in Progressive mode.
Interlaced TW	Render timewarps in Interlaced mode.

Timewarp Mix field Enter the mix value for assembled timewarps. You can enter any value from 0.00 to 1000.00.

Auto Render Assembly button Enable to render transitions and timewarps when you assemble the final clip.

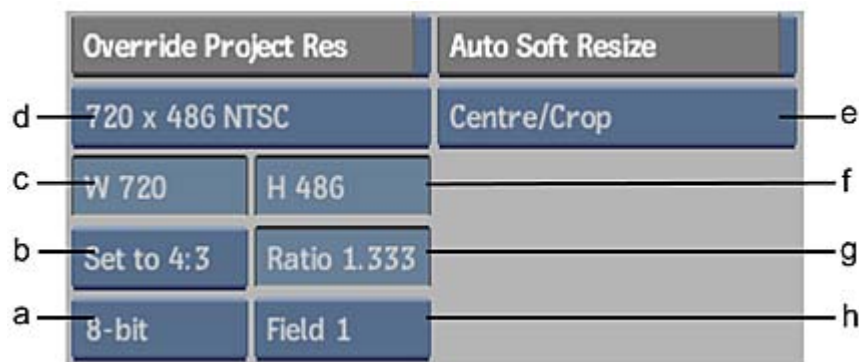

Sync Elements Assembly button Enable to automatically create Edit Sync groups for video and audio tracks that share the same timecode.

Create Unlinked Media button Enable to assemble an EDL, even if you do not have all the sources and, later, use the Recapture/Relink media feature to bring the missing media into your work-in-progress timeline clip.

When you disable this option, you get virtual sources with no indication of source timecode and tape name for the events when no recapture media exists for an event.

Increment Name button Enable to increment the assembled clip name (when assembling the same clip multiple times).

Increment field Enter a number by which the name is incremented. Active only when the Increment Name button is enabled.

(a) Frame Depth box (b) Aspect Ratio Presets box (c) Frame Width field (d) Resolution Presets box (e) Fit Method box (f) Frame Height field (g) Aspect Ratio field (h) Scan Mode box

Override Project Resolution button Enable to assemble pre-captured material of a different resolution than your project's default resolution. Additional controls become active that you use to specify the resolution options for assembly.

During assembly, the system searches the specified library reel for matching media. For media to match an event during EDL assembly, all the specified parameters must be the same (including frame rate, resolution, bit depth, and so on). When a match occurs for an event, the event is marked as captured.

By default, Override Project Resolution is disabled and the project's default resolution is used when matching EDL events to pre-captured media.

NOTE If an EDL refers to a clip that has the same tape name and timecode but is of a different resolution than the default resolution or that of the first matched event, the clip will not be marked as captured. For example, if you are assembling an NTSC EDL and the EDL refers to a captured HD clip with the same tape name and timecode, the HD clip will not be marked as captured.

Resolution Presets box Select one of many standard resolutions, as well as a Custom option that you can use to specify non-standard resolutions.

Auto Soft Resize button Enable to apply a soft resize when assembling any clip that was captured at a resolution that differs from the native project resolution. Options become active that allow you to specify how the soft resize should be applied.

Fit Method box Select a fit method option to be applied to the imported clip.

Select:	To:
Centre/Crop	Fit the source image, centred, over the destination frame. If the source is larger than the destination, it is cropped. If the source is smaller than the destination, it is surrounded by a black border.
Crop Edges	Fit one edge of the source into the destination frame without stretching or squashing the frame. Excess parts of the source frame after resizing are cropped. If the source—after the one edge is resized—is wider than the destination, its overhanging left and right edges are cropped. If the source is taller than the destination, the upper and lower edges are cropped.
Fill	Fit the source, width and height, into the destination frame. If the source and destination frames do not have the same aspect ratio, the image can become distorted.
Letterbox	Fit the source to the destination frame without squashing or stretching it, and without cropping the source. If the source is wider than the destination, black bars fill the top and bottom of the destination frame. If the source is narrower than the destination, black bars fill the right and left sides of the frame. In all cases, the entire source frame is contained within the destination frame.

Frame Width field Displays the frame width of the selected resolution preset. If Resolution Presets is set to Custom then this field is active, allowing you to enter the frame width value that you want to use.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Frame Depth box Select from one of five frame depth options: 8-bit, 10-bit, 12-bit, 12-bit u, or 16-bit fp.

Frame Height field Displays the frame height of the selected resolution preset. If Resolution Presets is set to Custom then this field is active, allowing you to enter the frame height value that you want to use.

Aspect Ratio field Displays the aspect ratio of the imported clip. When Aspect Ratio Presets is set to Custom, this field becomes active so that you can enter a custom frame aspect ratio.

Scan Mode box Select an option to determine the order in which the fields of interlaced material are scanned.

Select:	To:
Progressive	Scan a frame-based clip with no interlacing.
Field 1	Scan Field 1 first, followed by Field 2.
Field 2	Scan Field 2 first, followed by Field 1.

Preferences Menu

Use the options in the Preferences menu to specify your EDL preferences.

Beep on Assembly Complete button Enable to hear an audible tone when the EDL is assembled.

Allow Zero-Length Transitions button Enable to allow zero-length wipes and dissolves. If this option is disabled and you change a transition duration to zero, the transition automatically becomes a cut.

Keep Cursor In View Area button Enable to keep the cursor from leaving the window when you scroll an EDL. When you scroll an EDL, the cursor will stop at the first or last event on the EDL page.

Compare Tape Names Search button Disable to ignore tape names during assembly.

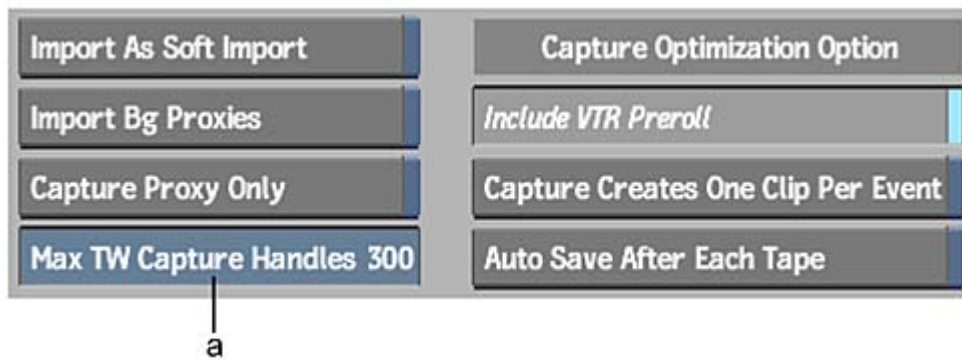

Clip Name Comments Capture button If your events contain clip names in their comments, enable this option to use those names during capture. If this option is disabled, the event number is used as the captured shot's name.

Use Hotkey For Add Selection button Use to change the functionality of selecting events. When this option is disabled, you add to your selection range by clicking the events. When this option is enabled, you must hold the **Ctrl** key or the pen button while clicking events to add them to your selection range.

Auto Disable Slip Tape button By default, the Slip Tape option remains enabled after you slip sources. Enable this option to disable the Slip Tape option automatically after you slip sources.

Clip Name Comments Assembly button If your events contain clip names in their comments, enable this option to use those names during assembly. If this option is disabled, the EDL title is used as the assembled clip's name.

Keep System Comments button Use the Keep System Comments option to protect system comments. When enabled, you can only delete user comments.

(a) Max TW Capture Handles field

Import As Soft Import button Enable to soft-import files with a file-based EDL that are located on a standard filesystem. If you disable this option, the files are hard-imported.

Import Background Proxies button Enable to allow proxies to be generated in the background.

Include VTR Preroll button Enable to capture the events in one pass and store them as individual clips in the clip library. By default, if events in an EDL are separated by a shorter duration than the VTR preroll and more than 10 frames, they are captured in a single pass.

Capture Proxy Only button Use this option in HD projects to auto-capture proxies only when conforming an EDL. This option does not appear in SD projects.

Max TW Capture Handles field You can set the maximum number of handles to be captured for source clips that are part of timewarped events. On timewarped events, the capture handles value is equal to the capture handles value multiplied by the speed of the timewarp. For example, for an EDL event with an increased speed of 500% (in NTSC), if the capture handles are set to 30 frames, 150 frames are captured as handles (30 frames multiplied by 5).

Standard handles may not be enough in the case of high-speed timewarps.

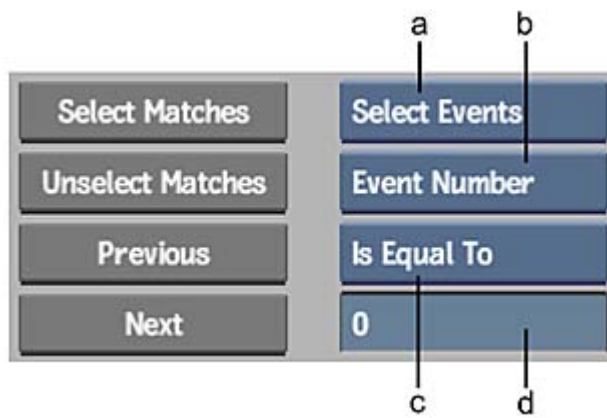

Capture Creates One Clip Per Event button Enable to create a clip in the clip library for every event in the EDL. When disabled, a single clip is created in the library for each group of events captured during the same pass. You can assemble the montage regardless of which option you chose to store EDL events in the clip library.

To reduce the size of clip libraries, you should disable this feature. However, if you need to reference back to individual shots, they may be easier to find if you enable the option and generate a clip for every event.

Auto Save After Each Tape button When this option is enabled, the system performs an AutoSave between each tape when auto-capturing.

Search Events Menu

Use the Search Events menu to search entries for text or timecode in an EDL. When you search the EDL, you need to specify the item you want to search, the filter type you want to use, and the criteria for which you want to search.

(a) Select Item box (b) Search Item box (c) Filter Type box (d) Search Criteria field

Select Matches button Highlight all items that match the search criteria.

Unselect Matches button Remove the highlight from all items that match the search criteria.

Select Item box Select the option that you want to search for.

Select:	To highlight:
Select Events	All events that match the search criteria.
Select Edits	All edits that match the search criteria.

Search Item box Specify the item that you want to search for in the EDL.

Select:	To search for:
Event Number	Event numbers.
Tape	Tape names.
Transition Length	A specific transition duration.
Source In	A source in timecode.
Source Out	A source out timecode.
Speed	A specific timewarp speed.
Record In	A record in timecode.
Record Out	A record out timecode.
Comment	A comment or text within a comment.
Track	A track.

Previous button Move the cursor to the previous item that matches the search criteria.

Next button Move the cursor to the next item that matches the search criteria.

Filter Type box Specify the filter type. The filter type will differ depending on the item you are searching. For numerical searches, select one of the following options from the Filter Type box.

Select:	To find:
Is Equal to	All event numbers that match your search criteria.
Is Not Equal to	All event numbers that do not match your search criteria.
Is Less Than	All event numbers that are less than your search criteria.
Is Greater Than	All event numbers that are greater than your search criteria.

For alphabetical searches, select one of the following options from the Filter Type box.

Select:	To search:
Matches	For all tapes that match your search criteria.
Does Not Match	For all tapes that do not match your search criteria.
Contains	For all tapes that contain your search criteria.
Does Not Contain	For all tapes that do not contain your search criteria.
Is Less Than	For all tapes lexicographically less than your search criteria.
Is Greater Than	For all tapes lexicographically greater than your search criteria.

Alphabetical searches are performed on Tape and Comment items by default. To perform a numeric search on these items, enable Treat As Numeric. To match results by case, enable Case Sensitive.

Search Criteria field Enter the search criteria.

Renumber Events Menu

Use the options in the Renumber Events menu to specify the value by which events are renumbered.

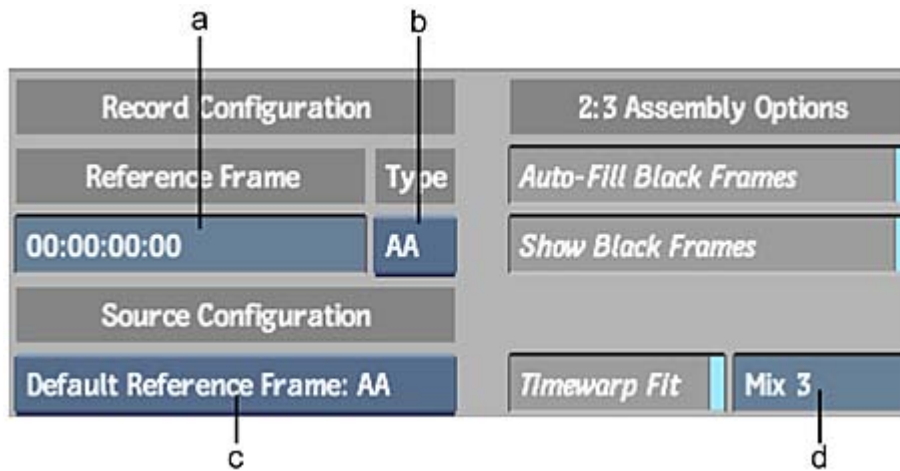

(a) Next Event field

Renumber Events button Renumbers the selected events according to the value specified in the Next Event field.

Next Event field Enter a value for the next event.

2:3 Pulldown Options Menu

Use the 2:3 Pulldown Options menu to set the parameters for 2:3 pulldown insertion upon import.

(a) Reference Frame field (b) Reference Frame Type box (c) Default Reference Frame box (d) Mix field

Reference Frame field Enter the timecode for the reference frame. This is only required for clips stored as files, and not for material on tapes.

Reference Frame Type box Set the reference frame type: AA or BB, corresponding to the timecode value entered in the Reference Frame field.

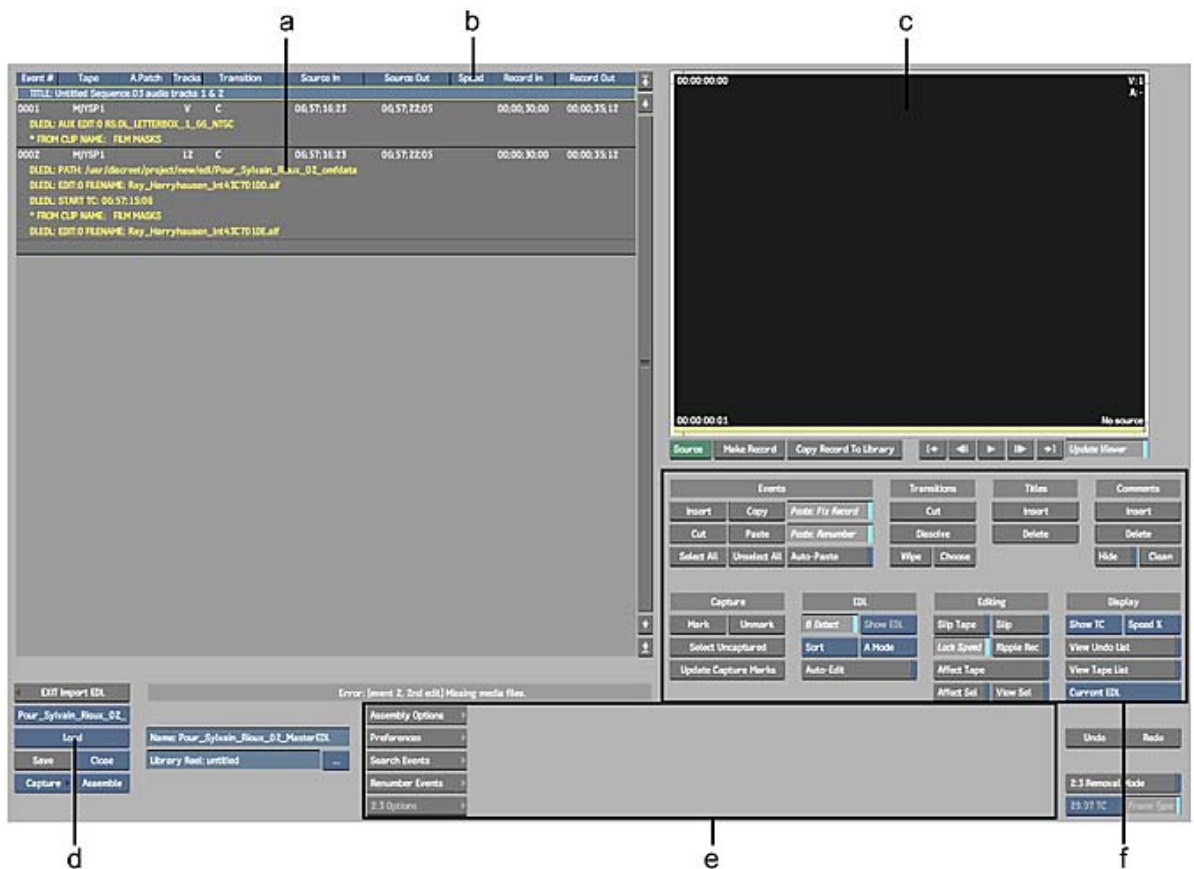

Auto-Fill Black Frames button Enable to fill black frames with the last frame of the outgoing event. By default, gaps occurring between EDL events are filled with black frames.

Default Reference Frame box Select AA or BB.

Show Black Frames button Enable to highlight the places in the currently loaded EDLs where gaps of black frames occur.

Timewarp Fit button Enable to automatically apply a timewarp to material on tapes referenced by EDLs where 2:3 pulldown removal was disabled (for example, when a tape contains native 30 fps interlaced video material), so that it can be easily integrated with 24 fps material.

Mix field Enter the number of frames to ensure that match frames on timewarped elements are maintained. This field is active when Timewarp Fit is enabled.

(a) EDL work area (b) Work area column headers (c) EDL Player (d) Load button (e) Import EDL menus (f) EDL editing tools

About EDL Editing Commands

Events Group

Use the commands in the Events group to cut or copy single or multiple events and paste them to a new location in any open EDL. You can also use special paste functions and selection tools for events.

Insert Event button Inserts a new event into the EDL.

Cut Event button Cuts the selected event. May be used with Paste Event button.

Copy Event button Copies the selected event. May be used with Paste Event button.

Paste Event button Pastes the previously cut or copied event to the selected location.

Paste: Fix Record button Enable to change Record In of the first pasted event to start at Record Out of the previous event. All pasted events are then rippled by the same amount.

Paste: Renumber button Enable to automatically renumber all events according to the Next Event value in the Renumber Events menu. If this option is disabled, the pasted events retain their original event numbers.

Select All button Click to select all events for capture.

Unselect All button Click to unselect all events.

Auto-Paste button Enable to quickly cut events from multiple EDLs and automatically paste them to a single EDL. For a selected EDL, when clicking the Paste button, any events that are cut or copied are automatically pasted to the first EDL.

Comments Group

You can add or delete comments from events using the commands in the Comments group of the EDL menu. Comments can contain up to 256 alphanumeric characters. You can also toggle comments on or off.

EDL comments become part of the source clip when assembling the EDL. Multiple comment lines are merged into one timeline comment line.

Insert Comment button Add a comment to the event selected in the EDL work area. You can add multiple comments to an event. To edit a comment, double-click it and enter the new comment.

Delete Comment button Delete a comment selected in the EDL work area.

Hide button When enabled, will hide all comments in the EDL work area.

Clean button Removes asterisks from comments.

Titles Group

You can add or delete a title from an EDL using commands in the Titles group of the Import EDL menu.

Insert Title button Enter a new title in the Titles area of the EDL work area. You can add multiple titles. To edit a title, double-click it and enter the new title.

Delete Title button Delete a title in the EDL work area.

Capture Group

You can mark events for capture or select only the uncaptured ones for recapture.

Mark button Click to mark the selected events for recapture with an “X”. This allows you to keep track of events that you want to recapture. Events that have already been captured are marked with a lower case x. Therefore, when you mark a captured event for recapture, a lower and upper case x appear (x X) to the right of the event number.

Event #	Tape	A.Patch
TITLE: COL_NOISE		
0001 x X	ZOZO	
FROM CLIP NAME: COL_NOISE		

(a) Capture mark (b) Recapture mark

Unmark button Click to remove a recapture mark from the selected events.

Select Uncaptured button Click to select all uncaptured events in the EDL. The next time you click Auto-Capture, only the selected events are captured.

Update Capture Marks button Click to update the list of captured events.

Transitions Group

Use the commands in the Transitions group to change any transition to a cut, dissolve, or standard SMPTE wipe.

Cut button Changes the transition type to a cut for the selected transition, or range of transitions.

Dissolve button Changes the transition type to a dissolve for the selected transition, or range of transitions.

Wipe button Changes the transition type to a wipe for the selected transition, or range of transitions. The wipe type is set to SMPTE 001.

Choose button Opens the Choose Wipe menu from which you can select from a variety of standard SMPTE wipe types.

EDL Group

You can use any of these options in the EDL group when using EDLs to capture media.

(a) Sort box (b) Show Timecode box (c) Sort Mode box

BRoll Detect button Enable to detect BRolls. BRolls appear as the original tape. You are not prompted for the tape containing the BRoll when you capture the clips. When disabled, BRolls are indicated with a “B” following the tape name in the Tape entry.

Show Timecode box Select the type of timecode to display.

Select:	To:
Show EDL	Display EDL timecode.
Show VC	Display Varicam timecode.

Sort box Click Sort to sort the current EDL, or click Sort All to sort all the EDLs. EDLs are sorted according to the sort order specified in the Sort Mode box. You can change the way an EDL is sorted.

Auto-Edit button Enable to quickly modify only the entries in the selected columns of the EDL. Click the column headers of the columns that you want to auto-edit. Starting with the first entry that you edit, press **Enter** to move automatically to the next entry. If no further entries exist, a new event is added.

Sort Mode box Select the appropriate sort order.

Select:	To sort the EDL:
A Mode	By Record In timecode. If you want to view the EDL in the order of the final assembly, sort the EDL in A Mode.
B Mode	By Tape and Record In timecode.
C Mode	By tape number and Source In timecode. If you want to view the EDL in the order the clips are captured, sort the EDL in C Mode. EDLs are always captured in C Mode, regardless of the sort mode you selected.

Select:	To sort the EDL:
S Mode	By Source In timecode, regardless of tape number. This sort mode is useful for multi-camera real-time EDLs.
by Event#	By event number.
by Tracks	By tracks. In this sort mode, video tracks are placed at the bottom of the list, and the highest audio track is placed at the top of the list.
by Uncaptured	By placing all uncaptured events at the top of the list.

Select Invalid Frame button Click to select a frames of 0 length.

Editing Group

When you modify an entry in an EDL, several options control how other entries are affected. Make sure these options are either enabled or disabled, depending on how you want to edit the EDL.

Slip Tape button Enable to slip all source clips on the tape, or all record clips in the EDL list. All the in and out points of all source or record clips change without affecting their duration.

Lock Speed button Enable to edit the timecode without changing the speed value for the event.

Slip button Enable to slip a source or record clip in a single event. The in and out points of the selected clip change without affecting its duration.

Ripple Rec button Enable to move all Record entries, following an edited or pasted Record Out entry, forward or backward accordingly. This is useful when you want to edit the Record Out of an event without overwriting or creating a gap between the following shots.

Affect Sel button Enable to affect only the selected events.

Affect Tape button Enable to affect every relevant entry on the same tape when you modify a single entry.

View Sel button Enable to view only the selected events.

Display Group

The Display group contains options for modifying the display of events in the EDL list.

(a) Show TC/KC box (b) Speed box (c) EDL Display box

Show TC/KC box Select whether to display keycode or timecode.

Select:	To:
Show TC	Display timecode.
Show KC	Display keycode.

Speed box Select a mode to display the speed change for timewarps.

Select:	To:
Speed %	Display the speed change as a percentage.
Speed FPS	Display the speed change in frames per second.

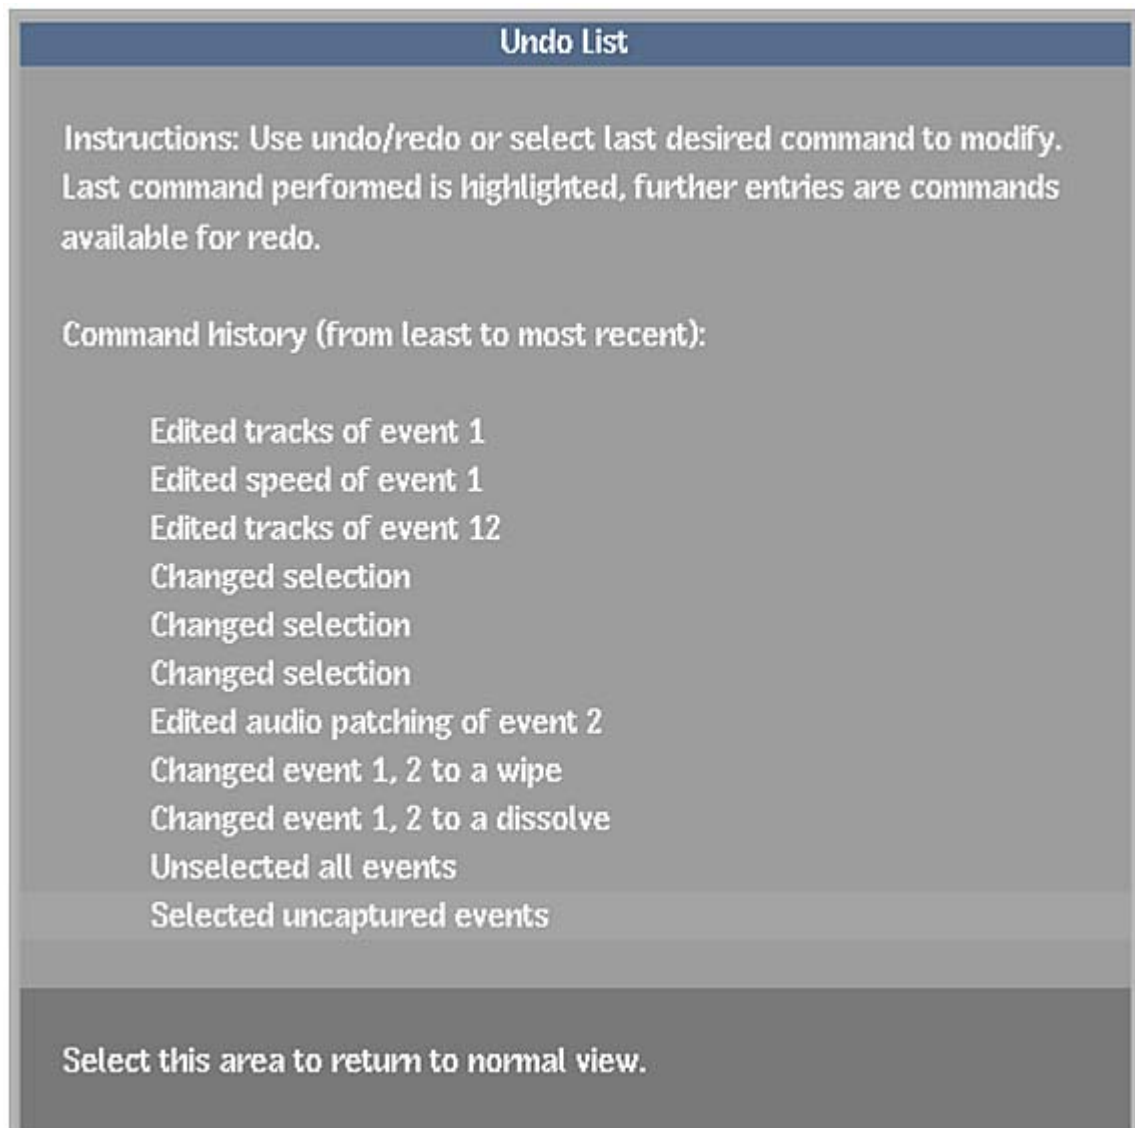

EDL Display box Select a display mode for EDLs, Tape List view, or Undo List view.

Select:	To:
EDL	Display timecode.
Undo List	View all modifications (up to the number of undo levels specified in the Preferences menu) that you made in the current session, and undo a single or series of commands. Click the item in the undo list that you want to undo. All operations are undone up to and including that modification. All operations prior to the highlighted modification are redone.
Tape List	Display the Tape List view, showing the last selected EDL.
Tape List (All EDLs)	Display the Tape List view, showing all selected EDLs.

Undo List View

Use the Undo List to view all modifications (up to the number of undo levels specified in the Preferences menu) that you made in the current session and undo a single or series of commands.

Click the item in the Undo List that you want to undo. All operations are undone up to and including that modification. All operations prior to the highlighted modification are redone.

Tape List View

You can use the tape list to modify information pertaining to events for a given tape.

As well, each tape's entry can be expanded in Tape List view to show keycode and 2:3 pulldown information associated with the source timecode.

Click the column header to sort the tape list in descending order using that column. Click the column heading again to sort the tape list in ascending order.

///	Tape ▾	Capture	FCM	Tracks	Start
▼	MASTER	On	23.976 fps	V1	00:00:03+17
○	TC Start		TC Duration	Film FCM	Keycode
○		03:59:59+14	00:00:00+15	N/A	N/A
○		04:00:00+04	00:00:01+10	23.976 fps	KK248181 6659+03 (1)
○		04:00:01+14	00:00:14+00	23.976 fps	KK248181 6660+14 (2)
○		04:00:15+19	00:00:18+15	23.976 fps	FN723405 8172+12 (2)
○		N/A	N/A	N/A	N/A

The work area of the Tape List view is divided into nine columns, and two sections for each tape.

The upper fields of each tape entry contain the following columns.

Tape The name of the tape that contains the source footage. To change the tape name, click and enter a new name.

Capture The capture flag for the tape. When set to On, the tape is captured during an auto-capture session. To set the capture flag for a given tape to On or Off, click the item under the Capture column and drag left or right to set it On or Off.

FCM The frame code mode for the tape. If the frame code mode is 29.97, you can drag over the item in this column to switch between DF/NDF modes.

Tracks The number and type of tracks that will be captured for the tape.

Start The starting timecode for the first event to be captured on the given tape.

Capture Time The duration of the material to capture for the given tape.

Telecine Indicates the telecine log associated with the tape.

Final Telecine Indicates the final telecine log associated with the tape.

Events The number of events to capture for the given tape. You cannot modify this value in Tape List view.

The lower fields of each tape entry contain the following columns.

TC Start Start timecode for each keycode sequence.

TC Duration Duration of time for the keycode sequence.

Film FCM Film frame code mode indicating the speed of the telecine when it scanned the film frames. Change the film FCM by clicking the Keycode field to access the calculator.

Keycode Keycode for the first frame of the sequence.

Removal Whether to apply 2:3 pulldown to the sequence.

Ref Frame Timecode of the reference frame.

Ref Type Type of reference frame.

DF Ref Frame Timecode of the drop frame reference frame.

EDL View

An EDL contains events, edits, and entries. An event is a complete element in the EDL such as a shot, dissolve, or wipe. An edit is an individual component that makes up an event, such as an outgoing shot or an incoming shot. An entry is an individual value for any variable in the edit, such as dissolve length, Source In, or Speed.

a	0011	250	V	C	01:00:06:06	01:00:08:03	00:01:18:04	00:01:20:01
	0012	250	V	C	01:00:05:14	01:00:15:09	00:01:00:00	00:01:09:15
	0012	250	V	D 10 (C)	01:00:20:07	01:00:25:05	00:01:09:15	00:01:14:13
b								
c								

(a) Edits (b) EDL events (c) EDL entries

Every event has a different event number. Some events, such as dissolves and wipes, consist of two edits. The two edits in a dissolve (outgoing and incoming shots) have the same event number.

Editing a Tape Name

You can change a single event's tape name, or the tape name for all events on the same tape. This is useful if the events you want to capture are on a different tape than that listed in the EDL.

Tape names can be up to 56 characters long. The EDL Editor displays only the first eight characters, but the clips maintain the original tape name.

To edit a tape name:

- 1 In the Import EDL menu, do one of the following:
 - To change the tape name for all events on the same tape, enable Affect Tape.
 - To change only the selected tape name, disable Affect Tape.
- 2 Click the Tape entry in the event you want to edit and enter the new name:
 - If the Affect Tape option is enabled, the tape name for all events on the same tape changes automatically.
 - If the Affect Tape option is disabled, only the tape name for the selected event changes.
 - If the Affect Selection option is enabled, only the tape names for selected events change.

Audio Patching

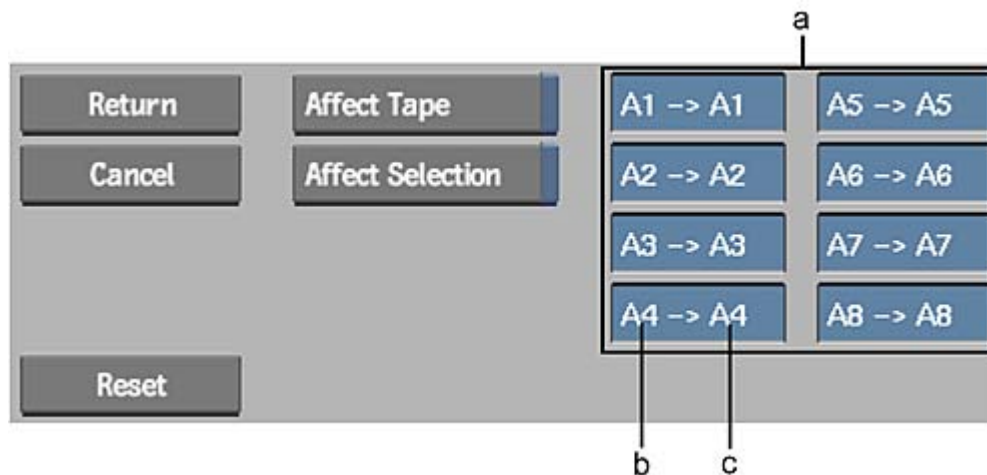

If you want to capture audio from a different track than that specified in the EDL, you can change the audio patching for a single event, selected events, or all events on the same tape. For example, if an edit specifies the audio tracks as 1 and 2, but you want to capture the audio from tracks 3 and 4, use the Audio Patching menu to reroute the audio during auto-capture.

To change audio patching:

- 1 In the EDL work area, select the events that you want to modify.
- 2 Click an Audio Patch field.

Event #	Tape	A.Patch	Tracks	Transition	Source In	Source Out
TITLE: 1010						
0001 x	BL		V	C	00:00:00:00	00:00:00:10
0001	250		V	D 10 (F)	01:02:07:29	01:02:08:15
FIREEDL: FOCUS_DESCR FROMCUT						
0002 x	BL		V12	C	00:00:00:00	00:00:00:11
0002	250		V	D 10 (F)	01:00:05:07	01:00:06:03
FIREEDL: FOCUS_DESCR FROMCUT						
0003 x	BL		V	C	00:00:00:00	00:00:00:11
0003	250		V	D 10 (F)	01:01:01:11	01:01:02:12
FIREEDL: FOCUS_DESCR FROMCUT						

The Audio Patching menu appears.

(a) Audio Patch boxes (b) Source audio track (c) Destination audio track

You can edit the source audio tracks. Each one of the eight available source audio tracks can be patched to one of the eight available destination audio tracks. You can patch the same source audio track to multiple destination audio tracks.

- 3 Enable or disable the Affect Tape and Affect Selection buttons.
- 4 Reroute the audio in the Audio Patch boxes by doing one of the following:
 - Drag in an Audio Patch box to cycle through source audio tracks one through eight.
 - Click an Audio Patch box to access the calculator, then type a value one through eight indicating the source audio track.
- 5 Click Return.

To exit the Audio Patching menu without changing the patching information, click Cancel.

The source tracks that have been patched to different audio tracks than the defaults are indicated in the affected event's Audio Patch Field. Dashes in the Audio Patch Field indicate the track is patched to its default. Comments are also added which indicate the name of audio tracks and their patching information.

When clips are captured, audio tracks are patched as indicated.

Event #	Tape	A Patch	Tracks	Transition	Source In	Source Out	Speed	Record In	Record Out
TITLE: FIN/L SHOW audio tracks 1 & 2									
0001	LORES	65-----	12	C	01:00:00:00	01:07:07:16		01:00:00:00	01:07:07:02
* FROM CLIP NAME: Lo Res Show									
* PATCH LORES: FROM SOURCE 6 TO RECORD 1									
* PATCH LORES: FROM SOURCE 5 TO RECORD 2									
0002	LORES	65-----	12	C	01:07:37:00	01:12:15:21		01:07:37:00	01:12:15:13
* FROM CLIP NAME: Lo Res Show									
* PATCH LORES: FROM SOURCE 6 TO RECORD 1									
* PATCH LORES: FROM SOURCE 5 TO RECORD 2									

(a) Comments indicate patching information (b) Source 1 and 2 patched to destinations 5 and 6

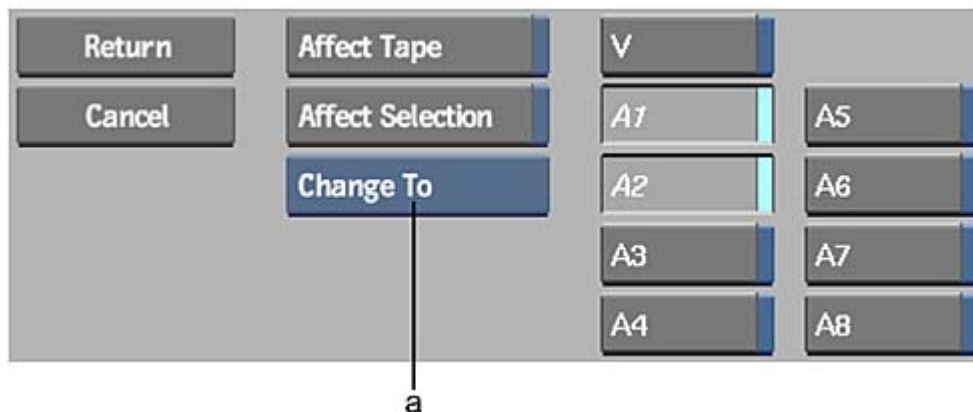

Editing Tracks

You can edit the tracks of an event in the EDL. Editing tracks is useful if you want to modify the tracks captured when you auto-capture or assemble the EDL.

For example, if the Track entry for an event is V1 and you want to capture only the video track (V), change the Track entry to V.

To edit the tracks for an event:

- 1 In the EDL work area, select the Track entries in the event that you want to edit from the EDL. The Track menu appears.

(a) Track Tools box

- 2 Enable the tracks that you want to edit.
- 3 Enable or disable the Affect Tape and Affect Selection buttons.
- 4 From the Track Tools box, select the mode that you want to use.

Select:	To:
Change To	Replace tracks in the event with tracks you specified in the Track menu.
Add	Add the tracks you specified in the Track menu to the tracks in the event.

Select:	To:
Filter	Keep only the tracks you specified in the Track menu. For example, if an event is "V12" and you specify "V1," audio track 2 is filtered out, and the resulting event has "V1."
Flip	Reverse the status of tracks you specified in the Track menu. For example, if an event is "V23" and you specify "V34," the resulting event has "V24."

- 5 Click Return to confirm the change or Cancel to exit back to the EDL module without making any modifications.

Editing Transitions in EDLs

You can change any transition to a cut, dissolve, or SMPTE wipe. If the effect of an event is a dissolve, you can edit its duration (Transition Duration). If the effect of an event is a wipe, you can also select the type of wipe in the SMPTE Wipe library.

You can add or modify transitions based on a selection range.

You can also change a cut to a dissolve by clicking the Transition entry of the cut. You can change a dissolve to a cut by setting the Transition Duration to 0, as long as the Allow Zero-Length Transitions option is disabled in the EDL preferences.

Dissolves in EDLs

Dissolves are represented in the EDL by two consecutive edits with the same event number. The first edit represents the outgoing shot of the dissolve and the second edit represents the incoming shot of the dissolve. The dissolve is listed in the Transition column of the second edit as D *n* (where *n* is the transition duration).

The Transition duration appears in the Transition entry of the second edit in the dissolve. The Start Location for the dissolve is also indicated in the Transition entry.

If the EDL was exported from Flame Premium, the dissolve can be Centred, From Cut, or Up To Cut. The start location for the dissolve appears beside the Transition duration.

The following illustration is a typical dissolve in an EDL.

a	0001 x	BL	C	00:00:00+00	00:00:01+00	01:00:59+15	01:00:59+15
	0001	BC01	D 24	01:00:27+21	01:00:50+00	01:00:59+15	01:01:21+18
b	^ BLEND DISSOLVE						
c							

(a) Outgoing shot (b) Incoming shot (c) Transition duration

If you change the Transition duration of a dissolve, the Source Out of the incoming shot changes by the same duration automatically.

Wipes in EDLs

Wipes are represented in the EDL by two consecutive edits with the same event number. The first edit represents the outgoing shot of the wipe and the second edit represents the incoming shot of the wipe. The wipe is listed in the Transition column of the second edit as W *n m* (where *n* is the wipe code and *m* is the wipe duration).

The SMPTE wipe number appears in the Transition entry of the second edit in the wipe. The Start Location for the wipe is also indicated in the Transition entry. A wipe can be Centred, From Cut, or Up To Cut. The start location for the wipe appears beside the Transition duration. The following illustration is a typical wipe in an EDL.

a	0001 x	BL	C	b	00:00:00+00	00:00:01+00	01:00:59+15	01:00:59+15
	0001	BC01	W 001	24	01:00:27+21	01:00:50+00	01:00:59+15	01:01:21+18
c	BLEND DISSOLVE							
d								

(a) Outgoing shot (b) Transition duration (c) Incoming shot (d) SMPTE wipe number

If you add 500 to the SMPTE wipe number, the wipe is inverted during assembly. For example:

If you change the Transition duration of a wipe, the Source Out of the incoming shot automatically changes by the same duration.

Editing Timecode

If you want to capture different material than what appears in the EDL, you can slip or trim the edits to specify the correct material for your final assembly. You can change any source or record timecode in the EDL.

You can also edit timecode and keycode in the Tape List.

To edit timecode:

- 1 If you want to edit source timecode, and keycode in and out values are displayed, toggle the Show Timecode/Show Keycode box to Timecode.
- 2 Do one of the following:
 - Click the source or record timecode entry you want to modify and drag right to increase the value or drag left to decrease the value. You can use hotkeys to change the values in varying increments.

Use:	To:
Shift-drag	Jump by seconds.
Ctrl-drag	Jump by minutes.

Use:	To:
Alt-drag	Jump by hours.

- Double-click the source or record timecode you want to modify to get the calculator, and then enter a new timecode. If the source or record timecode is already selected, click it again to get the calculator.

When you edit source timecode, the corresponding keycode changes to reflect the new frames to be captured. Toggle the Show Timecode/Show Keycode button to see the edited keycode in and out values. You cannot edit the keycode for events in the EDL work area.

NOTE Other entries in the same edit affected by your modifications become highlighted as you edit an entry.

Editing Tape List Timecode and Keycode

In Tape List view, you can slip all the start timecode values for a given tape. This is useful when you need to modify the start timecode of a tape that is used in multiple EDLs, because you edit the value only once.

You can also slip keycode and its associated start timecode and duration. This is similarly useful to alter keycode values correlated to the timecode for given sequences on the tapes.

To slip the start timecode value for a given tape:

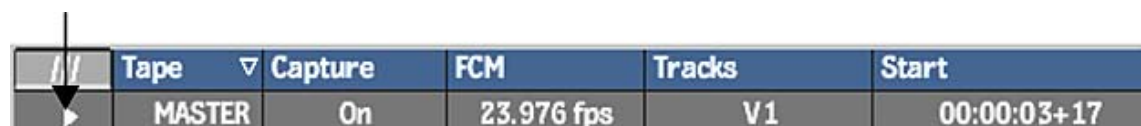

- 1 In the Import EDL menu, from the Display group, enable View Tape List.
- 2 Do one of the following:
 - Click the start timecode entry you want to modify and drag right to increase the value or drag left to decrease the value. You can use hotkeys to change the values in varying increments.

Use:	To:
Shift-drag	Jump by seconds.
Ctrl-drag	Jump by minutes.
Alt-drag	Jump by hours.

- Click the start timecode entry you want to modify to get the calculator, then enter a new timecode. See inferno flamesmoke.

To slip the keycode for a given tape:

- 1 In the Import EDL menu, from the Display group, enable View Tape List.
- 2 If necessary, click the triangle on the left of the tape entry to expand its contents.

	Tape ▾	Capture	FCM	Tracks	Start
	MASTER	On	23.976 fps	V1	00:00:03+17

Sequences of timecode on the tape are associated to keycode values. If no keycode is available from the telecine log(s) you loaded, N/A (not available) appears for the sequence.

///	Tape ▾	Capture	FCM	Tracks	Start
▼	MASTER	On	23.976 fps	V1	00:00:03+17
○	TC Start		TC Duration	Film FCM	Keycode
b ○		03:59:59+14	00:00:00+15	N/A	N/A
○		04:00:00+04	00:00:01+10	23.976 fps	KK248181 6659+03 (1)
a ○		04:00:01+14	00:00:14+00	23.976 fps	KK248181 6660+14 (2)
○		04:00:15+19	00:00:18+15	23.976 fps	FN723405 8172+12 (2)
○		N/A	N/A	N/A	N/A

(a) Timecode start and duration defines sequence, with corresponding keycode (b) Timecode without corresponding keycode

- To edit the keycode for a sequence, do one of the following:
 - Drag the keycode entry you want to modify to the right to increase the value or to the left to decrease the value.
 - Click the keycode entry you want to modify to get the keycode calculator, and then enter a new keycode.

The keycode values associated to the timecode sequence (defined by the values in TC Start and TC Duration fields) are altered.

If you change the frame rate in the keycode calculator, it is reflected in the Film FCM field.

Film FCM	Keycode
N/A	N/A
23.976 fps	KK248181 6659+03 (1)

Editing and Creating Timewarps

You can edit an existing timewarp or create a timewarp in your EDL. When you edit a timecode entry of an event with the Lock Speed option disabled, no other entries are affected. This results in a speed change because the source duration differs from the record duration.

For example, if you increase the Source In entry of an event by 5 seconds, the record clip of the same event is 5 seconds shorter than the source clip. The result clip is timewarped when assembled. No other entries are affected.

Timewarps are represented in the Speed column of the EDL. If the Speed value is blank, the event is not timewarped. If there is a Speed value, the event is timewarped.

0018	003	V	C	14:06:14:13	14:06:14:17	50.0%	10:00:16:07	10:00:16:15
						a		

(a) Speed value

To edit or create a timewarp:

- In the Import EDL menu, from the Editing group, disable Lock Speed.
- In the EDL, click the source or record timecode entry for the event that you want to edit and enter the new value.

The value of the timewarp appears in the Speed entry. You may also click directly in the Speed box to change the entry. If the event is already a timewarp, editing any timecode of that event changes its speed value.

You can view the speed value in either percentage or frames per second. Select the View mode in the EDL Preferences menu.

Conforming an EDL with VTR Recapture

NOTE The following requires that the workstation is connected to a VTR.

- 1 In the Conform tab, right-click the Event list and select Load New EDL.
- 2 From the window that appears, locate and select the EDL to import, and then click Load.
The EDL is loaded and opened as a sequence in the timeline view of the Conform tab.
- 3 Right-click the event list, and select Capture All From VTR.
The VTR module opens and cues the VTR.
- 4 Proceed with the recapture of the cued events.
- 5 Once back to the Conform tab, continue with the conform process as you would with a file-based sequence.

Conforming an Avid AAF

If after having imported an AAF some segments are still not linked to their media, use the Conform tab to relink both segments and media.

- 1 Display the AAF to conform in the Conform tab. Do one of the following:
 - If you imported the AAF using the MediaHub: switch to the Conform tab, right-click the AAF and select Open as a Sequence.
 - If you have not already imported the AAF: switch to the Conform tab, right-click the Event list and select Load New FCP XML/AAF/EDL.
From the window that appears, locate and select the AAF to conform, and then click Load.
- 2 Add potential sources to the Conform Media folder.
You now have two lists: the Events list, displaying all the events making up the sequence, and the Conform Media list, displaying the potential sources you selected.

NOTE By default, the Conform Media list displays only the sources matching the currently selected event. Disable **Options > Filter Potential Matches** to view all the possible sources.

- 3 With **Options > Filter Potential Matches** selected, click a event from the event list. The sources matching that event are displayed in the Potential Matches list.

NOTE You can also select a segment directly in the timeline. Both the timeline and the event list update to reflect the current selection.

- 4 What you do next depends on the Status column of each event.

Match Select Link Matched Sources from the Linking combo box. Link Matched Sources links all events

with the Match status to their unique sources. Match indicates that Flame Premium found only one source from the Sources list that fit the selected Match Criteria.

Multiple Matches Do one of the following:

- Select the event, the source to relink, and then select Link Selected from the Linking combo box.
- Select the event from the event list, right-click the source to relink, and then select Link.

If there are too many sources to choose from, set additional criteria using the Match Criteria drop-down menu; by trial and error you can reduce the number of matching sources.

No Match Found Either add more sources to the Media folder or modify the criteria selected in the Match Criteria drop-down box. Not Found indicates that either the criteria are too restrictive for Flame Premium to find a match, or that the source is simply not there.

Unlinked Add sources to the Media folder. Unlinked indicates that the event is not linked to any source. It appears only when no sources are available in the Media folder, and the Conform section of the Media panel displays 0 clip total.

Linked Nothing to do: the event is already linked to source. Linked events appear in the Events list only if **Options ► Hide Linked** is not enabled.

- 5 Once there all the events are linked to sources, you are done with the conform. You can leave the Conform tab.

Flame Premium does not automatically cache the relinked source media. To cache the source media: right-click the target and select **Media ► Cache Source Media**. You can target a segment on the timeline to cache only that segment, or the sequence itself to cache every segment in the sequence.

Conforming a Final Cut Pro XML

If after having imported an FCP XML some segments are still not linked to their media, use the Conform tab to relink both segments and media.

- 1 Display the FCP XML to conform in the Conform tab. Do one of the following:
 - If you imported the FCP XML using the MediaHub: switch to the Conform tab, right-click the FCP XML and select Open as a Sequence.
 - If you have not already imported the FCP XML: switch to the Conform tab, right-click the Event list and select Load New FCP XML/AAF/EDL.
From the window that appears, locate and select the FCP XML to conform, and then click Load.

- 2 Add potential sources to the Conform Media folder.

You now have two lists: the Events list, displaying all the events making up the sequence, and the Conform Media list, displaying the potential sources you selected.

NOTE By default, the Conform Media list displays only the sources matching the currently selected event. Disable **Options ► Filter Potential Matches** to view all the possible sources.

- 3 With **Options ► Filter Potential Matches** selected, click a event from the event list. The sources matching that event are displayed in the Potential Matches list.

NOTE You can also select a segment directly in the timeline. Both the timeline and the event list update to reflect the current selection.

- 4 What you do next depends on the Status column of each event.

Match Select Link Matched Sources from the Linking combo box. Link Matched Sources links all events with the Match status to their unique sources. Match indicates that Flame Premium found only one source from the Sources list that fit the selected Match Criteria.

Multiple Matches Do one of the following:

- Select the event, the source to relink, and then select Link Selected from the Linking combo box.
- Select the event from the event list, right-click the source to relink, and then select Link.

If there are too many sources to choose from, set additional criteria using the Match Criteria drop-down menu; by trial and error you can reduce the number of matching sources.

No Match Found Either add more sources to the Media folder or modify the criteria selected in the Match Criteria drop-down box. Not Found indicates that either the criteria are too restrictive for Flame Premium to find a match, or that the source is simply not there.

Unlinked Add sources to the Media folder. Unlinked indicates that the event is not linked to any source. It appears only when no sources are available in the Media folder, and the Conform section of the Media panel displays 0 clip total.

Linked Nothing to do: the event is already linked to source. Linked events appear in the Events list only if **Options ► Hide Linked** is not enabled.

- 5 Once there all the events are linked to sources, you are done with the conform. You can leave the Conform tab.

Clip Input/Output Using a VTR

Flame Premium allows you to perform numerous VTR-based clip input and output operations. You can capture individual clips or frames, or log clips for capture using an EDL. Similarly, the application allows you to output single clips or frames, as well as multiple clips to a VTR device.

Clip input and output general workflow:

- 1 Make sure all hardware devices involved in the clip input and output process are properly configured. If not, the VTR Input and VTR Output menu options are disabled.
- 2 Edit the software initialization configuration file to ensure the proper devices and settings are initialized on application start-up.

3 Do one of the following:

- Input clips.
- Output clips.

If you are using an NVIDIA graphics card with an SDI daughter card, Flame Premium also supports real-time operations for some deliverables.

Configuring Hardware For Clip Input and Output Using a VTR

When preparing for a VTR session, confirm the following:

- Audio and video outputs of the VTR are connected to the audio and video inputs of the Flame Premium system. Audio and video inputs of the VTR are connected to the audio and video outputs of the Flame Premium system.
- The VTR is connected, using an RS-422 video I/O control cable, to enable its remote control from the workstation.
- A video sync signal is connected to the sync input of the video device to ensure frame-accurate capture. If there is a separate audio device, an audio sync signal must be connected to it as well.

Configuring Software For Clip Input and Output Using a VTR

Software configuration in preparation for clip input and output session involves editing the software initialisation configuration file.

When you are preparing for a clip input and output session, consult the software initialization configuration file to confirm the following keyword sections are uncommented and properly configured:

- VIDEO KEYWORD

You do not need to specify the default video I/O timing. The initial timing corresponds to the default resolution and frame rate of the project that you select on start-up. If you select a film or custom resolution for your project on start-up, video I/O timing corresponds to the resolution that was selected as the preferred resolution when the application was installed.

- VTR KEYWORD

You must assign a specific VTR timing, such as NTSC, PAL, or 1920x1080_5994i. Multi-format video input and output capability of your system allows you to modify the VTR timing, without exiting the project, to any timing supported by your system's video board.

If you plan to perform input and output operations using a live video signal from a broadcast feed or from a device that does not support remote control functionality using RS-422 interface, such as a VCR or camcorder, uncomment the corresponding Live video keyword at the bottom of the SD DECKS section.

NOTE When working in HD projects and capturing material from a VariCam (variable frame rate 720p material), ensure that the following VTR are enabled: *VTR DVCProHD 720 59p*, *SERIAL1, 1280x720_5994P* and *VTR DVCProHD 720 60p*, *SERIAL1, 1280x720_60p*.

Inputting Clips From a VTR

Once you have set up your hardware devices and configured the software initialization file, you are ready to perform clip input and output. The VTR Input module contains various controls to help you perform operations, such as capturing a single frame, capturing a single clip, capturing and logging multiple clips.

Accessing the VTR Input Module

- 1 Select a folder from the Media Library. This is where the captured clips will be created.
- 2 Open the Tools tab.
- 3 In the Utilities tab, select Clip VTR Input.

The VTR Input module appears.

If VTR Input is not available, connect your workstation to a VTR, and configure Flame Premium to use the VTR.

Capturing Media with a VTR

You can capture a single clip from a VTR. You can capture on the fly with your in and out points determined by mouse clicks during playback, or be more precise by setting in and out points in the corresponding fields.

A single frame capture, or a frame grab, is the simplest clip input operation. This is useful for extracting snapshot frames for a preview or promotion piece.

To capture a single clip:

- 1 Cue up the tape to the frame at which you want to begin capturing.
- 2 Do one of the following:
 - From the Capture Method box, select Start On Click/Stop On Click.
 - Enter clip input in and out points in the In and Out fields.

- 3 To begin capturing, click Process.

The timecode field turns green, indicating that capture is in progress. Depending on your hardware configuration, the preview window may go black during capture.

- 4 To end the capture at any time, click the cursor anywhere over the preview window.

Depending on your project proxy settings, a post-process may occur, generating proxies for each captured frame. You can see a notification on the process that is taking place in the message bar.

Once all capture-related processes are complete, the clip is saved to the Workspace location that you selected before you entered the VTR Input module.

To capture a single frame:

- 1 Cue up to the frame you want to capture using the VTR Transport controls or by scrubbing the preview window.
- 2 Click Grab.

The captured frame is saved in the Workspace.

- 3 Click EXIT Input Clip to view the captured frame.
- 4 If you want to compare the captured frame against the frame in the preview window, load the clip into the VTR Input module and enable split-screen view.

NOTE If you notice that the previewed image is different from the captured one, edit the Video Input Delay field found in the Engineering menu and recapture that frame. If the two images now match, the delay is fine. If they do not match, you need to tweak the Input Delay until they do.

VTR Input Menu Options

The basic VTR Input controls are described as follows.

(a) Device Name box (b) Aspect Ratio box (c) Aspect Ratio field (d) EDL button (e) Current Timecode field (f) Proxy Quality box (g) Bit Depth box (h) Scan mode box (i) Tape Name field (j) Clip Name field (k) Increment Name field (l) Tape Type box

Device Name box Select the VTR and timing combination to use to capture clips. The available VTR are defined in the software configuration file using the VTR keyword. The available VTR are defined in the Smoke Setup application.

Engineering button Opens the engineering menu.

Aspect Ratio box Select the aspect ratio of the clip to capture.

Aspect Ratio field Displays the aspect ratio of the clip to capture. Editable.

Bit Depth box Select the bit depth used to capture the clip.

Scan Mode box Selects how to flag the captured clip: Progressive, Field 1 dominant, or Field 2 dominant. The flag is only there as a reminder; for example, setting Field 2 does not prevent you from de-interlacing on Field 1. In most cases, select the option that matches the format you are capturing.

Proxy Only button Enable to capture proxies only. In this case, the high-resolution media is captured, proxies are generated, but the high-resolution media is discarded. As a result, much storage space is required.

Only available if the current project is configured to use proxies. If your proxies are set to be generated as a post process in the Engineering menu, you can see an estimated time required for proxies generation in the message bar. You can abort this process at any time by clicking anywhere on the screen. When you click the screen, a message appears asking you to confirm the operation. Only the captured media that corresponds to completed proxy generation is preserved. Any captured frames for which no proxies have been generated are purged.

Proxy Quality box Proxies generated during capture are always of draft quality. Using the Proxy Quality box, you can set the default quality for proxy generation after capture. Results vary depending on the type of clips involved, so it is a good idea to try different settings. Only available if the current project is configured to use proxies.

Select:	To get:
Impulse	Quick, low-quality results.
Triangle	Moderate results with little processing overhead.
Mitchell	Best results when resizing a clip to a higher resolution.

Select:	To get:
Bicubic	Very good results for resizing soft-looking images. Use to sharpen the image.
Quadratic	Good results for resizing simple images with straight edges. Similar to Gaussian but with more blurring. Use to soften the image.
Gaussian	Excellent results when resizing a clip with no patterns and a lot of straight edges to a lower resolution. Useful for softening some detail.
Shannon	Excellent results when resizing a clip to a lower resolution. Very similar to Lanczos, but results are a little softer.
Lanczos	Best results when resizing a clip containing a variety of patterns and elements to a lower resolution. It is the most complex with the longest processing time.

Emulator button Enable to have the application emulate a VTR.

Capture button Starts the capture.

Grab button Grabs the current frame.

Input Type box Select the type of footage found on the tape. Use Standard for regular capture. 2X can only be used with HDCAM SR. Dual Image is for stereo footage recorded side-by-side on the tape; use Slice to create a single Stereoscopic clip on capture, but with half the horizontal resolution; use Scale to create a single Stereoscopic clip, but resized to full horizontal resolution. With Scale, use Engineering > Dual Image Resizing Filter to select the quality of the resize.

EDL Log button Logs the clip to the EDL.

EDL button Opens the EDL menu where you can capture and edit EDLs.

Log On Out button Enable to log EDL events every time you enter an out point.

Tape Name field Displays the name of the tape from which you are capturing. This name is important for EDL assembly and media recapture procedures. Editable.

Clip Name field Displays the name to use for the clip to capture. Editable.

Increment field Displays the number automatically appended to the clip name. Active when Increment is enabled.

Increment button Enable to append numerical increments to the clip name automatically. For example, enter "My_Clip" in the Clip Name field and then enable Increment Name. The first clip you capture is named "My_Clip-1", the second is named "My_Clip-2", and so on.

Start Mode box Determines the start mode for clip input.

Select:	To:
Start On Click	Capture starting from the currently displayed frame on the tape. Click Process to activate the start-on-click trigger.
Start On Timecode	Capture starting from the timecode you enter in the In field. Click Process to start the clip input process.

Stop Mode box Determines the stop mode for clip input.

Select:	To capture until:
Stop On Click	You click anywhere on the screen.
Stop After Frames	A specific number of frames have been captured. When you select this option, a field appears in which you enter the number of frames you want to capture.
Stop On Timecode	A timecode on the tape has been reached (entered in the Out Timecode field).

Current Timecode field Indicates the current timecode of the tape in the VTR.

The following controls are found on the right side of the menu (not shown in preceding illustration).

In Timecode field Displays the timecode on the tape at which point the clip input begins. Editable.

Out Timecode field Displays the timecode on the tape at which point the clip input process ends. Editable.

Duration field Displays the duration, in timecode, between the clip in point and out point. Editable.

Tape EE button Click to toggles E-to-E on and off. When lit, indicates that the VTR is in E-to-E mode (electronic to electronic). This means that the VTR output is showing its input signal.

Standby button When lit, the VTR is in standby mode. Click to toggle between standby modes.

Cue In button Cues the VTR to the value of the In Timecode field.

In button Sets the In Timecode field to the current VTR timecode.

Cue Out button Cues the VTR to the value of the Out Timecode field.

Out button Sets the Out Timecode field to the current VTR timecode.

Toggle Audio Tracks button Switch between audio banks of 4 audio tracks. The actual number of tracks depends on your capture device.

Video Track button Enable to capture the video track.

VTR Status display Indicates the current status of the VTR.

Selecting a VTR Device For Input

The VTR devices available depend on the VTR keyword lines uncommented in the software initialisation configuration file. Make sure the VTR you select is appropriately connected using the corresponding audio, video, and RS-422 connections.

In certain situations, Flame Premium pre-selects a VTR with appropriate timing for you.

To select the VTR device for input:

- 1 From the Device Name box, select an option corresponding to your VTR device.

- 2 Make sure that the selected device is in Remote mode.

Naming Tapes and Clips

Proper media management is an essential part of the clip input and output process. One of the elements of efficient media management is methodical and consistent naming of the clips you capture and the tapes from which they originate. Before capturing a clip, assign a name to the tape and the resulting clip. This assignment makes it easier to organize your clips, trace them back to the source tape, and, when necessary, recapture them.

To name a tape and clip:

- 1 In the Tape field, enter the tape name.
The tape name is stored with the clip. In the Workspace, you can **Alt**-click the clip to view its information, including the tape name.
- 2 In the Clip field, enter a clip name.
- 3 Enable Increment to use the same name for multiple clips captured in sequence. This appends a numerical tag at the end of each clip so you can differentiate them.
- 4 To change the number of the numerical tag for the next captured clip, enter a number in the Clip Index field. By default, the increment begins at 1.

Selecting Tracks and Channels to Capture

Whether you are inputting single frames, single clips, multiple clips or conforming EDLs, you must select the tracks and channels you want to capture from the VTR.

To select the tracks and channels to capture:

- 1 To capture the video track, enable V.
- 2 To switch between audio tracks banks, use the Toggle Audio Tracks button.
- 3 To capture audio channels, enable the corresponding channel selection buttons.

(a) Video track enabled for capture (b) Toggle Audio Tracks button (c) Audio channels 1 and 2 enabled for capture

Audio meters display the gain level being captured. You cannot change this level during capture. You can modify the gain of a clip once capture is complete.

HDCAM SR Double-Speed and Stereo Tape Capture

Using an HDCAM SR, you can capture material from specially formatted double-speed and stereoscopic tapes.

Double-speed tapes allows you to capture material twice as fast. Stereoscopic tapes essentially stores in an interlaced timing two progressive clips; a 60i (50i) “clip” contains two 30p(25p) clips.

This feature does have the following limitations:

- To use this feature, you must use specially formatted tapes. If you insert a regular tape in the HDCAM SR and try to capture it as double-speed or stereoscopic material, the capture fails.
- Audio monitoring is not available during capture.
- When capturing stereo tapes, only audio channels 1 through 8 are available.

To capture material recorded at double-speed:

- 1 Ensure that the HDCAM SR is connected to the AJA card using a dual-link.
- 2 Set the HDCAM SR VTR to DBL 422.
- 3 From the Device Name box, select the HDCAM SR VTR.
- 4 From the Input Type box, select 2x-DOUBLE.

NOTE If the player displays the clip with some colour bias, it is because the player falsely interprets the 4:2:2 signal from the VTR as a 4:4:4 signal. This does not impact the capture; the stereoscopic clip will be captured without that bias. To remove this bias, go to the Engineering menu and set the Input Connection box to Serial 1 4:2:2.

- 5 Capture the clip. See [Capturing Media with a VTR](#) (page 198).

To capture material recorded on stereoscopic tapes:

- 1 Ensure that the HDCAM SR is connected to the AJA card using a dual-link.
- 2 Set the HDCAM SR VTR to the stereoscopic setting.
- 3 From the VTR Input menu, select the HDCAM SR VTR from the Device Name box.
- 4 From the Input Type box, select 2x-STEREO.

NOTE If the player displays the clip with some colour bias, it is because the player falsely interprets the 4:2:2 signal from the VTR as a 4:4:4 signal. This does not impact the capture; the stereoscopic clip will be captured without that bias. To remove this bias, go to the Engineering menu and set the Input Connection box to Serial 1 4:2:2.

- 5 Capture the clip. See [Capturing Media with a VTR](#) (page 198).

The stereoscopic material is captured as a single, regular stereoscopic clip, with two layers, one for each eye.

Outputting Clips To a VTR

Once you have clips that are ready for output to tape, use the VTR Output module to perform this operation. Like capturing, you can output single clips or multiple clips, and enable a split view to preview the clip you want to output alongside the media on the tape simultaneously.

Another way to output multiple clips is to generate an EDL and then output the clips using the EDL.

Most of the procedures in this section assume that you have already blacked your tape. However, if necessary, you can output in assemble mode, which allows you to perform clip output to a tape that was only partially blacked. See [Outputting Clips in Assemble Mode](#) (page 215).

Accessing the VTR Output Module

- 1 Open the Tools tab.
 - 2 In the Utilities tab, select Clip VTR Output.
 - 3 Select the clip to output from the Media Library, **Ctrl+click** to select multiple clips. You can also select a folder if you wish to output multiple clips in one session.
- The VTR Output module appears.

If VTR Output is not available, connect your workstation to a VTR, and configure Flame Premium to use the VTR.

VTR Output Menu Options

You can view the VTR Output menu in large or small format depending on which tab is selected.

When one of the Output, Audio, or Engineering tabs is selected, both the large and small formats are available. To toggle between the large and small formats, **Ctrl-swipe** the bottom of the screen.

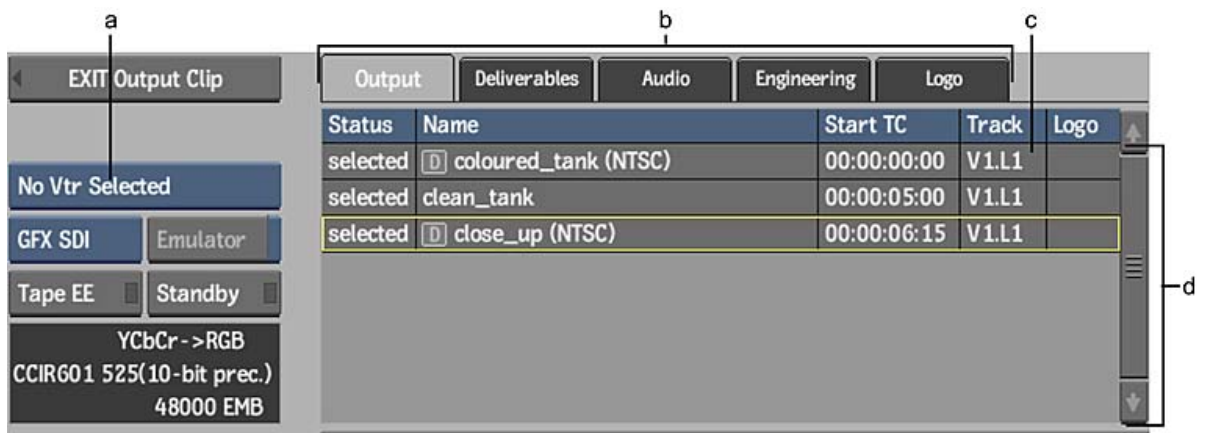

When the Deliverables or Logo tab is selected, only the large format is available, but additional Pan and Zoom controls are available.

If you are using the large Output menu with an HD clip, the menu automatically switches to the smaller format during clip output, and then switches back when output is complete. This gives you an unobstructed view of the clip during output.

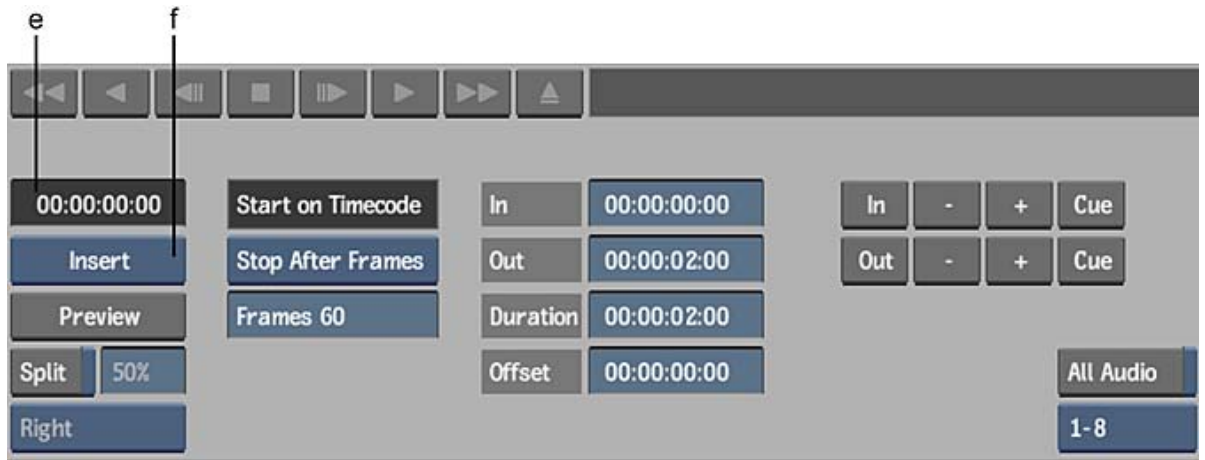

Small VTR Output module (left portion):

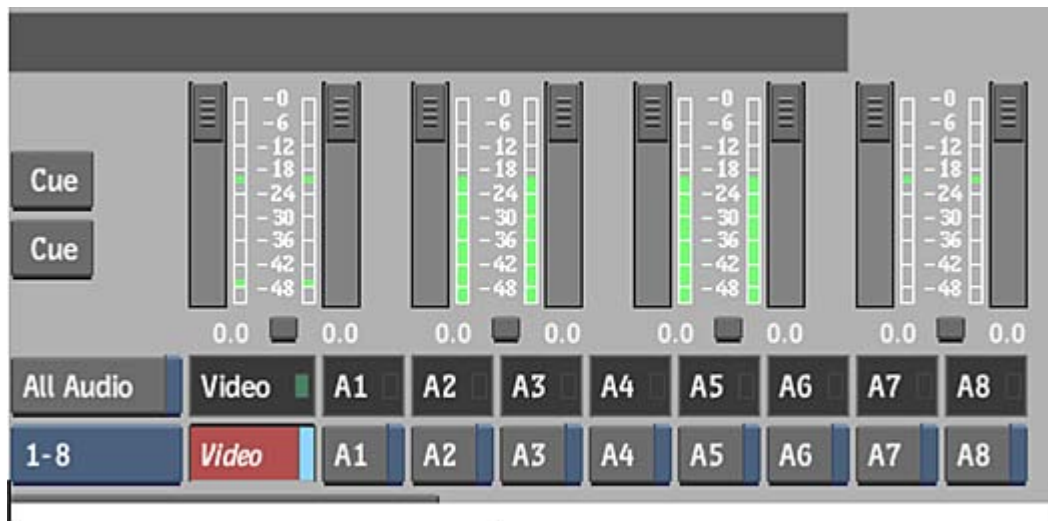

Large VTR Output module (broken into three parts):

(a) Device Name box (b) Navigation tabs (c) Video Layer field (d) Output list

(e) Current Timecode field (f) Output box

(g) Audio controls

In this documentation, the large menu is described. Differences present in the small menu are noted where applicable.

Device Name box Displays the options for each uncommented VTR keyword line in the software initialisation configuration file. Select the option corresponding to the VTR to which you want to output clips.

Navigation tabs Switch between different VTR Output tabs.

Select:	To:
Output	Configure the output settings described in this section. This is the default menu.
Deliverables	Set up Real-Time Deliverables on output, such as Letterboxes or LUTs.
Audio	Set Audio preferences. Changes are reflected in the Audio section of the Preferences menu, and vice versa.
Engineering	View the VTR Output module Engineering menu.
Logo	Set up a logo on output.

NOTE The Deliverables and Logo tabs are only available if the workstation uses an NVIDIA Quadro FX 5600 SDI graphics card.

Output list Displays information about the clip selected for output. If there are multiple clips, you can sort them by clicking the column headings. This changes the output sequence order. You can also edit the Timecode field in this list.

If the list includes Deliverables and you do not have the hardware required by Real-Time Deliverables, the Deliverables are greyed out.

Video Layer field Indicates the track to output in a multi-track clip. Drag the field to browse through the video tracks and versions. This field is red when the selected track is not the top track of the selected video version; this does not prevent output.

Graphics Card box If you have the NVIDIA Quadro FX 5600 SDI graphics card for using Real-Time Deliverables, switch between it and the standard AJA_OEM2K card using this box.

Tape EE button When lit, indicates that the VTR is in E-to-E mode (electronic to electronic). This means that the VTR output is showing its input signal. When E-to-E is off, the VTR shows the contents of the tape it contains. Click this button to toggle E-to-E on and off.

Standby button When lit, indicates that the VTR is in standby mode. Click this button to toggle between on and off.

VTR Status display Indicates the current status of the VTR.

Current Timecode field Indicates the current timecode of the tape in the VTR.

Output box Switch between insert or assemble mode. Click to perform the selected action.

Preview button Triggers a simulation of the output process. The VTR behaves as if it is inserting material, however no material is recorded to tape.

Split View button Enable to simultaneously monitor the clip selected for output and the contents of the tape.

Start On Timecode field A locked field indicating that clip output begins at the timecode entered in the In Timecode field.

Stop Mode box Determines the stop mode for clip output.

Select:	To output the current clip until:
Stop On Timecode	A timecode on the tape is reached (indicated in the Out Timecode field).
Stop After Frames	A specified number of frames is output. When you select this option, a field appears in which you enter the number of frames to output.

In Timecode field Indicates the timecode on the tape at which point the clip output process begins.

Out Timecode field Indicates the timecode on the tape at which point the clip output process ends.

Duration field Indicates the duration, in timecode, between the clip output in and out points.

Offset field Indicates the offset, in timecode, by which the selected clip is output. For example, an offset of 00:00:00:05 indicates that the first five frames of the clip to be output are skipped. The first frame to be output is frame 5 of the clip (counting frames from 0).

In/Out Point controls Use to enter, adjust, and cue the in and out points.

All Audio button Enable to output all audio channels for monitoring, even if only some audio channels are enabled for recording to tape.

Audio Channel buttons Enable and control audio output signals.

Selecting a VTR Device For Output

The VTR devices available depend on the VTR keyword lines uncommented in the software initialisation configuration file. Make sure the VTR you select is appropriately connected using the corresponding audio, video, and RS-422 connections.

Flame Premium pre-selects a VTR with appropriate timing when entering the Output clip module.

To select the VTR device for output:

- 1 From the Device Name box, select a VTR device.
- 2 Make sure that the selected device is in Remote mode.

Outputting a Single Clip

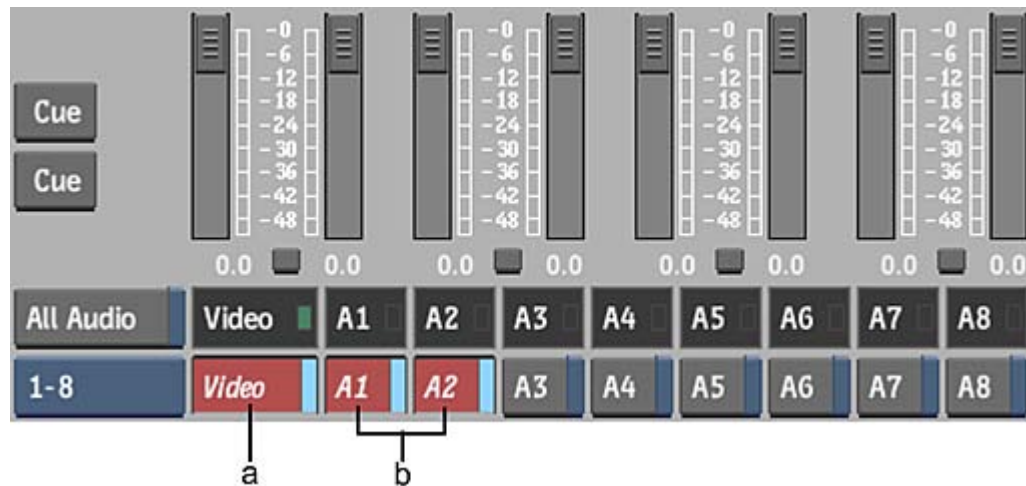

To output a clip to a VTR, load a clip into the VTR Output module and then set the in and out points for clip output. If necessary, enable the options to offset the start frame for output and to apply a letterbox overlay. See [VTR Output Menu Options](#) (page 204).

If the duration marked by the in and out points that you set for output is greater than the duration of the clip you are outputting, the last frame of the clip is repeated to fill the gap between the end of the clip and the out point of clip output. For example, if you set an in point at 01:00:00:00 and an out point at 01:01:00:00, the clip output process has a duration of one minute. If the clip you are outputting is 30 seconds long, the last 30 seconds of the output result on tape are filled with the last frame of the clip you are outputting.

To output a single clip to a VTR:

- 1 Load the clip that you want to output into the VTR Output module. See [Accessing the VTR Output Module](#) (page 204).

- 2 Make sure that the correct video track and audio channel buttons are enabled so that the corresponding video track and audio channels are output to tape.

(a) Video track enabled for output (b) Audio channels 1 and 2 enabled for output

- 3 Enable or disable All Audio in the Clip Output menu (to the left of the audio controls).
When All Audio is enabled, all audio channels are sent to the audio converter, not just the ones you enabled in the previous step.
This means you can monitor all audio, even though you are only recording one or two tracks to the VTR. You can also route the other audio channels to a mixer or any other device capable of capturing an audio signal.
- 4 Make sure the appropriate VTR is selected in the Device Name box. See [Selecting a VTR Device For Output](#) (page 207).
The preview window displays the contents of the tape currently in the selected VTR.
- 5 To preview the clip before outputting, click Preview.
- 6 To preview the clip you are outputting against the contents on the tape, enable Split View. See [Monitoring Video During Clip Output](#) (page 216).
- 7 To output the selected clip starting at any frame other than the first one, enter the start timecode in the Start Offset field.
- 8 Set the in and out points for clip output. See [Setting Input and Output In and Out Points](#) (page 216).
- 9 To output the clip to the VTR, select Insert from the Output box.
The clips with Status *selected* are output to tape. During output, the Status column is updated to reflect the status of each clip:
 - Pending: the clip is waiting to be output to tape.
 - Output: the clip is being output to tape.
 - Done: the clip has been output to tape.
- 10 After the transfer is complete, verify that it was successful by playing the transferred clip. To do so, cue to the in timecode and click the Play button in the VTR Transport controls.
- 11 When you are done, click EXIT.

Outputting Multiple Clips

You can output more than one clip to a VTR in a single pass. When you load multiple clips into the VTR Output module, you must define in and out points (and any other output options) for each clip before starting the clip output process.

When multiple clips in the same session are selected for output, the application performs a validation check to determine if certain parameters match the project settings and whether or not the video device is capable of outputting these clips. The following outcomes are possible:

- If the clips have mixed timing settings, you are prompted to select which timing you want to use. Clips having timings different from the one you select are discarded.
- Clips with field dominance mismatch are discarded or kept, depending on your selection.
- Clips exceeding the maximum bit depth are discarded from the selection. A selection containing 8- and 10-bit clips can be output.
- If all the clips are discarded from the selection after the validation check, a message appears allowing you to confirm.

If some of the clips have overlapping timecodes, their timecodes are highlighted in red in the clip list. To fix overlapping timecodes, edit the timecodes in the clip list, or use the timecode fields in the Output tab.

To output multiple clips to VTR:

- 1 Load the clips that you want to output into the VTR Output module. See [Accessing the VTR Output Module](#) (page 204).
- 2 If the clips have conflicting timings, you are prompted to select the timing you want to use. Clips that do not match this timing are discarded.
- 3 To output a clip, its status field must have the *selected* indicator. Click the Status field to alternate between the *selected* indicator and an empty field.
- 4 Set output options for each clip.
- 5 Optional: Click the column headers to sort the list. This changes the order of the output sequence.
- 6 To output the clip to the VTR, select Insert from the Output box.
The clips with Status selected are output to tape. During output, the Status column is updated to reflect the status of each clip:
 - Pending: the clip is waiting to be output to tape.
 - Output: the clip is being output to tape.
 - Done: the clip has been output to tape.
- 7 After the transfer is complete, verify that it was successful by playing the transferred clips: cue to the in timecodes and click the Play button in the VTR Transport controls. Clips that have been output are highlighted in the clip list of the large VTR Output module.
- 8 When finished, click EXIT.

When outputting multiple clips with the small VTR Output module, note the following differences:

- Use the Previous and Next buttons to navigate the clip list.
- Once output options have been set for each clip, make sure you are viewing the first clip you want to output.
- When you select Insert in the Output box, the clip you are viewing, and all subsequent clips, are output to tape. Clips that precede the clip you are viewing are not output to tape.

Outputting Clips With a Letterbox Overlay

You can apply a letterbox overlay on output. The letterbox does not affect the clip itself; it is applied on the fly as part of the real time output process.

To output clips with a letterbox overlay:

- 1 In the Output Clip menu, click the Deliverables tab to see the Letterbox controls.

(a) Letterbox Offset field (b) Letterbox aspect ratio field (c) Colour selector box

- 2 Enable Letterbox.
- 3 Set the letterbox options:
 - In the Aspect Ratio field, enter a value to set the aspect ratio of the letterbox overlay. Alternatively, select a preset from the Aspect Ratio box.
 - In the Letterbox Offset field, enter a value to shift the letterbox overlay up or down, as required.
 - Use the Colour Selector box to set the colour of the letterbox overlay.

Outputting Clips with a Logo Overlay

You can add a logo overlay on output, in real time. This feature is available only if your workstation is equipped with an NVIDIA Quadro FX 5600 SDI graphics card.

To add a logo, make sure the FX 5600 SDI card is selected in the engineering menu of the VTR Output module. If AJA_OEM2K is selected, you cannot use the Logo Overlay feature.

To select the FX 5600 SDI card in the Output Clip menu:

- 1 Open the Output Clip menu.
- 2 From the Graphics Card box, select GFX SDI.

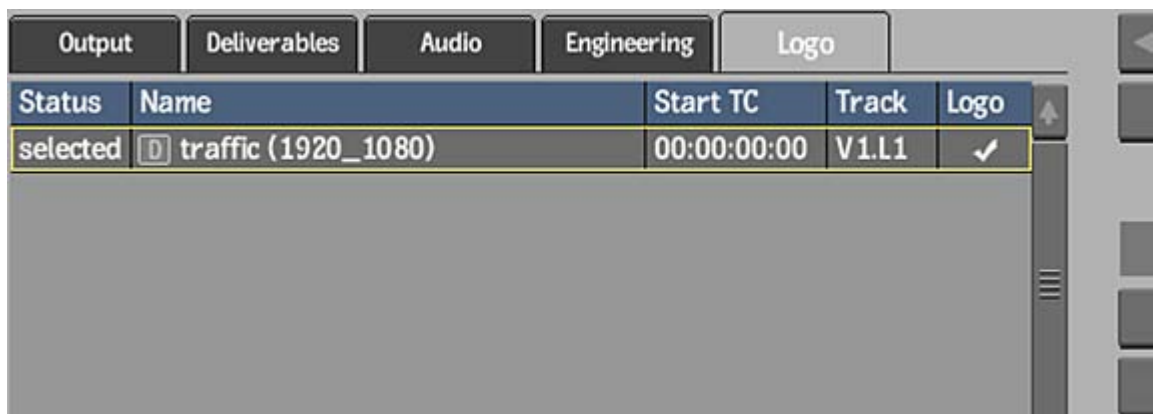

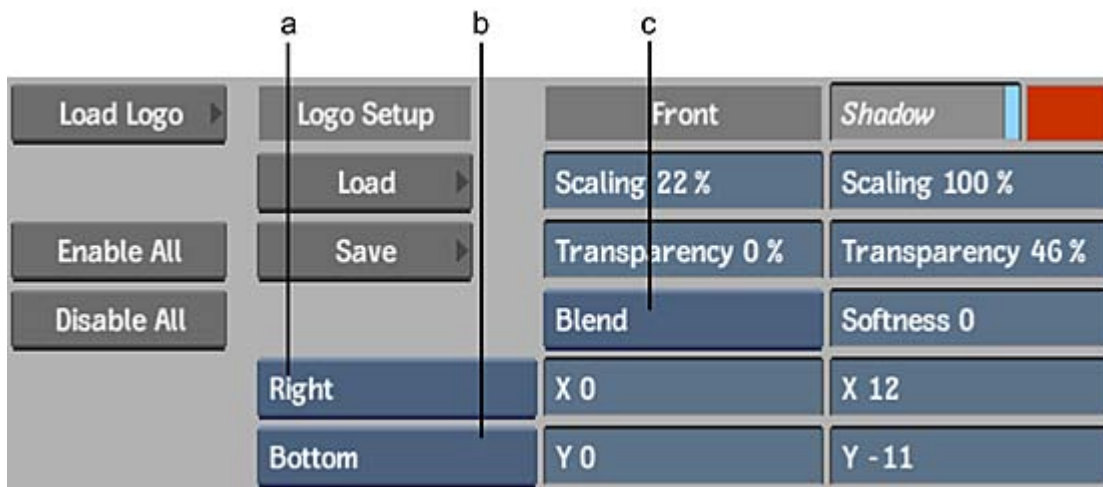

If you do not see GFX SDI as an available option in the Graphics Card box, it is either not installed, or it is not set up or configured properly.

About the Logo Controls

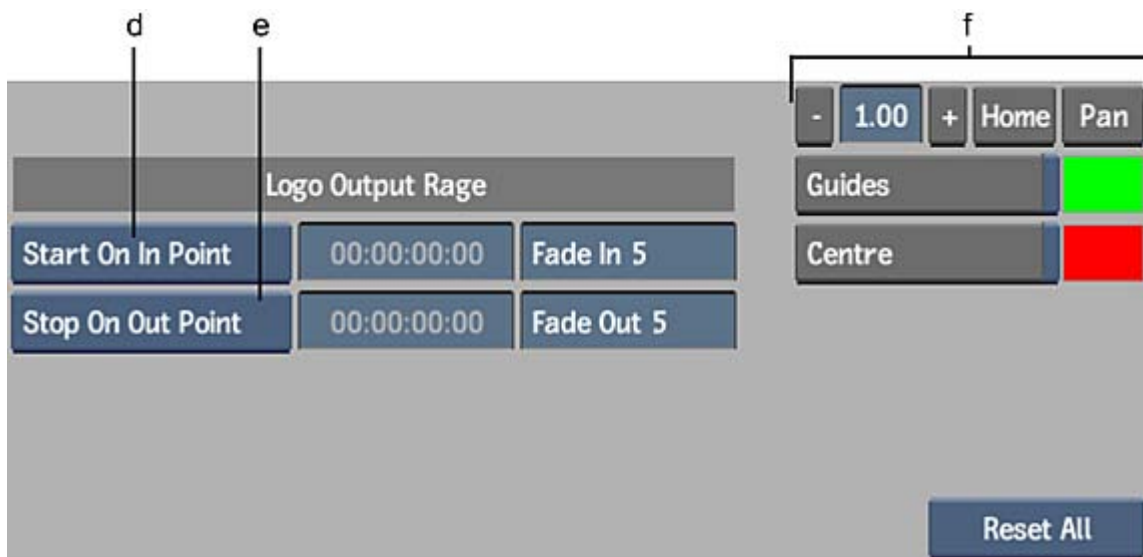

The logo controls are found in the VTR Output module, under the Logo tab.

NOTE When you select the Logo tab, you see the clip selected in the Output list instead of the VTR feedback.

(a) Horizontal alignment button (b) Vertical alignment button (c) Blend Mode box

(d) In point (e) Out point (f) Zoom controls

Logo Enables or disables burning of the selected logo on output.

Load Logo Opens the Clip Select menu where you can select logo clips.

Enable All Use to display the logo on all clips to output.

Disable All Use to remove the logo from all clips to output.

Scaling (Front) Changes the size of the Logo clip. The range of values is 0 to 100, with 100 being the actual size of the Logo clip.

Transparency (Front) Changes the transparency of the Logo (front clip). 0% is Opaque. 100% is Transparent.

Position controls (X and Y fields) Moves the logo along the X and Y axes.

Blend Mode box Selects how the front and matte clips or the front and back clips are combined.

Select:	To:
Add Trans	Compensate for the soft or anti-aliased edge on an object in a front and matte clip media, with transparency.

Select:	To:
Blend	Punch the matte through the front. This blends the edge of the front clip and adds additional softness to the media.

Shadow Uses the Matte clip to add a Shadow. The default position is set to X:-5 and Y:-5. A colour pot on the right allows for the shadow colour to be changed.

Scaling (Shadow) Changes the size of the shadow. The range of values is 0 to 100, with 100 being the actual size of the shadow.

Transparency (Shadow) Changes the transparency of the Shadow. 0% is Opaque. 100% is Transparent.

Softness Softness can be added to the Shadow. The range of values is 0 to 200.

Horizontal alignment Positions the logo along the X-axis using one of the following options.

Select:	To:
Horizontal Centre	Center the logo on the X-axis.
Left	Snap the left edge of the clip to the Safe Title guide on the left.
Right	Snap the right edge of the clip to the Safe Title guide on the right.

Vertical alignment Positions the logo along the Y-axis using one of the following options.

Select:	To:
Vertical Centre	Center the logo on the Y-axis.
Top	Snap the top edge of the logo to the Safe Title guide at the top.
Bottom	Snap the bottom edge of the clip to the Safe Title guide at the bottom.

Guides Enables the display of the Safe Action and Safe Title guides within the Clip Preview window. Use the colour pot to change the colour of the guides.

Centre Enables the display of the Centre guide within the Clip Preview window. Use the colour pot to change the colour of the Centre guide.

In point Select an option to specify when the logo appears on the clip.

Select:	To:
Start On In Point	Have the logo appear at the in point of the clip.
Start After Frames	Specify after how many frames the logo appears. Enter the number of frames in the adjacent field.

Out point Select an option to specify when the logo disappears from the clip.

Select:	To:
Stop on Out Point	Have the logo disappear at the out point of the clip.
Duration	Specify how long the logo remains on screen. Enter the duration in the adjacent field.
Stop Before Frames	Hide the logo before the end of the clip, by the number of frames specified in the adjacent field. For example, selecting this option and entering a value of 5 makes the logo disappear by frame 15 in a 20-frame clip.

Fade In Defines the length of the logo fade in. A value of 0 indicates there is no fade in.

Fade Out Defines the length of the logo fade out. A value of 0 indicates there is no fade out.

Zoom controls The small VTR Output module is not available from the Logo tab. Use the Zoom controls to view oversized clips.

Reset All Use to reset the Logo controls to default.

Select:	To:
Reset All	Reset every field, and delete the logo.
Reset	Reset every field, but keep the logo.

Inserting Logos for Real-Time Output

Keep in mind the following when selecting clips to use as logos:

- If the clip has more than one frame, only the first frame is used.
- If the clip is BurnTM pending, unlinked or unlinked HiRes, it cannot be used.
- The higher the resolution for the clip, the more impact it has on the capacity of the application to output in real time.

Logo settings are persistent, and previous logo settings are loaded when you open the VTR Output module.

NOTE The same logo, with its settings, is applied to all clips for which you have checked the Logo column in the VTR Output module list.

To insert a logo in real time:

- 1 Select clips from the Media List and select File > VTR Output...
- 2 In the VTR Output module, use the Logo column to indicate which clips are to be output with the logo.
- 3 Click the Logo tab to access the logo controls.
- 4 Select one or two clips to use as logo:
 - If you select one clip, it is used as the front clip and a luminance key is applied to it. If the clip has multiple frames, only the first frame is used.
 - If you select two clips, the first is used as the front and the second as the matte.

- 5 Use the logo controls to position and configure the appearance of your logo, and to define in and out points. See [About the Logo Controls](#) (page 211).
- 6 Output the clip.

Outputting Clips in Assemble Mode

If you do not have time to black an entire tape, you can black a small portion of the tape and output clips to the tape in assemble mode. In this mode, the timecode on the tape is generated by the VTR as part of the recording process. Make sure that timecode regeneration is properly configured on the VTR. The standing recommendation is blacking one minute at the beginning of the tape.

If outputting a clip in assemble mode, extend the duration of the output to avoid problems when you need to recapture the segment. For example, this can be done by adding 5 to 10 seconds of black at the beginning and at the end of the clip, before entering the output clip module.

To output a clip in assemble mode:

- 1 On the VTR, set the TC generator switch to Internal and Regen to make the VTR generate the timecode. Refer to your VTR manual for instructions on setting the TC generator.

TIP If you have just added black to your tape, the VTR should already have these settings.

- 2 Set clip output options. See [Outputting a Single Clip](#) (page 207).
- 3 With the clip you want to output in the VTR Output module, set the clip output in and out points. See [Setting Input and Output In and Out Points](#) (page 216).
- 4 If black was not added at the end of the clip, make sure the out point exceeds the duration of the clip by five to ten seconds.
- 5 Select the Assemble option from the Output box.
- 6 Click Assemble to output the clip in assemble mode.

HDCAM SR Stereo Tape Output

Using an HDCAM SR, you can output material to specially formatted stereoscopic tapes. Stereoscopic tapes essentially stores in an interlaced timing two progressive clips; a 60i (50i) “clip” contains two 30p(25p) clips.

To output stereoscopic material to stereoscopic tape:

- 1 Ensure that the HDCAM SR is connected to the output device using a dual-link.

IMPORTANT If you use an NVIDIA SDI card to output the stereoscopic material, the NVIDIA card downconverts the material to 8-bit.

- 2 Set the HDCAM SR VTR to the stereoscopic setting and insert a stereoscopic tape.
- 3 In the application, enter the VTR Output module with a stereoscopic clip. The presence of an **S** in the bottom right corner of a proxy indicates a stereoscopic clip.

NOTE You can output only clips at 23, 24, 50 or 59 fps, with a 1080i or 1080PsF resolution.

- 4 Output the clip. See [Outputting a Single Clip](#) (page 207).

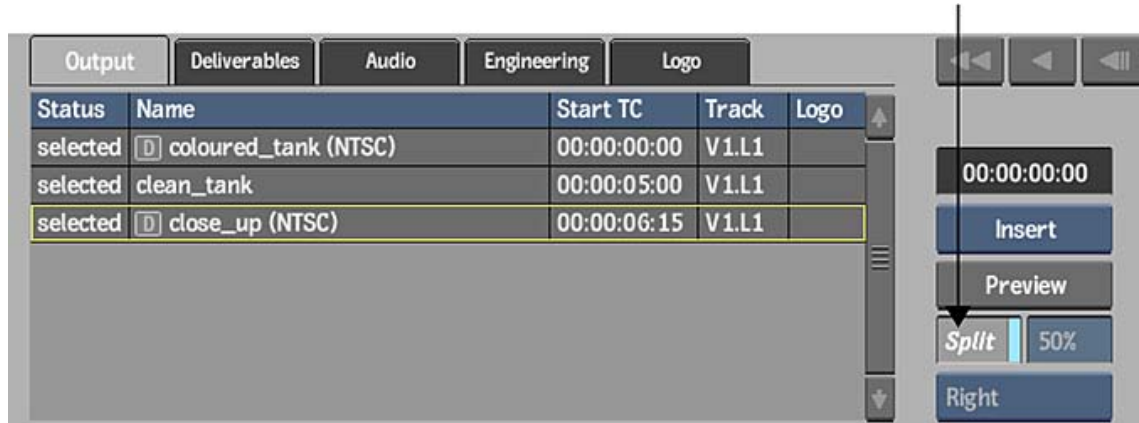

The player in the VTR Output module displays only the left-eye layer, but the application outputs both right- and left-eye tracks, in a 4:2:2 colour space.

Monitoring Video During Clip Output

When you output a clip to a tape that already has media on it, you can enable a split view to compare a clip with a portion of tape, in much the same way as split view allows to compare two video segments in the player. This can be especially useful if you are outputting a clip to seamlessly overwrite a section on the tape.

To use the split view preview option:

- 1 In the Output tab of the VTR Output module, enable Split.

The Split View controls are enabled and you can view the clip that is currently set for output alongside the content on the tape.

- 2 Set Split View preview options:
 - In the Split field, enter a value to set the relative position of the split.
 - From the Current Clip Display box, select an option to set the location of the current clip display.
 - From the Split Orientation box, select Horizontal Split or Vertical Split to set the Split View orientation.
- 3 With Split View enabled, you can scrub the VTR to locate the frame that matches the frame of the current clip.
- 4 Set the In point to the timecode of the frame on tape that corresponds to the first frame of the clip.
- 5 Cue to the In point. The first frame of the clip and matching frame on tape are displayed in Split View.
- 6 Click Play to play the tape and the clip simultaneously in Split View.
- 7 Click Stop, and disable Split View when you are finished.

Setting Input and Output In and Out Points

You can enter timecode values directly in the In, Out, and Dur fields to set in and out points for clip input and output. However, there are other methods of setting the in and out points that are more convenient if you are scrubbing the tape in the VTR to locate reference frames for clip input and output. For example, if you output a clip to overwrite a segment on a tape, you scrub the tape to locate the frame that matches the first frame of the clip you are outputting.

You can also enter in and out points, as well as duration values based on the timecode value of a clip selected for input. Simply click Input Clip, then while holding down the left **Ctrl** key, select a clip and a destination reel.

Besides the described methods of entering timecodes in the In, Out, and Dur fields, you can modify clip in and out points or cue the VTR to these points using the following controls on the right side of the Input or Output menu.

Start on Timecode	In	00:00:00:00	In	-	+	Cue
Stop After Frames	Out	00:00:01:00	Out	-	+	Cue
Frames 30	Duration	00:00:01:00				
	Offset	00:00:00:00				

In button Click to set the In field to the VTR's current timecode.

Out button Click to set the Out field to the VTR's current timecode.

+ and - buttons Click to frame-step the In or Out timecodes forward or backward. If Stop After Frames is selected from the Stop Mode box, both the in and out points move because the duration between them is locked.

Cue buttons Click to cue the VTR to the in or out point.

Inputting and Outputting a Live Video Signal

In the configuration file, if you uncomment the `live NTSC` or `live PAL` VTR lines, you can capture a live video signal or crash-record a clip using a click to start and stop the clip input or output process.

On input, use the Live NTSC or PAL option to capture directly from a camera, VCR, or any other device that does not support remote control via RS-422. You can also feed a live video signal from satellite or any other broadcast source.

On output, use the Live Video option to output clips to a device that does not support remote control via RS-422.

To input a live video signal:

- 1 Enter the VTR Input module.
- 2 From the VTR Device box, select Live NTSC or Live PAL.

The incoming live video signal appears in the preview window. The Start Mode box is unavailable. With Live Video capture, you must use Start On Click mode. You can use Stop On Click or Stop On Frames to end the capture.

Start on Pen	In	00:00:00:00
Stop on Pen	Out	04:00:00:00
	Dur	04:00:00:00

NOTE When Stop On Click is selected as the preferred capture stop mode, the out point and the duration timecode fields are updated to reflect the longest possible duration corresponding to the full capacity of a framestore. The capture stops either when you click anywhere on the screen or the timecode indicated is reached, meaning that the framestore is full.

- 3 Set input options. For example, enter the clip name and enable the video tracks and audio channels that you want to capture. See [Inputting Clips From a VTR](#) (page 197).

- 4 Make sure you are receiving the live video signal.
- 5 If you are capturing from a device that does not support remote control, press Play (allowing enough time to click Process in Flame Premium).
- 6 To begin capturing, click Process.
After a moment, you are prompted to click anywhere to begin the output process.
- 7 Click anywhere on the screen.
- 8 To end capturing in Stop On Click mode, click anywhere on the screen.

To output a live video signal:

- 1 Load a clip into the VTR Output module.
- 2 From the VTR Device box, select Live NTSC or Live PAL.
The Start Mode box is unavailable. With Live Video output, you must use Start On Click mode. You can use Stop On Click or Stop On Frames to end the output.
- 3 Set output options. For example, enter the clip name and enable the video tracks and audio channels that you want to capture. See [Outputting Clips To a VTR](#) (page 204).
- 4 If you are outputting to a device, click Record, or take any action required to enable the device and capture the signal being output from Flame Premium.
- 5 To begin capturing, click Process.
After a moment, you are prompted to click anywhere to begin the output process.
- 6 Click anywhere on the screen.
- 7 To end capturing in Stop On Click mode, click anywhere on the screen.

Supported Timings and Resolutions for Video I/O

In addition to 2K broadcast and SD timings, the following HD formats are supported.

Format	Resolution	Scanning	Supported Frame Rates
720p	1280 x 720	Progressive	50, 59.94, and 60 Fps, Hz
1080i	1920 x 1080	Interlaced	25, 29.97, and 30 Fps, Hz
1080p	1920 x 1080	Progressive	23.976, 24, 25, 29.97, 30, 50, 59.94, and 60 Fps, Hz
1080PsF	1920 x 1080	Progressive	23.976, 24, 25, 29.97, and 30 Fps, Hz

Generating Proxies from VTR Input

With sufficient processing power, proxies are generated in real time. Otherwise, this occurs as a post-process. To achieve better performance, or to use higher quality proxy types, you might want to perform clip input without proxy generation, then edit project settings to generate proxies overnight.

The following guidelines refer to working on projects set to generate proxies.

You may create projects with proxy management options set to generate proxies for HD clips. If your hardware configuration supports on-the-fly proxy generation, your clips are captured and proxies are generated as

part of the real-time input process. Otherwise, you may be required to wait for proxy generation once the capture process itself is complete.

If you are capturing many clips one-at-a-time, you may want to turn off proxy generation for your project. That way, you can capture your clips without having to wait for proxy generation.

Once you have completed the capture process, turn proxy generation back on. If you have captured many clips, this process could take a long time. You may want to do this when you can leave the workstation unattended, for example, overnight.

Capturing Material with Variable Frame Rate

To perform frame-accurate video input and output using Panasonic® variable frame rate VTR decks, you must use the following firmware versions:

- AJ-HD3700H D5-HD deck:
 - SYSICON: 1.04 or later
 - AV: 0.21 or later
 - FRONT: 0.13 or later
- AJ-HD1200A DVCPro HD deck:
 - SYSIF: 1.30 or later
 - AVDV: 1.39 or later
 - SERVO: 1.22 or later

Regular video input and output is not affected by a firmware version.

NOTE Refer to your Panasonic documentation for information on verifying the firmware version.

To capture material from a VariCam device:

- 1 Ensure your devices are properly connected and the corresponding VTR keywords are enabled in the software initialization configuration file. See [Configuring Software For Clip Input and Output Using a VTR](#) (page 197).
- 2 Open the VTR Input module. See [Accessing the VTR Input Module](#) (page 198).
- 3 From the Device Name box, select a video device, supporting variable frame rate (for example, one of the following options: VTR DVCProHD 720 59p or VTR DVCProHD 720 60p).

- 4 Enter the Engineering menu and enable Varicam (on the right side).

- 5 Make sure the Video Input Delay is set to zero or a positive value (negative video input delay is not supported on VariCam capture).
- 6 From the Timecode Mode box, select the required timecode.

- 7 Exit the Engineering menu and click Process.
- Flame Premium removes the redundant frames so that the frame rate of the captured clip corresponds to the frame rate of the project. You can monitor the process using the VTR Status display. The Current Frame Rate field is updated depending on the frame rate of the captured material.

(a) Current Frame Rate field

NOTE When performing operations in Varicam mode, audio/video synchronization largely depends on frame rate compatibility and can be guaranteed only if the following conditions are observed: (1) Material shot at 24 fps and captured into a 24 fps project (2) Material shot at 30 fps and captured into a 30 fps project (3) Material shot at 60 fps and captured into a 60 fps project.

Controlling a VTR

The RS-422 serial connection between the VTR and your workstation enables full remote control of the device from Flame Premium. Connected VTR devices send their current status to Flame Premium, and this status is displayed in the VTR Input and VTR Output modules.

Verifying the VTR Status

The following illustration shows a VTR status display.

(a) VTR Status (b) VTR Timing (c) Colour Space (d) Bit Precision (e) Control Mode (f) Audio Sample Rate (g) Audio Input/Output Type

Other VTR status values include.

VTR field:	Indicates:
VTR Status	Play, Play Lock, Stop, Jog, Fast Forward (FFW), Rewind (RWD), 3x, 4x, 8x, 15x, 30x. When the field is blank the VTR is disengaged.

VTR field:	Indicates:
VTR Timing	The video timing currently configured on the video device.
Colour Space	The colour space conversion method for both input and output of clips.
Control Mode (LOCAL, REMOTE, or REC INHIBIT)	Whether the VTR is in Local or Remote control mode. Local appears in yellow when the VTR is in Local mode. In Local mode, the VTR cannot be controlled from Flame Premium. You can switch the VTR between Local and Remote mode only on the VTR. Rec Inhibit implies REMOTE mode, but you cannot output to the tape.
Audio Sample Rate	The audio sampling rate when you input or output from the VTR.
Audio Input/Output Type	The source audio interface type when inputting and the destination audio interface type when outputting.
Bit Precision	The accuracy used (SDI bit depth) when transferring data. This cannot be changed.

Using the VTR Transport Controls

The current frame on the cassette in the VTR appears in the image window and the Current Timecode field (the uppermost timecode field in the Clip Input and Output menus) displays the timecode of the current frame.

(a) Current Timecode field

Use the following VTR Transport controls to play the VTR.

NOTE The VTR must be in Remote mode to use the VTR Transport controls.

Click:	To:	Hotkey:
	Rewind the tape.	Home
	Play the tape backward.	-
	Move backward one frame. Hold down to slowly jog backward.	left arrow key (down arrow key for -5 frames)
	Stop the tape.	spacebar

Click:	To:	Hotkey:
	Move forward one frame. Hold down to slowly jog forward.	right arrow key (up arrow key for +5 frames)
	Play the tape forward.	Enter
	Fast-forward the tape.	End
	Eject the tape.	none

You can also shuttle the VTR by dragging the cursor in the image window. Place the cursor on the image, press the pen or mouse button, and drag the cursor to the right to shuttle forward and to the left to shuttle backward. The farther away you move the cursor horizontally from the middle of the image, the faster the speed.

You can also change the reverse or forward playback speed by pressing the Up or Down arrow keys on your keyboard. Each press reduces or increases the speed by two.

Audio Gain Adjustment Settings

Audio gain adjustment is a part of the clip output process only. The clips you are outputting are unaffected by audio gain adjustments made using the VTR Output module.

On output, you can adjust the audio gain, for example, to restore the levels you had monitored on capture.

(a) Audio Tracks Toggle button (b) Channel Selection buttons and indicators (c) Audio Level fields (d) Fader Lock buttons

All Audio button When enabled, outputs to the audio monitor every audio channels. When disabled, outputs only the enabled audio channels to the audio monitor. The All Audio button has no impact on the audio tracks recorded by the VTR.

Audio Tracks Toggle button Toggles the Channel Selection buttons and indicators between audio tracks 1-8 and 9-16.

Channel Selection buttons and indicators Controls and displays which audio channels are recorded by the VTR. The black boxes with the green LEDs indicate video tracks and audio channels that are part of the clip that you want to output. The red buttons indicate the tracks and channels the VTR records on output.

Audio Level fields Displays the audio gain, in decibels. Adjust using the faders. In the small VTR Output module, increase or decrease the gain by dragging left or right on the fields. By default, audio gain is 0 db.

Fader Lock buttons When enabled, locks the faders for the corresponding pair of audio channels together.

Adjusting Audio Gain on Clip Output

To adjust the audio gain on output clip:

- 1 Enable the Fader Lock buttons (so that they are light grey) if you want to apply the identical value to pairs of audio channels.
- 2 Slide the faders to adjust the audio gain before you start processing. Use the All Audio button to monitor all the audio tracks that are output, regardless of what audio tracks the VTR records.
- 3 In the VTR Output module, enable Output All Audio.
- 4 Select or deselect channels for output by clicking the Channel Selection button for each channel as needed.

NOTE In a multiple clip selection, channel selection is independent for each clip but the gain levels set with the faders are the same for all clips.

- 5 Process the clip.
Selected channels are output.

Setting Video Input and Output Engineering Menu Controls

Clip input and output engineering options include video I/O settings such as pre-roll, post-roll, play delay, colour space conversion, and settings that define the process by which YUV video material on a tape is converted to the RGB format used by Flame Premium, and vice-versa.

Each VTR device is associated with a set of default engineering settings that are specified in the software initialisation configuration file, in the VTR KEYWORD section.

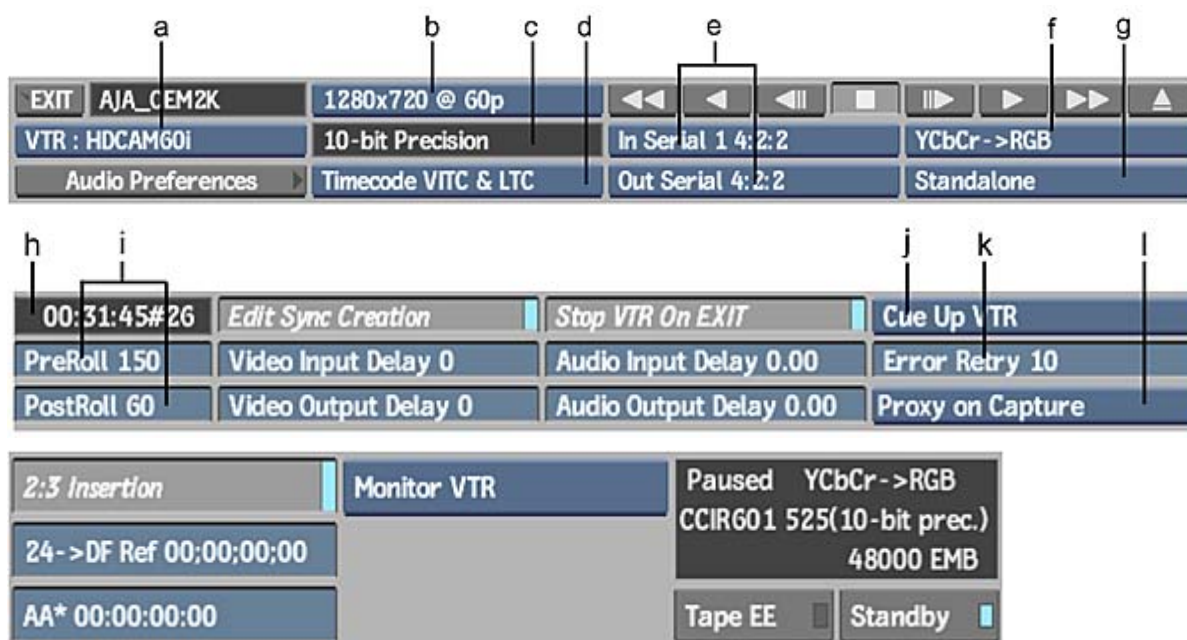

When you start Flame Premium and set the video I/O timing for your project, enabled VTR devices are initialized, and the settings in the Engineering menu are populated accordingly. However, if necessary, you can modify these settings on a session-to-session basis.

To open the Engineering menu:

- 1 From the VTR Input module, click Eng, or from the VTR Output module, click the Engineering tab, to open the Engineering menu.

Engineering Menu Options

Consult the following illustration (broken into three parts) and explanations of the options in the Engineering menu. These illustrations are of the VTR Input Engineering menu. The VTR Clip Engineering menu contains a subset of these controls.

(a) Device Name box (b) Video I/O Timing box (c) Precision box (d) Timecode Source box (e) Input and Output Connection boxes (f) Colour Space box (g) Output Sync box (h) VTR Current Timecode field (i) PreRoll/PostRoll fields (j) Cue Up box (k) Error Retry field (l) Proxy Box

Device name box The Device Name box differentiates between 3G and non-3G capable VTR and provides an option for each enabled VTR in the software initialisation configuration file. To modify settings for a specific VTR device, select the corresponding option from this box.

Video I/O Timing box Provides video timing options (resolution and frame rate) corresponding to different video formats supported by the video input/output board of the system.

Precision box Determines the video interface precision, or SDI bit depth used. This value cannot be changed.

Audio Preferences button Click to view the Audio Preferences menu.

Timecode Source box Determines which type of timecode is obtained from the VTR device. Timecode VITC & LTC is the default, and recommended option. You should only have to switch to Timecode VITC or Timecode LTC if one of the timecode tracks is corrupted.

Select:	To obtain:
Timecode VITC	Vertical interval timecode (VITC).
Timecode LTC	Longitudinal timecode (LTC).
Timecode VITC & LTC	Both types of timecode. At normal playback speed, Flame Premium obtains LTC, but switched to VITC when the tape is rewinding, fast-forwarding, or otherwise moving at a non-playback speed.

Input and Output Connection boxes These boxes determine the connection by which the video signal is transferred. This box is automatically set to reflect the selected VTR.

- **In Serial 1 3G / Out serial 1 3G:** The video signal is transferred through one SDI 3G link. This is the only available option when you use a 3G VTR. The VTR Status field indicates any conversion that might happen because of the sampling used, 4:2:2 (conversion YCbCr <-> RGB) or 4:4:4 (no conversion RGB <-> RGB).

- In serial Dual 444 / Out serial Dual 444: The video signal is transferred through dual SDI links; one video field is sent through one SDI cable, the other field through the other cable.
- In Serial 1 4:2:2 / Out serial 422: Traditional VTR, single-SDI connection.

Colour Space box Determines the YCrCb colour space conversion method.

Select:	To perform clip I/O with:
YCrCb->RGB	A standard YCrCb-RGB conversion process that clips superblack and superwhite luma (Y). Use this option for typical clip I/O processes with VTR devices.
YCrCb->RGB + Headroom	A YCrCb-RGB conversion process that preserves superblack and superwhite colour information. Use this option when inputting or outputting greyscale mattes or other clips where preserving extremes in the luma channel is required.
No Conversion	This is available when using dual link for RGB input and output. Video black and white levels on the SDI stream are mapped to black and white values in RGB on the framestore. Use this option in conjunction with 4:2:2 input and output connections to input and output 4:4:4 video using dual-links (4:2:2 and 0:2:2).
No Conversion + Headroom	Also available when using dual link for RGB input and output. This mode uses all levels available and preserves all but a few RGB values. Use this option with the 4:4:4 input and output connections to input clips from and output clips to a Telecine.

Output Sync box Determines the output sync reference source. The reference signal may originate from several different sources. Select the source you are using from this box according to the following table.

Source type	Available on:	Description:
House	All systems	A centralized analogue reference signal, originating from a sync generator, sent to the genlock port on the video board or VBOB.
Digital 1 and Digital 2	Most HP® 8400s and all HP 8600s and 9400s	Same as Digital, except you can choose between two inputs: Digital 1 or Digital 2. On the HP 8400 with the AJA SD (OEM-LH) video board, only Digital 1 is available.
Standalone	All systems	The reference signal generated internally by the Flame Premium workstation.

PreRoll field Indicates the pre-roll, in frames.

PostRoll field Indicates the post-roll, in frames.

Video Input Delay field Indicates the video delay on input, in frames. If this value is incorrect, the result clip when you click Frame Grab in the VTR Input module does not match the frame you see in the preview window.

Video Output Delay field Indicates the video delay on output, in frames. If this value is incorrect, the clip you output does not get recorded to the proper place on the tape.

Audio Input Delay field Indicates the video delay on input, in frames.

Audio Output Delay field Indicates the video delay on output, in frames.

Stop VTR on EXIT button When enabled, sends a stop command to the VTR when you exit the Input Clip, Output Clip, Auto-Capture, or Archiving menu. For example, if the VTR is playing a clip, or if it is cueing to an in point, the transport operation in-progress is interrupted.

Cue Up box Determines the speed of the cueing process.

Select:	To cue up the VTR:
Cue Up VTR	Using the internal cueing algorithm of the VTR.
Cue Up Fast Forward	Using Flame Premium. Use this option if Cue Up VTR is too slow for far cue points, such as on the betacam SP.

Error Retry field Indicates the number of times Flame Premium retries failed input or output processes.

2:3 Removal/Insertion button Enables automatic, real-time 2:3 removal on output and insertion on input. This is only available when the VTR is set to 29.97i or 59.94i.

Proxy box Determines proxy management when inputting clips.

Select:	To generate:
Proxy in Post	Proxies as a post-processing step
Proxy on Capture	Proxies during capture

Generating proxy during capture is the quickest method. Depending on hardware configuration of your system, capture may be performed in real time with playback. Some extra required processing, however, may prevent the graphics board from updating the image window and broadcast monitor in real time, so you may not be able to view the clip being played as it is captured.

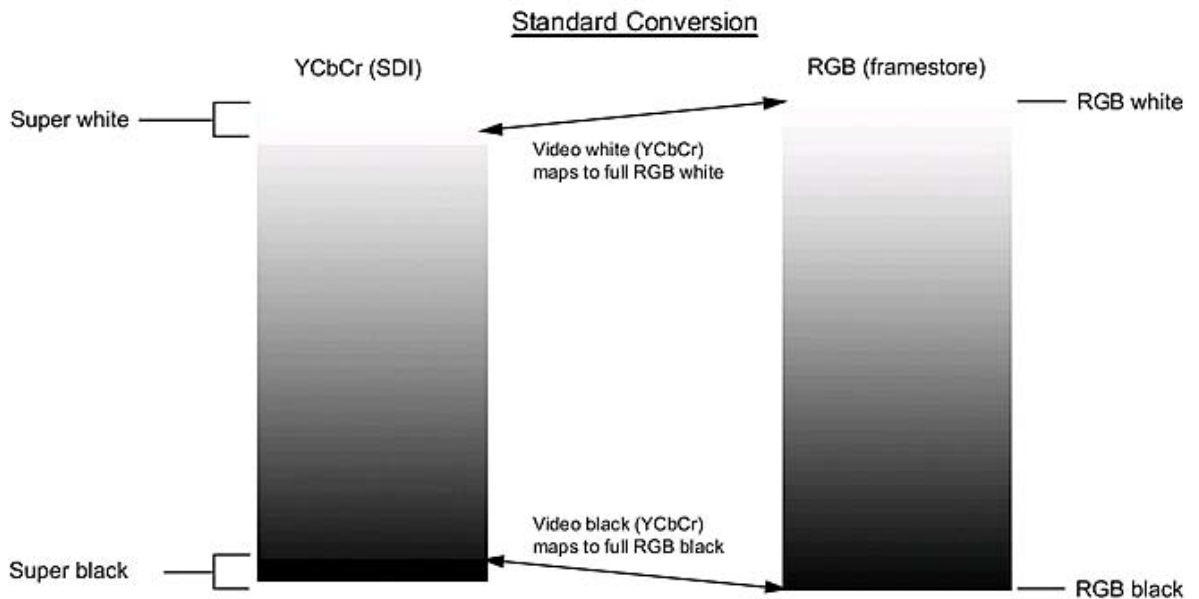

Monitor box Set this to Monitor VTR or Monitor Output. In Monitor VTR mode, the signal coming back from the VTR is displayed, and video may be appear to be late compared to the audio. In Monitor Output mode, the signal being output to tape is displayed, and the video and audio should be in sync.

Dual Image Resizing Filter box Select the resize algorithm used to scale back to full resolution clips captured using the Dual Image - Scale resolution. Ordered from lowest quality (Triangle) to highest (Lanczos). On some lower-end workstation, you might need to select a lower quality algorithm to capture every frame.

Inputting and Outputting with Headroom

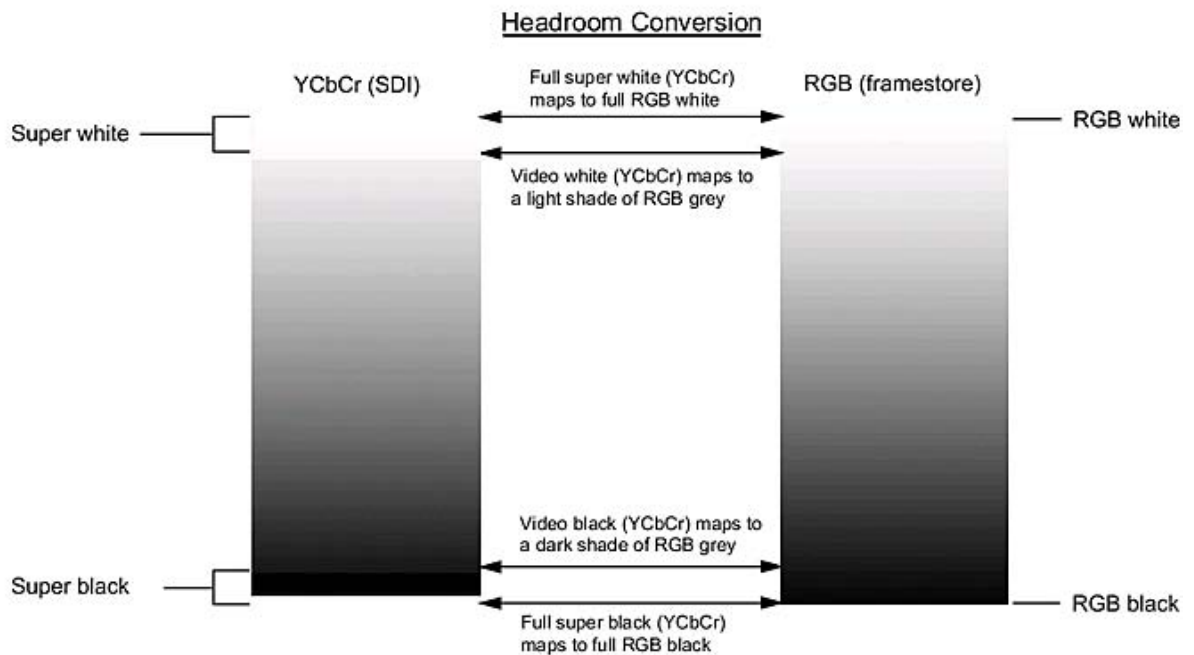

With 4:2:2 serial digital interface (SDI) input and output connections, the colour components of video signals are Y (luma), Cb (blue colour difference), and Cr (red colour difference). For standard video signals in 10 bits, black has a luma value of 64 and white has a luma value of 940. When performing standard captures to RGB values on Flame Premium systems, black YCbCr (64,512,512) maps to RGB (0,0,0) and white YCbCr (940,512,512) maps to RGB (1023,1023,1023). SDI values 0 to 3 and 1020 to 1023 are reserved values for synchronization purposes.

Some cameras record shadow details below the video luma black value of 64 and white detail above the video luma white value of 940. These details are called super blacks and super whites. These are also referred to as “headroom” and “footroom.” Under normal circumstances, headroom is not converted during capture, and the super black and super white details are lost, as described in the following illustration:

In this illustration, headroom and footroom information is lost.

Using the YCbCr<->RGB with headroom colour space option during input on Flame Premium systems, it is possible to capture these super black and super white values. In this case, video black YCbCr (64,512,512) maps to RGB (64,64,64) in 10 bits, and video white YCbCr (940,512,512) maps to RGB (940,940,940). YCbCr Luma values between 4 and 64 and between 940 and 1019 are converted to RGB on capture. While this gives you the advantage of being able to capture super black and super white values, it also means that video black will not map to full black in RGB, and video white will not map to full white in RGB. The following image illustrates this:

In this illustration, headroom and footroom information is conserved

For 4:4:4 RGB standard input and output, a similar explanation applies. On capture using the No Conversion setting, RGB 4:4:4 SDI video black at value (64,64,64) maps to RGB (0,0,0), and RGB 4:4:4 SDI video white at value (940,940,940) maps to RGB (1023,1023,1023).

With the No Conversion with Headroom option, the maximum possible SDI value range is used. RGB 4:4:4 SDI values ranging from (4,4,4) to (1019,1019,1019) map to the same RGB range on capture.

Enabling Colour Space Conversion on Clip Input

To enable colour space conversion on clip input:

- 1 In the VTR Input module, click Engineering.
The Engineering menu appears.

(a) Input Connection box (b) Colour Space box

- 2 From the Input Connection box, select the input connection.
- 3 From the Colour Space box, select YCbCr->RGB+Headroom.
- 4 Capture the material.
Material is captured with headroom and footroom.

To enable colour space conversion on clip output:

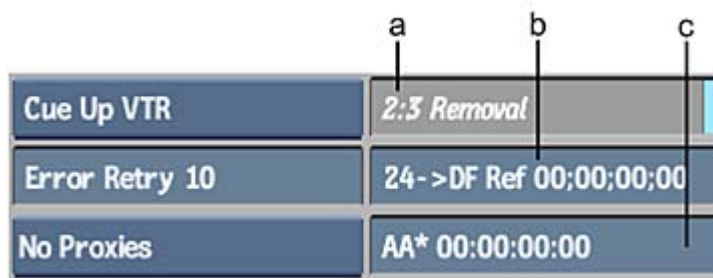

- 1 Open the clip library with the clip(s) you want to output.
- 2 Click Output Clip and prepare output clip settings.
- 3 In the VTR Output module, click Engineering.
- 4 In the Engineering menu, select the output connection from the Output Connection box.
- 5 From the Colour Space box, select YCbCr->RGB+Headroom.
- 6 Output the material.
Material is output with headroom and footroom.

Capturing 60i Material with 2:3 Pulldown Removal

Using the VTR Input module, you can capture 30 fps film-based material and convert it to 24 fps material in real-time as you capture. The procedure for enabling automatic 2:3 removal differs depending on whether your tape uses non-drop or drop 60i timecode.

To capture 60i material with 2:3 pulldown removal:

- 1 Set up your capture.
- 2 In the VTR Input module, click Eng.
The Engineering menu appears. It contains options for removing 2:3 pulldown in real time while capturing.

(a) 2:3 Removal button (b) 24>DF Reference field (c) AA Reference field

- 3 Enable 2:3 Removal.
- 4 In the AA Reference field, enter a timecode that corresponds with an AA frame on the tape that is currently in the VTR.

TIP To determine an AA frame, frame-step (Right arrow) the tape and look closely at each frame. In 2:3 pulldown, two jitter frames with field artefacts are followed by three normal frames. The second frame after the two jitter frames is an AA frame.
- 5 When you capture material from a tape that uses 30 fps drop-frame timecode with 2:3 removal enabled, a slight discrepancy between timecodes is introduced due to the reference timecode used to determine the 30 drop frame to 24 timecode conversion. To optimize correspondence between the timecodes, enter the timecode in the 24 >DF Reference field that matches the start reel timecode for the tape.

TIP The start clip timecode can be deduced from the hour-mark of the timecode used by your clips. For example, 1;00;00;00 drop-frame would require a 1;00;00;00 value in the 24p>DF reference field to get a clip starting at 01;00;00+00.
- 6 Make sure the project's field dominance is set to field1. If the project's field dominance is set to field 2, you must switch the field dominance back to field 1.
- 7 Click EXIT to return to the VTR Input module.
- 8 Using the In and Out timecode fields, set the in and out points for the capture session.

(a) In and Out timecode fields (b) 2:3 In and Out pulldown display

With the in and out timecodes set, the corresponding 2:3 pulldown frame is indicated in the In and Out 2:3 pulldown display. Use the 2:3 Pulldown display to determine the 24 fps result in and out frames.

2:3 Pulldown Frame	24 fps Result Frame
In/Out AA	In/Out A
In/Out BB	In/Out B
In/Out DD	In/Out D
In BC	In C

2:3 Pulldown Frame	24 fps Result Frame
In CD	In D
Out CD	Out C

- 9 Click Process to capture the material with 2:3 pulldown removal.

Configuring Dual-Serial Link I/O

Flame Premium supports dual-serial link input and output connections for 4:4:4 clip I/O. Configure the type of I/O connection (single- or dual-link serial) using the Input Connection and Output Connection boxes in the Engineering menu.

When you select an input or output connection for clip I/O, you usually also select the colour space conversion method using the Colour Space box on the Engineering menu. The conversion methods that appear in this box depend on the type of I/O connection used. The following table shows the colour space conversion methods that are available for single-link and for dual-link I/O connections.

Colour Space Conversion Method	Supported for Single-Link Serial (4:2:2) I/O	Supported for Dual-Link Serial (4:4:4) I/O
YCbCR -> RGB	Yes	No
YCbCR -> RGB + Headroom	Yes	No
No Conversion	No	Yes
No Conversion + Headroom	No	Yes

Clip Output Using Real-Time Deliverables

About Real-Time Deliverables

The Real-Time Deliverables mastering solution allows you to perform certain types of operations on material during clip output without having to first render the clips. For example, you can output from a master source format to many output formats directly to tape without rendering. Using the concept of the Deliverable—a virtual clip containing real-time operations and linked to its original source clip—you can create and manage multiple real-time output formats from one clip.

Supported operations include:

- Resize
- Pan and Scan
- Application of 3D and 1D LUTs
- Frame rate change with deceleration or acceleration with 2:3 insertion
- Audio timewarp
- Letterbox overlay

The Real-Time Deliverables feature supports source material up to 2K (10-bit) depending on the hardware setup. Good performance may be achieved beyond 2K (10-bit), but is not guaranteed. Soft effects are not supported for real-time output, unless processed before output. Embedded audio is also not supported.

Real-Time Deliverables sections explain important concepts and workflows for how to manage, preview, and output real-time operations, and references other sections of the user guide for more details, where appropriate.

Make sure to follow the hardware requirements described in [Hardware Requirements for Real-Time Deliverables](#) (page 231).

What Is a Deliverable?

The settings created in Real-Time Deliverables panel are saved as a Deliverable, which is central to the Real-Time Deliverables workflow.

A Deliverable is a virtual clip that is associated with the source clip from that point on, in the library or on the Desktop. A clip can have multiple Deliverables, and each Deliverable that you create is itself treated like a clip—a modified version of the original clip. As with clips, you can enter the Output Clip menu and output a Deliverable to tape. See [Managing Deliverables](#) (page 238).

Hardware Requirements for Real-Time Deliverables

To follow the Real-Time Deliverables procedures, you must be using an NVIDIA Quadro FX 5600, FX 5800, or FX 6000 SDI graphics card. The configuration for using these cards is described in the *Hardware Setup Guide* for your workstation.

When installing this release of the application for use with Real-Time Deliverables, it is important to use the settings in the new version of the *init.cfg* file. These settings specify the new hardware to be used as your preview device. For example:

```
VideoPreviewDevice 1920x1080@23976psf, nvidia, 1, 1920, 1080, 23976psf, DTVsync
```

If there are settings in your previous *init.cfg* file that you want to keep, port them to the new version during installation.

To use Real-Time Deliverables, make sure the appropriate SDI card is selected in the Output Clip menu.

To select the appropriate SDI card in the Output Clip menu:

- 1 Open the Output Clip menu as described in [Outputting Clips To a VTR](#) (page 204).
- 2 From the Graphics Card box, select GFX SDI.

When GFX SDI is selected, the installed SDI card is automatically used for video output.

When AJA_OEM2K is selected, the AJA OEM-2K is used for video output. The AJA OEM-2K does not support Real-Time Deliverables, and the corresponding options are not displayed when it is selected.

GFX SDI is not an available option in the Graphics Card box if:

- The SDI card is not installed.
- The SDI card is not set up or configured properly.

To install or configure an FX 5600, FX 5800, or FX 6000 SDI, see one of the hardware guides previously cited in this topic.

Real-Time Deliverables Use Cases

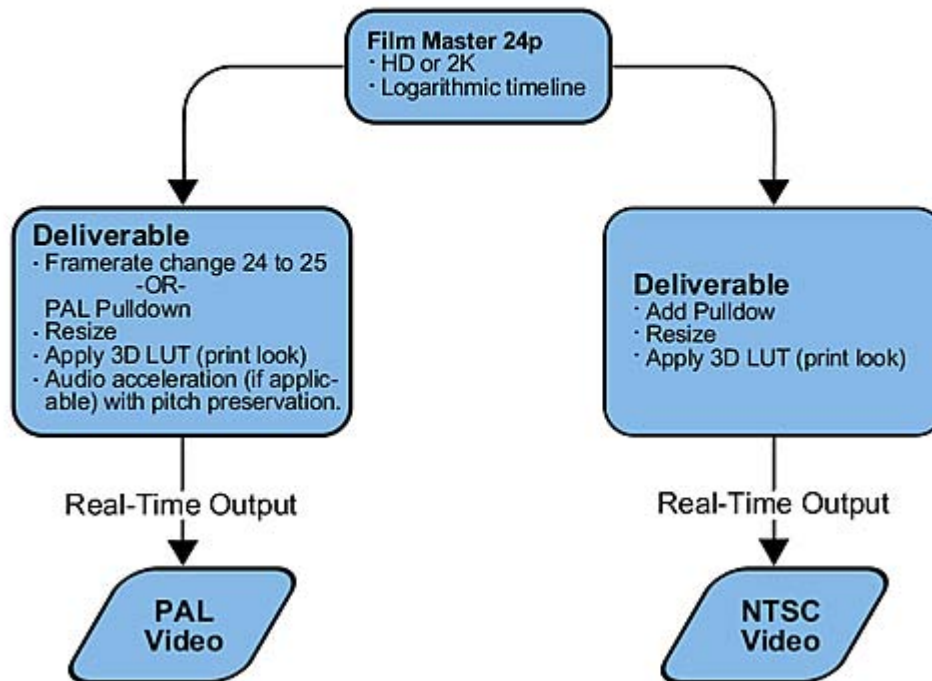

This section provides two examples of how Real-Time Deliverables can be applied.

Film Master 24p, HD, or 2K Logarithmic Timeline, to Video

An important case addressed by Real-Time Deliverables is when an organization wants to take a 24p film master with an HD or 2K logarithmic timeline, and create real-time output to PAL and NTSC video format.

Use Case 1

Film master 24p, HD or 2K logarithmic timeline, to Video

To output to PAL video, you would create a Deliverable that does the following:

- Increases the frame rate from 24 to 25, or uses PAL Pulldown
- Resizes the clip
- Applies a print-look 3D LUT
- Accelerates the audio while preserving the pitch, if necessary

To output to NTSC video, you would create a Deliverable that does the following:

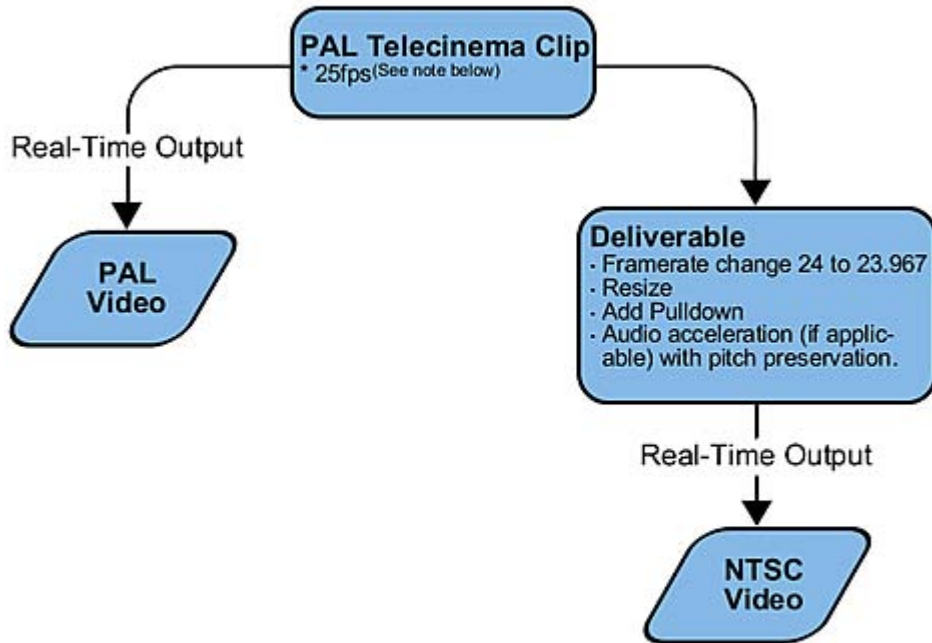

- Adds 2:3 pulldown
- Resizes the clip
- Applies a print-look 3D LUT

From the Clip Output menu, the clip is output to tape with no need to render the preceding settings.

PAL Telecinema to Video

In this example, NTSC and PAL video are output, but the source material is a PAL Telecinema clip. Because a PAL Telecinema clip is not field-based, the resulting video can be treated as progressive. Its video fields are spatially complementary.

Use Case 2 - PAL Telecinema to Video

Note: A PAL Telecinema clip is not field-based, so the resulting video can be treated as progressive. Video fields are spacially complimentary (correlated).

To output to PAL video, you would not need to create a Deliverable. You can output the clip directly to tape from the Output Clip menu.

To output to NTSC video, you would create a Deliverable that does the following:

- Decreases the frame rate from 25 to 23.967
- Resizes the clip
- Adds 2:3 pulldown
- Accelerates the audio while preserving the pitch, if necessary

From the Clip Output menu, the clip is output to tape with no need to render the preceding settings.

Accessing the Real-Time Deliverables Panel

Use the Real-Time Deliverables Panel to manage Real-Time Deliverables, and to configure real-time operations such as resize, pulldown, and so on. Many of these settings can also be altered in the Output Clip menu.

To access the Real-Time Deliverables panel:

- 1 Select the clip you want to work on and open the Player.
- 2 From the Options box, select Show Real-Time Deliverables.
The Real-Time Deliverables panel will open to the right of the Player.

Most of the controls in the Real-Time Deliverables panel are common to various parts of the software, and their functions are explained in their respective sections. The following does not describe how to use the controls, but rather how to manage the results using Deliverables and output them to tape in real time. The settings you create in the Real-Time Deliverables panel can be previewed in the Player and are applied in real time during clip output.

To configure real-time operations, see [Managing Deliverables](#) (page 238).

NOTE Settings in the Real-Time Deliverables panel override clip settings from other modules. These settings are overridden, not discarded. For example, if a Deliverable has LUTs set, the LUTs from the source clip are not used.

Source clip information Displays information about the source clip before real-time operations are applied.

Resize controls Displays values set in the Resize editor, accessible with the Editor button. You can edit the values directly in the Real-Time Deliverables panel. The available destination resolutions and timings depend on the format of the source material.

Audio controls Displays the audio speed. To preserve audio pitch, enable Preserve Pitch.

LUT controls (3D and 1D) Enables or disables the use of LUTs. You can specify a 3D LUT to use, and access the LUT editor.

Stereo controls Enables stereoscopic output settings, if a stereo track is detected. You can select a Stereo Mode option and a corresponding Method option.

Select:	To:
Anaglyph	Output the left eye and right eye as a red/cyan clip. You can reduce ghosting (Dubois), remove RGB values (Mono) or create custom anaglyph results.
Interlaced	Output the left eye and right eye as an interlaced RGB clip. You can output the left eye as field 1 or field 2.
Dual Image - Scale	Output the left eye and right eye so that they are adjacent to each other in the same clip, either in a left and right or top and bottom orientation.
Dual Image - Splice	Output the left eye and right eye so that they are side by side in the same clip. Only available when each eye track's horizontal resolution is half that of the output resolution (2 tracks at 960 for a 1920 output).
Dual Output	Output the left and right eye separately to dual streams of a tape.

Letterbox controls Enables or disables a letterbox overlay.

Start TC field Set the start timecode of the Deliverable. The start timecode is used during output, it indicates where on the tape the clip is recorded.

Previewing and Processing Material for Real-Time Output

Preview Deliverables to verify your settings. If necessary, process source clips or Deliverables before outputting in real time.

Previewing Deliverables

The real-time operations you create in the Real-Time Deliverables panel can be previewed in the Player.

To preview the result of a Deliverable in the Player:

- 1 From the Options box, select Show Real-Time Deliverables.
The Real-Time Deliverables panel will open to the right of the Player.

With this option selected, your real-time settings are displayed during playback or when you jog or scrub through the clip.

You can also preview real-time operations in the Clip Output menu. See [Outputting Deliverables](#) (page 236).

Processing Source Clips and Deliverables

The purpose of Real-Time Deliverables is to be able to output material without having to process first. However, there are exceptions where, before outputting, you must process:

- Source material that has an unrendered soft effect applied to it.
- A Deliverable whose settings place unusually high demands on hardware and cannot be output in real time.

If you open the Real-Time Deliverables panel with a clip that has an unprocessed soft effect applied to it, you can configure Deliverable settings for it, but you cannot output the Deliverable until the effect is processed. To do so, click Process in the source clip information section of the Deliverables menu.

Once you set up your Deliverable, it is possible that your hardware cannot output the Deliverable to tape in real time. The status of the GPU Benchmark button helps you decide whether to process the Deliverable.

Status:	Processing status:
Green	You can output the Deliverable in real time, without first rendering.
Yellow	You should process the Deliverable before going to Output Clip, as real-time output might not be possible.
Red	Real-time output is not possible: you must process the Deliverable before going to Output Clip.

If the GPU Benchmark button indicates that real-time output is impossible, click Process in the resize and frame rate group of the Real-Time Deliverables panel.

A new clip is created with “_<Deliverable Name>” appended to the clip name. Any settings from the Real-Time Deliverables panel are burned into the clip. Because it is a new clip, it does not have any associated Deliverables associated. But the new clip uses the start timecode of the Deliverable. Enter the Output Clip menu with the clip and output it to tape.

Outputting Deliverables

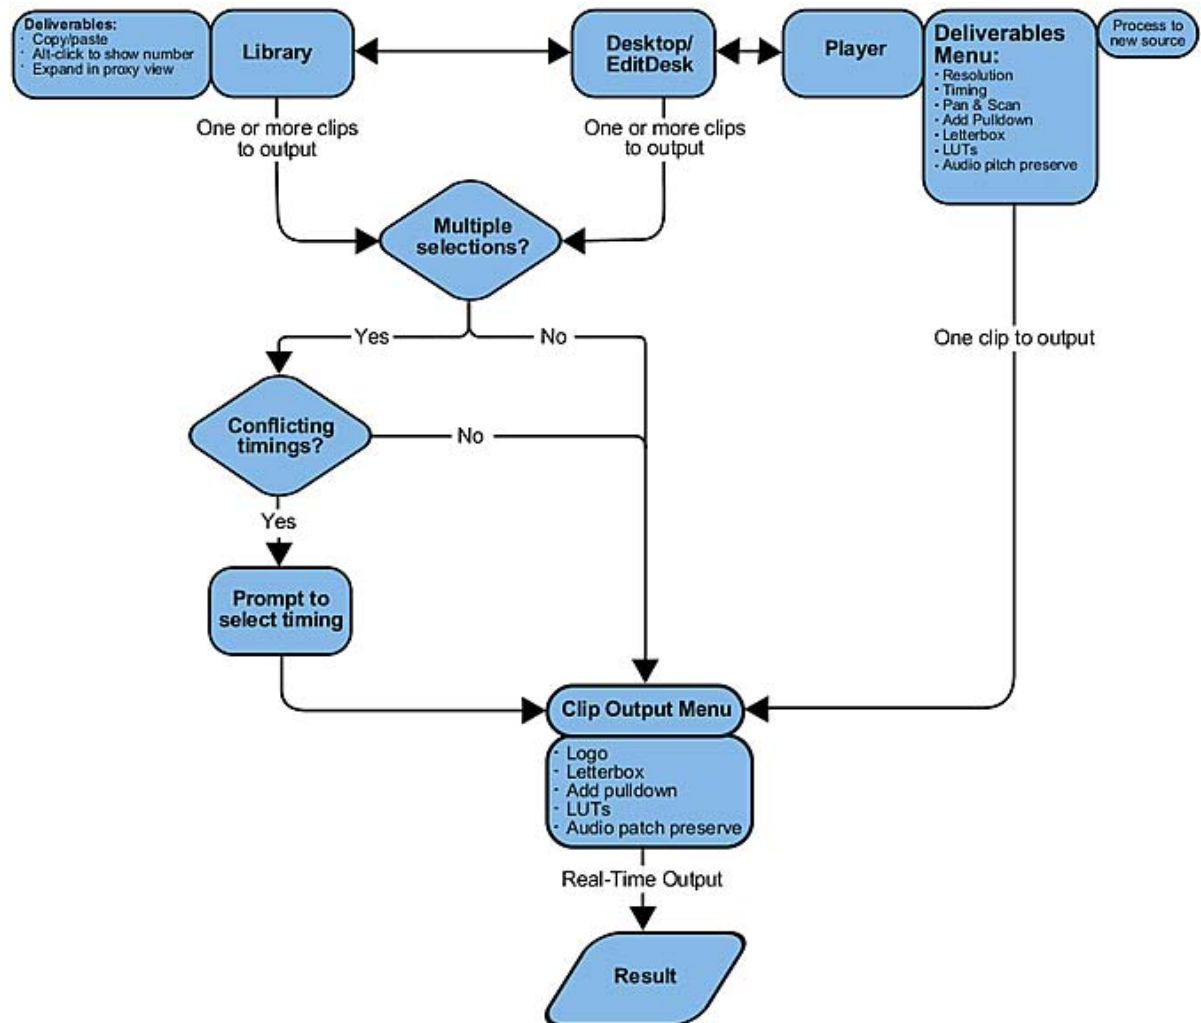

The workflow for outputting Deliverables is like the standard clip output workflow described in [Outputting Clips To a VTR](#) (page 204).

Each Deliverable that you create is treated like a clip. You can enter the Output Clip menu from the library with a Deliverable and output it to tape as you would any clip.

From the Real-Time Deliverables panel, click the Output Clip button to enter the Output Clip menu with the current Deliverable.

If you enter the Output Clip menu from the library with multiple items (clips, Deliverables, or both), the resulting behaviour is the same as when outputting multiple clips. If there are conflicting timings, you are prompted to select the timing you want to use, and items that do not match this timing are discarded. See [Outputting Multiple Clips](#) (page 209).

If you select a clip in the library to bring it into the Output Clip menu, all its Deliverables are also selected. If there are conflicting timings, you are prompted to select the timing to use. This can result in the exclusion of the original clip.

Once in the Output Clip menu, you can alter Letterbox and LUT settings in the Deliverables panel, as well as preserve audio pitch. You can also add a logo in the Logo tab, although it does not require a Deliverable.

These changes are saved to the Deliverable. The next time you work with that Deliverable in the library or Player, the changes you made in the Output Clip menu are loaded.

NOTE When you select the Real-Time Deliverables panel, you do not see the VTR feedback; instead you see the clip selected in the Output Clip list.

To create real-time settings for a clip and output to tape in real time:

- 1 From the Player, create a Deliverable. See [Accessing the Real-Time Deliverables Panel](#) (page 234).
- 2 Do one of the following:
 - From the Real-Time Deliverables panel, access the Output Clip menu.
 - From the library or Desktop, select the Deliverable or multiple clips and Deliverables, and access the Output Clip menu. If you selected multiple items and they have conflicting timings, you are prompted to select which timing you want to use.
- 3 In the Output Clip menu, make adjustments to real-time settings if necessary.
- 4 To preview real-time operations before outputting, use the Player controls in the Real-Time Deliverables panel.
- 5 Output the material to tape.

Managing Deliverables

A Deliverable results when you create real-time settings for a clip, in the Real-Time Deliverables panel. Deliverables are virtual clips associated with the original clip. You can:

- Rename or delete a Deliverable.
- Create multiple Deliverables for one clip, so that you can output many different formats of that clip.
- Save a Deliverable as a reusable Deliverable template.
- Load a Deliverable template onto another clip to apply the settings of that Deliverable to the clip.
- View information about Deliverables in the Desktop.
- Transfer clips and their Deliverables to other systems.

NOTE Any change to the frame rate (timing) or resolution of the clip deletes all Deliverables attached to that clip.

Creating and Modifying Deliverables

From the Real-Time Deliverables panel, you can create, rename, and delete Deliverables.

To create a Deliverable:

- 1 Access the Real-Time Deliverables panel, as described in [Accessing the Real-Time Deliverables Panel](#) (page 234).
- 2 From the Deliverable box, select <New Deliverable>.
- 3 Type a name for the Deliverable and press **Enter**.

Once the Deliverable is created, set up real-time operations in the Real-Time Deliverables panel. The operations you set up are automatically stored in the Deliverable you created.

You can create multiple Deliverables for a clip. If you create another Deliverable:

- The settings of the previous Deliverable are cleared from the Real-Time Deliverables panel.
- The new Deliverable name is added to the list in the Deliverables box.

To rename a Deliverable:

- 1 With the Deliverable loaded menu, click **Name**.
- 2 Type a new name for the Deliverable and press **Enter**.

To delete a Deliverable:

- 1 With the Deliverable loaded, click Delete.
- 2 Click Confirm.

The Deliverable is deleted, and the previously-loaded Deliverable (if there was one) is reloaded.

Exporting and Loading Deliverables as Templates

Use the Save and Load buttons in the Real-Time Deliverables panel to export a Deliverable as a template and load it on another clip.

You can only load a Deliverable on clips that have identical resolutions and timings with the original clip.

When you load a Deliverable template:

- Its settings are loaded to the Real-Time Deliverables panel.
- A new Deliverable is appended to the list in the Deliverables box.

Viewing Deliverables in the Desktop

Clips with Deliverables are indicated by a “D” overlay on their proxies.

There are two types of “D” overlays, each indicating the selection in the Playback Resolution box:

Grey “D” The Player displays the Deliverable. See [Previewing Deliverables](#) (page 236).

Black “D” The Player displays Proxies or Full Res.

To open the Real-Time Deliverables panel from the clip proxy on the Desktop, double-click the “D” overlay.

To see quickly a list of Deliverables for a clip, **Alt**-click the clip proxy on the Desktop.

The list of Deliverables is included in the clip information. A “D” appears beside the active Deliverable (the Deliverable most recently selected in the Real-Time Deliverables panel).

In the library, Deliverable proxies are black and include the Deliverable name. Playing the Deliverable gives you the actual deliverable result.

Transferring Deliverables to Other Systems

When a clip is transferred to an Autodesk Visual Effects and Finishing system using Wire, its Deliverables are also transferred.

If the other system does not have the hardware needed for Real-Time Deliverables, users of that system will see that the clip has Deliverables, but will not be able to edit or preview them. The Deliverables will be greyed out in the Output Clip menu.

Users on such systems will be able to work with the original clip and transfer it back to the original system, with its Deliverables intact. As usual, changes to the frame rate (timing) or resolution of the clip deletes all Deliverables attached to that clip.

You cannot export Deliverables to other file formats. You cannot use Deliverables with EDLs.

Real-Time Deliverables Timing Specifications

When you set up a Deliverable to modify the timing of a clip during real-time output, the timing is changed according to the following tables.

NOTE In the following tables, N/A stands for *not applicable* and NC stands for *no change in timing*.

Destination timings 23.967psf through 25p:

Source					Destination			
	23.967psf	23.967p	24psf	24p	PAL	50i	25psf	25p
23.967psf	N/A	NC	Speed up	Speed up	Speed up to 25 or speed up to 24 + PAL Pulldown	Speed up	Speed up	Speed up
23.967p	NC	N/A	Speed up	Speed up	Speed up to 25 or speed up to 24 + PAL Pulldown	Speed up	Speed up	Speed up
24psf	Slow down	Slow down	N/A	NC	Speed up to 25 or apply PAL Pulldown	Speed up	Speed up	Speed up
24p	Slow down	Slow down	NC	N/A	Speed up to 25 or apply PAL Pulldown	Speed up	Speed up	Speed up
PAL	Slow down	Slow down	Slow down	Slow down	N/A	NC	NC	NC
50i	Slow down	Slow down	Slow down	Slow down	NC	N/A	NC	NC
25psf	Slow down	Slow down	Slow down	Slow down	NC	NC	N/A	NC

Source					Destination			
	23.967psf	23.967p	24psf	24p	PAL	50i	25psf	25p
25p	Slow down	Slow down	Slow down	Slow down	NC	NC	NC	N/A

NOTE When going from 23.967 to PAL, you can choose between increasing the frame rate to 25 or increasing to 24 and adding PAL Pulldown. When going from 24 to PAL, you can choose between increasing the frame rate to 25 or adding PAL Pulldown.

Destination timings NTSC through 60p:

Source					Destination		
	NTSC	29.97p	30 psf	30p	60i	59.94p	60p
23.967psf	Add Pulldown	Not supported	Not supported	Not supported	Speed up to 24 + Add Pulldown	Not supported	Not supported
23.967p	Add Pulldown	Not supported	Not supported	Not supported	Speed up to 24 + Add Pulldown	Not supported	Not supported
24psf	Slow Down to 23.976 + Add Pulldown	Not supported	Not supported	Not supported	Add Pulldown	Not supported	Not supported
24p	Slow Down to 23.976 + Add Pulldown	Not supported	Not supported	Not supported	Add Pulldown	Not supported	Not supported
PAL	Slow Down to 23.976 + Add Pulldown	Not supported	Not supported	Not supported	Slow Down to 24 + Add Pulldown	Not supported	Not supported
50i	Slow Down to 23.976 + Add Pulldown	Not supported	Not supported	Not supported	Slow Down to 24 + Add Pulldown	Not supported	Not supported
25psf	Slow Down to 23.976 + Add Pulldown	Not supported	Not supported	Not supported	Slow Down to 24 + Add Pulldown	Not supported	Not supported
25p	Slow Down to 23.976 + Add Pulldown	Not supported	Not supported	Not supported	Slow Down to 24 + Add Pulldown	Not supported	Not supported
NTSC	N/A	NC	Speed up	Speed up	Speed up	Not supported	Not supported
29.97p	NC	N/A	Speed up	Speed up	Speed up	Not supported	Not supported
30 psf	Slow down	Slow down	N/A	NC	NC	Not supported	Not supported

Source					Destination		
	NTSC	29.97p	30 psf	30p	60i	59.94p	60p
30p	Slow down	Slow down	NC	N/A	NC	Not supported	Not supported
60i	Slow down	Slow down	NC	Field merge	N/A	Not supported	Not supported
59.94p	Not supported	Not supported	Not supported	Not supported	Not supported	N/A	Speed up
60p	Not supported	Not supported	Not supported	Not supported	Not supported	Slow down	N/A

Archiving in Flame Premium

8

Archiving in Flame Premium saves your media and project setups on external storage devices or in a filesystem. This frees up space for new projects. It is also a convenient way to store your projects offline in a fully restorable form.

A project archive includes all of a project's Media panel content, including the Media library, Shared libraries, Batch and Desktop snapshots, as well as all of a project's workspaces.

Or you can archive individual clips from the Media panel.

Choosing a Medium for Archiving

Choosing a medium or device for your archiving needs largely depends on your technical resources and overall needs. There are certain advantages and disadvantages to using each medium/device.

Flame can read and write archives from the following devices: file systems, VTRs, and tape drives.

Smoke can read and write archives from filesystems. While Smoke can read VTR archives, it cannot write to them.

Filesystem Archive

A filesystem archive is an archive stored on a hard disk drive, such as external USB/FireWire® (IEEE 1394) hard drives offers, or shared storage such as a SAN. The device can use any of the formats supported by your workstation, usually ext2 or ext3 for Linux, and HFS+ for Mac. NTFS is not supported.

Using a filesystem to archive your material provides the quickest method of archiving and restoring your material, which can be of any bit depth or resolution.

Tape Drives

A tape archive is an archive written directly to a device such as an LTO tape device. Tape provides fast and reliable read and write performance. And, contrary to VTR archives, tape archives can be of any bit depth or resolution.

However, data archives (tape archives) can only be restored to a Flame Premium workstation and are unreadable by other applications. Also, magnetic tape is a delicate media and is greatly affected by environmental conditions that cause its deterioration. The procedure of archiving to a tape device is similar to archiving to file.

Flame Premium only supports fibre channel tape devices connected to ports 1 or 4 of a four-port fibre channel adapter, and which the vendor confirms that:

- The device driver is compliant with standard UNIX tape device calls.
- The specific version of your operating system and kernel is supported.

The initialization file (*init.cfg*) for your Flame Premium contains examples of the ClipMgtDevice Tape keyword to help you set up the appropriate block size value for your tape device and define a text label to identify the device in the Archiving

module. Please refer to the documentation from your archiving device vendor for guidelines on the actual block size to use.

VTRs

NOTE Smoke only reads VTR archives.

You can use a VTR to archive your material. However, they do have limitations. As a long-term archiving medium, VTR tapes are subject to physical deterioration and format obsolescence. Also, the following clips cannot be archived to a VTR:

- Clips with a colour depth higher than 10-bit
- Clips referencing media, either directly or through clip history, with a resolution that does not match that of the VTR

You can use the following VTRs for archiving your material in Flame Premium:

- Uncompressed SD VTRs such as D-1 or lightly compressed SD VTRs such as Digital Betacam
- Uncompressed HD VTRs or lightly compressed HD VTRs such as Sony HDCAM SR or Panasonic HD D5
- Compressed HD VTRs such as Sony HDCAM (using "HDCAM" rather than "VTR" as the archive device type)

Archiving a Project to a File-based Archive

Archiving a project to a file archive (as opposed to a VTR tape archive) consists of opening an existing archive file, or creating a new archive file, on storage such as an external hard drive, and archiving the project to it.

To archive a project to a new archive:

- 1 In the MediaHub, enable Browse for Archives.
- 2 In the Local Devices list, navigate to the location where to store the archive.
- 3 Click New Archive.
- 4 In the New Archive Creation dialog, enter the required information and click Create.
Flame Premium creates and opens the archive.
- 5 Set as required the options displayed in the Archive Options tab.
- 6 Click Archive Project.
Flame Premium starts archiving the project. The actual duration of the archive process depends on the size of the project and on the options you enabled or disabled. To cancel the process, click anywhere on the screen; you cannot use Flame Premium while it archives your project.
- 7 Click Close Archive to finalize the archive. The project is now archived.

To add a project to an existing archive:

- 1 In the MediaHub, enable Browse for Archives.
- 2 Do one of the following:
 - In the Archives list, select the archive to which you want to add the project.
 - If you want to use an archive that is not displayed in the Archives list: open a volume displayed in the local devices and navigate to the archive. Select it.

You can recognize an archive by its icon:

- 3 Click Open Archive.
The contents of the archive are displayed in the archive browser.
- 4 Set as required the options displayed in the Archive Options tab.
- 5 Click Archive Project.
Flame Premium starts archiving the project. The actual duration of the archive process depends on the size of the project and on the options you enabled or disabled. To cancel the process, click anywhere on the screen; you cannot use Flame Premium while it archives your project.
- 6 Click Close Archive to finalize the archive. The project is now archived.

About Project Archives

You want to archive a project when you need to backup your project so that you can restore it in its entirety at a later time. A Project Archive stores all workspaces found in the project, and their contents:

- Project Setups (aka module setups)
- Desktop snapshots
- Desktop's reel and their contents
- Media Library's libraries and their contents
- Batch snapshots
- Shared Libraries

Restoring a Project from a File-based Archive

You can only perform the complete project restoration described below if the project to restore *does not* already exist on the workstation. You can see a list of all the projects in **MediaHub ► Browse for Projects ► Local Projects**.

You can delete projects from the menu **Flame Premium ► Project and User Settings**. See [To delete a project](#): (page 24).

NOTE If the project exists on your workstation and you do not want to delete it, you can always restore setups or individual clips from a Project Archive.

To restore a project from a file archive:

- 1 In the MediaHub, enable Browse for Archives.
- 2 Open the archive. Do one of the following:
 - In the Archives list, select the archive from which you want to restore the project. Click Open Archive.
 - If you want to use an archive that is not displayed in the Archives list: open a volume displayed in the local devices and navigate to the archive. Select it and click Open Archive.

You can recognize an archive by its icon:

- 3 Navigate the contents of the archive, and click the project to restore to select it.

You can recognize a project by its icon:

.

Every archived project is created in a folder named Archive Session, timestamped with the date and time when the project was archived.

4 Click Restore Project.

Flame Premium starts restoring the project. The actual duration of the archive process depends on the size of the project.

You can cancel the process at any time by clicking anywhere on the screen: you cannot use the application while Flame Premium restores your project.

Once restored, access the project through **Flame ► Project and User Settings**.

Archiving Clips to a File-based Archive

Archiving clips to a file archive (as opposed to a VTR tape archive) consists of opening an existing archive file, or creating a new archive file, on storage such as an external hard drive, and archiving contents to it.

To archive material to a new archive:

- 1 In the MediaHub, enable Browse for Archive.
- 2 In the Local Devices list, navigate to the location where to store the archive.
- 3 Click New Archive.
- 4 In the New Archive Creation dialog, enter the required information and click Create.

Flame Premium creates and opens the archive.

- 5 Set as required the options displayed in the Archive Options tab.
- 6 From the Media panel, drag and drop the clips and folders to archive to the Archive browser.

What you add to the archive appears as greyed out in the Browser, indicating that it is yet to be committed to the archive: ready to be archived, but not yet written to the archive. The Pending Archive folder can also be used as a summary of what is being archived.

NOTE In the archive information panel, the Archive Size Pending field indicates the number of clips that will be archived, and the Archive Size Total field displays the size of the archive once those clips are archived.

- 7 Click Archive to start the archiving process.

The actual duration of the archive process depends on the size of the material being archived and on the options you enabled. You cannot use the application for anything else while Flame Premium archives the material. Cancel the process at any time by clicking anywhere on the screen.

To add material to an existing archive:

- 1 In the MediaHub, enable Browse for Archive.
- 2 In the Archives list, double-click the archive to use for archiving.
- 3 Drag and drop clips and folders to archive from the Media panel to the archive.

What you add to the archive appears greyed out in the archive, indicating that it is yet to be committed to the archive: ready to be archived, but not yet copied to the archive. The Pending Archive folder can also be used as a summary of what is being archived.

NOTE In the archive information panel, the Archive Size Pending field indicates the number of clips that will be archived, and the Archive Size Total field displays the size of the archive once those clips are archived.

- 4 Click Archive to start the archiving process.

The actual duration of the archive process depends on the size of the material being archived and on the options you enabled. You cannot use the application for anything else while Flame Premium archives the material. Cancel the process at any time by clicking anywhere on the screen.

Restoring Material from a File-based Archive

To restore material from an archive:

- 1 In the MediaHub, enable Browse for Archive.
- 2 In the Archives list, double-click the archive that contains the material to restore.
- 3 Drag and drop clips and folders from the archive to the Media panel.
Material you drag and drop appears greyed out in the Media panel, and is not restored until you click Restore.
- 4 Click Restore.
The length of the restoration process depends on the size of the material being restored. You cannot use the application for anything else while Flame Premium restores the material. Cancel the process at any time by clicking anywhere in the MediaHub.

To see how much space restored items will take on your storage:

- 1 In the archive, select the items to restore.
- 2 Click the MediaHub Gear menu and select Update Selection Information.
- 3 The right of the MediaHub status bar now displays the number of frames and the space required to restore the selected items.

It also displays the archive segments that contain the selected items, and that are required to restore them.

Tips for Using Archives

Although the way you organize your archives is a matter of personal preference, the following guidelines may be helpful:

- After you have processed a clip, remove any material that you are no longer using before you create your archive.
- Try to keep your libraries clean at all times. Remove clips that are no longer being used or earlier unused versions of your work.
- Use a consistent and clear naming technique so that you can easily find your material when you want to create or open an archive.
- Consolidate clips before archiving in order to save space.
- If you want to use the workstation that archived the material as an access point for the contents of the archive: in Archive Options, set Linked Archive Options to Use Archived Path, and then restore the archived project.

TIP The path for media is displayed in the Location column in the MediaHub browser, when viewing the archive in Workspace view.

NOTE Multiple users can connect to the same file archive and restore material, projects, and settings from it. But only the first user to open it can write to it! Once that user closes the archive, someone else can open it and write to it.

Archiving When Working On-location

For projects done on remote location and which are archived without their media, it is possible to relink later the archived clips to their media files, even if the media are not in the same location.

Archive the project using the following Archive Options:

- Cache Media on Archive: disabled.
- Archive Renders box: set to Exclude Renders and Cache.

These two archive options create the smallest possible archive: it contains only the clips of the imported media files (links), and the media generated by tools such as Paint. Renderings from Timeline FX are not archived with these settings.

Restore and relink:

- 1 Restore the archived project Flame Premium.
 - If the media is stored at the path displayed in the Location column, then all the clips are automatically relinked to their media once restored. You have nothing else to do.
 - If the media is stored in a different location, then the restored clips are unlinked. Continue with this procedure.

TIP Location column is visible in the MediaHub browser, when viewing the archive using the Workspace view.

- 2 In the Media panel, right-click the sequence and clips to relink. Select **Media ► Unlink Reloadable Media**.

This deletes from the sequence the old paths that linked the clips to the media. Since the media is no longer accessible, these paths are obsolete.

- 3 Relink the clips to the media:
 - 1 Open the sequence and go to Conform tab.
 - 2 Set the Match Criteria to *File Name*.
 - 3 Click Set Search Location and navigate to the folder where you want to search from, and click Set.
 - 4 When media files are found, press Link Matched Sources.
 - 5 Your sequence is now ready to be used.

NOTE Since audio files do not have a frame rate, you need to make sure to work within a project that has the same frame rate as the original project.

Managing the Size of an Archive

While the clips are always archived in a project archive, you can decide to not include the media and Timeline FX renders to reduce the size of that archive. Batch renders and other renders, such as the result of the Paint tool, and virtual clips, are always archived in a project archive.

You need:	Archive Options Settings:		What is included in the archive:		
	Cache Media on Archive:	Archive Renders box:	Cached source media:	Uncached source media:	Timeline FX renders:
The largest, most inclusive archive.	Enabled	Include Renders	Included	Included	Included
An archive which can easily rebuild the Timeline FX renders.	Enabled	Exclude Renders	Included	Included	Excluded
An archive where media already cached and renders are all included in the archive. Uncached media are not archived.	Disabled	Include Renders and Cache	Included	Excluded	Included
An archive where renders are archived, source media are not.	Disabled	Exclude Source Media Cache	Excluded	Excluded	Included
An archive where media already cached are included in the archive. Uncached media and renders are not archived.	Disabled	Exclude Renders	Excluded	Included	Excluded
An archive where media and renders are not archived, only the clips. This is the smallest possible project archive.	Disabled	Exclude Renders and Cache	Excluded	Excluded	Excluded

Flame Premium also compresses the size of an archive by archiving a single copy of a repeated frame.

Configuring a Data Tape Device

Before you start archiving to a data tape device, configure both the hardware and the software.

Software Configuration

Before you start Flame Premium to archive, edit the following keyword in the software initialization configuration file.

- CLIPMGTDVICE: Define as many tape devices as you need; only those detected at start are actually listed in the Archives browser.

NOTE The software initialization configuration file is located here: `/usr/discreet/Flame Premium_VERSION/cfg/init.cfg`.

Hardware Configuration

Setting the Default Block Size for New Tape Archives

In **MediaHub ► Browse for Archives ► Archive Options** when you format a new tape archive, the default block size matches the value in the Block Size field.

Keep track of the block size value for each tape in case you need to reset the block size at a later time.

To verify the block size of your tape device:

- 1 In a command shell, log in as root.
- 2 Verify the block size of your tape device by typing:

```
mt -f /dev/st <archive device number> status
```

Example:

```
mt -f /dev/st0 status
```

This command provides feedback similar to the following:

```
SCSI 2 tape drive:

File number=0, block number=0, partition=0.

Tape block size 65536 bytes.

Density code 0x40 (DLT1 40 GB, or Ultrium).

Soft error count since last status=0

General status bits on (41010000):

BOT ONLINE IM_REP_EN
```

Determining the Device Number for the Archive Device

If you receive an error message when verifying the block size, you may not be using the correct archive device number. Look in the software initialization configuration file to determine the correct number.

To determine the archive device number:

- 1 In a terminal, type:
dlcfg
- 2 Look for the line that begins with the following:
`ClipMgtDeviceTape, /dev/st<archive device number>`
The archive device number should be listed on this line. If it is not, or appears to be incorrect, consult the administrator for your system.

Resetting the Block Size for an Existing Tape Archive

If you rebooted the machine or reformatted another archive with a different block size, you must reset the block size for your archive in the command shell.

To reset the block size of your tape:

- 1 In the command shell, log in as root.
- 2 Set the correct block size by typing:
mt -f /dev/st<archive device number> defblksize<block size of your tape device>

Example:

mt -f /dev/st0 defblksize 4096

The block size for your tape is reset and you can continue to archive to this tape.

Archiving a Project to a Tape Device Archive

Archiving a project to a tape device archive consists of opening an existing tape archive, or creating a tape archive using a tape device such as a DLT.

To archive a project to a blank tape:

- 1 Load the blank to the tape device.
- 2 In the MediaHub, enable Browse for Archives.
- 3 In the Local Devices list, double-click the tape device to open it.
- 4 Click Format to create a new archive.

WARNING Formatting the tape erases all data already present on it. If you want to add to an existing archive, click Open, and follow the procedure described below.

- 5 In the New Archive Creation window, enter the required information and click Create.
Flame Premium creates and opens the archive in the MediaHub. You can now archive the project.
- 6 Set as required the options displayed in the Archive Options tab.
- 7 Click Archive Project.
Flame Premium starts archiving the project. The actual duration of the archive process depends on the size of the project and on the options you enabled or disabled. To cancel the process, click anywhere on the screen; you cannot use the application for anything else while Flame Premium archives your project.
- 8 Click Close Archive to finalize the archive.

To add a project to a tape already containing an archive:

- 1 Load the tape to the tape device.
- 2 In the MediaHub, enable Browse for Archives.
- 3 In the Local Devices list, double-click the tape device to open it.
- 4 Click Open to open archive.

WARNING Do not select Format, as this would erase all data on the tape.

- 5 Click Archive Project.
Flame Premium starts archiving the project. The actual duration of the archive process depends on the size of the project and on the options you enabled or disabled. You can cancel the process at any time by clicking anywhere on the screen; you cannot use the application for anything else while Flame Premium archives your project.
- 6 Click Close Archive to finalize the archive.

Restoring a Project from a Tape Device Archive

You can only perform the complete project restoration described below if the project to restore *does not* already exist on the workstation. You can see a list of all the projects in **MediaHub > Projects > Local Projects**.

You can delete projects from **Flame Premium > Project and User Settings**.

And even if the project exists on your workstation, you can always restore manually selected clips from the project archive.

To restore a project from a tape archive:

- 1 Load the tape with the archive to the tape device.
- 2 In the MediaHub, enable Browse for Archives.
- 3 In the Local Devices list, double-click the tape device to open it and select Open.

WARNING Do not select Format, as this would erase all data on the tape.

- 4 Navigate the archive, and select the project to restore. Projects are created at the root of an archive tape.
- 5 Click Restore Project.

Flame Premium starts restoring the project. The actual duration of the archive process depends on the size of the project. You can cancel the process at any time by clicking anywhere on the screen: you cannot use the application for anything else while Flame Premium restores your project. Once restored, you can switch to the restored project using **Flame Premium > Project and User Settings**.

To restore project setups from a tape archive:

- 1 Load the tape with the archive to the tape device.
- 2 In the MediaHub, enable Browse for Archives.
- 3 In the Local Devices list, double-click the tape device and click Open.

WARNING Do not select Format, as this would erase all data on the tape.

- 4 Navigate the archive, and open the project that contains the setups to restore.
- 5 Locate and select the Project Setups folder.
- 6 Click Restore Setups.

Flame Premium starts restoring the project. The actual duration of the archive process depends on the size of the project. You can cancel the process at any time by clicking anywhere on the screen: you cannot use the application for anything else while Flame Premium restores your project. Once restored, you can switch to the restored project using **Flame Premium > Project and User Settings**.

Archiving Clips to a Tape Device Archive

Archiving material to a file archive (as opposed to a VTR tape archive) consists of opening an existing archive file, or creating a new archive file, on a DLT tape device.

To archive a project to a blank tape:

- 1 Load the blank to the tape device.
- 2 In the MediaHub, enable Browse for Archives.

- 3 In the Local Devices list, double-click the tape device to open it.
- 4 Click Format to create a new archive.

WARNING Formatting the tape erases all data already present on it. If you want to add to an existing archive, click Open, and follow the procedure described below.

- 5 In the New Archive Creation window, enter the required information and click Create.
Flame Premium creates and opens the archive in the MediaHub. You can now archive the project.
- 6 Drag and drop clips and folders to archive from the Media panel to the archive.
What you add to the archive appears greyed out in the archive, indicating that it is yet to be committed to the archive: ready to be archived, but not yet copied to the archive. The Pending Archive folder can also be used as a summary of what is being archived.

NOTE In the archive information panel, the Archive Size Pending field indicates the number of clips that will be archived, and the Archive Size Total field displays the size of the archive once those clips are archived.
- 7 Click Archive to start the archiving process.
The actual duration of the archive process depends on the size of the material being archived. You cannot use the application for anything else while Flame Premium archives the material. Cancel the process at any time by clicking anywhere on the screen.

To add clips to a tape already containing an archive:

- 1 Load the tape to the tape device.
- 2 In the MediaHub, enable Browse for Archives.
- 3 In the Local Devices list, double-click the tape device to open it.
- 4 Click Open to open archive.

WARNING Do not select Format, as this would erase all data on the tape.

- 5 Drag and drop clips and folders to archive from the Media panel to the archive.
What you add to the archive appears greyed out in the archive, indicating that it is yet to be committed to the archive: ready to be archived, but not yet copied to the archive. The Pending Archive folder can also be used as a summary of what is being archived.

NOTE In the archive information panel, the Archive Size Pending field indicates the number of clips that will be archived, and the Archive Size Total field displays the size of the archive once those clips are archived.
- 6 Click Archive to start the archiving process.
The actual duration of the archive process depends on the size of the material being archived. You cannot use the application for anything else while Flame Premium archives the material. Cancel the process at any time by clicking anywhere on the screen.

Restoring Material from a Tape Device Archive

To restore material from an archive on a tape device:

- 1 Load the tape containing the archive to the tape device.
- 2 In the MediaHub, enable Browse for Archives.
- 3 In the Local Devices list, double-click the tape device and click Open.

WARNING Do not select Format, as this would erase all data on the tape.

- 4 Drag and drop clips and folders from the archive to the Media panel.
Material you drag and drop appears greyed out in the Media panel, and is not restored until you click Restore.
- 5 Click Restore.
The length of the restoration process depends on the size of the material being restored. You cannot use the application for anything else while Flame Premium restores the material. Cancel the process at any time by clicking anywhere in the MediaHub.

To see how much space restored items will take on your storage:

- 1 In the archive, select the items to restore.
- 2 Click the MediaHub Gear menu and select Update Selection Information.
- 3 The right of the MediaHub status bar now displays the number of frames and the space required to restore the selected items.

It also displays the archive segments that contain the selected items, and that are required to restore them.

About VTR Archives

NOTE Smoke can only read VTR archives, it cannot create nor write to VTR archives.

You can create a VTR archive for clips of any resolution supported by your video board and VTR device. To archive and restore from a VTR archive, your clips FPS, resolution and bit depth need to match your VTR tape device settings.

When you change projects without exiting Flame Premium, the video timing selected at start-up applies to the project you are switching to.

Header Information Slate

All VTR archives contain a Header Info Slate, which is a single frame providing information about the archive. Located in the archive before the table of contents, the Header Info Slate provides information such as:

- Name of the archive
- Name of the Online Table of Contents (OTOC)
- Name of the workstation where the archive was created and name and version of the Autodesk application used for archive creation
- Start timecode
- Creation date and time
- Modification date and time
- Minimum size of the clip library buffer (in MB) required to restore the archive

(a) Header Info Slate example

Configuring a VTR for Archiving

Before you start archiving to a VTR, configure both the hardware and the software.

Also make sure that the video hardware and application match the FPS, resolution, and bit depth of the clips, or project, you are archiving.

Hardware Configuration

- Your VTR device is properly connected to video and audio sources and RS-422.
- The sync is properly set up.

Software Configuration

Before you start Flame Premium to archive, edit the following keywords according to the software initialization configuration file. You'll need to restart Flame Premium for these changes to take effect.

NOTE The software initialization configuration file is located here: */usr/discreet/Flame Premium_VERSION/cfg/init.cfg*.

- VTR section: Enable every VTR that you plan to use, either as an archive device or as a regular VTR.
- VIDEO: Enter the video card used by the workstation.
- CLIPMGTDVICE: Make sure there is a defined VTR unless you plan on using an HDCAM VTR to restore archives, in which case you would select HDCAM. For HDCAM SR, you must select VTR. Note that CLIPMGTDVICE can define more than just VTR, it can also list File and Tape: they are not mutually exclusive.

NOTE You can only restore an HDCAM-created archive by using an HDCAM VTR.

Creating a New VTR Archive

Before archiving to VTR, do the following:

- 1 Prepare striped tapes for each resolution.
The tapes must be striped continuous non-drop-frame timecode.
- 2 If the tapes already have material on them, figure out the start timecode for the archive.
- 3 Determine if your archive requires multiple tapes.
- 4 Make sure your VTR is in TC (Timecode) timer mode.
If you are working with an HD board and you selected the 1920x1080 video timing option in the Video Timing box when you started your project, you should specify the exact 1080 line video timing (including framerate) that you are using in the 1080 Video Timing box in the Engineering menu.

To create a VTR archive:

- 1 Insert a striped tape with continuous non-drop-frame timecode in the VTR.
- 2 In Flame, select **MediaHub ► Browse for Archives**.
- 3 Select the VTR from the list of Local Devices.
- 4 Optional: Click Engineering and set Engineering options, and then return to the MediaHub.

NOTE When you open an archive in read/write mode, play delay and pre- and postroll values are verified and set in the auto test run before archiving begins. Therefore, you do not need to set these options.

- 5 Click New Archive and enter the required information.

NOTE If you create the archive on a tape that already contains material, make sure you define the length of the archive as the space you want the archive to use, not the length of the tape.

- 6 Click Format to ready the tape to receive the contents you will archive.
The new archive is created on the VTR tape and opens automatically in the MediaHub.
- 7 Drag and drop clips from the Media Panel to the archive, or click Archive Project to archive the whole project.
- 8 Click Close Archive to commit the clips and files to tape.

TIP Write down the archive name and creation date on the tape label. This will help you to locate the appropriate table of contents file if you need to restore your archive.

About the Listed VTR

Only those VTRs with a timing that matches the video timing are available for use in the MediaHub. When you want to archive or restore clips of multiple resolutions in one project, enable the VTR lines in the VTR keyword of the configuration file for all the resolutions you use on the project. This way, each time you change the video timing for archiving, the compatible VTR is available in MediaHub.

When you archive to a VTR, only clips with a resolution compatible with the selected VTR device are archived. If you select a set of clips of differing resolutions, only the compatible clips are archived. Clips that are not compatible are greyed out in the library.

VTR Archives and Mixed Resolutions

Generally, archiving to data tape or filesystem is easier for archiving mixed-resolution projects, as clips of any resolution can be archived on the same medium.

While it is possible to archive mixed resolutions projects to a VTR, it will require different tapes with timings matching each segment resolution. Alternatively, you can use the Unlink tool to unlink media from clips of any resolution, archive unlinked clips, and then relink the media at restore time.

NOTE Before starting to archive a mixed-resolution project to a VTR, make sure you have enough tapes matching each resolution used in your project.

Archiving Clips Containing Sources with Different Bit Depths

If you want to archive a clip that contains sources with different bit depths, archive the clip to file or data tape. To archive the clip to a VTR, you must convert all sources to the same bit depth (less than 12).

8- and 10-bit VTR Archiving

A VTR archive can contain 8- or 10-bit clips—although all clips in the archive must have the same bit depth. When archiving 8-bit material to 8- or 10-bit VTRs, the clip metadata remains in an 8-bit format.

You can archive 10-bit material to 8- or 10-bit VTRs. However, when archiving 10-bit material to an 8-bit VTR, you reduce the quality of the archived material. A warning message appears notifying you of the downgrade. 10-bit clips archived to 8-bit format are flagged as such in the archive. Similarly, when archiving 12-bit material to 8- and 10-bit VTRs, a warning message appears, and the 12-bit clips are flagged in the archive. You cannot restore downgraded clips to their original bit depth.

Before archiving to any device in Flame Premium, you can perform archive size estimation. Before proceeding, make sure you have enough tapes ready. You can perform size estimation before archiving to a filesystem to make sure you have enough space on disk.

About Using an HDCAM SR for Archiving

The HDCAM SR device supports 4:2:2 and 4:4:4 archiving. The options required in the Engineering menu are as follows.

Input and Output Connection	Colourspace
In Serial 4:2:2 / Out Serial 4:2:2	YCrCb-->RGB
In Serial Dual 4:4:4 / Out serial Dual 4:4:4	No Conversion

When you switch between 4:2:2 and 4:4:4 options, the Colourspace option changes automatically to ensure the proper settings.

Archiving to a VTR Tape Containing Material

You can create a VTR archive on a tape that already contains material or add material to an archive on a tape. For example, on a 60-minute tape, you could allocate 20 minutes to an archive by setting its start timecode at 01:00:00:00 and defining the length of the archive as 20 minutes in the Length field. You can then add any material, starting after 01:20:00:00.

Restoring Material from a VTR Archive

NOTE When you open a VTR archive in read/write mode, Flame Premium performs an auto-test. The auto-test involves checking whether it can write, read, and verify the integrity of the archived material. This auto-test also scans binary and play/record delay information to verify the quality and accuracy of the video signal.

- 1 Insert the archive tape in the VTR.
- 2 In Flame Premium, select **MediaHub ► Browse for Archives**.
- 3 Select the VTR from the list of Local Devices.
- 4 Select the start timecode by doing one of the following:
 - Select Autostart if you selected this option when you created the archive (the archive rewinds the tape to find the correct start timecode).
 - Select Manual Start and enter the appropriate timecode if you selected this option when you created the archive.

5 Do one of the following:

- Click Open Archive. Select Open Read/Write or Open Read Only from the Open Mode box.

NOTE When you try to open a VTR archive in read/write mode, Flame Premium checks for machine errors (for example, dirty heads). If a problem is detected, the archive does not open. If the tape is write-protected, the archive opens in read-only mode.

- Click the Open Using OTOC button and select the OTOC in the file browser. You are given the option to read slates from the tape. Answer 'Y' if you wish to see clip proxies.

The Flame Premium cues the VTR. Once it's done reading the archive, displays its contents in the MediaHub.

- 6 Restore clips one by one using drag and drop, or click Restore Project to restore a full project.
- 7 Click Close Archive once you are done.

VTR Archiving Tips

Troubleshooting

The following tips may help avoid some common VTR archiving problems:

- Do not attempt to archive material captured with Headroom as the Output mode. Such material cannot be archived.
- Check the scan mode of Flame Premium and make it consistent with your VTR and VCP settings. Use the F1 Scan mode in the Engineering menu. You cannot create an archive on a VTR when the Scan Mode option in the Engineering menu is set to F2.
- Archives must be written to tapes striped with non-drop-frame timecode. However, media with drop-frame timecode can be written to non-drop-frame timecode tapes, as long as the framerate of the timecodes match.

Tips for Better VTR Archiving

Use the following tips to get better results when archiving to a VTR tape:

- Make sure the input from the computer to the VTR is connected properly. If it is not, yet the output from the VTR to the computer is correct, everything will appear normal when archiving and the monitor will show your material being saved. However, black or random noise is actually being saved to tape.
- Turn the video breakout box on *before* powering up the computer.
- On the video breakout box, make sure that your house sync is connected to the Sync Genlock and *not* to the Sync port in the GBRA/YUVA component. The sync should be connected to the Genlock input of the computer and be terminated with a 75-ohm terminator.
- Set the system reference of the VTR to External Analog.
- Track the VTR to get the best RF (Reference) value and error-rate level. If your VTR has an auto-tracking feature, disable it and track manually, or place it on “one shot.”
- Check the following Engineering menu settings:
 - Timecode type: Make sure the VITC & LTC timecodes are the same. If they are not, set timecode type to LTC.
 - Input format and sync: Make sure that input format and sync match the device.
 - Output format and sync: “House” is the recommended output sync.
 - The required Scan Mode option is F1.

Archiving to Multiple Volumes

If the items you select for archiving exceed the capacity of the archiving device, Flame Premium splits the archive across multiple devices of the same type. The splitting of archives is seamless and virtually transparent to the archiving process.

The procedure for creating a multiple tape archive (an archive that is too large for a single tape) is almost the same as for creating an archive on a single tape. If the entries selected for archiving exceed the capacity of the tape, a message appears indicating that the archive requires multiple tapes. The archiving process begins for the first tape. When the first tape is full, you are prompted to insert a second tape. Insert and format this tape and continue with the archiving. This process continues for as many tapes as are required.

Opening Multi-Tape Archives

When creating large archives, you can use multiple volumes to store one archive. By splitting the contents of one archive onto separate tapes, you can keep similar types of material together in the same archive.

You can open material on any tape in a multiple tape archive but you need the last tape in the multiple tape archive sequence. The last tape contains necessary header information for locating the material you want to restore.

To open material from a multi-tape archive:

- 1 Insert the last tape in the VTR or tape device.
- 2 In the MediaHub, browse for Archives.
- 3 Select the VTR or tape device from the list of Local Devices.
- 4 Click Open Archive.
- 5 Follow the instruction.

You can now restore a project or any part of the archived material.

Supplementing Archives with System Drive Backups

The recommended backup strategy for your Flame Premium workstation is to archive project media and setups to an archive that can be saved to a remote file server or storage device. Do this as often as necessary to protect your media from storage or system failure.

The archiving approach, however, does not protect the data contained on your workstation's system drive. The system drive should not contain any media data, but it does include important project management data. In the event of hardware failure without a system drive backup, you will need to recreate this project data for each archive you restore. This can be a time-consuming and frustrating process, and is a significant issue in large SAN environments, where large quantities of media files are referenced from a shared standard FS volume. In such environments, consider using the data backup method of your choice to save key system drive information. This will facilitate restoration of multiple project archives.

Even with a system drive backup, you will still need to reinstall your software and restore archived projects in the event of a system drive failure.

There are several methods and commercial tools available for backing up system drives. Choose the method and tool that is right for you. Autodesk does not recommend any particular method or tool, and only presents

the directories of note that you should consider backing up. Depending on your requirements and available tools, you may decide to back up your full system drive or only the following critical files or directories.

File/directory	Purpose	Consequence of failure if system drive is not backed up
/usr/discreet/clip	Contains all clip metadata.	Metadata will have to be recreated for each valid archive that is restored.
/usr/discreet/project	Contains full project structures, including settings such as names, resolutions, user information, and so on.	Project settings will have to be recreated for each valid archive that is restored.
/usr/discreet/sw/swdb	Contains the standard FS links database.	Media on a shared SAN volume will have to be re-imported.
/usr/discreet/sw	Contains all Stone® and Wire software and configuration files, including the preceding directory, swdb.	Storage and Wire settings will have to be reconfigured after installation.
/usr/discreet	Contains your product software, as well as all other directories described in this table.	See consequences for all previous items. Back up this directory if you want to be sure to restore all critical data, and do not mind including some superfluous files (such as old unused versions of the application.)

Browsing an Archive Offline

Each archive includes a header file, which is located at the beginning of the archive and contains the metadata necessary for properly restoring the archive. When you create an archive, two versions of the same table of contents are created: one as an ASCII file, and another as an HTML one. Created by default in

/usr/discreet/archive, and displayed in the list of Archives in **MediaHub ► Browse for Archives**, they can be used in cases where the header information becomes corrupted.

You can view the table of contents with the ASCII or HTML TOC.

To view the contents of an archive using its HTML TOC:

- 1 Open **MediaHub ► Browse for Archives**.
- 2 Select the archive you want to view from the the Archives list.
- 3 Click View Content.

A Web browser opens the HTML TOC, allowing you to browse the contents of the archive without actually opening it.

To view contents of an archive using its ASCII TOC:

- 1 Open the ASCII version of the table of contents using a text editor to view the contents of an archive without opening it. ASCII TOC filenames have the following format:

<archive name>_<creation date>.atoc

Code	Meaning
P	Project
S	Project setups
W	Workspace or Shared folder
X	Desktop snapshots
L	Folder
R	Reel
C	Clip
E	Source clip
M	Media library
B	Batch snapshots
F	Snapshot folder
D	Desktop

Online Tables of Contents

The table of contents lists the contents of the archive, as well as information such as the order in which clips are assembled on the archive, clip IDs, transitions, and timecodes. When you restore an archive with the table of contents, Flame Premium uses this information to restore the material.

A copy of the table of contents is saved in the filesystem. This copy is referred to as the Online Table of Contents (OTOC). You can open an archive in read-only mode using the OTOC. In read-only mode, you can load but not save or delete entries from the archive. With VTR archives, you can open an archive in read-write mode using the OTOC, and save and delete entries from the archive.

The OTOC is useful for:

- Recovering material in an archive when the table of contents on the medium is corrupted.
- Viewing the contents of an archive without opening it, which is often faster than actually opening the archive.

When an OTOC is created, Flame Premium creates an ASCII text copy of it (ATOC) as well as an HTML and XML copy. Use the ASCII and HTML copies to view the contents of an archive without opening it. For example, use them to view the contents of a VTR archive without connecting to the VTR.

Use the XML TOC to easily populate a database with information about your archives.

The OTOC, ATOC, HTML, and XML table of contents are saved by default to `/usr/discreet/archive`. Or define the location by adding the following token to the `init.cfg` file:

ArchiveLibrary<directory>

where <directory> is the location for storing your archives.

The OTOC is updated each time you close the archive.

Deleting Tables of Contents

To prevent the loss of important data, Flame Premium never overwrites the previously created tables of contents. If the archive becomes obsolete or if you are sure that older versions of an archive OTOCs are obsolete, you can delete tables of contents. The following name formats are used for the tables of contents.

Type	Format
Online (two files)	<code><archive name>_<creation date>.otoc</code> <code><archive name>_<creation date>.otocx</code>
ASCII	<code><archive name>_<creation date>.atoc</code>
XML	<code><archive name>_<creation_date>.xml</code>
HTML (two or more files)	<code><archive name>_<creation_date>.html</code> <code><archive name>_<creation_date>/*</code>

where <archive name> is the name that you type in the Name field when you create the archive.

Recovering a Corrupted Archive

If the table of contents of an archive on tape is corrupted, Flame Premium may not be able to read it. If this happens, open the archive using the OTOC.

Once you open the archive, you can restore the entire contents of the archive and save it to a new tape. Do this, for example, if the tape has been damaged.

For VTR archives, you can also overwrite the corrupted table of contents by saving a single frame to the archive. If the table of contents is successfully overwritten, you can open the archive using the Open button.

To restore the archive:

- 1 Open the archive.
If the table of contents is corrupted, the following message appears:
`CLIP MGT: Warning! Cannot read archive header. Select online TOC?`
- 2 Click Confirm to open the OTOC.
The file browser appears.
- 3 Select the OTOC for the archive you are trying to open and click Confirm.
- 4 If the archive is on a VTR, a prompt asks if you wish to retrieve the slates (proxies).
After a moment, the archive appears.

NOTE When you open an archive with the OTOC, proxies only appear if the archive is on a VTR, and you answered Yes to the prompt. For all other types of archives, proxies appear as black images.

- 5 Select the entire contents of the archive. Make sure you have sufficient space on your storage for the contents of the archive.
- 6 Click Restore.
- 7 When the restore is complete, click Close.
The restored clips appear in the selected clip library.
- 8 Re-archive the material onto a new tape.

VTR Only: To overwrite a corrupted table of contents:

- 1 Open the archive.
If the table of contents is corrupted, the following message appears:
`CLIP MGT: Warning! Cannot read archive header. Select online TOC?`
- 2 Click Confirm to open the OTOC.
The file browser appears.
- 3 Select the OTOC for the archive you are trying to open and click Confirm.
A prompt asks if you wish to retrieve the slates (proxies).
- 4 Click Y to see proxies in the archive or N to have no proxy images.
After a moment, the archive appears.
- 5 From the Library Type box, select a clip library.
- 6 Select a reel entry by **Alt**-clicking the reel and then click Archive.

NOTE When you select a reel, no media is appended to the archive but the header is still forced to update.
- 7 Click Close to close the archive.
- 8 Click Open to open the archive.
If the archive still does not open using the table of contents on the tape, restore the entire archive.

Restoring Legacy Archives

In earlier versions of Inferno, Flame, and Smoke, archives did not include all the metadata that the current version needs to restore archives with the correct scan mode and aspect ratio. The Default Resolutions menu makes it possible to assign the scan mode and aspect ratio preferences to older archives. The information you need to assign depends on the software version in which the archive was created. Assign the information using the Default Resolutions menu. Use the following table to determine which information you need to assign to your old archive.

Archived clips prior to:	Information you must assign:
Smoke 6.0, Fire® 6.0, Inferno 5.5, Flame 8.5, Flint 8.5, and Backdraft 5.5	Scan mode
Smoke 5.2, Fire 5.2, Inferno 5.0, Flame 8.0, Flint 8.0, and Backdraft 5.0	Scan mode and aspect ratio

The parameters listed in the Default Resolutions menu act as default values for all listed resolutions. For example, if you want to change the default values for PAL clips, you must change the values for the PAL

entry, which is the entry that has a width value of 720 and a height value of 576. If you are working with a PAL archive created in an earlier version, the aspect ratio would have automatically been set to 1.3333, but you may want to restore all your PAL archives with 16:9 aspect ratio. You can change this setting by changing the aspect ratio to 16:9 for the PAL entry.

NOTE You should only restore an old clip at its original resolution. If you restore versions of the same clip at different resolutions, you may encounter problems with the clip.

To add a default resolution:

- 1 In the MediaHub, browse for Archives and click Default Resolutions.
The Default Resolutions list and menu are displayed.

Width ▾	Height ▾	Aspect Ratio	Scan Mode	Frame Rate
640	480	1.333333	P	Undefined fps
720	486	1.333330	F1	29.97 fps
720	576	1.333333	F1	25 fps
1280	720	1.777778	P	59.94 fps
1828	1332	1.372372	P	24 fps

(a) Add Resolution box (b) Apply Changes button (c) Width and Height fields

(d) Aspect Ratio field (e) Aspect Ratio box (f) Scan Mode box (g) Framerate box

- 2 Add new preferences to correspond to a specific clip resolution contained in the archive that you plan to open.
- 3 Click Add Resolution.
- 4 Click Apply Changes.
The new archive preference is added to the list. The next time you restore an archive missing either Scan mode or aspect ratio, Flame Premium knows how to process that material.

TIP When you decide to open a VTR legacy archive, set the Open Mode box to Open Read Only to keep you from mixing new content with the old.

Restoring Pre-2013 Extension 1 Flame Projects

On Flame Reactor configurations, using Project Restore restores every project as a Flame Reactor-enabled project, even if that project did not use Flame Reactor originally (as is that case with every pre-2013 extension 1 projects). Due to differences in rendering engines, you might want to the restored project to use the Classic Engine instead of the newer Flame Reactor.

To switch back to the old Classic Engine:

- 1 Quit Flame and restart.

- 2 From the Project box, select the restored project.
- 3 Click the Edit Project button.
- 4 From the Rendering box, select Classic Engine, and then click Done.
- 5 Click Start.

Deleting Content from an Archive

To ensure data integrity and prevent archive corruption, you cannot delete entries from an archive.

MediaHub Reference: Browsing for Archives

Archives Options

With No Opened Archive

New Archive button Creates a new archive in the location displayed in the file browser. Opens the New Archive Creation dialogue box.

View Content button Displays basic information about the contents of the selected archive, in a web browser. This does not open the archive.

Open Archive button Opens the selected archive or device.

With an Opened Archive

Close Archive button Closes the archive and returns to the file browser.

Archive Project button Adds the current project to the archive; this includes every Workspace of the project, Shared Folders, as well as Batch and Desktop; also includes all the setups.

Clear Pending Tasks button Clears the Pending Archive or Pending Restore folders. This does not delete material already archived or in the Media panel: it only clears out the queue.

Archive/Restore button Commits the Pending folders, either to archive or restore material clips. Nothing is archived or restored until you click this button.

The folder Pending Restore displays all that will be restored. The folder Pending Archive displays all that will be archived. Only one operation is permitted at any given time: you either restore or archive, you cannot do both simultaneously.

Archive/Restore Setups button Click to archive or restore all of the application's modules setups. You must be at the root of the archive to archive setups. You must select a Projects Setup folder to restore setups.

File-based Archive Options

Linked Archive Option box Select how archive paths are treated when restoring an archive. Use Archived Path is best used when you are restoring the archive on the workstation used to create the archive. Select Convert to Local Path in other cases.

Archive Verification box Verify Source Media checks the integrity of the source media before adding it to the archive. In case of missing source media, the archive proceeds without the clip. Verify Archived Data checks the integrity of the data as it is being written to the archive: archiving stops as soon as it detects an error.

Verify Source Media validates all the media, which can be time consuming.

The Archived column from the Details view of the Media Panel displays either the last time the clip was successfully archived, or why it failed to archive.

Cache Media on Archive button Enable to archive all source media as cached source media. This means that all media is cached in the archive in an uncompressed format. Use the Archive Renders box to decide whether or not to archive Timeline FX renders. Disable to archive already cached source media, but to archive only links for source media that are not already cached. In this case, use Archive Renders to decide how to handle Timeline FX renders and already cached media.

Archive Renders box With Cache Media on Archive enabled, select whether or not to archive the Timeline FX renders. With Cache Media on Archive disabled, select how to handle both the Timeline FX renders and the already cached source media.

Default Resolutions button Legacy option. Opens the Default Resolutions List menu, used by the application to restore legacy archives from Smoke 6.0 and Flame 8.5 (or earlier).

These versions did not store resolutions and associated pixel aspect ratios, and the Default Resolutions table fills that gap.

VTR Device Options

Auto/Manual Start box Select Auto Start to have the application rewind the tape and then go forward to try and discover the location of an archive. Select Manual to enter the start timecode and get to the archive faster.

Timecode field Displays the start timecode. Editable.

Rewind On Close button Rewinds the tape after when the archive is closed.

Open Mode box Select whether to open in read only mode or in read/write mode.

Playing Back Media

9

Playback

Quick Access to the Players

You can quickly access the players by the following shortcuts:

- Esc: Player for selected clip.
- Ctrl-Esc: Fullscreen player.
- Ctrl-1: Player view.
- Ctrl-2: Source-Sequence player.
- Ctrl-3: Triptych player.

The shortcut opens the players from the Workspace panel, the Thumbnail view, the Reels view, the Source-Sequence view, and the Triptych player. When re-applied, the shortcuts return to the previously selected view.

NOTE Use of Esc does not bring the user to the Player when used from the Fullscreen player.

Playing Back Clips in the Full Screen Player

To play back clips in the full screen player:

- 1 Click the Timeline tab.
- 2 Do one of the following to select the Player:
 - Click the Layout button and select Player.
 - If you've enabled Layout Selection Overlay in the preferences, swipe the right swipe bar, then select Player.
 - Double-click on the clip in the media library.

The clip appears in the Player viewer.

- 3 Click the Full Screen button.

The player displays as a full screen.

To return to the previous display size, click the Full Screen button.

NOTE While in the Full Screen Player, the Player Option Box lists Show Play Reel. This is the only viewer that provides this option. Selecting this option will open up a scrolling clip list of available clips under the control bar.

Jogging and Panning a Clip

You can pan and zoom in the player, tryptich and source sequence viewport. By selecting the Viewing Mode button you can select the Zoom or Pan pointers.

- The Zoom pointer increases the zoom of the clip with a left-to-right motion, and will decrease the zoom in a right-to-left motion.
- The Pan pointer lets you grab the clip and move it around the viewer.

NOTE The pan and zoom values of the players are kept until a clip from a different resolution is loaded; you can change the clip selection without losing the pan and zoom values as long as the clip resolution is maintained. If changing to a clip of a different resolution, the clip will be resized into the viewer.

To jog through a clip:

- 1 You can jog through a clip by doing one of the following:
 - Drag the positioner along the timebar.

When you jog through an edit sequence (a series of clips edited together), you can constrain the jogging to the current clip in the sequence by holding down Command while jogging.
 - Use the arrow keys on your keyboard.

By default, pressing the left arrow and right arrow keys steps frame-by-frame.
 - Place the pointer in the viewer, above the control bar.

The cursor will change to indicate it can jog/shuttle the clip. The further from the center of the clip the cursor is placed, the faster the shuttling.

Switching the Playback Focus between the Source and Sequence Clips

You can switch the focus between the source and sequence viewers by clicking on either of the Source-Sequence viewers, by selecting a track on the timeline, or by selecting the green (source) or red (sequence) tabs above the Player, Source-Sequence, or Triptych viewers.

Clicking the Lock icon that appears when the pointer is hovering over the source-or-sequence tab will lock the focus on that tab. Clicking again unlocks the viewer.

NOTE Changing the focus through the timeline will also switch the focus between the Source and Sequence viewers. Changing the focus through the Source-Sequence viewer, however, will not change the focus in the timeline. In other words, the player doesn't drive the timeline, but the timeline drives the player.

To switch the playback focus between the source and sequence clips in the Source-Sequence Player:

- 1 Click the Timeline tab.

- 2 Do one of the following to select the Source-Sequence Player:
 - Click the Layout button and select Source-Sequence Player.
 - If you've enabled swipe in the preferences, swipe the right swipe bar, then select Source-Sequence Player.
- 3 Switch viewers by clicking in either the Source or Sequence viewer, or on the green (Source) or red (Sequence) tab.

The viewer with the focus has a white outline.

Comparing Three Shots in the Triptych Player

The triptych player provides three players, side-by-side, which you can use to simultaneously view the same clip in different contexts. For example, you can set the middle player to play the clip, the left player to show the clip's incoming frame of the current element in the timeline, and the right player to show the clip's outgoing frame.

To compare three shots in the triptych player:

- 1 Click the Timeline tab.
- 2 Do one of the following to select the Triptych Player:
 - Click the Layout button and select Triptych Player.
 - If you've enabled swipe in the preferences, swipe the right swipe bar, then select Triptych Player.
- 3 Select a clip from the Media Library.

The clip appears in the triptych player in all three viewers.

The default positions for the positioner is the start of the clip for the first viewer, the middle of the clip for the middle viewer, and the end of the clip for the last viewer. You can scrub each of the viewers independently of each other.

Play Back Speed Indicators

As you play clips, the positioner in the image window time bar changes colours if frames are dropped. The colours indicate the following:

Colour:	Indicates:
Yellow	Real-time playback with no dropped frames.
Orange	Real-time playback with no dropped frames of soft-imported clips.
Green/Blue	Alternating dropped frames. Green indicates the first and subsequent alternating dropped frame.
Red/White	Alternating occurrences of dropped audio. Red indicates the first occurrence.

Comparing Tracks in Split Screen

Use the split screen to compare two tracks, such as an online and offline version. Generally this is used to compare a rough cut to the final assembly. By merging both tracks into a single image, you can compare the two for editing synchronization, color matching, etc.

The split screen compares versions as well as video tracks.

To compare tracks in split screen:

- 1 Click the Timeline tab.
- 2 [Set the Primary and Secondary tracks.](#) (page 308)
- 3 In the View Area menu bar, select Options.
- 4 Select Show Viewing Settings.
- 5 Select the split you will use to compare the two clips in the Compare Mode/Stereo section.

Depending on the split, you will have different attributes available to change the partition between the two clips. Modify the values in these attributes to provide the best comparison.

You can now compare the two tracks on the split-screen.

Creating a Subclip in the Player

You can create subclips anywhere that you have access to the source clip (i.e. Thumbnail, Player, Triptych and Source-Sequence viewers).

NOTE Remember you will need handles for trimming and effects that you apply later. It is recommended to cue the tape a couple of seconds before the desired footage starts.

To create a subclip in the player:

- 1 Click the Timeline tab.
- 2 Set the positioner to the in point.
- 3 Click the In button.
The start of the sub-clip is marked.
- 4 Set the positioner to the end point.
- 5 Click the Out button.
The end of the sub-clip is marked.
The section of the clip that is between the In and Out marks is the sub-clip.
- 6 From the Clip menu, select Create Subclip.
The subclip is created as a new clip in the Media library. It has the original name and append ("_Subclip_") with an incremented number, starting with ("001").

Accessing Clip Information

Any viewer contains the following information located at the bottom right corner of the viewer:

- Name of the viewer OR name of the clip,
- Resolution and aspect ratio of the clip,
- LUT information of the clip (if LUT has been set).

Also, by alt-clicking on a clip proxy you will see additional clip information detail

Cue Marks

Adding Cue Marks

Cue marks are displayed in the player timebar, as well as the timeline.

To add a cue mark:

- 1 In the timebar, do one of the following:
 - Drag the yellow positioner to the desired frame, or
 - Click on the desired frame on the time bar.
- 2 Click the Cue Mark button.

A cue mark is placed in the player timebar, as well as the timeline, to indicate the marked frame. You can change the colour of a cue mark by clicking the colour pot.

To delete a cue mark:

- 1 Click the Timeline tab.
- 2 Select the specific cue mark to be deleted.
- 3 From the Timeline Gear menu, select **Marks ► Delete Selected Markers**.

Adding In and Out Marks

In and out marks are displayed in the player timebar, as well as the timeline.

To add in and out marks in the player:

- 1 In the timebar, do one of the following:
 - Drag the yellow positioner to the desired frame, or
 - Click on the desired frame on the timebar.
- 2 Click the In or Out button.

TIP Press `Ctrl` and click the In or Out button to delete the mark.

Navigating between Marks in the Clip

To navigate between marks in the clip:

- 1 Click the Timeline tab.
- 2 From the Timeline Gear menu, select a Go To option:
 - In Mark or Out Mark
 - For a cue mark, select the mark's label from the Mark list.

The positioner is set to the mark.

Changing the Color of Cue Marks in the Clip

You can set the color of the current Player cue mark to one of your preference.

NOTE To cancel the color selection, click on the Close (x) button in the Color Picker window.

The Color Picker window will close and the color swath will revert to the previous color.

To change the color of cue marks:

- 1 Click the Timeline tab.
- 2 On the View Area menu bar, click on the color swatch to the right of the Mark button.
A Color Picker window appears.
- 3 Do one of the following:
 - Click the Pick button.
The cursor changes to a color picker, which you can use to select a color from one of the three color columns.
 - Drag the colour sliders.
- 4 Click Ok to apply the color to this and any future cue marks.
The color swatch changes to reflect the color selected.

Playback Options

Setting up the Image Display Viewer in the Tools

To set up the image display viewer in the tools:

- 1 Click the View button.
- 2 Modify the display attributes.
The viewer updates the display with your changes.

Setting up the Image Display Viewer in the Player

You can change the display of an image based on the exposure and contrast settings, as well as the type of image data you are working with. By default, all images are displayed in RGB mode with a transformation for video images. You can apply transformations to the image to display an optimal view of logarithmic and linear images.

By modifying the display attributes in Viewing Settings, you can change the way the clip is displayed in the player. Settings are persistent throughout different Player modes, depending on the timeline tab type (Source or Sequence).

NOTE In the case of the Triptych Player, the middle image window shares this persistency; while the left and right image windows each can have their own settings.

To set up the image display viewer in the player:

- 1 Click the Timeline tab.

- 2 Select the Player.
- 3 In the View Area menu bar, select Options.
- 4 Select Show Viewing Settings.
- 5 Modify the display attributes.
The viewer updates the display with your changes.

Viewing Image Overlays in the Tools

To view image overlays in the Tools:

- 1 Click the Grid button.
- 2 Set your preference for overlay attributes.
The new overlay attributes are set.

Viewing Image Overlays in the Player

To view image overlays in the player:

- 1 Click the Timeline tab.
- 2 Select the Player.
- 3 In the View Area menu bar, select Options.
- 4 Select Show Overlays.
- 5 Set your preference for overlay attributes.
The new overlay attributes are set.

Modifying Exposure and Contrast in the Image Display

You can modify the overall brightness of images displayed on the workstation or broadcast monitor, as well as the contrast between light and dark colours. Note that these settings affect only the display, and do not modify the underlying colour values of the clips.

To modify exposure and contrast interactively in an image window

- 1 Click in an image window to make it active.
- 2 Do any of the following:
 - Press and hold Shift+E while clicking and dragging the mouse to modify the exposure offset (overall brightness). Dragging to the right increases values and dragging to the left decreases them.
 - Press and hold Shift+C while clicking and dragging the mouse to modify the contrast between light and dark colours.
 - Click Reset to restore the default values.

To modify exposure and contrast using the Image Display settings

- 1 Access the Image Display Viewer settings.
- 2 Do either of the following:
 - Edit the Exposure slider to modify overall brightness.
 - Edit the Contrast slider to modify the contrast between light and dark colours.

NOTE If you have applied a colour transform to the display, then you cannot modify the exposure and contrast unless there is a dynamic ExposureContrast operator in the CTF file.

Enabling Aspect Ratio Display in the Player

When you work with clips that have a resolution that does not use square pixels, such as NTSC or PAL, you can adjust the display so that it appears with the correct aspect ratio. By default, the adjusted image is sent to the broadcast monitor. You can switch the adjusted display from the broadcast monitor to the Player.

To enable the aspect ratio display in the Player:

- 1 Click the Timeline tab.
- 2 In the View Area menu bar, select Options.
- 3 Select Show Viewing Settings.
- 4 Enable the Use Ratio button.

NOTE The Use Ratio button is only active if you are viewing a clip with a resolution that does not use square pixels.

The original aspect ratio of the clip is applied to the clip.

Changing Playback Scan Mode Options in the Player

Use the playback scan mode option to define how you want the clip to play and display. By default, everything will be automatically set to the correct scan mode.

To set playback mode in the Player:

- 1 Click the Timeline tab.
- 2 Select the Player.
- 3 In the View Area menu bar, select Options.
- 4 Select Edit Viewing Settings.
- 5 Click on the Scan Mode button.

NOTE The default choice is the clip's native scan mode.

- 6 Adjust the display to the desired scan mode format.
- 7 Click Done.

The player displays the clip in that scan mode.

Displaying a Clip in the Broadcast Monitor

To set broadcast monitoring preferences:

- 1 Click the Timeline tab.
 - 2 In the View Area menu bar, select Options.
 - 3 Select Show Viewing Settings.
 - 4 Enter the preferences for the broadcast monitor in the Broadcast Monitor, Broadcast Multiview and Broadcast LUT boxes.
- Your preferences will be set for broadcast monitoring.

The broadcast monitor outputs a complete image or a selected viewport.

Use the Show Selected Item option in the Broadcast Monitor box to display the clip you selected in the broadcast monitor. Use the Broadcast Monitor buttons to resize and set the proportions of the clip. If the clip is zoomed in on the application monitor, the clip is still displayed in its entirety on the broadcast monitor.

When you select multiple clips, the broadcast monitor displays the first clip in a selection.

When the Show Selected Item option is selected, you can manage additional preferences.

Color and Light Levels

Accessing the Vectorscope

To access the Vectorscope:

- 1 Click the Timeline tab.
- 2 Select the Player.
- 3 In the View Area menu bar, select Options.
- 4 Select Show Vectorscope.

The Vectorscope is displayed.

Changing the Settings in the Vectorscope

To change the settings in the Vectorscope:

- 1 Click the Timeline tab.
- 2 Select the Player.
- 3 In the View Area menu bar, select Options.
- 4 Select Show Vectorscope.
- 5 Click the Vectorscope Display button.
- 6 Select Vectorscope Settings.

The Vectorscope Settings window opens.

Scaling the Vectorscope

To scale the Vectorscope:

- 1 Click the Timeline tab.
 - 2 Select the Player.
 - 3 In the View Area menu bar, select Options.
 - 4 Select Show Vectorscope.
 - 5 Click the Vectorscope Display button.
 - 6 Select Vectorscope > Colour 2D.
 - 7 Shift + drag in the Vectorscope.
- The scale in the Vectorscope scales to a new size.

Preview options

To access the preview options below, select the Player Options box in the View menu bar.

You can select between playing all frames and playing back media in real-time mode, with or without Timeline FX. When playing back all frames, you can choose to cache frames from memory to increase performance. If your project uses proxies or real-time deliverables, you can select the resolution at which to play back media.

Select This:	To Do This:
Play All Frames	Play back all frames as quickly as they are rendered, even if it results in lack of audio synchronization.
Play Real-Time	Play back frames synchronized with audio. May result in some frames being dropped.
Hide Effects	Play back without any rendered effects, except Resize and Timewarp. Toggle to render all Timeline FX on-the-fly.
Cache Intermediates	Cache scrubbed frames. Toggle to turn off caching. Enabled when Play All Frames is selected.
Full Resolution	Play back the full-resolution clip.
Proxy Resolution	Play back using the clip's proxies.
Deliverables	Play back using the current Real-Time Deliverable.

Changing Playback Scan Mode Options

To set playback mode in the Player:

- 1 Click the View button.
- 2 Click on the Scan Mode button.

NOTE The default choice is the clip's native scan mode.

- 3 Select a scan mode.
 - 4 Click Done.
- The player displays the clip in that scan mode.

Enabling the Aspect Ratio Display

To enable the aspect ratio display:

- 1 Click the View button.
- 2 Enable the Use Ratio button.

NOTE The Use Ratio button is only active if you are viewing a clip with a resolution that does not use square pixels.

The original aspect ratio of the clip is applied to the clip.

Setting up the Image Display Viewer in the Tools

To set up the image display viewer in the tools:

- 1 Click the View button.
- 2 Modify the display attributes.

The viewer updates the display with your changes.

Displaying the Reference Area

In the image window of the tools that support multiple viewports, you can view the reference area with the currently displayed clip. A split bar divides the view between the current clip display (above the bar) and the reference area. The reference area can either display one of the current tool's working clips (for example, front, back, or matte), or one of the reference frames that you grab on-the-fly.

Using the Split Bar

To turn on the split bar, enable Compare in the Reference Buffer section of the View menu (also available below the viewports in Batch or Batch FX). When the split bar is on, by default it lies along the lower edge of the image window.

The split bar has a pivot point (indicated by a small box) around which the split bar can be rotated, or from which the split bar can be moved. The letter R next to the pivot box indicates the side of the bar where the reference clip is displayed.

(a) Pivot point (b) Split bar (c) Current display (d) Reference display
 (a) Pivot point (b) Split bar (c) Current display (d) Reference display

Rotate and move the split bar using these techniques:

- To rotate the split bar around its pivot point, drag the split bar.
- To move the split bar, drag the pivot point. You can also **Ctrl+Alt**-click the image to place the pivot point under the cursor, and then drag over the image to move the split bar.
- To restore the split bar to its default position, **Ctrl**-click the pivot point.

Showing and Hiding the Split Bar

When the split bar is on, you can show or hide it in the image window.

To show or hide the split bar:

- 1 **Ctrl**-click the split bar.

When the split bar is hidden, it is still active. The letter **R** is displayed indicating the location of the reference clip.

Loading a Clip into the Reference Area

You can display one of the tool's clip views in the reference area. For example, turn on the split bar to show the reference area, and then display the matte of a Colour Corrector clip while working on its result.

To load a clip into the reference area:

- 1 Select an option from the Reference box.

Storing Reference Frames in the Reference Buffer

You can grab any number of reference frames in the reference area, limited only by framestore space.

To store reference frames in the reference area:

- 1 Display the frame you want to grab in the viewport.
- 2 In the Reference Buffer section of the View menu of a tool, click Grab.
The current frame appears in the reference area.
- 3 To grab another frame, display it in the viewport (or make the changes to the current frame) and then do one of the following:
 - Press **Ctrl+G** to replace the current reference frame.
 - Press **Ctrl+Shift+G** to append the new frame to all existing reference frames.

Cycling Through Multiple Reference Frames

When you work with several frames stored in the reference buffer, you can cycle their display in the reference area.

To cycle through multiple reference frames:

- 1 With the split bar on and the reference area showing, click the Prev and Next buttons in the View menu.

To cycle through multiple reference frames using the reference overlay:

- 1 Press and hold **Ctrl+NUM5** to display the reference overlay.
- 2 While holding **Ctrl**, press **NUM4** and **NUM6** to cycle backwards and forwards through all stored reference frames.

Displaying Multiple Views

You can display up to four viewports at a time in the image window of most tools. Multiple viewports are convenient for setting channel values, working in Schematic view, and previewing your results all at the same time without having to switch views.

NOTE The Resize tool supports two viewports; other tools support up to four viewports.

You can apply a different 3D LUT to each viewport.

To view multiple viewports:

- 1 In a tool that supports multiple viewports, click View.
- 2 Select an option from the Viewport Layout box.

Select:	To view:
1-up	A single viewport (Alt+1).
2-up	Two viewports, side-by-side (Alt+2).
3-up split	Three viewports, two side-by-side, and one on top (Alt+3).
3-up	Three viewports, side-by-side (Alt+3).
4-up	Four viewports, two up and two down (Alt+4).

To display views in multiple viewports:

- 1 Do one of the following:
 - Place the cursor over the applicable viewport and press its associated keyboard shortcut.
 - Click a viewport to select it and then select an option from the View box.

Displaying Widgets in Selected Viewports

If you are working in multiple viewports, you can display widgets such as icons, crop boxes, and 3D scope in all viewports or in a selected viewport.

To display widgets in selected viewports:

- 1 In a tool that supports multiple views, click View.
- 2 From the Widget Display box, select Widget Sel to display widgets in the selected viewport, or select Widget All to display widgets in all viewports.

Changing the Multiview Layout

When you select a multiple viewport layout, a default layout appears, and each viewport is set to display a default view. You can change both the default layout and the views in each viewport to suit your needs.

To change the default viewport layout:

- 1 Do one or more of the following:
 - Hold the cursor over the lines dividing the image window and **Ctrl**-drag. The current zoom/pan settings automatically change so the frame matches its viewport's width.
 - Select the viewport to make it current (a yellow border indicates the current viewport) and then select a view option (for example, Front) or press a hotkey (for example, **F1**).
- 2 To restore the default settings, select an option from the Reset box.

Select:	To:
Reset Layout	Restore the default layout for the current viewport layout option. You can also Alt -click a viewport border.
Reset All	Restore the default layout for all viewport layout options.

Synchronizing Current Frame Display Across All Viewports

By default, when you scrub or jog a clip, only the current viewport (a yellow border indicates the current viewport) is updated. The other viewports continue to display the last frame at which they were parked until you release the cursor. However, you can set all viewports to be updated in sync with the current viewport.

To synchronize the current frame display across all viewports:

- 1 Display the View menu.
- 2 Select an option from the Viewport Update box.

Select:	To:
Update All	Update all viewports to display the same frame as the current viewport.

Select:	To:
Update Sel	Update only the current viewport. Other viewports continue to display the last frame at which they were parked only once you release the cursor.

Viewing Settings tab

Compare Mode /Stereo

Primary Video Track field Displays the track and layer assigned as the Primary track in the Player. Editable.

Secondary Video Track field Displays the track and layer assigned as the Secondary track in the Player. Editable.

Preview Setup box Select which tracks to display in the Player. If displaying both tracks, select a split screen option.

Image

Use Ratio button Enable to simulate rectangular pixel display that corresponds to the delivery format.

Filtering button Enable to set the filtering.

Scan Mode button Adjusts the display to the desired scan mode format.

Playback

Hide Effects button Enable to hide effects during playback. Disable to display effects (may affect performance).

Preroll field Displays the number of preroll frames when playing a clip. Editable.

Postroll field Displays the number of postroll frames when playing a clip. Editable.

Colour Mode box Select the colourspace and bit rate for playback. Select Clip Format (the default) to use the original clip settings.

In Timecode field Displays the timecode at which to begin playback. Editable.

Out Timecode field Displays the timecode at which to end playback. Editable.

Reload From Current button Click to reload the buffer with the current Colour Mode settings.

Exposure & Contrast

Exposure field Sets the exposure that is used to transform image display in the image window. Editable.

Contrast field Sets the contrast that is used to transform image display in the image window. Editable.

Enable Look Transform Toggles the dynamic look of a colour transform on and off. Available only when the selected viewing transform has dynamic look operators defined. Editable.

Channels

Red Channel button Display the red channel of the clip.

Green Channel button Display the green channel of the clip.

Blue Channel button Display the blue channel of the clip.

Exclusive button Enable to display an exclusive greyscale representation of the selected colour channel.

Image Data Type

Image Data Type box Select the type of image data that you are displaying in the image window.

If you are not using a 3D LUT, then logathmic and linear data are converted to video for display.

If you are using a 3D LUT, then linear and video data are first converted to logarithmic before being processed by the LUT for display.

If you are using a colour transform for display, then the image data type is ignored and the transform is applied directly.

Apply All button Enable to apply the transformation for the current viewport to all viewports.

Bypass button Enable to deactivate display settings in the current image window.

Preset box Select an option to preview the image in either RGB or Matte mode.

The color management settings that are appropriate for displaying RGB images is not always appropriate for displaying mattes. Matte mode defaults to Video, which is best for viewing mattes.

1D LUT Display

Use 1D LUT button Enable to select and use a gamma or 1D LUT.

1D LUT List box Select a preloaded gamma or 1D LUT.

3D LUT & Colour Transform Display

Use 3D LUT button Enable to select and apply a 3D LUT or colour transform to the image.

3D LUT box Select a preloaded 3D LUT or colour transform.

Editing Clips and Sequences

10

The following procedures list a few methods to add clips quickly to a timeline after starting Flame Premium for the first time. These methods are certainly not the only way to edit, but should give you a start in familiarizing yourself with editing in Flame Premium.

When first starting Flame Premium with a new project, you can select a workspace with a Source-Sequence player and then switch to the Timeline tab to see an empty sequence on the timeline. Once you have loaded some media into the Media Library using the MediaHub, you are ready to add clips to the timeline. You can also create new sequences from the Workspace Media panel, or right-click a clip and select Open as Sequence.

To insert a first clip on the timeline:

- 1 Select a clip in the Media panel to display it in the source player.
- 2 Drag the positioner in the timebar to the frame where you want your clip to start, then click In.
- 3 Drag the positioner in the timebar to the frame where you want your clip to end, then click Out.
- 4 Click the Insert button.

The clip is added to the timeline. Extra frames outside of your selected In and Out points remain as handles.

To insert a second clip on the timeline:

- 1 Select another clip in the Media panel to display it in the source player viewer.
- 2 Drag the positioner in the timebar to the frame where you want your clip to start, then click In.
- 3 Drag the positioner in the timebar to the frame where you want your clip to end, then click Out.
- 4 Click the Insert button.

The clip is added to the timeline starting at the positioner location. If you hadn't moved the positioner after inserting the first clip, the positioner was located at the last frame.

To overwrite a clip on the timeline:

- 1 Move the timeline positioner to the first frame of the second clip that you inserted on the timeline.
- 2 Select another clip in the Media panel to display it in the source player.

- 3 Drag the positioner in the timebar to the frame where you want your clip to start, then click In.
- 4 Drag the positioner in the timebar to the frame where you want your clip to end, then click Out.
- 5 Click the Overwrite button.

Depending where the positioner was placed and the length of the second and third clips, existing material is overwritten, but the overall length of the timeline sequence does not change.

Continue adding clips to your sequence, as needed. At this point, you are ready to fine-tune your edit sequence by trimming clips, adding tracks for compositing, adding effects to your timeline clips, and using other Flame Premium timeline and editing tools.

Editing with Keyboard Shortcuts

If you like to edit with keyboard shortcuts, a useful workflow to follow is to switch between the **F5**, **F6**, and **F7** shortcuts. It is good practice to open the sequence in which you plan to make edits, so that it shows up as a red tab on the timeline.

- **F5** forces the focus back to the timeline, and is useful if you explicitly click on a clip in the workspace, but want to switch back to editorial and drive timeline navigation.
- When the focus is on the timeline, **F6** switches to the source timeline tab, but also enables keyboard shortcut navigation within the media panel folder where the current source is located (using Select Next Clip or Select Previous Clip). You can use this to quickly navigate through your sources, yet not lose focus on the timeline.
- When the focus is on the timeline, **F7** sets the focus on the current active sequence, and allows you to navigate through its timeline using keyboard shortcuts (for example for Next or Previous Transition).

TIP If the focus is on the Player or the Source-Sequence Player, you can also use the **F6** and **F7** shortcuts to switch the focus between source and sequence players.

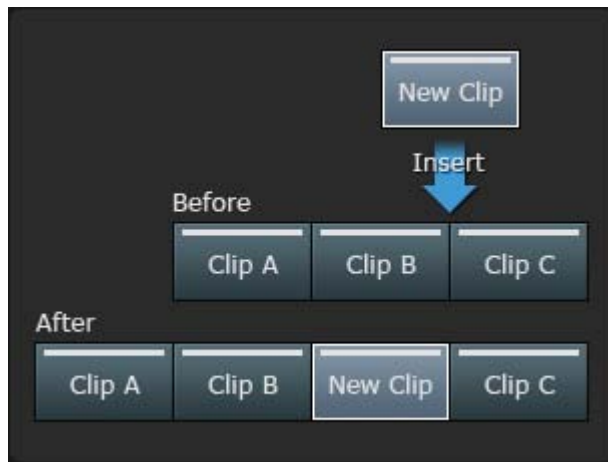

Inserting a Clip on the Timeline

To insert a clip to the timeline using the Insert button:

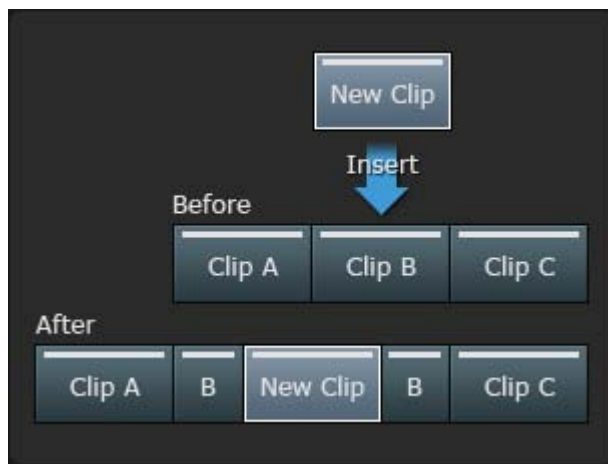

- 1 Move the timeline positioner to the frame that you want to use as the beginning of the insert.
- 2 From the workspace, select the clip that you want to insert.
- 3 Add In and Out points, if needed.
- 4 Click the Insert button.

Depending where the positioner is placed, the clip is inserted, and the overall length of the timeline sequence is changed. The following example shows a New Clip inserted at the transition between Clip B and Clip C. Everything after the transition is moved ahead in order to make room for New Clip.

This example demonstrates the result of inserting New Clip at a frame in the middle of Clip B. Every frame after the edit point is moved ahead to accommodate New Clip.

NOTE You can also perform three-point or four-point insert edits with In and Out points on the source and timeline clips.

To insert a clip to the timeline gesturally:

- 1 Enable Ripple.
- 2 From the Workspace Media panel or Viewing panel, select the clip that you want to insert.
- 3 Add In and Out points, if needed.
- 4 Drag the clip towards the timeline.

As you hover over the timeline with your clip, you see a phantom visual guide as to the space on the track or tracks your clip will take when dropped.

- 5 Release the clip on the timeline.

TIP You can also drag and drop a clip to the timeline from the source tab of the Player.

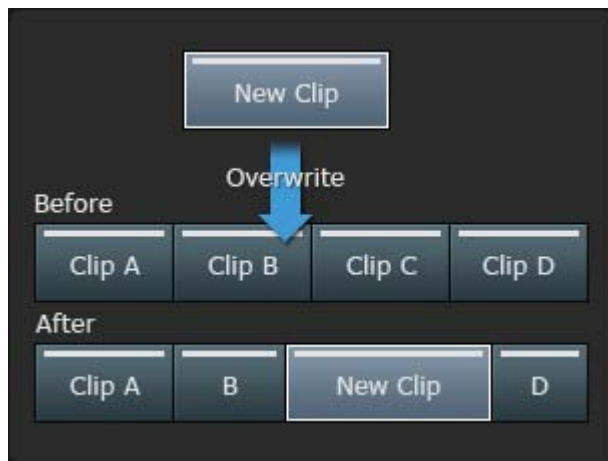

Overwriting a Clip on the Timeline

To overwrite a clip to the timeline using the Overwrite button:

- 1 Move the timeline positioner to the frame that you want to use as the beginning of the overwrite.
- 2 From the workspace, select the clip that you want to overwrite.
- 3 Add In and Out points, if needed.
- 4 Click the Overwrite button.

Depending where the positioner is placed, existing material is overwritten, and the overall length of the timeline sequence does not change. In the following illustration, New Clip is edited into the sequence at a frame in Clip B. Frames after the insertion point are overwritten by New Clip. All of Clip C and some of Clip B and D are overwritten.

NOTE You can also perform three-point or four-point overwrite edits with In and Out points on the source and timeline clips. In the case of a four-point edit, a Timewarp may be applied if the number of frames differs between the source and timeline clips. You can enable or disable Auto Timewarp in the Timeline section of the Preferences menu.

To overwrite a clip to the timeline gesturally:

- 1 Disable Ripple.
- 2 From the Workspace Media panel or Viewing panel, select the clip that you want to overwrite.
- 3 Add In and Out points, if needed.
- 4 Drag the clip to the timeline.

As you hover over the timeline with your clip, you see a phantom visual guide as to the space on the track or tracks your clip will take when dropped.

- 5 Release the clip on the timeline.

TIP You can also drag and drop a clip to the timeline from the source tab of the Player.

Replacing a Clip on the Timeline

To replace a clip on the timeline using the Replace button:

- 1 Do one of the following:
 - Move the timeline positioner over the clip that you want to replace.
 - Select a clip or multiple clips on the timeline that you want to replace.
- 2 From the workspace, select the clip that you want to use as the replacement clip.
- 3 Click the Replace button.

The overall length of the sequence does not change. The replace clip must be of equal length or longer than each clip it is replacing. If longer, extra frames are loaded as tail frames.

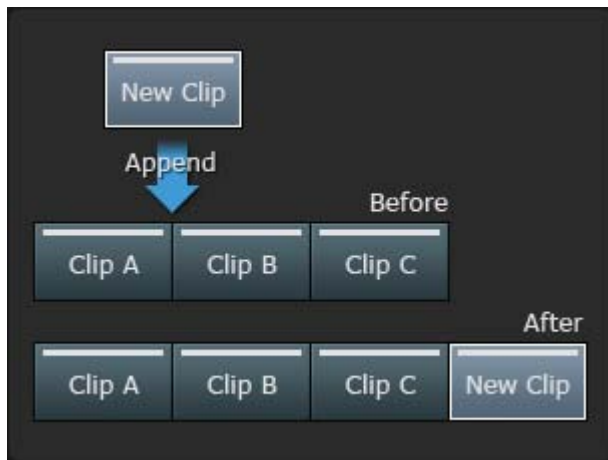

Other Editing Operations

While insert, overwrite, and replace are the editing operations you use most often, there are other editing options available. For each of these operations, you select your source clip in the same manner as for an insert, overwrite, or replace edit. Then you select the appropriate editing operation from the Secondary Edit box.

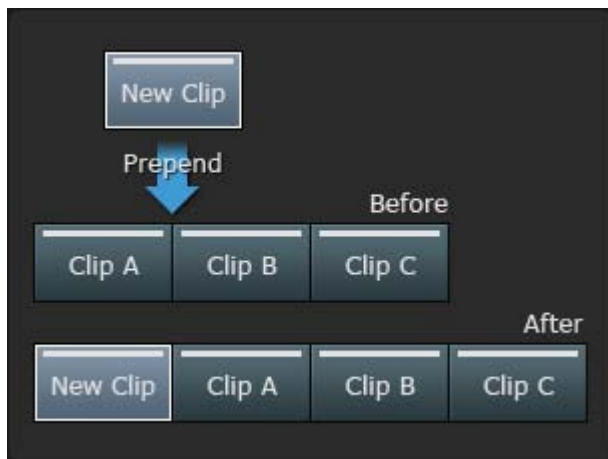

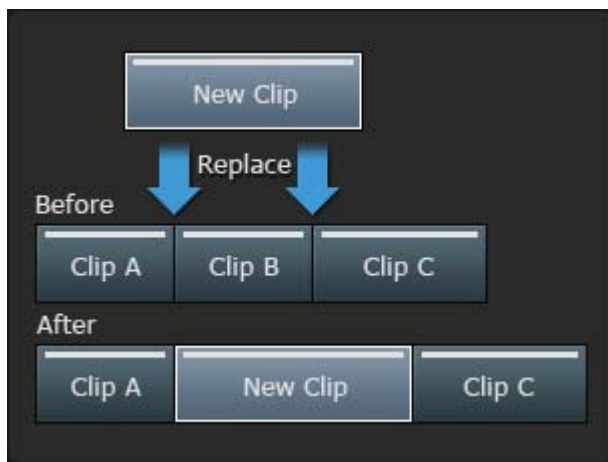

An Aligned Edit is usually performed on two tracks. You set the positioner on the timeline to a point you want to align to, then move the focus point of the positioner to a different track. Set the positioner of the source track to the point you want aligned. The source clip is added to the track, and both points are aligned.

Append applies an edit that adds your source clip to the end of the edit sequence on the timeline.

Prepend applies an edit that adds your source clip to the beginning of the edit sequence on the timeline.

Ripple Replace functions as a combination of an insert and replace edit. The source clip replaces the selected clip on the timeline, and all of the clips to the right ripple to accommodate the length of the new clip.

Replace Media performs a replace edit but retains any effects applied to the replaced clip or clips on the timeline.

A Fit To Fill edit functions as a replace edit, but instead of adding tail frames to a longer source clip, a Timewarp is added to the replaced clip so that it fits the same space occupied by the clip it is replacing.

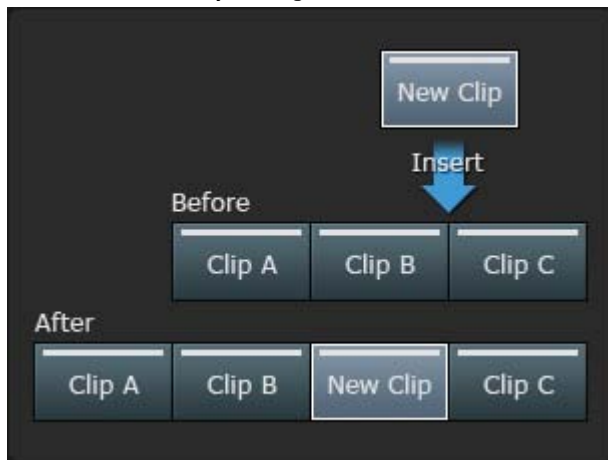

Timeline Editing Settings

The settings you use for editing to and on the timeline can be found to the right and above the timeline. Most of these settings also have a keyboard shortcut associated with them.

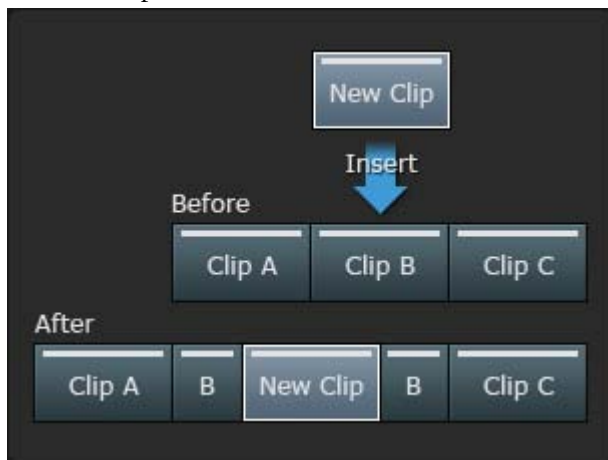

Editing Operations

Insert Edit button Click to insert the selected source into the timeline at the positioner. The overall length of the timeline may change.

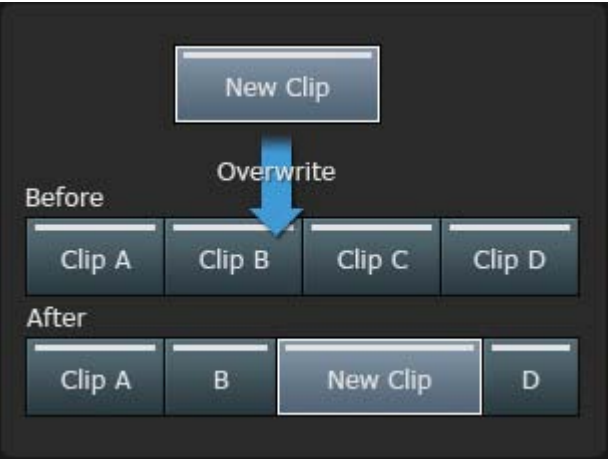

Insert Example 1

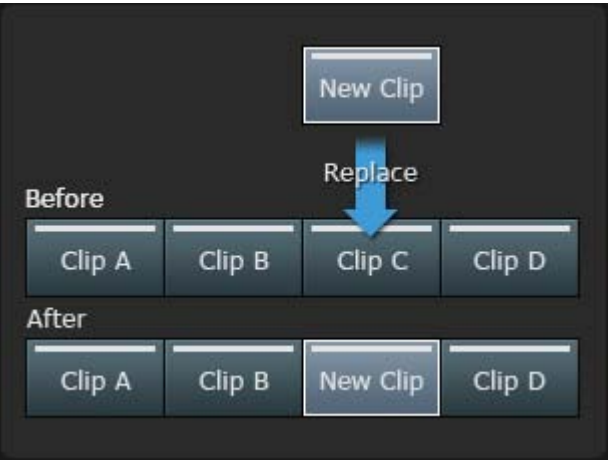

Insert Example 2

Overwrite Edit button Click to overwrite material in the timeline (at the positioner) with the selected source. The overall length of the timeline does not change.

Overwrite Example

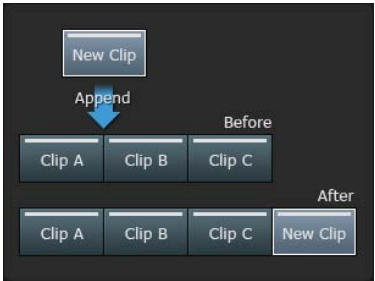

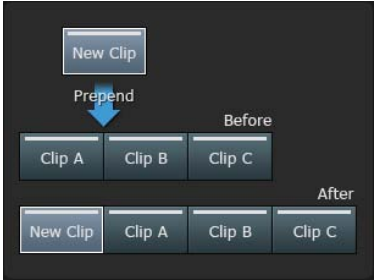

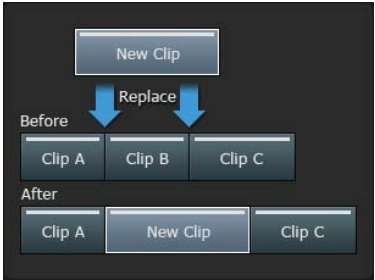

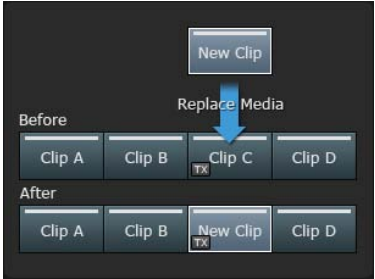

Replace Edit button Click to replace the selected timeline clip or clips with the selected source clip. The overall length of the timeline sequence does not change. The replacement clip must be of equal length or longer than each clip it is replacing. If longer, extra frames are added as tail frames.

Replace Example

Secondary Edit box Select an editing operation to apply to the selected source clip.

Select:	To apply:	Example
Aligned Edit	An edit aligning a point on the timeline with a point on the source clip.	<p>The diagram shows a timeline editing interface. At the top, a button labeled 'New Clip' is shown. Below it, a blue arrow labeled 'Aligned Edit' points to a timeline. The timeline is divided into two sections: 'Before' and 'After'. In the 'Before' section, there are three clips labeled 'Clip A', 'Clip B', and 'Clip C'. In the 'After' section, the clips are 'Clip A', 'New Clip', and 'Clip C'. This illustrates that the 'Aligned Edit' operation aligns the 'New Clip' with the selected clip in the timeline.</p>

Select:	To apply:	Example
Append	An insert edit that adds your source clip to the end of the edit sequence on the timeline.	
Prepend	An insert edit that adds your source clip to the beginning of the edit sequence on the timeline.	
Ripple Replace	A combination of an insert and replace edit; where the source clip replaces the selected clip on the timeline, and the all of the clips to the right ripple to accommodate the length of the new clip.	
Replace Media	A replace edit that retains any effects applied to the replaced clip or clips on the timeline.	

Select:	To apply:	Example
Fit To Fill	A replace edit; but instead of adding tail frames to a longer source clip, a time-warp is added to the replacement clip so that it fits the same duration occupied by the clip it is replacing.	

Trimming Operations

Editorial Mode box Choose an editorial mode for working with clips on the timeline.

Select:		To:
Select		Select or move a timeline element, without performing any trim operations.
Trim		Set Trim mode to perform general trim (or roll) operations on a clip.
Slip		Set Slip mode, a trimming mode that offsets the frames in a clip without trimming the clips before or after it.
Slide		Set Slide mode, a trimming mode that trims the clips before and after the clip without changing the frames used in it. The state of the Ripple button has an effect on this mode.
Slide Cuts		Set Slide Cuts mode, a trimming mode that trims the clips before and after it, while also changing the frames used in a clip. The state of the Ripple button has an effect on this mode.
Slide Keyframes		Set Slide Keyframes mode, a trimming mode that slides only animation keyframes on a clip.

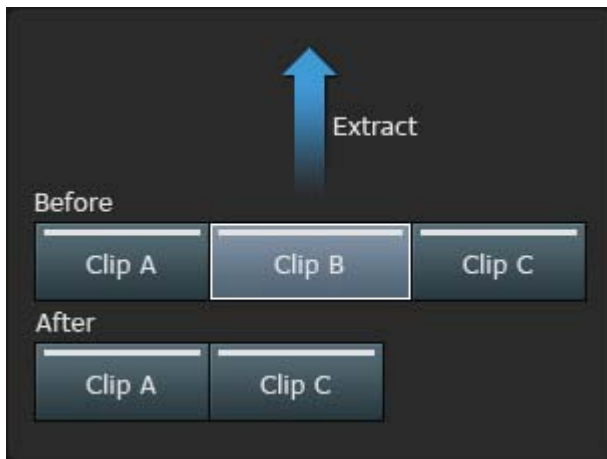

NOTE Trim, Slide, and Slide Cuts modes are affected by the state of the Ripple button. The icons display as yellow when ripple is enabled, and red when ripple is disabled.

Link button Enable to select and link all elements in an editorial group. This is useful if you want to trim all clips in a group by the same number of frames, for example. You can invert the Link mode on-the-fly during manipulation, with the Invert Group Selection keyboard shortcut.

Link Example

Ripple button When gesturally adding material into an edit sequence, enable to perform an insert edit, disable to perform an overwrite edit. When moving (or trimming) clips on the timeline, enable to fill the gap left by the removed clip or frames, disable to leave the gap.

Ripple On

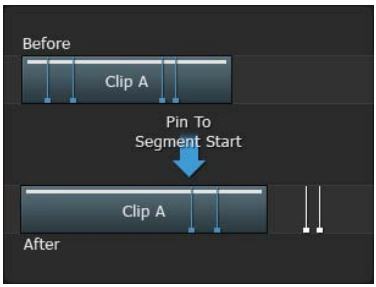

Ripple Off

Snap button Enable to snap to the closest transition, positioner, or mark to help gesturally align edits on the timeline. Press Shift to invert the snap mode during manipulation.

Keyframe Move Modes box Select how the animation channel is affected when you trim elements with animated effects.

Select:	To:	Example
Reposition Proportionally	Resize the channel as you trim. The animation channel is scaled to fit into the timeline element. This option has no effect when you slip or slide.	
Shift With Media	Link the keyframes to their original frame numbers. The animation channel moves to follow the original frames as you trim.	

Select:	To:	Example
Pin To Segment Start	Unlink the keyframes from their original frame number. The animation channel remains with the timeline element as you trim.	

Trimming Clips

Use the trimming tools to fine-tune your rough edits. You can trim video or audio clips (with or without effects), cuts, and transitions on the timeline. You can trim multiple tracks or segments at the same time. Flame Premium keeps track of the source material that goes into trimmed shots, so you can go back and reintroduce material you had previously trimmed out.

You can trim using the Trim View, with keyboard shortcuts, or gesturally on the timeline. You can also trim by any combination of these methods, depending on your editing style. In Trim mode, the Trim View displays the last (outgoing) and first (incoming) frame above the timeline from the two clips you are trimming, allowing you to visualize your trimming operation. In Slip or Slide mode, the Trim View changes to a four frame display, which, in addition to the incoming and outgoing frames of the clip you are slipping or sliding, also displays the outgoing frame of the preceding clip and the incoming frame of the subsequent clip on the timeline.

The state of the Ripple button has an effect on *some* trimming operations. You can set the ripple state explicitly before trimming, or on-the-fly by pressing **Alt** while you are trimming.

Audio tracks are divided into sub-frames. There are 100 sub-frames of audio for every frame of video. When trimming audio tracks, you can trim on a sub-frame level by holding down the **Shift** key while you trim.

NOTE You cannot trim on a sub-frame level when simultaneously trimming audio and video tracks.

Trimming Quickstart

Use the following procedure to quickly start trimming. This method is certainly not the only way to trim, but should give you a start in familiarizing yourself with trimming in Flame Premium. For more detailed explanations of the various trimming modes, see the related topics below.

- 1 Double-click a cut between two clips on the timeline. The positioner moves to this location, and a yellow or red highlight appears on either side of the cut (depending if Ripple is enabled or not).

The Trim View also opens, (provided that Auto-Toggle Trim View is enabled in **Preferences > General > Player**) displaying the outgoing and incoming frame of the two clips.

TIP You can also access Trim View from the View mode box. In this case, the closest cut on the timeline is automatically selected. You can use the Previous or Next Transition buttons to select a different cut.

- 2 From the Editorial Mode box, select Trim.

- 3 Drag the Outgoing or Incoming Trim Offset fields to your desired trim offset value (in frames). The corresponding view (incoming, outgoing, or both), and the timeline clips are updated.

Notice that the offset fields have the same colour borders as the highlight on the timeline cut (yellow when Ripple is enabled, or red when Ripple is disabled).

- 4 Use the loop option of the Play button to loop around your trim with a number of preroll and postroll frames to preview your trim.

Performing a Trim

Trim (or roll) a clip to add frames to, or remove frames from, a clip's head or tail.

To trim (or roll) a clip or transition on the timeline:

- 1 From the Editorial Mode box, select Trim.
- 2 Position the cursor near the head or tail of a clip or transition on the timeline.
The cursor turns to a trim cursor (a yellow arrow and line if ripple is enabled, or a red arrow and line if ripple is disabled). If you want to trim a cut, position the cursor over the cut, and notice that the trim cursor becomes a double arrow with a line.
- 3 Drag left or right to remove the number of frames that you need.
You can see the head or tail number on the clip change as you trim.

TIP Enable Focus On Trim in the Timeline Options menu to snap the timeline positioner to the transition while trimming, allowing you to view the frames you are trimming in the Player, or switch to Trim View to see your incoming and outgoing frames.

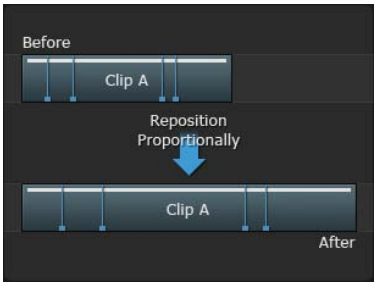

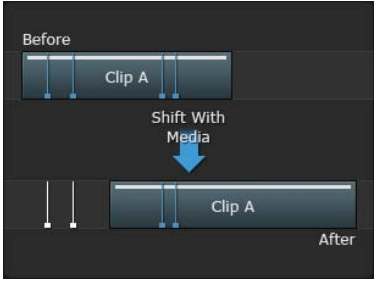

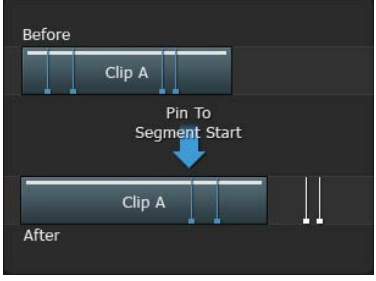

To trim (or roll) a clip or transition using Trim View:

- 1 Double-click a cut between two clips on the timeline, or select Trim View from the View Mode box.
Trim View appears in the Viewing panel, displaying the last (outgoing) and first (incoming) frame from the two clips you are trimming.
- 2 Use any of the following techniques to trim your clips to the desired frames:
 - Click and drag directly in the left or right Trim View window. You can see the trim icon as you drag. The icon is displayed in yellow or red, depending on the state of the Ripple button.
 - Click and drag toward the middle of the two Trim View windows. Notice that the trim icon appears as a double-sided arrow, indicating that you are trimming the cut between the two clips.

- Click any of the timecode or duration fields at the top of Trim View windows to enter specific values. If a timecode or duration field is not enabled, click the corresponding Trim View window or offset field to enable it.
- Click and drag the outgoing or incoming Trim Offset field to specify the number of frames offset in the clip. You can also click the minus or plus buttons to offset by those amounts.
- You can also trim on the timeline, and use the Trim View as a viewing aid.

Trimming Keyframes

If you set animation keyframes on timeline effects, you have different options as to their behaviour while trimming. Use the Keyframe Move Modes box to select how the animation channel is affected when you trim elements with animated effects.

Select:	To:	Example
Reposition Proportionally	Resize the channel as you trim. The animation channel is scaled to fit into the timeline element. This option has no effect when you slip or slide.	
Shift With Media	Link the keyframes to their original frame numbers. The animation channel moves to follow the original frames as you trim.	
Pin To Segment Start	Unlink the keyframes from their original frame number. The animation channel remains with the timeline element as you trim.	

In the Editorial Mode box, you can also select Slide Keyframes mode, which allows you to slide all of the keyframes of a specific timeline effect on a clip. For example, you can slide all of the Axis keyframes on a clip.

Performing a Slip

Slip a clip to offset the frames in a clip (by trimming head and tail frames of the clip) without trimming the clips before or after it. The state of the Ripple button has no effect on slip operations.

To slip a clip on the timeline:

- 1 From the Editorial Mode box, select Slip.
- 2 Position the cursor in the middle of a clip on the timeline.
The cursor turns to a slip cursor.
- 3 Drag left or right.
You can see the head and tail numbers on the clip change as you slip.

To slip a clip in Trim View:

- 1 Select the clip you want to slip on the timeline.
- 2 From the Editorial Mode box, select Slip.
- 3 Double-click the clip you want to slip, or select Trim View from the View Mode box.
In Slip mode, the Trim View displays four panels. In addition to the incoming and outgoing frames of the clip you are slipping, you can see the outgoing frame of the preceding clip and the incoming frame of the subsequent clip on the timeline.
- 4 Use any of the following techniques to slip your clip:
 - Click and drag left or right directly in the Trim View window. You can see the slip icon as you drag.
 - Click any of the timecode fields at the top of Trim View windows to enter specific values.
 - Click the minus or plus buttons to offset by those amounts.
 - You can also slip on the timeline, and use the Trim View as a viewing aid.

NOTE In Slip mode, the Duration and Offset fields of the Trim View update as you slip, but are non-editable.

Performing a Slide

Sliding changes a clip's position in the edit sequence. It simultaneously slides the clip under the cursor and trims the head and tail of the surrounding clips. The state of the Ripple button has an effect on slide operations.

NOTE Instead of using Slide mode, you can select Slide Cuts from the Editorial Mode box, a modified Slide mode that trims the clips before and after it, while also changing the frames used in a clip.

To slide a clip on the timeline:

- 1 From the Editorial Mode box, select Slide.
- 2 Position the cursor in the middle of a clip on the timeline.
The cursor turns to a slide cursor (a white square with yellow arrows if ripple is enabled, or a white square with red arrows if ripple is disabled).
- 3 Drag left or right.
The position of the clip changes, and surrounding clips' head and tails are trimmed.

To slide a clip in Trim View:

- 1 Select the clip you want to slide on the timeline.
- 2 From the Editorial Mode box, select Slide.
- 3 Double-click the clip you want to slide, or select Trim View from the View Mode box.
In Slide mode, the Trim View displays four panels. In addition to the incoming and outgoing frames of the clip you are sliding, you can see the outgoing frame of the preceding clip and the incoming frame of the subsequent clip on the timeline.
- 4 Use any of the following techniques to slide your clip:
 - Click and drag left or right directly in the Trim View window. You can see the slide icon as you drag.
 - Click any of the timecode fields at the top of Trim View windows to enter specific values.
 - Click the minus or plus buttons to offset by those amounts.
 - You can also slide on the timeline, and use the Trim View as a viewing aid.

NOTE In Slide mode, the Duration and Offset fields of the Trim View update as you slide, but are non-editable.

Trimming with Keyboard Shortcuts and the Calculator

You can use selection-based keyboard shortcuts to perform your trim, slip, or slide operations (depending on the mode selected in the Editorial Mode box).

- 1 On the timeline, select the segment that you want to trim.
- 2 From the Editorial Mode box, select the trim mode that you want to perform (for example, Slip).
TIP Specific keyboard shortcuts are available to switch to each trim mode (Trim, Slip, Slide, Slide Cuts, and Slide Keyframes). See the Keyboard Shortcut editor for more information.
- 3 Use the keyboard shortcut appropriate to the action you want to perform (in the descriptions below, Trim refers to the selected trim mode).

Description	Smoke (FCP 7) Shortcut	Smoke Classic Shortcut	Flame Shortcut
Trim 1 Frame Forward	. (period)	N	. (period)
Trim 1 Frame Backward	, (comma)	B	, (comma)
Trim <n> Frames Forward	Shift+. (period)	Shift+N	Shift+. (period)
Trim <n> Frames Backward	Shift+, (comma)	Shift+B	Shift+, (comma)
Trim to In Mark	Ctrl+I	Ctrl+B	Shift+[
Trim to Out Mark	Ctrl+O	Ctrl+N	Shift+]
Trim to Positioner	E	Ctrl+P	Shift+P

Trimming with the Keypad and Calculator

If you know the amount of frames by which you want to trim, a quick way to perform the trim is by using the keypad to enter the amount into the calculator.

- 1 On the timeline, select the clip or cut you want to trim.
- 2 On the keyboard keypad, enter the number of frames by which you want to trim (positive or negative).
- 3 Press Enter.

NOTE If there is no explicit selection on the timeline, trim operations are not performed using this method. Instead, the positioner is moved by the number of frames that you enter.

Dynamic Trimming

In Trim View, you can use key combinations to dynamically trim while your outgoing and incoming clips are playing.

To trim with the J-K-L keys:

- 1 In Trim View, select either the incoming, outgoing, or both clips.
- 2 Use one of the following J-K-L key combinations to trim:
 - Press the J or L key once to play backward or forward, then press K to stop and perform the trim at the desired frame. You can also press J or L multiple times to play faster before pressing K. This method works for Trim mode only.
 - Press and hold K, then press J to trim one frame backward or L to trim one frame forward. This method works for Trim, Slip, and Slide modes.

The trim viewports and the timeline update as you perform your trim. While pressing J or L, you can see a phantom positioner moving along the timeline to help you see where you want to trim.

To trim during playback:

- 1 In Trim View (with Trim, Slip, or Slide mode selected), select a playback option from the Play button (such as Loop), and click Play.
- 2 While your selection is playing (with the desired number of preroll and postroll frames), you can use the Trim 1 Frame Forward, Trim 1 Frame Backward, Trim <n> Frames Forward, and Trim <n> Frames Backward keyboard shortcuts.

Trim View Settings

In Trim mode, the Trim View displays the last (outgoing) and first (incoming) frame from the two clips you are trimming (as seen in the example, above). In Slip or Slide mode, the Trim View changes to a four frame display, which, in addition to the incoming and outgoing frames of the clip you are slipping or sliding, also displays the outgoing frame of the preceding clip and the incoming frame of the subsequent clip on the timeline.

Use these settings while working in Trim View. Most of the settings are available for all Trim View modes; exceptions are noted below.

Tail Source Timecode field Displays the tail source timecode of the outgoing segment. Non-editable if the outgoing trim offset is not selected.

Outgoing Duration field Displays the duration of the outgoing clip. Non-editable if the outgoing trim offset is not selected. Available in Trim mode only.

Incoming Duration field Displays the duration of the incoming clip. Non-editable if the incoming trim offset is not selected. Available in Trim mode only.

Head Source Timecode field Displays the head source timecode of the incoming segment. Non-editable if the incoming trim offset is not selected.

Duration field Displays the duration of the selected segment. Non-editable. Available in Slip and Slide mode. (Not shown)

Timecode field Displays the current timecode of the focus clip (green signifies a source clip, while red signifies a sequence clip). Editable.

View Mode box Select a view mode for the Viewing panel layout.

Previous Transition button Click to select the previous transition on the selected track.

Next Transition button Click to select the next transition on the selected track.

Outgoing Trim Offset field Displays the number of frames offset in the outgoing clip. Click to select the offset, and drag to change the offset value. A selected offset has a yellow border if Ripple is enabled, and a red border if Ripple is disabled. Available in Trim mode only.

Incoming Trim Offset field Displays the number of frames offset in the incoming clip. Click to select the offset, and drag to change the offset value. A selected offset has a yellow border if Ripple is enabled, and a red border if Ripple is disabled. Available in Trim mode only.

Trim Offset field Displays the number of frames offset as the result of the slip or slide operation performed on the selection. Non-editable. (Not shown)

-5 button Click to trim the selection five frames to the left.

-1 button Click to trim the selection one frame to the left.

+1 button Click to trim the selection one frame to the right.

+5 button Click to trim the selection five frames to the right.

Preroll field Displays the number of preroll frames when playing a clip. Editable.

Play button Click to activate the current play behaviour selected for this button. Click and hold to list a selection of playback types. The Play button will change to display the current play status; Once, Loop, or Back and Forth.

Postroll field Displays the number of postroll frames when playing a clip. Editable.

Player Options box Select an option for working in the player. Available options differ depending on the view selected.

About Timeline Tracks and Versions

Different areas on the timeline form a hierarchy that allows you the flexibility to composite on multiple tracks while maintaining different video streams or versions of your work.

Think of a version as a single stream of video on the timeline. Each version can have multiple tracks. While you can also use sequences on the timeline to accomplish similar results, use versions for the following:

- Compare two streams, such as an offline and online version. You can use the player in a split view to compare versions.
- Create matte containers with an Axis timeline effect, to help you key using a separate fill and matte, for example.
- Create different versions of a track or tracks, to try out different effects without affecting each other.

Tracks on the timeline are stacked vertically within a version to help you composite.

Track Indicators and Tools

On the left side of the timeline, in the Patch Panel area, you can find indicators and other tools for working with tracks and versions.

In the example above, the upper track (version 1 track 2) is highlighted, and therefore selected. To highlight a track and select all clips on the track, click in an empty space in the Patch Panel area for that track.

The track indicators and tools for this track are (from left to right):

Grab area Grab the handle area of the track to move and reorder a track or group of tracks. As you are dragging, a red message gives you an indication as to the operation being performed.

Track Collapse/Expand arrow Click to collapse or expand all tracks within a version. You can collapse tracks to remove clutter from your timeline.

Patch Identifier (Source track) Indicates which source track is patched to the track (in green).

Track Identifier (Destination or Sequence track) Displays the version and track number (in dark grey).

Track Visibility icon Displays or hides the track.

Track Lock icon Enable track lock to prevent editing operations from being performed on the track. A locked track displays grey diagonal lines.

Sync Lock icon Enable to maintain sequence sync on a track or tracks.

Video Track indicator Indicates if a track is the primary or secondary track. The primary track can also be set by moving the focus point on the positioner.

Adding Tracks and Versions

To add a new video track:

- 1 On the timeline, select the version you want to add a track to.
- 2 On the bottom left of the timeline, click Track+, or from the Timeline Gear menu, select **New ► Video Track**.

A new track is added to the version above the last existing track. If you want the track to be added below the last existing track, press **Ctrl** while clicking Track+. You can re-order your tracks, or even move a track to a different version by dragging the track from the handle at the left of the track.

To add a new audio track:

- 1 On the bottom left of the timeline, click Audio+ for a mono track or **Alt+Audio+** for a stereo track, or from the Timeline Gear menu, select **New ► Mono Audio Track** or **New ► Stereo Audio Track**.

A new audio track is added to the timeline below the last existing audio track.

To add a new version:

- 1 On the bottom left of the timeline, click Version+ for a mono version or **Alt+Version+** for a stereo version, or from the Timeline Gear menu, select **New ► Mono Version** or **New ► Stereo Version**.

A new version is added to the timeline above the last existing version. If you want the version to be added below the last existing version, press **Ctrl** while clicking Version+.

TIP To add multiple versions or tracks, you can use the keyboard to enter the number of versions or tracks you want to add, before using one of the above methods.

Moving, Resizing, and Deleting Tracks

To move a track:

- 1 Select the track or tracks that you want to move.
- 2 Grab the selected track from the left end of the Patch Panel area, and drag up or down to the desired location.

A red message appears while dragging to help guide while dragging the track.

- 3 Let go of the track to perform the move.

NOTE You cannot move a video track to the audio track area and vice-versa.

To resize a track:

- 1 Place the cursor at the bottom of the Patch Panel area for the track that you want to resize. Notice that the cursor becomes a line with a double-headed arrow.

- 2 Drag down to increase the height of the track (to see more information on the tracks clips, for example), or drag up to decrease the height of the track.

TIP To increase or decrease the height of all tracks, drag left or right on the vertical scroll bar to the right of the timeline.

To delete a track:

- 1 Right-click on the Patch Panel area of the track you want to delete.
- 2 Click Delete Track.

About Timeline Patching

When you record a source clip to a sequence, you must decide what source clip channels you want to use, and to which tracks you want to record them. To connect the source channels to the destination timeline tracks, you use patching. When you select the source clip, green patch identifiers indicate what channels you can record from the source to the timeline.

In the above example, the top track (V1.3) is patched, but no source is assigned. The middle track (V1.2) is not patched and no source is assigned. The bottom track (V1.1) is not patched, but a source is assigned. If you click the source patch or destination identifier on the bottom track, the track becomes patched, identified by the green patch.

With the patch identifiers, patching information is kept with the sequence clip. If you patch a source clip and then add a new track to the timeline, the source clip follows the track to which it was originally patched. This allows for a natural workflow of setting up the patch for a source clip, adding a new track, then setting up the patching for another source clip.

Patching on the Timeline

To patch a source channel to a sequence track:

- 1 Select a source in the workspace.
Source track patch identifiers appear in the Patch Panel area for each channel in the source.
- 2 Create the patch by right-clicking in the Patch Panel area, and using the Track Patching contextual menu to assign source tracks (from a list of available tracks). You can also select No Assignment to remove destination patch assignments. An assigned source can also be dragged up or down to change the assignment to a different track.
The patch identifier turns green and its source channel number indicates what source you have recorded to the track.

While the Track Patching contextual menu can be used for all your patching needs, there are particular cases where you can use different patching methods:

- If the track is patched but no source is assigned, drag on the grey patch identifier until the source channel that you want to use appears.
- If the track is not patched and no source is assigned, drag on the grey patch identifier until the source channel that you want to use appears and then click the patch identifier.
- If the track is not patched but a source is assigned, click the grey source channel number on the patch identifier.

Navigating and Searching the Timeline

Although you can search for elements by scrolling the timeline and displaying information about each element, the Find and Select in Timeline options make it easier to find specific elements. You can also refine your search when searching specifically on segments. Once your search is complete, or if you have multiple segments selected on the timeline, you can easily navigate through them.

Navigating with the Positioner

The frame directly beneath the positioner is displayed in the Player or is the current location for an edit such as a dissolve or cut. Drag the positioner to the desired frame on your timeline.

In the timecode area below the tracks, a lighter yellow box attached to the positioner indicates the length of the current frame, at the timeline zoom level. Click and drag this yellow box to move the positioner, so as not to accidentally move clips on the timeline.

If you know the amount of frames by which you want to move, a quick way to navigate the timeline is by using the keypad to enter the amount into the calculator.

- 1 On the timeline, make sure that there is no explicit selection of a clip or cut (in this case, a trim may be performed).
- 2 On the keyboard keypad, do one of the following:
 - Enter the number of frames by which you want to move the positioner (for example, +10 or -10).
 - Enter a number (without a + or -) to navigate to the closest timecode value that finishes with the value entered (for example, enter 10 to move the positioner to the closest timecode value that finishes by :10)
- 3 Press Enter.

TIP Use the timeline scroll bars to zoom timeline, if needed. Click Home in the Timeline Layout combo box to reset the timeline view.

Searching the Timeline

- 1 Click the magnifying glass icon at the bottom right side of the timeline.

The Find and Select in Timeline window opens.

- 2 Enable a button or multiple buttons to set your search criteria. For example, you can enable Dissolve in the Video Transitions area to search for all dissolves.

TIP You can enable Get Information From Current Element to automatically fill in information from the selected element into the search criteria.

- 3 Choose whether to search segments, containers, gaps, cue marks, or segment marks. You can select more than one or all of these options.
- 4 Set the strictness of the search by enabling Every Criteria Below or Any Criteria Below.
- 5 Click Select on Current Track or Select on All Tracks to perform the search.

The Find and Select in Timeline windows closes, and results are highlighted on the timeline.

Navigating Selected Elements on the Timeline

If you have multiple segments selected on the timeline (as the result of a search, or as a manual selection), you can easily navigate through them with keyboard shortcuts or with these procedures.

To navigate on the timeline in a linear manner:

- 1 In the Player, select and hold the Go To Next button to display more options.
- 2 Click Selected Element.
- 3 Use the Go To Previous and Go To Next buttons to scroll through the selected timeline elements.

To navigate to a specific selected timeline segment:

- 1 In the FX pipeline above the timeline, click the arrow beside the segment thumbnail.

You can see a list of all selected segments.

- 2 From the list, select the element you want to navigate to.
The timeline positioner moves to the selected segment.

Using Reveal to Locate Clips or Segments

To help you locate timeline clips or segments in the Workspace Media panel, you can use the reveal options. To locate a clip, you can double-click the timeline tab, or right-click the clip on the timeline, and select **Reveal ► Clip in Media Panel**. You can also locate a specific clip segment by right-clicking it on the timeline, and selecting **Reveal ► Segment in Media Panel**. The clip or segment is then highlighted in the Workspace Media panel, and the Thumbnail or Reels view, if displayed.

Using Markers on the Timeline

Use cue marks or segment marks to mark frames of interest on a clip. You can then quickly go to the marked frames. These marks are for reference purposes only; they do not affect the clip and are not used in any editing operations. You can add a mark to all tracks (*cue mark*) or to a single track or version (*segment mark*) on the timeline. Segment marks move on the timeline as you trim, slip, or slide a clip whereas cue marks stay at the same position on the timeline.

You can also add In and Out marks on timeline clips, as you can in the player.

To add marks on the timeline:

- 1 Go to the frame where you want to insert the mark.
- 2 From the Timeline Gear menu, in the Marks section, select an option to add an In, Out, Cue, or Segment mark.
- 3 If you added a cue or segment mark, you can change the name and colour of the mark to help you identify it more easily.

NOTE The Marks section of the Timeline Gear menu offers other options for clearing or deleting marks. The Go To section of the Timeline Gear menu offers navigation aids for existing marks.

About Timeline Containers

Containers are a convenient way to remove clutter from the timeline by grouping or nesting elements together. The elements, which can come from different tracks or versions, are treated as one unit yet remain individually editable. Containers behave like any other element but they appear in a separate timeline tab when you enter their editor. You can also add containers within a container.

Containers can also be used to take a clip and matte that are separate and add them to the timeline as a single element.

NOTE You cannot contain audio across tracks, but you can contain adjacent audio elements.

Creating a Timeline Container

To create a container:

- 1 Select all the elements on tracks or versions on the timeline that you want to collapse into the same container.

NOTE The bottom track is always trimmed out so that you can dissolve from an element to a container.

- 2 From the Timeline Gear menu, select Contain Selection.
All the selected elements are collapsed into a container and the element changes to a dark blue. You can add effects or perform other timeline operations to the contained element.
- 3 To edit the contents of the container individually, double-click the container, or click Open in the Container quick menu.
The elements that make up the container appear in their own timeline tab (the tab has a blue line). Yellow marks indicate the duration of the container. From this view, you can add effects, tracks, versions, or any other timeline operation.

To remove a container:

- 1 Select the container in the sequence where it was created.
- 2 From the Container quick menu, click Uncontain.
The container is removed and its contents are restored to the sequence.

About Timeline Gaps

Gaps are spaces on a track that do not contain media. You can use gaps to see through one layer to another or to apply effects to the tracks below the gap. If a gap exists on a track, the next track that contains video media is included in the edit as long as it is also below the focus track.

Since timeline gaps are independent of all media, they are useful for applying Timeline FX or Batch FX (as an Adjustment Segment) that affect all tracks under the gap.

By default, empty gaps are transparent. However, you can make an empty gap opaque if you do not want to see through to the next track. To do so, select the gap on the timeline, then click Opaque in the Gap quick menu.

While editing on the timeline, you can also quickly remove a gap between elements by right-clicking the gap, and choosing Close Gap.

When selecting elements on the timeline with a rectangle selection (that is, when drawing a bounding box around them), you can choose whether to include gaps by enabling or disabling Selection Includes Gaps in the Timeline Options menu.

Playing the Timeline

You can control how the timeline plays back. For example, frame-step through a shot to isolate a frame or jump to the start of an element to play a specific shot. The image window updates as the positioner moves on the timeline. While you can play your timeline in any of the Viewing panel's View modes, if the Player is displayed, you can also use any of the playback controls to move through the timeline. The Player also offers compare modes, where you can set up a split view to play primary and secondary versions or tracks at the same time.

To play the timeline:

- 1 Press **L** to play forward.
- 2 Press **J** to play backward.
- 3 Press **K** to stop playback.

TIP Press **J** or **L** multiple times to play faster. Press **Shift** along with **J** or **L** to play slower.

To scrub the timeline:

- 1 Drag the positioner, or the scrub area at the bottom of the timeline, left or right.
When scrubbing in the Source tab, you cannot navigate past the first or last frame of the clip.

To jump to a particular location:

- 1 Do one of the following:
 - Click the scrub area at a particular location.
 - Enter a value in the Current Timecode field.

TIP To enter a frame number instead of timecode, click the field to bring up the numeric keypad. Click **TC** to change to **FRM**, and then enter a frame number.

To frame-step the timeline:

- 1 Press the left or right arrow key.

TIP To frame-step a specific number of frames, enter a number in the numeric keypad and then press the left or right arrow key.

Cutting Clips on the Timeline

When you splice clips together, the location at which one clip changes to another is called a cut. A cut is useful when you want to extract part of an element or end a shot at a given frame.

You can make a cut at any point on a segment. A cut creates a transition with a head equivalent to the duration of the segment before the cut and a tail equivalent to the duration after the cut. For example, if you make a cut after the 5th frame in a 10-frame clip, the cut has a tail of 5 frames and a head of 5 frames.

In a match frame cut, the outgoing and incoming shots are from the same source and the outgoing and incoming frames are consecutive. Match frame cuts can be applied to clips with no effects added, and are indicated by an “=” on the cut point.

To add a cut on the timeline:

- 1 Move the positioner and focus point over the frame where you want to add a cut.
- 2 Select **Cut** from the Timeline Gear menu.
A cut is added at the specified location.

TIP You can also add cuts while the clip is playing by pressing the cut keyboard shortcut.

To remove a match frame cut:

- 1 Select the cut on the timeline.
- 2 Right-click and choose **Remove Match Cut**.
The cut is removed and the two elements are joined together.

Swapping Timeline Elements

You can quickly swap elements on the timeline. If segments contain timeline effects, they are swapped as well.

You can swap the following elements:

- Video segments or containers
- Audio segments or containers
- Tracks
- Versions
- Contiguous sequences of elements
- Video transitions (unless they start or end a contiguous sequence of elements)
- Audio transitions
- Gap effects

Elements must be compatible to be swapped. Compatible elements are:

- Video segments, video containers, gap effects
- Audio segments and audio containers
- Video transitions
- Audio transitions
- Tracks and versions

The following elements cannot be swapped:

- Gaps (unless they are between elements in a contiguous sequence)
- Cuts
- Cue marks
- Individual timeline effects

To swap timeline elements:

- 1 Select two elements belonging to the same family.

A contiguous sequence of elements is treated as a single element as long as the transition between the elements is selected. A gap can be part of a contiguous element as long as it is not at the beginning or end of the sequence.

- 2 Press **Shift+S**.

The elements are swapped according to the ripple setting. If the segments contain any timeline effects, they are swapped as well.

If Ripple is disabled, the segments are timewarped using a Constant Fit-to-Fill timewarp to fill each other's location. If there is already a timewarp on the segment, the timewarp is replaced by the Constant Fit-to-Fill timewarp. Gap effects, Matte containers, and contiguous sequences ripple regardless of Ripple status because they cannot be timewarped.

Transitions keep their alignment but their duration changes based on the head and tail frames of the destination segments.

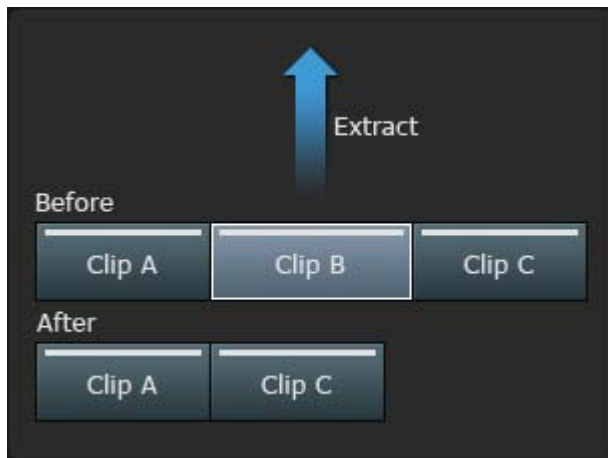

Removing Elements From the Timeline

When you remove an element from an edit sequence gesturally, the effect depends on whether Ripple is on or off.

When Ripple is off, you *lift* an element, leaving a gap in place of the lifted element.

When Ripple is on, you *extract* an element, and the edit sequence collapses to fill the gap left by the extracted element. This is also called a *ripple delete*.

You can lift or extract elements from the timeline independently of the Ripple mode using the contextual menu or keyboard shortcuts.

To lift or extract an element from using the contextual menu:

- 1 Select the element (or gap) you want to lift or extract or mark in and out points around the material.
- 2 Right-click the element and select one of the following:
 - Select Lift to lift the element from the timeline, leaving a gap in place of the lifted element.
 - Select Ripple Delete to extract the element from the timeline and ripple the remainder of the timeline to fill the gap.

To gesturally remove an element from an edit sequence:

- 1 Do one of the following:
 - Turn off Ripple to lift.
 - Turn on Ripple to extract.
- 2 Select the element (or gap) that you want to lift or extract and drag it out of the timeline.

NOTE Performing a Lift or Ripple Delete (Extract) operation on the timeline does not delete a segment between marks if another explicit selection is made.

Matching Clips with Their Sources

Matched sources are the original, untrimmed clips with their original names and timecode information. There are numerous ways to match clips with their sources:

- **Match Frame:** Displays the source and matches the frame and the In / Out markers of the selected clip.
- **Match Source:** Displays the source of the selected clip while retaining its original markers, if any.
- **Match Source and Keep Handles:** As above while retaining the handles.
- **Match Content:** Displays the sources of clips contained within transitions, containers, matte containers and Batch FX clips.
- **Match Content and Keep Handles:** As above while retaining the handles.

NOTE The Match Content options can also be performed on timeline clips.

- **Match All Sources:** Displays all the sources within a selected sequence.
- **Match All Sources and Keep Handles:** As above while retaining the handles.

If the source is already on the Desktop, it is centred on its reel. If the source is not on the Desktop, the cursor becomes a white arrow, prompting you to select a destination reel on which to display the source(s).

To match a frame:

- 1 Select a clip on the Desktop and place the cursor at the frame you want to match.
- 2 From the contextual menu, select **Match ► Frame**.
- 3 Select a destination if the source is not already on the Desktop.
The source is displayed centred on the destination reel at the appropriate frame.

To match a source:

- 1 Select a clip on the Desktop .
- 2 From the contextual menu, select **Match ► Source** .
- 3 Select a destination if the source is not already on the Desktop.
The source is displayed centred on the destination reel at the appropriate frame.

To match content:

- 1 Select a transition, container, matte container, or Batch FX clip on the Desktop , or a timeline clip.
- 2 From the contextual menu, select **Match ► Content**.
- 3 Select a destination if the sources are not already on the Desktop.
The sources are displayed centred on the destination reel.

To match all sources within a sequence:

- 1 Select a sequence on the Desktop.
- 2 From the contextual menu, select **Match ► All Sources**.
- 3 Select a destination if the sources are not already on the Desktop.
The sources are displayed centred on the destination reel.

Grouping and Syncing Elements on the Timeline

You can create editorial groups to preserve the relationship between timeline elements in a vertical composition. For example, if you have a video clip with two tracks of audio overlapping on the timeline, you can create a group for them. When you edit one segment that is part of a group, all segments in the group are edited in the same way. If your group becomes out of sync, a visual cue is displayed on the timeline, and tools are available to help you resync the elements.

To create an editorial group:

- 1 On the timeline, select the overlapping video or audio elements to include in the group.
- 2 From the Timeline Gear menu, select **Group ► Group**.

NOTE You can also right-click your selection, and choose Group from the contextual menu. If Group is unavailable in the contextual menu or the Timeline Gear menu, the selection is not able to be grouped.

Once a group is created, file names on the elements are underlined to indicate group status.

- 3 Enable Link to allow elements in the group to be edited together (you can use the keyboard shortcut for Invert Group Selection to temporarily change the status of the Link button during manipulation).

TIP If you cut a segment that is part of a linked group, all elements in the group are cut at the positioner location, and two separate groups are created from the cut segments.

Resetting Sync

If an editing operation removes the sync for a track in a group, a red plus (+) or minus (-) symbol appears in the element with the amount of frames that are out of sync to the left (-) or right (+).

You can attempt to manually fix the sync issue by editing the out-of-sync element. In this case, make sure that Link is disabled. Once you have resynced, you can enable Link again.

You can either resync the elements or reset the offsets, creating a new sync relationship based on the current position of the segments.

To regain sync:

- 1 Select the element that is out of sync.
- 2 Right-click the element, and select Resync.
The element is resynced, if possible, and the out-of-sync symbol disappears.

To reset sync offsets:

- 1 Select any element in the edit sync group.
- 2 Right-click the element, and select Reset.
The segments remain in their current positions. The sync offsets are removed creating a new edit sync group.

Deleting and Disabling Editorial Groups

When you delete an editorial group, the sync is removed from all elements that were part of the group. You can also temporarily disable an editorial group.

To delete an editorial group:

- 1 Select one of the elements that make up the group.
- 2 From the Timeline Gear menu, select **Group ► Ungroup**.

NOTE You can also right-click your selection, and choose Ungroup from the contextual menu.

To remove sync temporarily:

- 1 Select one of the elements that make up the group.
- 2 Disable Link.
- 3 Edit an element of the group.

No other elements in the edit sync group are affected. A red plus (+) or minus (-) symbol appears on every element that is out of sync.

TIP You can change the Link mode temporarily on-the-fly by using the keyboard shortcut for Invert Group Selection.

Syncing Tracks and Versions

You can use the track and version-based sync locks to decide the behaviour of tracks or versions when performing editing operations, such as trimming or an insert edit. In this case, you do not have to select individual elements on tracks.

The contents of a track set to Sync can ripple even when nothing is selected for the edit on it. This is to keep segments in sync throughout many tracks and versions. For example, performing an insert edit on a track can have the effect of a gap of the same length as the inserted material being created on another synced track.

To turn on or off syncing for tracks or versions, click the sync lock icon in the Patch Panel area. In the following example, sync is enabled for tracks V1.1 and V1.3, and disabled for track V1.2.

You can also right-click a sync lock icon and select to sync or remove sync from all tracks or versions.

Affected Editorial Operations

The state of the track or version sync lock is taken into account when performing the following operations:

- Insert
- Extract
- Delete*
- Trim*
- Move*
- Slide*

*Ripple must be enabled.

These editing operations ignore sync lock:

- Aligned Edit
- Overwrite
- Replace
- Append
- Prepend
- Lift
- Slip

Timeline Reference

Use these settings to help you navigate and perform tasks on the timeline. You can also right-click anywhere on the timeline to display a contextual menu of relevant operations for the type of element selected.

Navigation

Positioner The “playhead” for playing the clip, displayed as a vertical yellow bar. The frame directly beneath the positioner is displayed in the Player or is the current location for an edit such as a dissolve or cut.

In the timecode area below the tracks, a lighter yellow box attached to the positioner indicates the length of the current frame, at the timeline zoom level. Click and drag this yellow box to move the positioner, so as not to accidentally move clips on the timeline.

Focus point A horizontal yellow line on the positioner indicating the current track.

Back button Click to move back one page in the timeline window.

Horizontal scroll bar To pan, drag left or right. To zoom the timeline, drag up or down.

Horizontal Zoom

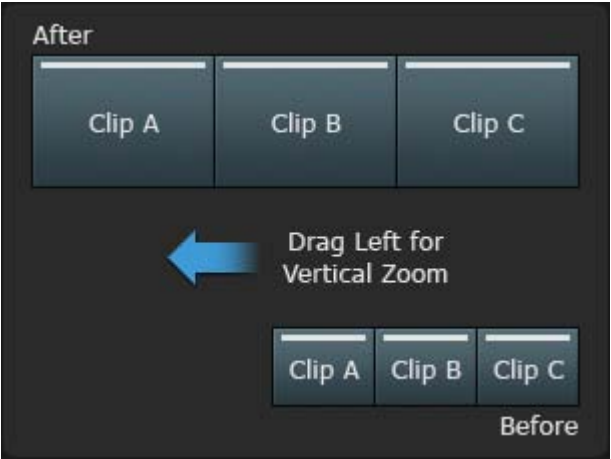

Forward button Click to move forward one page in the timeline window.

Current Timecode field Displays the timecode of the current position. Editable.

- **button** Click to expand track height.

+ **button** Click to decrease track height.

Vertical scroll bar To pan, drag up or down. To zoom the timeline, drag left or right.

Vertical Zoom

Timeline Search button Click to open the Find and Select in Timeline window to search the timeline using many different criteria.

Timeline Layout combo box Select an option to display the timeline.

Select:	To:
Home	Reset the view of the timeline.
Reset Height	Reset the height of the tracks in the timeline.
Fit to Width	Reset the horizontal scale of the timeline.

Select:	To:
Fit Selection	Centre the timeline on the selected element.

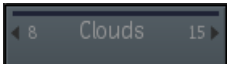

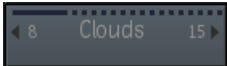

Rendering

Rendering combo box Select an option to render timeline effects. You can edit effects after rendering.

Select:	To:
Render Selection (or Burn Selection)	Render the selected elements.
Render (or Burn)	Render to topmost track in the timeline.
Use Proxies	Render proxies only, not the corresponding high-resolution images. An amber outline appears on the timeline segment to indicate the state of the rendering. Available if proxies are selected during the setup of a project.

NOTE If you need to refresh (or force) a render on a selection, first select Flush Renders from the Media submenu in the Timeline Gear menu, then re-render the selection.

Depending on how a clip is rendered, you can see a visual representation on the render bar at the top of the clip on the timeline:

Render Bar:	State:
	Unrendered.
	Rendered.
	Partially rendered.
	Proxy rendered.
	Proxy partially rendered.
	Sent to Burn.

Viewing

Timeline View Mode box Select a viewing mode for working in the timeline.

Select:	To Display:
Timeline	Video and audio tracks in a timeline format with a positioner at the location of the current frame.
Collapsed	Only the current frame of each edit sequence. The edit sequence appears in the form of a stack. Shuttle through the sequence by dragging the cursor across the bottom of the frame.
Head-Tail	The first and last frames of each clip. Shuttle through the sequence by dragging the cursor across the bottom of any frame.
Storyboard	Only the first frame of each clip in the edit sequence. Shuttle through the sequence by dragging the cursor across the bottom of any frame.
Frames	Every frame in the edit sequence is displayed. Although you cannot edit in this mode, it is useful for viewing your entire edit.
History	A schematic or list representation of the majority of operations performed on a clip or timeline element.
Clip List	A list of objects and information about these objects that make up the timeline.

TIP In Collapsed or Storyboard view, you can drag sequences to reorder them. If you switch back to Timeline view, the new order of sequences is maintained.

Timeline Tasks

Timeline Gear menu Select a task to perform on the timeline. Some of the options have sub-menus with more options.

Select:	To:
New Tracks and Versions	Add new tracks or versions to the timeline.
Edit	Perform various element or timeline editing operations.
Rename	Rename the selected timeline element.
Rename Track	Rename the selected track.
Media	Options to flush renders, and to break the link between an element's metadata and media or high-resolution media.
Select All	Select all elements in the timeline.

Select:	To:
Deselect All	Deselect all elements in the timeline.
Container	Work with containers on the timeline.
Group	Create an edit sync group for selected timeline elements.
Go To	Navigate to various areas of the sequence.
Marks	Work with In and Out, Cue, or Segment marks.
Stereo	Work with stereo tracks on the timeline.
Cut	Add a cut to the selected element at the positioner location.
Cut All Tracks	Add a cut to all tracks at the positioner location.
Merge Tracks	Merge timeline tracks into a single track.
Swap Effects	Copy timeline effects between clips.
Lift	Remove the selected element from the edit sequence, and leave a gap in its place.
Ripple Delete	Remove the selected element from the edit sequence, and close the gap.
Close Gap	Remove a gap and collapse the elements to fill the gap.
Commit	Options to manage your timeline to simplify or save space.
Hard Commit	Commit an edit sequence to one continuous clip. Soft properties of the sequence such as transitions, head and tail frames, and timewarp data are removed.
Render	Manage render options for the timeline.

Other Options

Timeline Options menu Select an option for working on the timeline.

There are a number of audio options in this menu:

Select:	To:
Scrub Audio	Enable scrubbing audio while dragging the positioner.
Show Gain Animation	Display the animatable Segment Gain level.

Select:	To:
Show Waveforms With Effects	Display waveforms after an effect is applied to an audio segment.
Show Waveforms Without Effects	Display waveforms before an effect is applied to an audio segment.
Hide Waveforms	Not display waveforms.
Increase Waveform Range	Zoom in on the waveform.
Decrease Waveform Range	Zoom out on the waveform.

Use the Rectangle Selection options to select how timeline elements are included in a selection when drawing a bounding box around them.

Choose:	To select:
Inclusive	All elements that are partially or entirely included in the bounding box.
Partial	Only the portions of the elements that fall within the bounding box. Audio is selected on a sub-frame basis if Sub-frame Positioner is selected in the Timeline section of the Preferences menu.
Partial A/V	Only the portions of the elements that fall within the bounding box. Audio is selected on a frame basis even if Sub-frame Positioner is selected in the Timeline section of the Preferences menu.
Bounded	Only elements that are fully in the bounding box.

Enable Selection Includes Gaps to include empty gaps when performing a timeline selection.

Enable one or both snap options to include in the timeline snap criteria:

- Snap To Positioner on Gestural Insert
- Snap Includes Marks

Enable Focus on Trim if you want the timeline positioner to snap to the transition while trimming, allowing you to view frames in the player.

Timeline Media Management Options

The Commit area of the Timeline Gear menu offers a number of options to help you clean up your timeline or save space when archiving a project.

Commit Options

When you commit an edit sequence, it becomes one continuous clip. The soft properties of the sequence such as transitions, head and tail frames, and timewarp data are removed. The visual effects of the transitions and timewarps remain but you cannot edit them.

You can commit any selection of elements or tracks, or the entire timeline. Commit a portion of an edited sequence to simplify a timeline that is too complex or to recoup disk space.

You cannot recapture or reimport committed clips.

The following rules apply to hard commits:

- Hard commits are permanent; however, they can be undone using the Undo button (as long as undos remain in the undo buffer). If you want to consolidate elements but have the ability to make changes at a later time, use containers.
- Hard commits cannot be restored—the commit is permanent.
- Hard commits force a render on the selected elements.

You can also choose to only commit Timeline FX or Batch FX segments on the timeline.

Consolidate Handles

If you have video or audio elements on the timeline that have excessive handles, use the Consolidate option to remove head and tail frames. Consolidate your clip before archiving a project to avoid archiving a large number of unused frames. You can keep a specified number of head and tail frames when you consolidate (the calculator appears when you select Consolidate for you to enter the number of handles you want to keep). You can consolidate a single element or a selection of elements.

History Options

You can commit a clip with a history, or a clip segment with a history just as you would any other clip. When committing a clip, you delete the clip history without removing the clip or element's soft properties. Delete History deletes history frames for all selected segments.

Editing on the Desktop

11

About Editing on the Desktop

You can apply many types of edits to clips on the Desktop - splitting clips in two, splicing clips together, and adding dissolves.

Editing functions such as splicing clips create soft edits, which you can modify any time until you commit them. Soft edits created on the Desktop can be brought into the timeline for further manipulation.

All Desktop editing operations are applied to the audio and video by default. To edit the video only, select Edit Video Only from the Option box.

Some Desktop editing operations can be accomplished in two ways - by using menu commands and by using drag and drop gestures with the mouse or stylus. For these cases, this chapter describes both methods.

You can disable broadcast monitor support option in the User Interface tab of the Preferences. Disabling this option enhances interactivity when manipulating clips and performing gestural edits on the Desktop Reels.

NOTE When this option is disabled, Timeline FX are not automatically rendered and display Unrendered Frame on the Reels. However, the frame on which the Timeline positioner is parked, is rendered.

Editing Multiple-Resolution Clips

Editing operations that are performed on more than one clip, such as splicing two clips together, can only be done on clips of the same resolution, aspect ratio, and bit depth. For most editing operations involving two clips, if you attempt to use clips of differing resolutions, a pop-up menu appears stating that the source and destination clips are mismatched. If you click confirm, the source clip will be resized to match the destination clip.

Gestural Editing on the Desktop

Gestural editing is a technique in which you use your mouse or stylus to move clips among reels on the Desktop, and to perform cut, copy, insert, splice, and replace edits.

Gestural Editing Cursors

When you drag a source clip over a target clip, the cursor changes as the source clip moves over different areas of the target clip. The type of cursor indicates the type of edit that occurs when you drop the source clip on that spot.

All gestural splices, insert edits, and replace edits ripple the edit sequence; that is, they change the duration of the target clip unless you replace a clip with another clip of the same duration.

Cursor:	Appears when:	Use to:
<div> Insert</div>	The source clip is positioned between frames on the target clip.	Perform an insert edit.
<div> Replace</div>	The source clip is grabbed at any frame other than its first or last frame, and is positioned over a frame on the target clip.	Perform a replace edit. You cannot gesturally replace frames with a two-frame clip. However, you can perform this type of edit with a one-frame clip.
<div> Replace ahead</div>	The source clip is grabbed at its first frame and is positioned directly over a frame on the target clip.	Perform a replace edit starting at the frame under the cursor and moving in the direction of the arrow.
<div> Replace back</div>	The source clip is grabbed at its last frame and is positioned directly over a frame on the target clip.	Perform a replace edit starting at the frame under the cursor and moving in the direction of the arrow.

To perform a gestural insert or replace edit:

- 1 Drag the source clip over the frame in the target clip where you want to make the edit until you see the appropriate edit cursor.

- 2 Drop the source clip.
The clip is updated with the edit. The source clip replaces the frames of the target clip

Ganging Clips on the Desktop

You can gang clips and sequences together on the Desktop so that when you jog one, they are all jogged. This is useful for multicam setups. When you play a clip that is part of a gang, the current frame of all other ganged clips is updated once playback has stopped.

To gang two clips on the Desktop:

- 1 Make sure the clips are on different reels.
 - 2 Align each clip to be ganged to the timecode you want to lock.
 - 3 Select the clips while holding the `Ctrl` key, to make a multi selection.
 - 4 From the contextual menu, select Gang.
- The selected clips are ganged and the clip information turns green.

To select all clips in a gang:

- 1 Select any clip and/or sequence that is part of a gang.
 - 2 From the contextual menu, select **Gang > Select Gang**.
- All ganged clips/sequences are selected.

To remove a clip from a gang:

- 1 Select the clip(s) and/or sequence(s) you want to remove from the group.
 - 2 From the contextual menu, select **Gang > Ungang**
- All selected clips and/or sequences are unganged.

Cutting Clips

You can split a clip into two or more clips using the Cut command. When you cut a clip, you can retain the cut frames as head and tail frames (handles) on each resulting clip, creating a soft clip, or you can discard the frames.

The Cut options are described as follows.

Select:	To cut the clip:
After Selected Frame	After the frame that you select when in Cut mode.
At Splices	At every soft splice that occurs on the clip.
Every Nth Frame	At the intervals that you specify in the numeric field that appears when you select this option.

To cut a clip after the selected frame:

- 1 Select the frame after which you want to apply a cut.
- 2 From the contextual menu, select **Cut ► After Selected Frame**.
The clip is divided into two cuts after the selected frame. The frames in the second clip are renumbered starting at frame number 00001.

To cut a clip at its splices:

- 1 Select the clip on which you want to perform the cut operation.
- 2 From the contextual menu, select **Cut ► At Each Splice**.
The clip is cut into segments at every splice point. If the clip contained no splices, no cuts are made.

To cut a clip at every Nth frame:

- 1 Select the clip on which you want to perform the cut operation.
- 2 From the contextual menu, select **Cut ► At (n) Frame**.
- 3 Enter the number of frames to be contained in each cut in the Frame Number field.
The clip is cut into segments of the selected number of frames.

Cutting Dissolves and Timewarps

Performing a cut on an uncommitted dissolve or timewarp divides the soft edit into two soft cuts.

If the cut is performed on a frame within a dissolve, the dissolve is committed before the cut is made. The two resulting cuts are soft edits linked to the original source clips.

If the cut is performed on a frame within a timewarp, two clips with unrendered timewarps are created.

NOTE You should commit a soft cutout prior to archiving to avoid saving the soft cutout's source clip. See [Hard Committing from the Desktop](#) (page 334).

Cutting Clips Gesturally

Each frame in a clip contains two types of “hot spots”. The Move Clip hot spot is the part of the clip that is used to move clips around on the Desktop. The Cut Clip hot spots are the parts of the clips that are used to cut the clip.

(a) Move Clip hot spot (b) Cut Clip hot spots

To cut a clip gesturally:

- 1 Position the cursor over the frame where you want to make the cut. Place the cursor in the Cut Clip hot spot on the frame edge closest to the cutting point.
- 2 Grab the frame and drag up or down to cut it from the clip.
- 3 Drop it in another location on a reel.

Splicing Clips

You can join together either two or more clips on a reel. This creates a single clip with a soft edit (a splice) at the location where the clips were joined.

To splice two or more clips together:

- 1 Select the clips you want to splice together, by Ctrl+clicking them.
- 2 From the contextual menu, select Splice Selected.

The two clips are spliced together to form a single clip. A yellow transition handle indicates where the two clips were spliced together. To remove the yellow handle, hard commit the clip. See [Hard Committing from the Desktop](#) (page 334).

To splice together all clips on a reel:

- 1 Place the cursor in an empty area to the right or left of the reel.
- 2 From the contextual menu, select Splice Reel.
All clips on the reel are spliced together into one clip.
Yellow transition handles indicate where the clips were spliced together. To remove the yellow handle, hard commit the clip. See [Hard Committing from the Desktop](#) (page 334).

Splicing Clips Gesturally

To splice two clips together gesturally:

- 1 Select the source clip you want to splice into a target clip, using the Move Clip hot spot.
- 2 Move the selected clip so that it overlaps either the first or last frame of the target clip. The Insert cursor is displayed.
- 3 Release the clip.

The two clips are spliced together to form a single clip. A yellow transition handle indicates where the two clips were spliced together. To remove the yellow handle, hard commit the clip. See [Hard Committing from the Desktop](#) (page 334).

Inserting Frames and Clips

You can insert a source clip or a portion of a source clip after a frame in the target clip.

Inserting Frames Gesturally

You can insert a portion of a source clip after a selected frame in the target clip.

To insert frames:

- 1 Select the source clip from which you want to insert frames into a target clip.
- 2 In Collapsed mode, scrub the source clip to the first frame you want to insert and drop a marker, using the Open Bracket key ([).
- 3 Scrub the source clip to the last frame you want to insert and drop a marker, using the Close Bracket key (]).
- 4 While holding Ctrl+Alt+Shift, drag up from the source clip to extract the selected frames.
- 5 Move the selected frames so that they overlap the target clip in between the two frames within which you want to insert the source frames. The Insert cursor is displayed.
- 6 Release the frames.

The source frames are inserted in between the selected frames in the target clip. The remaining frames of the target clip are placed at the end of the inserted clip.

Inserting Clips Gesturally

You can insert an entire clip between two frames in the target clip.

To insert a clip:

- 1 Select the source clip you want to insert into a target clip, using the Move Clip hot spot.
- 2 Move the selected clip so that it overlaps the target clip in between the two frames within which you want to insert the source clip. The Insert cursor is displayed.
- 3 Release the clip.

The source clip is inserted in between the selected frames in the target clip. The remaining frames of the target clip are placed at the end of the inserted clip.

Replacing Frames and Clips

You can replace frames in the target clip with a source clip or with frames from a source clip.

Replacing Frames Gesturally

You can replace frames in a clip with an entire source clip. There are two ways to replace clips gesturally:

- **Replace** will replace the frame on which you drop the source with the current frame of the source and the source frames before and after the current source frame will replace the corresponding frames in the target clip.
- **Replace Ahead** will replace the frames after the selected frame in the target clip (including the frame on which the source clip was dropped).
- **Replace Back** will replace all the frames before the selected frame in the target clip (including the frame on which the source clip was dropped).

To perform a Replace frames operation:

- 1 Make sure the source clip used is not at the first or last frame.
- 2 Move the selected clip over the first frame that you want to replace in the target clip. The Replace cursor is displayed.
- 3 Release the clip.

The current frame in the source clip is matched to and replaces the frame on which you dropped the source clip and the source frames before and after the current source frame replace the corresponding frames in the target clip.

To perform a Replace Ahead operation:

- 1 Make sure the source clip used is at frame 1.
- 2 Move the selected clip over the first frame that you want to replace in the target clip. The Replace Ahead cursor is displayed.
- 3 Release the clip.

The current frame in the source clip is matched to the frame on which you dropped the source clip and the frames after the selected frame in the target clip are replaced with the frames of the source clip, including the frame on which the source clip was dropped.

To perform a Replace Back operation:

- 1 Make sure the source clip used is at the last frame.
- 2 Move the selected clip over the first frame that you want to replace in the target clip.
The Replace Back cursor is displayed.
- 3 Release the clip.
The current frame in the source clip is matched to the frame on which you dropped the source clip and the frames before the selected frame in the target clip are replaced with the frames of the source clip, including the frame on which the source clip was dropped.

Replacing Clips Gesturally

You can replace frames in a clip with an entire source clip. There are two ways to replace clips gesturally:

- **Replace Ahead** will replace the frames after the selected frame in the target clip (including the frame on which the source clip was dropped).
- **Replace Back** will replace all the frames before the selected frame in the target clip (including the frame on which the source clip was dropped).

To replace frames with a clip using the Replace Ahead operation:

- 1 Make sure the source clip used is at frame 1.
- 2 Move the selected clip over the first frame that you want to replace in the target clip.
The Replace Ahead cursor is displayed.
- 3 Release the clip.
The source clip replaces the frames after the selected frame in the target clip, including the frame on which the source clip was dropped.

To replace frames with a clip using the Replace Back operation:

- 1 Make sure the source clip used is at the last frame.
- 2 Move the selected clip over the first frame that you want to replace in the target clip.
The Replace Back cursor is displayed.
- 3 Release the clip.
The source clip replaces the frames before the selected frame in the target clip, including the frame on which the source clip was dropped.

Matching Clips with Their Sources

Matched sources are the original, untrimmed clips with their original names and timecode information. There are numerous ways to match clips with their sources:

- **Match Frame:** Displays the source and matches the frame and the In / Out markers of the selected clip.
- **Match Source:** Displays the source of the selected clip while retaining its original markers, if any.
- **Match Source and Keep Handles:** As above while retaining the handles.
- **Match Content:** Displays the sources of clips contained within transitions, containers, matte containers and Batch FX clips.
- **Match Content and Keep Handles:** As above while retaining the handles.

NOTE The Match Content options can also be performed on timeline clips.

- **Match All Sources:** Displays all the sources within a selected sequence.
- **Match All Sources and Keep Handles:** As above while retaining the handles.

If the source is already on the Desktop, it is centred on its reel. If the source is not on the Desktop, the cursor becomes a white arrow, prompting you to select a destination reel on which to display the source(s).

To match a frame:

- 1 Select a clip on the Desktop and place the cursor at the frame you want to match.
- 2 From the contextual menu, select **Match ► Frame**.
- 3 Select a destination if the source is not already on the Desktop.
The source is displayed centred on the destination reel at the appropriate frame.

To match a source:

- 1 Select a clip on the Desktop .
- 2 From the contextual menu, select **Match ► Source** .
- 3 Select a destination if the source is not already on the Desktop.
The source is displayed centred on the destination reel at the appropriate frame.

To match content:

- 1 Select a transition, container, matte container, or Batch FX clip on the Desktop , or a timeline clip.
- 2 From the contextual menu, select **Match ► Content**.
- 3 Select a destination if the sources are not already on the Desktop.
The sources are displayed centred on the destination reel.

To match all sources within a sequence:

- 1 Select a sequence on the Desktop.
- 2 From the contextual menu, select **Match ► All Sources**.
- 3 Select a destination if the sources are not already on the Desktop.
The sources are displayed centred on the destination reel.

Swapping Segments

You can swap a segment within a sequence with a source clip, directly from the Desktop, while preserving any Timeline FX applied to the original segment. When you swap segments, you select a frame in the target clip and a frame in the source clip. When the swap operation is performed, the selected frame from the source clip takes the place of the selected frame in the target segment and the remaining frames are aligned relative to this position.

To swap segments:

- 1 In the target clip, select a frame in the segment to be swapped.

NOTE If you are in collapsed view, the soft positioner at the bottom of the clip determines the selected frame. If you are in storyboard view, the first frame of the segment is selected by default.

- 2 From the contextual menu, select Swap Segment.

NOTE If you are swapping a shot in a dissolve, from the contextual menu, select **Swap Segment ► Incoming** or **Swap Segment ► Outgoing** to determine whether you are swapping the outgoing or incoming segment.

- 3 Click a frame in the source clip.

The selected segment in the target clip is replaced by the source clip and the selected frame from the source clip takes the place of the selected frame in the target segment and the remaining frames are aligned relative to this position. The selected frames are aligned in the swap operation.

NOTE If there are not enough frames before or after the align frame in the source clip to fit before or after the align frame in the selected shot an error message appears in the message bar.

Two clips on the Desktop prior to the Swap Segment operation. In this example, the operation will swap the green segment for the blue clip while aligning frame 8 from the green clip to frame 11 from the blue clip.

After the Swap Segment operation, the green segment has been swapped with the blue clip, while aligning frame 8 from the green clip and frame 11 from the blue clip.

Hard Committing from the Desktop

You can hard commit sequences and segments from the Desktop. When you commit a sequence or segment, the soft properties of the sequence such as cuts, transitions, head and tail frames, and timewarp data are removed. The visual effects of the transitions and timewarps remain but you cannot edit them.

To hard commit a segment:

- 1 Make sure the clip is at a frame within the segment to be committed.
- 2 From the contextual menu, select **Hard Commit ► Segment**.
The segment is committed.

To hard commit a sequence:

- 1 Select a sequence on a Desktop reel.
- 2 From the contextual menu, select **Hard Commit ► Sequence**.
The sequence is committed.

NOTE You can hard commit a sequence via Burn, by selecting **Hard Commit ► Burn**, from the contextual menu.

Rendering from the Desktop

You can render segments or sequences directly from the Desktop.

To render a segment:

- 1 Make sure the clip is at a frame within the segment to be rendered.
- 2 From the contextual menu, select **Render ► Segment**.
The segment is rendered.

To render a sequence:

- 1 Select a sequence on a Desktop reel.
- 2 From the contextual menu, select **Render ► Sequence**.
The sequence is rendered.

NOTE You can render a sequence via Burn, by selecting **Render ► Burn**, from the contextual menu.

Audio

12

You can perform many of the same editing operations on audio that you use to edit video, such as cutting, trimming, adding fades, and creating stereo tracks. A comprehensive set of audio effects tools is available in the timeline and Audio Desk for mixing and mastering your audio.

When working with audio you can:

- In the MediaHub, import and export audio files using a variety of formats.
- In the timeline, synchronize audio with video, and apply audio fades. You can edit these on the fly while the clip is playing. You can also assign input strips to output strips. You can also assign audio tracks to Audio Desk input strips.
- In the Audio Desk, adjust Gain, Pan, Mute, Phase Shift, and Solo settings for up to 32 individual input strips. You can apply these on the fly while the clip is playing. You can also assign input strips to output strips.
- In the EQ Desk, apply and adjust High Shelf, Mid Notch, Mid Presence, and Low Shelf filters to input strips.
- In the Auxiliary Effects Desk, adjust global settings for the Modulation, Delay, and Reverb Auxiliary Effects.
- In the Audio Desk, adjust the output Gain and Limiting for output strips.

NOTE You can only see the Audio Desk in the single player.

Accessing the Audio Desk

The Audio Desk components are split into two panels; the patch panel will display to the left of the viewer, while the EQ Desk and the Auxiliary Effects Desk will display to the right of the viewer.

NOTE The Audio Desk is accessible from the Player.

To access the Audio Desk:

- 1 From the Player view, select the Options drop down.
- 2 Click Show Audio Desk.
The Audio Desk panels are split to either side of the viewer.
- 3 Click the Audio Desk Panel button to switch between the Auxiliary Effects Desk and the Eq Desk panels.

Importing Audio Files

To import an audio file:

- 1 Click the MediaHub tab.
- 2 Enable Browse for: Files.
- 3 Browse to the location of the audio file.
The audio file thumbnail appears in the browser display.
- 4 Drag and drop the audio file from the browser into a media panel folder.

Monitoring Audio in Batch orBatch FX

You can select different audio sources to monitor in Batch orBatch FX. In the Batch Prefs menu, under the Preferences tab, you can choose your audio source from the Audio Source box.

Options are:

- **No Audio:** No audio is monitored.
- **Main Level:** Monitors the audio of the Timeline containing the Batch FX. This option is only available in Batch FX, not Batch.
- **Context 2:** Monitors the audio of the Batch orBatch FX clip set to Context 2 in the flow graph.
- **Context 1:** Monitors the audio of the Batch orBatch FX clip set to Context 1 in the flow graph.
- **Current:** Monitors the audio of the current selection in the flow graph.

Once you've selected an audio source, there are several ways you can monitor it.

- You can scrub your audio tracks from the Batch orBatch FX Timebar:
 - To analog scrub your audio, hold down `Ctrl+Shift` and scrub the Timebar.
 - To digital scrub your audio, hold down `Ctrl` and scrub the Timebar.
- From the Animation menu, under the Audio tab, you can playback your audio in real time, using the playback controls. See also [Generating Keyframes Based on Audio Analysis](#) (page 1508).
- Within Action, you can select a clip from the Action schematic and press `F2` to playback the audio of the selected clip in real time, using the playback controls above the Timebar.

Adding an Audio Effect on a Segment

To add an audio effect on a segment:

- 1 Select the audio segment.
- 2 Right-click on the segment and select Add Effects.
- 3 Enable one of the audio effects.
- 4 Adjust the parameters for the audio effect on the Effects Ribbon.

Adjusting the Audio Levels on Part of an Audio Segment

To adjust the audio level on part of an audio segment:

- 1 Select an audio segment.
- 2 Set the positioner to the relevant part of the segment.
- 3 Right-click on the segment and select Add Effect.
The Effects Ribbon for audio effects is displayed.
- 4 Select Gain Audio effects.
The toolbar displays the Gain features.
- 5 Enable Edit and Auto Key.
- 6 Right-click on the Gain slider and set Key frame.
- 7 Move the positioner down the sequence.
- 8 Adjust the Gain slider.
Another key frame is automatically created at the gain level selected.
The audio level is adjusted to the new gain.

You can click and drag the keyframes in the segment to adjust the audio level. Holding Shift + dragging constrains the adjustment vertically or horizontally. Setting the gain slider to zero brings the audio level back to the segment default.

Cross-fading Two Audio Segments Together

To cross-fade two audio segments together:

- 1 Move the vertical focus point inline with the relevant audio track.
- 2 Navigate to the cut point of the two audio segments with the positioner.
- 3 Click the Transition button.
- 4 In the Audio Transitions tab, enable Fade.
An audio transition is applied to the cut point of the two audio segments.
- 5 Adjust the length of the fade.
The audio cross-fades between the two audio segments.

Fading Audio Into or Out of a Clip

To fade audio into or out of a clip:

- 1 Move the vertical focus point inline with the relevant audio track.
- 2 Navigate to the beginning (or end) of the segment.
- 3 Click the Transition button.
- 4 In the Audio Transitions tab, enable Fade.
An audio transition is applied to the audio segment.
- 5 Adjust the length of the fade.
The audio is now fading into (or out of) the clip.

Scaling the Size of the Waveform

To scale the size of the waveform:

- 1 Do one of the following:
 - Drag the audio track to increase or decrease the track size, or
 - From the Audio pull down menu in the Timeline Menu Bar, choose Increase Wave Form (or to decrease it, Decrease Wave Form).

Displaying Audio Waveforms

To turn audio waveforms on:

- 1 From the Timeline Menu Bar at the bottom of the screen, select Audio > Show Waveforms With Effects.
The Waveform display for all audio segments is turned on.

To turn audio waveforms off:

- 1 From the Timeline Menu Bar, select Audio > Hide Waveforms.
The Waveform display for all audio segments is turned off.

To show audio waveforms without effects:

- 1 From the Timeline Menu Bar, select Audio > Show Waveforms Without Effects.
All Waveforms from the source are displayed and any audio timeline effects modifications are not reflected in the Waveforms.

Muting Audio Tracks

To mute an audio track in the timeline:

- 1 Locate the track you want to mute.
- 2 Click the speaker icon in the track identifier strip.
The speaker icon displays as a crossed-out icon to indicate the track is muted.

To mute an input strip:

- 1 In the Audio Desk, enable the Mute button for the input strip that you want to mute.
The strip is muted. In the case of a stereo audio track, both strips are muted.

Mapping Audio Tracks to Audio Desk Input Strips

In the patch panel each audio track has a small square box with a number. That number is the audio input that is matched to the numbers at the bottom of each audio strip at the bottom of the audio desk.

To map audio tracks:

- 1 Click on the audio input channel box in the patch panel.

- 2 Drag right or left and choose the audio input strip into the audio desk you would like this particular audio track to be patched too.
An audio track input is selected.

If the input channel box is empty, the audio track is not patched to an audio desk input. You will not hear audio segments for that track.

Normally all these mappings are automated. It is important to understand these outputs are either the audio channel outputs for your hardware or discrete channel outputs for files exported to the application.

Converting Audio from Stereo to Mono or Mono to Stereo

To convert a stereo audio track to two mono audio tracks:

- 1 Select the stereo track by clicking on the audio channel strip.
- 2 From the Timeline Gear menu, select **Stereo ► Split Stereo Track**.

To convert mono audio to stereo audio:

- 1 Select two mono tracks by control-clicking on the audio channel strips.
- 2 From the Timeline Gear menu, select **Stereo ► Merge Into Stereo Track**.

Timeline FX and Transitions

13

Timeline FX are effects you add directly to clips on the timeline. Timeline transitions are effects you apply directly to the cuts between clips. As such, Timeline FX and transitions accelerate the process of creating and modifying effects because you don't have to enter the editor to apply them. Some adjustments can be applied using a selected transition's quick menu.

There are separate video and audio effects, depending on what type of clip you want to apply effects to. Timeline FX, can be accessed, by selecting a Timeline FX in the timeline, the workspace or the Timeline FX pipeline. In order to access the timeline transitions, you must explicitly select a cut or transition in the timeline or in the Timeline FX pipeline.

Working with Timeline FX

Adding Timeline FX

To add Timeline FX to a clip:

- 1 Select a clip from the timeline.
- 2 Do one of the following:
 - Click the FX button.
 - Right-click on a segment in the timeline and choose Add Effect.

The Effects ribbon appears.

NOTE Effects that are enabled have already been added to the current Timeline FX pipeline.

- 3 Select the effect you want to apply.

The effect appears in the Timeline FX pipeline and on the timeline segment.

NOTE You may have to resize the video or audio track so that Timeline FX are visible on the timeline.

- 4 You can adjust the effect's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

Copying Timeline FX

You can copy Timeline FX from the timeline to the workspace, from the workspace back to the timeline, or from one segment on the timeline to another. Additionally, you can copy multiple Timeline FX simultaneously, as long as the Timeline FX you want to copy are from the same segment. You can also copy to and from the Media Panel or the Desktop reels.

A copy can be made gesturally or using contextual menus. Contextual menu operations can simplify copying operations when segments are far apart or in a different timeline, or if you plan to do other editing operations between copying and pasting.)

When you copy Timeline FX of the same type over another Timeline FX, the copied effect overwrites the preexisting one.

NOTE You may have to resize the video or audio track so that Timeline FX are visible on the timeline.

To copy Timeline FX to the workspace:

- 1 Do one of the following:
 - Select a Timeline FX in the Timeline FX pipeline.
 - Select a Timeline FX in a segment on the timeline.
 - Select a Timeline FX in the Media Panel.
 - Select a Timeline FX in the Desktop reels.
- 2 Do one of the following:
 - Drag the Timeline FX to the workspace. If you want to copy multiple Timeline FX, **Ctrl**-click the ones you wish to copy and drag them to the workspace.
 - In the Timeline FX pipeline, Media Panel or Desktop reels, right-click the Timeline FX, and select Copy. In the workspace, right-click and select Paste.

The Timeline FX appears in the workspace. It displays a thumbnail with the front view of the effect, and the shortened name of the effect(s) you copied.

To copy Timeline FX to the timeline:

- 1 Do one of the following:
 - Select a Timeline FX in the workspace.
 - Select a Timeline FX in the Timeline FX pipeline.
 - Select a Timeline FX in a segment on the timeline.
 - Select a Timeline FX in the Media Panel.
 - Select a Timeline FX in a Desktop reel.
- 2 Do one of the following:
 - Drag the Timeline FX to the Timeline FX pipeline.
 - Drag the Timeline FX to a segment on the timeline.

The Timeline FX appears in the Timeline FX pipeline and in the timeline segment.

To copy Timeline FX from one segment in the timeline to another:

- 1 Do one of the following:
 - Select a Timeline FX in the Timeline FX pipeline.
 - Select a Timeline FX in a segment on the timeline.
- 2 Do one of the following:
 - Drag the Timeline FX to a different segment on the timeline.
 - Right-click the Timeline FX in the Timeline FX pipeline, and select Copy. In the the current timeline or another timeline, right-click a segment and select Paste.

To copy Timeline FX to the workspace:

- 1 Do one of the following:
 - Select a Timeline FX in the Timeline FX pipeline.
 - Select a Timeline FX in a segment on the timeline.
 - Select a Timeline FX in the Media Panel.
 - Select a Timeline FX in a Desktop reel.
- 2 Do one of the following:
 - Drag the Timeline FX to the workspace. If you want to copy multiple Timeline FX, **Ctrl**-click the ones you wish to copy and drag them to the workspace.
 - In the Timeline FX pipeline, Media Panel, right-click the Timeline FX, and select Copy. In the workspace, right-click and select Paste.

To copy Timeline FX to the Desktop reels:

- 1 Do one of the following:
 - Select a Timeline FX in the workspace.
 - Select a Timeline FX in the Timeline FX pipeline.
 - Select a Timeline FX in a segment on the timeline.
 - Select a Timeline FX in the Media Panel.
 - Select a Timeline FX in a Desktop reel.
- 2 Do one of the following:
 - Drag the Timeline FX to the Desktop reel. If you want to copy multiple Timeline FX, **Ctrl**-click the ones you wish to copy and drag them to the workspace.
 - In the workspace, Timeline FX pipeline, or Media Panel, right-click the Timeline FX, and select Copy. Right-click a Desktop reel and select Paste.

Muting and Deleting Timeline FX

If you want to temporarily remove Timeline FX from a clip, you can mute it. You can quickly assess if a Timeline FX has been muted, because its LED is turned off.

To mute Timeline FX:

- 1 On the timeline, select the segment with the Timeline FX you want to mute.
- 2 In the Timeline FX pipeline, click the blue LED on the Timeline FX.
The LED darkens to indicate that the Timeline FX is turned off.
- 3 To unmute an effect, click the LED on the Timeline FX in the Timeline FX pipeline. The LED will turn blue, to indicate an unmuted Timeline FX.

To delete Timeline FX:

- 1 On the timeline, select the segment with the Timeline FX you want to delete.
- 2 Do one of the following:
 - From the Timeline FX pipeline or the timeline segment, drag the Timeline FX to the bottom of the screen.
 - Right-click the Timeline FX and select Delete.

Modifying Multiple Timeline FX

You can modify Timeline FX from different clips at the same time by multi-selecting clip segments. Selecting multiple segments allows you to apply changes to effects in one segment, and have those changes applied to the same effects in the other segments.

To add multiple Timeline FX to a segment:

- 1 Select a clip from the timeline.
- 2 Click the FX ribbon.
- 3 **Ctrl**-click the effects you want to apply to the segment.
- 4 Do any of the following:
 - Click a final effect button to add it to the selection.
 - Click outside of the FX ribbon.
- 5 The FX ribbon closes. The selected effects are applied to the segment.

To copy and paste multiple Timeline FX from the timeline:

- 1 Do one of the following:
 - **Ctrl**-click to select Timeline FX in the Timeline FX pipeline.
 - **Ctrl**-click to select Timeline FX in the segment.
- 2 Do one of the following:
 - **Ctrl**-drag the selection to the workspace.
 - **Ctrl**-drag the selection to another segment in the timeline.
 - Right-click the another segment and select Paste Effects.

To delete multiple effects:

- 1 Do one of the following:
 - **Ctrl**-click to select Timeline FX in the Timeline FX pipeline.
 - **Ctrl**-click to select Timeline FX in the segment.
- 2 Do one of the following:
 - From the Timeline FX pipeline or the timeline segment, **Ctrl**-drag the selection to the bottom of the screen.
 - Right-click the effects and select Delete.

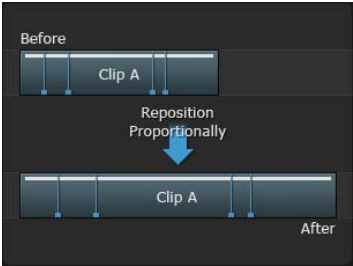

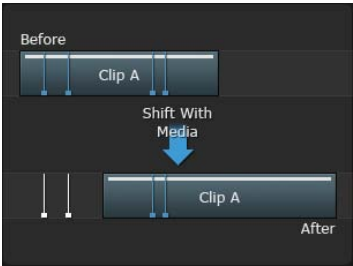

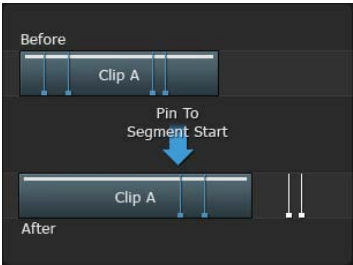

To modify a Timeline FX on multiple segments:

- 1 **Ctrl**-click to select multiple segments in the timeline.
- 2 Do one of the following:
 - Select the FX button. The FX ribbon appears and you can add one more effects.
 - Mute, unmute or delete Timeline FX in the Timeline FX pipeline. The effect state is updated in selected segments.
 - Right-click the segment and select Paste Effects to paste to all selected segments.

Sliding Timeline FX Keyframes

To slide Timeline FX within a clip:

- 1 In the Timeline FX pipeline or in the timeline segment, select the Timeline FX that you want to slide.
- 2 If the clip does not already contain animation keyframes, set keyframes on the clip to animate the FX.
- 3 Select how the animation channel is affected when you slide the animated effects by choosing an option from the Keyframe Move Modes box.

Select:	To:	Example
Reposition Proportionally	Resize the channel as you trim. The animation channel is scaled to fit into the timeline element. This option has no effect when you slip or slide.	
Shift With Media	Link the keyframes to their original frame numbers. The animation channel moves to follow the original frames as you trim.	
Pin To Segment Start	Unlink the keyframes from their original frame number. The animation channel remains with the timeline element as you trim.	

- 4 From the Editorial Mode box, select Slide Keyframes, which allows you to slide all of the keyframes of a specific Timeline FX on a clip.

NOTE You can only slide keyframes from one Timeline FX at a time.

Working with Timeline Transitions

Adding Timeline Transitions

To add a transition to the timeline:

- 1 Select a cut or transition in the timeline to enable the Transition button.
A proxy of the last frame of the left-hand segment, and a proxy of the first frame of the right-hand segment appears in the Timeline FX pipeline, with a cut or existing transition between the segments.
- 2 Do one of the following:
 - Click the Transition button to display the Transitions ribbon.
 - Right-click the transition on the timeline or in the Timeline FX pipeline.
- 3 Select the transition that you want to apply.
- 4 You can adjust the transition's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

NOTE Only one timeline transition can be applied at a time. Each time you apply a new transition, the latest transition that you applied appears between the segments, and you are only able to modify the settings of the current transition.

Copying, Moving and Removing Timeline Transitions

A transition that is copied or moved over another transition overwrites the prior transition and replaces any prior settings.

To copy and paste a timeline transition:

- 1 Select a timeline transition.
- 2 Right-click the transition on the timeline or in the Timeline FX pipeline and select Copy or press `Ctrl+C`.
- 3 Select a cut or another transition in the timeline or in the Timeline FX pipeline and either right-click and select Paste or press `Ctrl+V`.

To gesturally move a transition:

- 1 Select a transition on the timeline.
- 2 Drag the timeline transition over another cut or transition and release the cursor.

To remove a transition:

- 1 Select a timeline transition on the timeline or in the Timeline FX pipeline.
- 2 Do one of the following:
 - Right-click the transition on the timeline or in the Timeline FX pipeline and select Delete.
 - `Alt+click` the selected transition.
 - Drag the transition to the bottom of the screen and release the cursor.

Working with Timeline FX and Transition Presets

A library of presets is available for certain Timeline FX and transitions. A preset can be applied as is to achieve a particular effect, or it can be tweaked as needed, also speeding up the process compared to customizing a Timeline FX from its default settings in the Editor.

All Timeline FX quick menus display a Presets box to the right of the Editor button. If the Presets button is enabled, then presets can be applied from the quick menu or in the Editor. If the Presets box is greyed out there are currently none available for that type of Timeline FX.

To load a preset to a Timeline FX:

- 1 Display a Timeline FX quick menu (for example, a GMask Timeline FX).
- 2 Do one of the following:
 - Click the Presets drop-down list to select a preset by a filename in the list.
 - Click the Presets button to open the file browser. Navigate to the preset and select it to return to the quick menu.

TIP Switch to Proxies view to see a visual representation of the presets.

Menu settings are changed to reflect the chosen preset.

Navigating Timeline FX and Transitions

If you have multiple Timeline FX or transitions in a segment, or use the same type of Timeline FX in a track, you can easily navigate them with keyboard shortcuts.

Navigating timeline transitions updates the display of the timeline and the Timeline FX pipeline with the current selection. Navigating Timeline FX will update the timeline, and Timeline FX, and the player. If you are in an effects editor, Timeline FX navigation shortcuts are still active and will update the image display window.

To select:	Press:
The previous effect in the Timeline FX pipeline of the current segment (muted effects are not selected).	Ctrl+Shift+Left Arrow
The next effect in the Timeline FX pipeline of the current segment (muted effects are not selected).	Ctrl+Shift+Right Arrow
The same effect in the previous segment with the same effect.	Shift+Up Arrow
The same effect in the next segment with the same effect.	Shift+Down Arrow
The previous transition in the timeline track.	Up Arrow
The next transition in the timeline track.	Down Arrow
The outgoing frame before the cut.	Win (Smoke)+Left Arrow
The incoming frame before the cut.	Win (Smoke)+Right Arrow

To select:	Press:
The outgoing frame and incoming frame adjacent to the cut.	Win (Smoke)+Down Arrow

Adding Timeline FX to Gaps

Gaps are empty spaces between elements in an edit sequence. When you apply Timeline FX to a gap, you create a gap effect.

The effects applied to gaps affect the media under them.

Gaps usually appear in the following places:

- The empty space between media elements on a video track.
- An empty video track.
- The space between cut points on an empty video track. Cut points are useful for containing a gap effect applied to an empty video track. The areas to either side of the cut points are also gaps.

Gap effects are not restricted by in points, out points, cuts and transitions, so they are easily trimmed, moved and duplicated. You can trim a gap effect over the entire duration of the video track regardless of the underlying cut points.

You can also freely edit cuts and transitions between elements on video tracks under the gap effect. You can cut an element, add a transition at the cut point, and then replace the incoming element without affecting the gap effect. In addition, gap effects can be copied and placed over different media in the timeline.

To add Timeline FX to a gap:

- 1 Do one of the following:
 - Move the positioner and its focus point over the gap.
 - Select a gap between two segments or two cuts.
 - Select a gap between a segment and a cut.
 - Select an empty video track.
- 2 Click the FX button to display the Effects ribbon.
- 3 Select the Timeline FX you wish to apply to the gap.
- 4 Edit the Timeline FX using the quick menu or click the Enter Editor button to access the full editor.

Working With Clip Format and Import Options on the Timeline

You can access format and import settings of an imported clip directly on the timeline. In the Editing panel, these options are represented in the Timeline FX pipeline, prior to the application of any Timeline FX. These options can be edited for the selected clip, and copied and pasted to other segments that use the same clip format.

For example, after importing R3D footage and adding it to the timeline, you can edit the colour curves of a clip in the Timeline FX pipeline, and also copy the option from the Timeline FX pipeline directly to other R3D clips that are used in the same timeline.

To access the Format and Pre-processing Options Editor:

- 1 Click the Timeline tab.
- 2 Select the clip in the timeline to display its Timeline FX pipeline.
- 3 Do one of the following:

NOTE Format and import options are accessible in the same editor. You can open the editor once, then switch between menus in the editor to edit different option types.

- Select the Format Options button in the Timeline FX pipeline, and click Editor in the quick menu. The Basic menu opens. Format options will be saved to this menu.
- Select the Pre-Processing button in the Timeline FX pipeline, and click Editor in the quick menu. The Resize menu opens. Import options will be saved to this menu and the RGB LUT menu.

To copy format and import options to another segment on the timeline:

- 1 Select the clip you wish to copy in the timeline.
- 2 In the Timeline FX pipeline, do one of the following:
 - To copy basic clip format settings, Click and drag the Format Options button to another segment on the timeline.
 - To copy resize and RGB LUT settings, click and drag the Pre-processing button to another segment on the timeline.

2D Compositing on the Timeline

Use Comp Timeline FX to control the composition of a segment with the input on the track beneath it. By default, the currently selected segment is used as the foreground of the composition, and the layer underneath it is used as the background, however these inputs can be swapped. The type of composition is determined by the blending mode and the level of transparency of the foreground input.

By default, the Comp Timeline FX button is unmuted: compositing is active and, by default, the foreground and background mattes are on. When muted, only the RGB clip is displayed.

You can use Comp Timeline FX to control the composition and display of the output matte used in the segment's Timeline FX pipeline. In the editor, you can view the composited matte, and edit how it is blended.

Adding Matte Containers

A matte container is a container with the RGB portion of an image on one track and its matte on another. If the matte for a clip exists separately from it, you can add the clip and its matte to the timeline as a single element by creating a matte container for them.

To create a matte container:

- 1 In the timeline, select the clip you want to add the matte container to.
- 2 In the Timeline FX pipeline, select the proxy for the clip.
Underneath the pipeline, a quick menu appears.
- 3 Click the Add Matte button.
- 4 Select a matte from the workspace. The Matte Container button appears in the Timeline FX pipeline.

- 5 To open the Matte Container, click once on the Matte Container button and then click Open in the quick menu, or double-click on the Matte Container button.
- 6 Once the Matte container is open, you can adjust the settings for the matte or add other effects to it.
- 7 If you want to mute the matte, right-click the Matte Container button and select Mute.
- 8 If you want to remove the matte, click once on the Matte Container button and then click on the Uncontain button.

Working with Mattes and Masks on the Timeline

Masks and mattes increase the versatility of the effects you apply on the timeline, allowing you to delimit the regions used for processing and effect, with a mask, and to create regions of total or partial transparency in the clip, with a matte.

Using Mattes in 2D Transform Timeline FX

In the timeline, a matte container on a track is stacked on a track with a clip of a cloud image.

The 2D Transform Timeline FX is applied, with the Matte Offset controls disabled. The front clip and matte transformations are linked.

The 2D Transform Timeline FX is applied, with the Matte Offset controls active. The matte position is offset independently of the RGB clip in the matte container.

The matte can be offset from its original position by changing its position along the X and Y axes, or by rotating or scaling it.

Edit the offset in the 2D Transform quick menu or editor. In the 2D Transform quick menu, use the 2D Transform Tab selector to display the Matte Offset menu and its controls.

Using Mattes in Blur Timeline FX

In the timeline, The matte container of the talent's head is stacked on a cloud image background.

The Blur Timeline FX is applied, and the same blur is applied to the clip and the matte (Lock to Front is enabled).

The Blur Timeline FX is applied, and a blur is applied to the matte instead of the clip (Lock to Front is disabled).

Image courtesy of The House

The matte values can be blurred separately or with the same values as the front clip.

In the Blur quick menu or the editor, you can apply blur values to the matte. Click the Lock to Front button to use the same blur values that are applied to the front clip. In the Blur editor, you can also invert the matte or use the matte to apply blending in the regions defined by the matte.

Using Masks in Colour Correct and Colour Warper Timeline FX

The RGB clip will be added to a matte container with a matte surrounding the talent.

A Colour Warper Timeline FX is applied to the matte container. By default, it creates a transparency.

When the matte clip is used as a mask, it defines where to apply the Colour Warper Timeline FX on the RGB clip.

Image courtesy of Das Werk

You can change the default functionality of the matte clip and instead use it as a mask to isolate the area in which you want to add colour effects and corrections.

In the Colour Corrector or Colour Warper quick menu, enable the Use Mask button, which uses the matte to delimit the region that will be processed with the colour effects.

NOTE When Use Mask is on, all mattes generated before the Colour Correct or Colour Warper Timeline FX are ingested for use in these effects as masks, and matte functionality is no longer available for Timeline FX used after it in the pipeline.

Using Mattes in Comp Timeline FX

In a matte container containing a logo, The Comp Timeline FX is active by default. An image of a gladiator was stacked on a track underneath, so it is composited in the result.

When the Comp Timeline FX is disabled or the matte is turned off, only the RGB clip is displayed.

Image courtesy of Buzz Image Group, Inc.

All mattes used in the Timeline FX pipeline for the segment are composited using this effect. The composited mattes for each segment can be turned on or off, or be inverted.

A clip can be in a premultiplied or unpremultiplied state. An unpremultiplied clip has its pixels divided by the pixels in the matte. A premultiplied clip has its pixels multiplied by the pixels in the matte. Use the Comp Timeline FX quick menu or the editor to set the Segment and Background Premultiplication boxes to the appropriate states.

By default, a segment on a track is blended with the background, and the matte is turned on by default. In the Comp quick menu and editor, use the Matte box to also turn the matte off or invert it.

See [2D Compositing on the Timeline](#) (page 351).

Using the GMask Timeline FX

On an RGB clip, using GMask Timeline FX will apply the matte to create a garbage mask that defines which areas of the image appear in the result clip. With a matte container, the matte clip and the GMask matte are composited in the result matte.

Use the GMask quick menu to select a shape from a library of presets, or enter the editor to create your own.

See [Masking and Rotoscoping](#) (page 905).

Using Masks in Text Timeline FX

In RGB rendering mode, the Text Timeline FX is overlaid on the clip.

In RGBA rendering mode, only the text appears on the clip and the image is masked out. In this example, a cloud image was stacked on a track underneath, so it appears as a background.

In A Only rendering mode, the text appears with the RGB clip used as a fill. In this example, a cloud image was stacked on a track underneath, so it appears as a background.

There are three states in which you can manage text in Timeline FX, (two of which allow masking functionality).

In the Text Timeline FX quick menu, use the Alpha Rendering Mode box to select a state:

- **RGB:** If you are using an RGB clip (or matte container), to generate a clip (or RGB portion of the clip) with the text overlaid.
- **RGBA:** If you are using an RGBA clip/matte container, to generate a text overlay and use the text outline as a mask to display it on background tracks.
- **A Only:** To generate a source based on the text as a mask and segment as a fill. For best results, use unpremultiplied input. In the segment's Comp Timeline FX, verify that the Segment Premultiplication box is set to Unpremultiplied.

Compositing in 3D Space on the Timeline Using Action

Use Action as a Timeline FX to work in 3D space directly on the timeline. Think of Action as a super tool on the timeline, unlocking many tools in a 3D environment, allowing you to:

- Import Alembic or FBX geometries (as well as other 3D formats).
- Create 3D text that you can extrude and manipulate as a geometry.
- Add lights and shadows, as well as other lighting effects, such as lens flares and rays.
- Look at, and work with your scene, through an Action camera.
- Access the Modular Keyer, where you can key out green screen footage.

TIP While Action can perform simple operations, such as picture-in-picture, there are other Timeline FX tools that you can use that may be more lightweight, such as 2D Transform or Flip.

Using Action on the timeline offers you a way to create complex compositions as an alternative to working in Batch or Batch FX flow-graph representations. But this workflow allows you to start compositing on the timeline with Action, then promote and explode your comp in Batch or Batch FX to continue working.

When applying an Action Timeline FX, a composition is created with an axis, surface, light, and camera. This allows you to start working directly from the quick menu. Use the Action Quick Menu selector to switch between Axis, Camera, Surface, Light, and Rendering settings. To access the full Action menu, click the Enter Editor button. When selecting multiple clips with Action Timeline FX applied, you can use the Quick Menu to apply settings to all the selected clips (except for camera settings).

Action is also available as a timeline transition, and has all the same options available as Action Timeline FX in the quick menu. In addition, you can access specific transition settings by choosing Transition from the Action Quick Menu selector. When you enter the full Action menu after applying an Action timeline transition, notice that the outgoing clip is listed in the Media list as the back media, while the incoming clip is listed as the front/matte media.

NOTE If you access Action as a Timeline FX or transition, you are limited to one front/matte media. Therefore, some Media menu settings and nodes are not available. For example, if you need to work with stereo clips, access Action from Batch or Batch FX, or from the Tools menu.

Compositing Examples

Depending on the effect you are trying to achieve, you can decide how your Action Timeline FX is composited (either by the Comp node, or by Action itself). The following two general examples show how you can comp your effect in different ways.

Example 1: Comping with the Comp node.

- 1 On the timeline, add an Action Timeline FX to a gap on a track above another clip.
- 2 In the FX ribbon, make sure that the Comp node is enabled.
- 3 Double-click the Action entry in the FX ribbon to enter the Action editor.
You can see that the lower clip from the timeline is the front/matte and background in Action.
- 4 In Action, add a 3D Text node, change and animate the text, as needed.
- 5 In the View box, select **Context ► Primary Track** to see your effect in the context of the timeline.

TIP You can also toggle the **F4** keyboard shortcut between the Comp output and Matte output.

- 6 In the Action Output menu's Comp box for the Comp output, select Use Colour.

Since Action as a Timeline FX is limited to Comp and Matte outputs, in this case you are creating a fill and alpha to then allow the Comp node to blend the Action result with the background. When you return to the timeline, you can change any blending settings in the Comp node menu.

Example 2: Comping in Action.

- 1 On the timeline, add a green screen clip on a track above a moving background.
- 2 Add an Action Timeline FX to the green screen clip, and enter the Action editor.
- 3 Use the Modular Keyer within Action to key the green screen footage onto the background.
- 4 Add lights, lens flares, and any other Action nodes, as needed.
- 5 In the Action Output menu's Comp box for the Comp output, select Use Background.

In this case, when you return to the timeline, you are sending the complete result, so there is no need to use the Comp node at the timeline level.

Keying on the Timeline

You can create chroma keys directly on the timeline using the Modular Keyer in Action. When you enter the Modular Keyer, the clip loaded as the Front and Matte (or Key In) is the clip with the Action Timeline FX, and the clip loaded as the Back is the next available track on the timeline.

To key on the timeline:

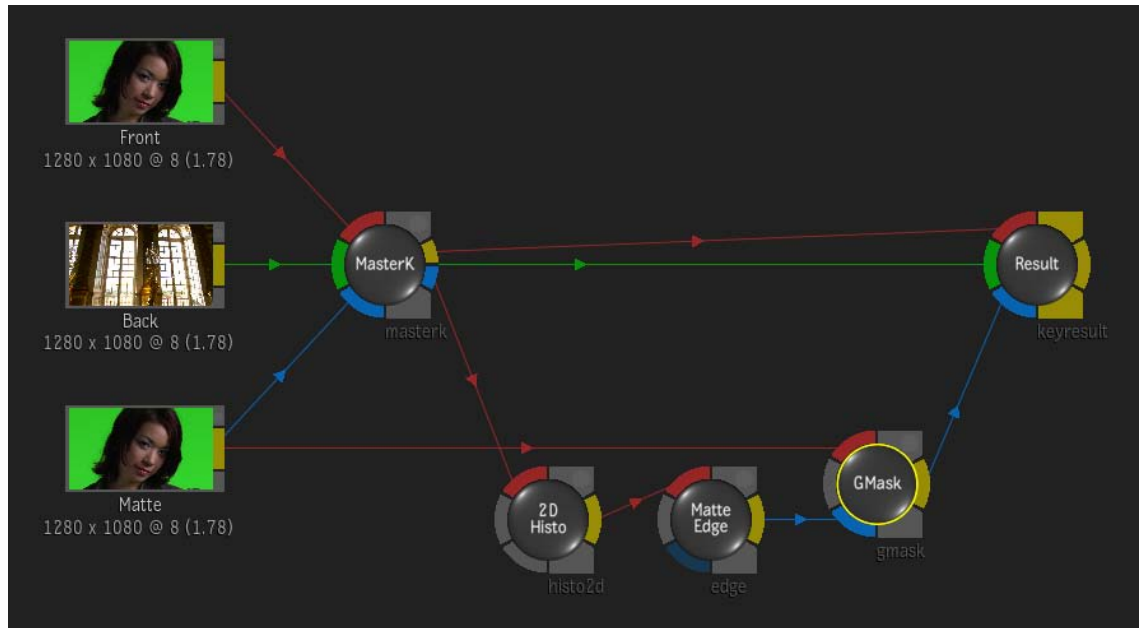

- 1 Build a multitrack timeline with a front layer and a background.

- 2 Select the track you want to key, and add an Action Timeline FX (in the example above, select the GreenScreen clip).
- 3 Double-click to Action entry in the FX ribbon, or click the Editor button to enter Action.
- 4 In Action, click the Media button to display the Media menu.

#	Name	K
B	[GlueMux]	
1F	[Source: GreenScreen]	#1
1M	[Source: GreenScreen]	

- Double-click the K field in the front/matte row to enter the Modular Keyer. Use the desired Start Mode, and create your key. The following example uses the Master Keyer start mode:

TIP You can set up the viewports in 2-up mode using the Viewport Layout box. In this case, you can use one View box to set one viewport to the modular keyer schematic view, and the other viewport to Result or Action Context view.

- When you are finished creating the key, click Return to return to Action. Notice that the K field in the front/matte row of the Media menu now has an MK displayed.

#	Name	K
B	[GlueMux]	
1F	[Source: GreenScreen]	#1
1M	[Source: GreenScreen]	MK

- Perform any other Action tasks, as needed, then click Exit to return to the timeline.

Creating New Sources Using Tools from the Tools Tab

14

The Tools tab provides access to numerous effects and tools allowing you to create modified clips that you can then use as sources on the timeline or in Batch or Batch FX. The tools use input clips (or in some cases are generated from scratch) that are then modified through parameters to produce a result directly in the workspace.

Some tools allow you to set parameters directly in the Tools quick menu, and instantly see a rendered result in the workspace. Other tools have full editors that you enter, allowing you to tweak numerous settings before rendering your result back to the workspace. In either case, new modified clips are created that you can use in your project.

Saving and Loading Tool Setups

For each tool that has a full editor, you are able to save and load setups. A setup is a file that contains a record of all changes you make to a clip in a particular tool. This record includes references to clips used—not the clips themselves. Setups let you save your work separately from clips, so you can load and work on the setup at anytime or apply the setup to other clips. Setups can be shared between instances of the same effect, whether accessed from the Tools tab, as a Timeline FX, or from the Batch or Batch FX node bin.

In the tool editor, use the Save and Load buttons to enter the file browser (pointing to the default directory location for each tool type). From the Load browser, you can also delete previously saved setups. For most tools, you can load or save setups or preferences/defaults. Preferences are settings that let you customize the display or functioning of some tool elements, keyboard shortcuts, pen and tablet, and audio (defaults are the default preferences). Some tools, such as Paint, have more saving and loading options.

Accessing Tools

To access specific tools

- 1 From the Tools tab, find and click the button for the tool you want to use.
- 2 If needed, use the Input Mode box to select the number of source clips you want to modify (for example, front only or combinations of front, back, and matte).
- 3 Set any tool parameters, as needed.
- 4 In the workspace, select the source clip(s) needed.
The colour and text of the cursor indicates which clip you should select next. After selecting the source clips, the cursor changes to white and the text Render Here appears.
- 5 Select the area to place your modified clip.

If the result requires no other settings (other than tool parameters), then the rendered result appears immediately. If more settings are required, a full editor appears.

TIP Some tools, such as Paint, allow you to enter the full editor without inputs. In this case, you can double-click the tool name, and directly apply the Render Here location.

To access a tool with the same clips as previously used:

- 1 From the Tools tab, find and click the button for the tool you want to use.
- 2 Click the "S" button to the right of the tool name, or click Use Current Setup.
- 3 Select the area to place your modified clip.

The result is rendered or the editor opens with the clips from the previous session. The most recent settings are also restored.

Procedural Compositing with Batch and Batch FX

15

Batch provides a flow graph environment where you perform procedural compositing with integrated access to almost all Flame effects and image-processing commands. Simply click the Batch tab to enter the Batch view. You can switch tabs, to Timeline or Tools for example, without losing your current Batch work.

A Batch FX is a setup applied directly to one or more segments on the timeline. Creating a Batch FX allows you to take a selection of timeline segments into a Batch flow graph environment for procedural compositing. You can edit and reorder any Batch FX node without affecting anything else in your pipeline.

You use the Batch processing environment to assemble a process tree of clips and nodes, where the result of each operation serves as the source for the next one. Because a Batch pipeline is not fixed, you have the flexibility of reordering and editing nodes.

Because the Media panel is integrated into Batch, it is easy to switch between the desktop, timeline, and Batch—and still keep track of all of your sources. You can add clips to Batch easily using the Media panel, or use the Read File node within Batch to bring in clips from anywhere on your network. You can bring in clips containing stereo tracks as well as clips of any resolution and bit depth. Some nodes require that the clips be of the same resolution and bit depth. You can change these clip settings directly in Batch.

- The default viewport layout for Batch and Batch FX is a 1-Up view displaying the schematic (displaying the process tree). Use the Layout settings under the left viewport to change the layout, or return to this default view. For Batch FX, you can also change the default layout to 2-Up in the Timeline FX / BFX section of the Preferences menu (displaying the schematic on the left, and the result view on the right).
- You can change the actual view of the selected viewport using the View box under the right viewport. If a selected node has its own views, such as Action, you can select node-specific views also.
- The bottom portion of the Batch or Batch FX view displays the nodes that you can add to your process tree. This bottom area can also display the menu for the selected node in the schematic view. To switch between the node view and selected menu view, use the FX Nodes button (located under the left viewport).

Accessing Batch

To access Batch:

- 1 Click the Batch tab.
- 2 Add clips and nodes to build your pipeline.

You can switch tabs, to Timeline or Tools for example, without losing your current Batch work.

Any media used in Batch is displayed in the Workspace Media panel under Batch Sources. You can drag media from any folder in the Media panel to the Batch Sources folder. This places a copy of the media in the Batch Sources folder and displays it in Batch. Dragging media directly from the Media panel to the Batch schematic also creates a copy of the media in the Batch Sources folder.

TIP Drag clips to the Batch header in the Workspace Media panel (above the Batch Sources folder) to add clips to Batch, and automatically switch to the Batch tab.

To clear a Batch setup:

- 1 Do one of the following:
 - From anywhere in Flame Premium where you can access the Workspace Media panel, right-click in the Batch area, and select Clear Batch Setup.
 - From within Batch, click the New Batch button.

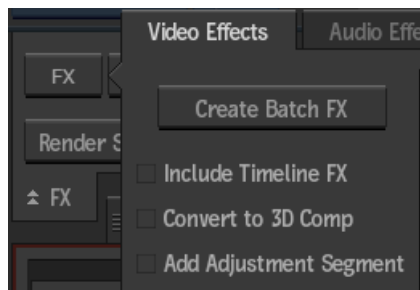

All nodes and sources are cleared, and any unsaved changes to the current Batch setup are lost.

Creating Batch FX

To create a Batch FX on a timeline segment:

- 1 Select one or more video segments on the sequence to which you want to apply a Batch FX.
- 2 Click the FX button.
- 3 Click Create Batch FX to quickly enter the Batch FX view. Use this method if you want to enter Batch FX with only one timeline segment without existing Timeline FX, or with Timeline FX that you don't want carried over into Batch FX.

NOTE Once you have returned to the timeline sequence from Batch FX, you can re-enter the same Batch FX by clicking Enter Editor in the FX pipeline, or by double-clicking the BFX icon on the segment, or in the pipeline.

Including Timeline FX in Batch FX

Use the Include Timeline FX option when creating a Batch FX if you want to convert any existing Timeline FX to a Batch FX pipeline. When you enter Batch FX, you'll see that your pre-existing Timeline FX are now displayed as Batch FX nodes, allowing you to edit these effects directly in the Batch FX view, or add or delete as many other effects as needed.

- 1 Select one or more video segments on the sequence to which you want to apply a Batch FX.
- 2 Click the FX button.
- 3 Select Include Timeline FX.

NOTE If you select multiple video elements on the sequence, this option is automatically selected.

- 4 Click Create Batch FX to enter the Batch FX view. The Batch FX recreates your timeline as a flow graph with effects nodes representing each Timeline FX (and Comp node). In some cases, MUX nodes are used to help connect multiple RGBA inputs to the outputs.

When you return to the timeline, only the BFX icon appears on your clip, as the previous Timeline FX are now included within the BFX.

In the case of entering Batch FX with multiple video elements, you can also see that upon exiting Batch FX, only one element exists, comprising the composite of the previous elements. To restore your previous vertical edit on the timeline, you can click Remove BFX and Recover Stack. The previous configuration of the video elements is restored, but any pre-existing Timeline FX are lost.

Converting to a 3D Comp Batch FX

If you know that you want to work with Action within Batch FX, you can use the Convert to Comp option. Similar to the Include Timeline FX option, you enter the Batch FX view with existing Timeline FX converted to a 3D composition pipeline with an Action node.

- 1 Select one or more video segments on the sequence to which you want to apply a Batch FX.
- 2 Click the FX button.
- 3 Select Convert to 3D Comp.

NOTE If you select multiple video elements on the sequence, the Include Timeline FX option is automatically selected, but you can switch to the Convert to 3D Comp option.

- 4 Click Create Batch FX to enter the Batch FX view. The Batch FX recreates your timeline as a flow graph with effects nodes representing each Timeline FX, all feeding an Action node. In some cases, MUX nodes are used to help connect multiple RGBA inputs to the outputs.

When you return to the timeline, only the BFX icon appears on your clip, as the previous Timeline FX are now included within the BFX.

In the case of entering Batch FX with multiple video elements, you can also see that upon exiting Batch FX, only one element exists, comprising the composite of the previous elements. To restore your previous vertical edit on the timeline, you can click Remove BFX and Recover Stack. The previous configuration of the video elements is restored, but any pre-existing Timeline FX are lost.

Adding an Adjustment Segment Batch FX

You can create an edit on the timeline in a gap above multiple clips, without losing any of the effects already on those clips. After creating an adjustment segment, you can add new clips or edit existing clips on the timeline under the adjustment segment gap, and the Batch FX is maintained above. You can perform edits on an adjustment segment as it is treated like any other timeline segment, such as trimming or even adding other Timeline FX.

There are two ways to add an adjustment segment to the timeline:

- Add a Batch FX to a gap in the timeline. In this case, an adjustment segment added by default.

- Manually click Add Adjustment Segment when adding a Batch FX anywhere on the timeline. In this case, a gap is automatically created on the track above selected segment.

The adjustment segment uses the top media of the tracks below the timeline gap as the input. Inside Batch FX, that input is called the Back Clip. For example, if you have three tracks composited together, and you add an adjustment segment on top of them, the image available through the Back Clip is only the output of the third track.

The Back Clip node is available in the Batch FX I/O bin. The Back Clip node does not contain any media; instead, it offers a link to the Timeline, giving access to the topmost media located below the BFX segment you are currently working on. Since the Back Clip is only a link to media, you cannot access common clip settings within Batch FX. The only settings that are available if you double-click the Back Clip node are to set what media is available for the head and tail of the adjustment segment.

About the Batch and Batch FX Process Tree

Use Batch or Batch FX to assemble a series of tasks using nodes. Each node represents a specific Flame Premium function. You connect clips with nodes and use the result of one node as the source for the next node. As you assemble this arrangement in the Batch or Batch FX schematic, you are building a process tree from left to right, that processes as many output clips as you want.

A process tree begins with a clip, contains at least one node, and ends with a Render, Write File, or BFX Output node.

Once you are working in Batch or Batch FX, it is easy to add more clips and nodes to achieve your desired result. Large schematic pipelines are common, so you can group nodes or add notes to nodes to help you manage clutter.

About Nodes

Nodes have one or more colour-coded input and output points (also called tabs) used for connecting to clips and to other nodes. All nodes have an output tab. For example, a Colour Correct node can accept a Front, Matte, and Back connection, whereas an Auto Matte node accepts a Front input.

As you add nodes, you connect them to the process tree by linking the result from one node and using it as a source (front, matte, or back) for the next node in the process tree. You can also connect by linking backward from the source of one node to the output of another (to reuse a node’s output).

To connect nodes, you use the coloured tabs on the node's left side; these tabs are called *source tabs*. The colours of the source tabs represent different input types. The yellow tab on the node’s right side is called the Result tab (for some nodes, a blue tab is also present on the right side, this is the OutMatte tab). You use the Result tab of a node to connect its result to the input tab of another node.

This is a typical node tab configuration. Some nodes have specific tabs related to their function (such as the forward vector tab on the Pixel Spread node).

(a) Matte tab (b) Back tab (c) Front tab (d) Warning tab (e) Result tab

TIP If Auto Display of tooltips is enabled in the Preferences menu (**Preferences > User Interface > Tooltips**), hover over a tab to see the name of the tab.

Colour	Tab	Description
Red	Front	Connects a front clip to a node.
Green	Back	Connects a back clip to a node.

Colour	Tab	Description
Blue	Matte	Connects a matte clip to a node.
Light Blue	Misc	Miscellaneous tab specific to certain nodes, such as a Z-Depth or Forward Vector input.
Turquoise	Audio	Connects a clip with audio to a Render node.
Yellow	Result	Connects the result of a node to other nodes.
Blue	Output Matte	Connects the output matte of a node to other nodes.
Red circle	Warning	Warns that clip input to this node is unconnected or is missing media, or clips parented to this node do not share the same resolution or a compatible bit-depth.

The available source tabs depend on the node. If the node accepts a front, back, and matte clip, all coloured source tabs are available. If the node only accepts a front clip, the red source tab is available and the other source tabs are grey. When a source tab or Result tab is not connected to a clip or to another node, the coloured tabs are dimmed.

TIP Right-click any node in the schematic to reveal a contextual menu of operations available for that type of node.

Adding Clips to the Process Tree

The quickest way to add clips to your Batch process tree is through the Workspace Media panel. Even though Batch FX process trees are pre-populated with clips from the timeline, you can also add more clips from the Workspace Media panel.

Another way to add clips is through the [Read File node](#) (page 368).

To add clips from the Workspace Media panel:

- 1 Select one or more clips from the Workspace Media panel.
- 2 Drag the clips into the Batch or Batch FX schematic.

The clips are now available to use in the process tree. Notice that the clips are also displayed in the Media panel's Batch or BFX Sources folder.

TIP You can also drag clips directly into the Batch or BFX Sources folder (you don't even have to be in Batch or Batch FX to do this). Any clips in the Sources folder can be seen in the schematic (with the exception of Read File clip nodes). Drag clips to the Batch header in the Workspace Media panel (above the Batch Sources folder) to add clips to Batch, and automatically switch to the Batch tab.

Once a clip is present in the Batch or Batch FX schematic, you can connect its output tab to other nodes in the same manner as connecting nodes to nodes. The same clip can be connected to multiple nodes in the process tree.

To replace a clip:

- 1 Drag a clip from the Workspace Media panel into the Batch or Batch FX schematic.

- 2 Release the clip on top of an existing schematic clip, once you see a replace icon.

The clip is replaced.

TIP If the clip proxy is black after replacing, right-click the clip and select Reset to reset the timing offset of the clip.

Clip Information Reference

You can display detailed information about clips in the schematic such as resolution, frame rate, and size. As well, visual cues such as symbols and letters identify clips as having had a specific type of operation applied.

The colour of the clip information and letters and symbols also provides specific information.

Clip Information

You can choose what clip information is displayed under clips in the schematic by selecting an option from the Clip Info box in the Batch or Batch FX Schematic Preferences:

Select:	To display:
Resolution	The clip's name, number of frames, dimension, frame depth, and aspect ratio.
Size	The clip's name, number of frames, and dimension (in pixels).
Framerate	The clip's name, number of frames, and number of frames per second (fps).
Size+Rate	The clip's name, number of frames, dimension (in pixels), and number of frames per second (fps).
Resolution+Rate	The clip's name, number of frames, dimension, frame depth, aspect ratio, and number of frames per second (fps). This option provides the most detailed level of clip information.
No Info	No information except the clip name and number of frames.

Clip Name Colouring

The colour of the clip name in the schematic helps you locate where the clip originated.

Colour:	Origin:
White	Media Panel
Blue	Batch Snapshots
Pink	Read File node
Red	No media found (clip is also displayed as a black proxy)
Green	BFX Back Clip

Clip Status Symbols

The following visual cues can help you track the type of clip and clip status.

(A) symbol and Audio Context outline Indicates that an audio context is set for this clip or node. In addition to the A, the clip has a dotted purple outline. The letter A is followed by the number of the context, for example, A2 is the second Audio context.

(C) symbol and Context outline Indicates that a context is set for this clip or node. In addition to the C, the clip has a dotted green outline. The letter C is followed by the number of the context, for example, C1 is the first video context.

LUT symbol Indicates that a LUT was applied to the clip. The first and second number represent the source and destination bit depths, for example [8 -> 16f].

[R] symbol Indicates that a Resize was applied to the clip.

(BFX) symbol Indicates that a Batch FX was applied to a timeline made up of one segment, or the clip was converted as a Create BFX. The clip can be expanded.

(bfx) symbol Indicates that a Batch FX was applied to a timeline made up of multiple segments. You cannot expand setups of clips containing more than one segment.

Importing With the Read File Node

To import images into Batch or Batch FX using the Read File node:

- 1 In the I/O node bin, select the Read File node and drag it to the schematic.
The Read Files browser appears.
- 2 Optional: Set General and Format Specific Options for the files to import.
- 3 Optional: For each file, set In and Out points using the Preview panel.
- 4 Select the clips to import.
- 5 Click Load.

You are returned to Batch or Batch FX and the file appears in the schematic. If you import more than one file, a Read File clip is created for each file. The clip name appears in pink to help you differentiate from other schematic clips.

NOTE Whenever you open a Batch or Batch FX setup which uses Read File clips that have been updated, Flame Premium asks for your permission to update the setup with updated versions of these clips (when updates exist). Updating the setup replaces the current Read File clips with the latest found versions. This ensures that you are using the correct versions, and in any case, Flame Premium maintains the appropriate schematic connections.

To Expand a Read File Clip

- 1 Select the Read File clip.
- 2 Press **Shift+C**.

To Replace the Current Read File Clip With Another One

- 1 Double-click the proxy of the Read File clip.
The Read Files browser appears.
- 2 Optional: Set General and Format Specific Options for the files to import.
- 3 Optional: For each file, set In and Out points using the Preview panel.

4 Select the clip to import.

5 Click Load.

You are returned to Batch or Batch FX and the Read File clip is updated with the selected file. The Schematic is also updated, using a channel matching strategy that preserves the links between the clip's channels and the linked nodes.

To Load a Clip as a Version

1 Double-click the proxy of the Read File clip.

The Read Files browser appears.

2 Optional: Set General and Format Specific Options for the files to import.

3 Optional: For each file, set In and Out points using the Preview panel.

4 Select the clip to import.

5 From the Load drop down menu, select Load as Version.

You are returned to Batch or Batch FX and the Read File clip is updated with the selected file. The previous clip is now available as a version from the Clip Versions box. You can have as many versions as you need.

To Switch Between Versions of a Read File Clip

NOTE Only possible with Read File clips loading clips with versions, or after loading a clip as a version.

1 Double-click the Read File clip.

2 Select a Clip Version using the Clip Version box.

The Read File clip now uses the selected version and the schematic is updated accordingly, using a channel matching strategy that preserves the links between the clip's channels and the linked nodes.

To Check for New Versions of Clips

NOTE The Check for Updated Versions button is only available if at least one Read File clip in the schematic has been updated.

1 Open the Batch or Batch FX Preferences menu.

2 Under Read File Nodes in the Preferences section, click Check for Updated Versions.

Every Read File clip in the schematic is checked for updated versions of their clip.

To Edit a Batch Setup Included with a Read File Clip

NOTE Only available to Read File clips with clips that were created using the Include Setup option.

1 Double-click the Read File clip.

2 Click Append to current Batch.

The Batch setup that created the open clip for the displayed Clip Version is added to the schematic as a Group Node.

Modifying the appended setup does not modify the open clip imported with the Read File clip. But since it includes the original Write File node, you can export a new open clip with the exact same export settings.

This means that you can create a new version of the open clip, and then use the Check For Updated Versions button to update the current open clip. A high level workflow could be as follows.

- 1 A Flare user processes a Batch setup to export a clip with the following options enabled.

- Create Clip Data
- Include Setup
- Version (set to version 1)

It creates open clip with a Batch setup, and versioning enabled.

- 2 A Flame user imports the open clip and starts using it in his own Batch setup.

Looking at the Read File clip, he can see that there is only one version of the clip (only one version in Clip Versions box) and that the Batch setup that created this open clip is included (Source Setup field has the name of the setup).

- 3 In the meantime, the Flare user touches up his Batch setup. Before processing it, he also updates the Write File node's Exports Settings (from JPEG to DPX), but makes sure to not change any of the Clip Data, Path, and Naming fields (the Flame updates the version automatically). Without further ado, he processes it.

The Write File clip updates the open clip file with new information: a new version which points to updated media files.

- 4 The next time the Flame user opens his Batch setup, he is prompted to check for updated open clips. He does check, and the clip he imported in a previous session is updated and set to the current version. Or, during his Batch session, the Flame user can use the Check for Updated Versions.

About the Read File Node

Why Use a Read File Node?

While you can import many types of media files using a Read File node, its primary use is to facilitate integration of Flame Premium in render pass workflows.

Using the Read File Node With Render Passes

The Read File node is more than just another way to import into the Batch or Batch FX schematic. It actually allows you to integrate Flame Premium inside a render pass pipeline very efficiently.

While you can use the Read File node to import almost any file format, three are of interest for multi-channel render pass workflows:

- open .clip
- multi-channel OpenEXR
- Maya .precomp

And while they differ in their basic structures, they all provide access to a powerful CG concept: Read File Nodes and Autodesk Maya. The render pass allows you to composite within Flame Premium the many components, or passes, making up the scene. By working directly with the render passes, you end up performing tasks quicker, such as colour correcting, that are much more time-consuming in the 3D application. The fact is that Flame Premium only needs to compute the value of pixels in a scene, while the 3D application needs to recompute the lighting of whole geometries: Flame Premium is just better for these tasks.

How to Use Flame Premium With Render Passes?

Working with render passes is not difficult, especially if you use the Read File node and one of the following file types: Open .clip, multi-channel OpenEXR, or Maya .precomp.

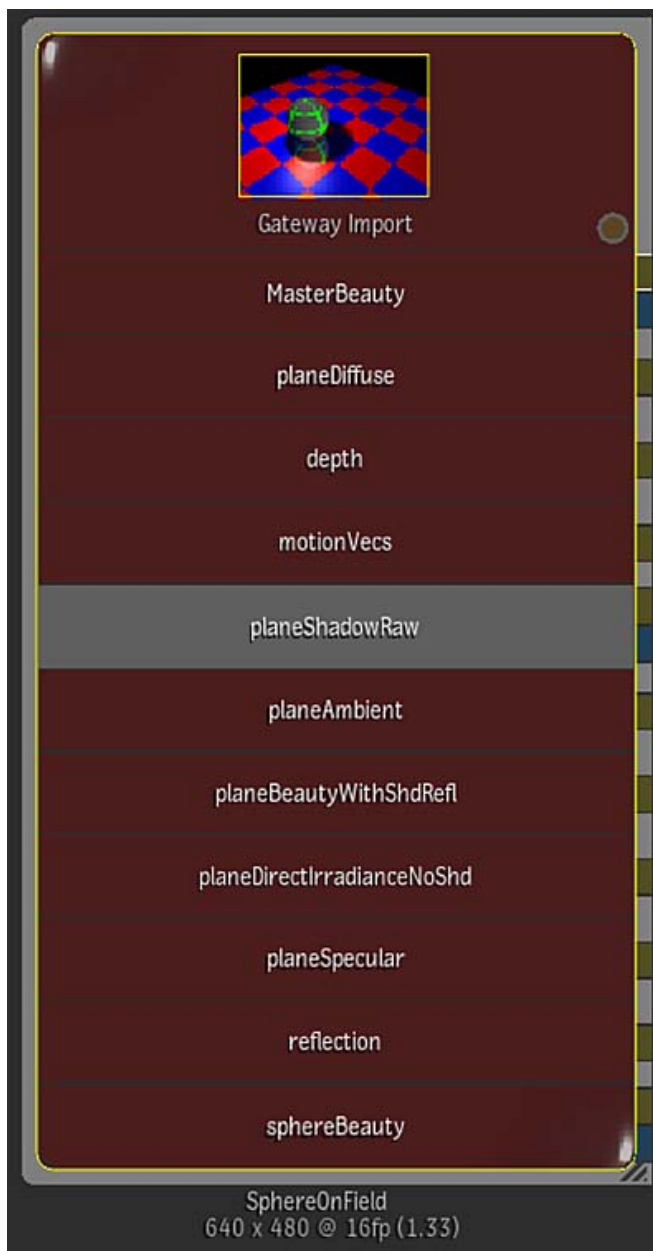

Consider the following example of an image generated in Maya.

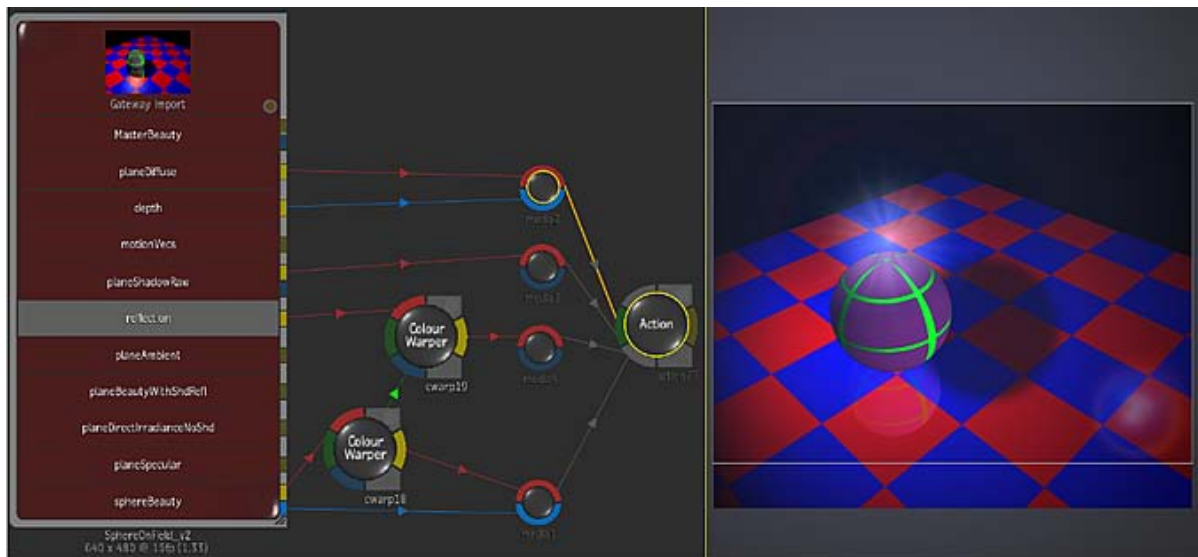

This image was exported from Maya using the following render passes.

- Beauty - scene
- Camera Depth
- Motion Vectors
- Ambient
- Beauty with Shadow and Reflections
- Diffuse
- Direct Irradiance Without Shadows
- Raw Shadow
- Specular
- Reflection
- Beauty - sphere-only

Importing this file using the Read File node, you have access to all these passes.

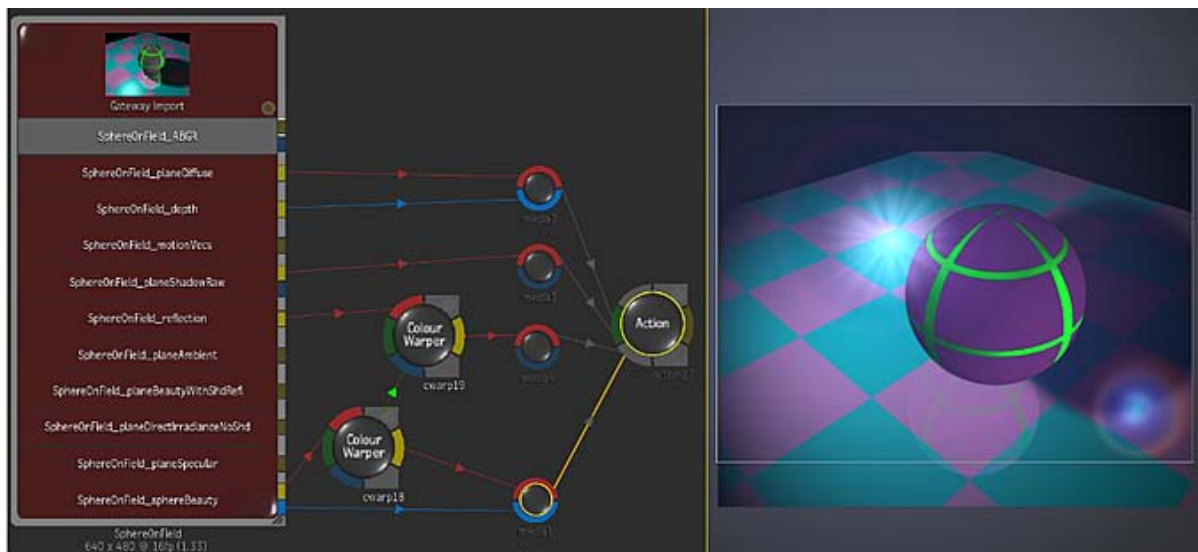

Once imported, you can create a simple Batch or Batch FX schematic and composition.

In this Batch or Batch FX setup, you can do the following, for example:

- Warp the sphere's colour.
- Warp the sphere reflexion's colour by the same amount.
- Remove the original shadow and replace it with a new one.
- Add a spot on the sphere.
- Change the overall lighting look.
- Add a lens flare.

If the CG artist updates their work, you can just replace the current clip with the updated version, performing a simple [replace operation](#) (page 368); all the compositing information is maintained.

In fact, the Read File node supports matching channels based not only on their UID and name, but also on their channel type. This allows you to replace sources with multiple render passes in a clip that are similar, but not identical, and maintain schematic connections to the Read File node within a composite.

About .precomp Files

A .precomp file is a file generated by Maya to facilitate data exchange with its Composite component. Flame Premium can read that file and extract render pass information. An actual .precomp export from Maya consists of two distinct elements:

- One .precomp file which describes the components of the scene. It is a Python plain-text file with compositing information and path to the render passes.
- Media files referred to by the .precomp file. In the simplest of cases, there is one OpenEXR file for every rendered frame. Each OpenEXR contains all the render passes for that frame.

An interesting aspect of .precomp files is their use of render layers as versions: this allows the Maya artist to create different versions of the same scene using render layers. You can then use the Read File node to import the .precomp file, and then use the Versions box to switch between looks.

Read File Node and Autodesk Maya

The Read File node automatically recognizes pass types from mental ray in Maya, allowing for more robust channel matching during clip updates or replacement.

Below is a list of supported mental ray render passes, with a short description.

Render Pass	Description
2D Motion Vector	Relative motion (in raster coordinates) of objects in your scene; in other words, how far each pixel is moving between two frames. Vector is expressed in normalized pixels.
3D Motion Vector	3D motion vector in world space. In mental ray for Maya, the 3D motion vector is expressed in internal space.
Ambient	Ambient contribution of the surface. In Maya, this is the material color multiplied by the ambient light color.
Ambient Irradiance	Amount of ambient light received by the surface.
Ambient Occlusion	Ambient occlusion contribution from both self ambient occlusion as well as primary ambient occlusion, which is derived from surrounding objects.
Ambient Material Color	Reflectivity of the material with respect to ambient light.
Beauty	Final colour computed by mental ray for Maya.
Beauty Without Reflections or Refractions	Beauty pass without reflections or refractions. Used to tune the tint and intensity of the reflection/refraction separately from the rest of the passes.
Camera Depth	Extracts the distance between the camera and the intersection point.
Coverage	mental ray Coverage frame buffer. This frame buffer offers only silhouette coverage. Self-coverage is currently not supported.
Diffuse	Diffuse shading of material.
Diffuse Without Shadows	Diffuse pass without shadowing information.

Render Pass	Description
Diffuse Material Colour	Provides constant diffuse colour or textured diffuse colour, excluding light contribution.
Direct Irradiance	Direct light arriving at each sample location.
Direct Irradiance Without Shadows	Direct irradiance without shadowing information.
Glow Source	outGlow output of surface shaders; affected by pass contribution maps.
Incandescence	Additive colour.
Incidence	Measures the difference between the direction of the light ray and the surface normal. If the surface normal is facing the light, this value is 1. If the normal is facing away from the light, the value is 0.
Indirect	Indirect lighting from final gather, global illumination, and caustics.
Light Volume	Extracts all light-centric volume effects, for example, a light cone volume effect.
Material Incidence	Measures the difference between the direction of the camera ray and the surface normal. If the surface normal is pointing to the camera, this value is 0. If the normal is facing away from the camera, the value is 1. Any angle greater than 90 degrees is also translated to 1. If bump mapping is applied to the shading network, it will appear in this pass.
Material Normal	Interpolated surface normal. If bump mapping is applied to the shading network, it will appear in this pass.
Matte	The object's matte, excluding transparency/opacity. This pass serves as the render layer compositing mask. Should be solid white in areas where objects are intersected. Independent of transparency/translucency.
Normalized 2D Motion Vector	Relative motion (in raster coordinates) of objects in your scene; in other words, how far each pixel is moving between two frames. Pixel displacement is normalized to (0—1). Static objects are expressed with 0.5,0.5 values.
Object Incidence	Similar to the Material Incidence pass but without support for bump mapping.
Object Normal	Similar to the Material Normal pass but without support for bump mapping.
Object Volume	Extracts all object-centric volume effects, for example, smoke that is contained in a glass object. Also includes volume particles, volume fur, and fluids.
Opacity	The object's opacity, which is derived from transparency/refraction. In compositing, the object's opacity can be controlled independently from the render layer matte.
Raw Shadow	Similar to the Shadow pass but calculated only with respect to the irradiance in the scene.

Render Pass	Description
Reflection	Reflection results. Includes self-reflection, primary reflections, secondary reflections and environment reflections.
Reflected Material Colour	The reflected colour parameter of the material. Pure constant reflection colour or textured reflection. Used as a reflection matte to determine where reflection would be revealed (coloured and non-coloured).
Refraction	Refraction results. Includes self-refraction, primary refraction, and environment refraction.
Refraction Material Colour	The transparency colour parameter of the material. Pure constant refraction colour or textured reflection. Used as a refraction/transparency matte to determine where refraction is revealed (coloured and non-coloured).
Scatter	Scattering effects that result from the material's scattering attributes.
Scene Volume	Extracts all scene-centric volume effects such as fog, layered fog, haze, and so forth.
Shadow	Pure shadow contribution for both self-shadowing as well as direct shadows. The shadow pass can be luminance or coloured shadows. Takes into account material contributions.
Specular	Specular shading. The specular component is modulated differently depending on the type of material associated with the object. For example, Phong, PhongE, Blinn, and Anisotropic materials produce specular contributions differently. On a Phong material, the specular pass can be modulated using cosine power and specular colour.
Specular Without Shadows	Similar to Specular but without shadow occlusions.
Translucence	Back shading contribution revealed on the front surface.
Translucence Without Shadows	Similar to Translucence but without shadows.

Read File Clip Settings

To access Read File clip settings, double-click a Read File node in the schematic.

Basic Settings

NOTE The Import Settings are dynamically generated according to the type of clip imported. You can get a quick description of each setting by viewing its tooltip.

Basic button Opens the Basic menu where you set the clip version, append the available setup, modify the import settings, and set the missing media options.

Versions box Select the active version of the clip. If the available channels differ between versions, the application updates the links to other nodes.

Creation Date field Displays the creation date of the version selected in the Clip Version box. Non-editable.

Source Setup Name field Displays the name of the Batch setup saved with the open clip. Only available to open clip output using a Write file node with Include Setup enabled.

Append to current Batch button Click to add to the current Batch schematic a group made of the Batch setup stored with the open clip. Only available to open clip output using a Write file node with Include Setup enabled.

Head Media box Select to substitute missing media at the beginning of a clip with black frames, the first frame of media, or leave as is.

Tail Media box Select to substitute missing media at the end of a clip with black frames, the first frame of media, or leave as is.

In field Set, as an offset of frames from frame 0, the In mark of a clip. Only frames located after the mark are available and rendered.

Out field Set, in frames from frame 0, the Out mark of a clip. Only frames located before the mark are available and rendered.

Frame field Displays the absolute frame number of the current frame, from the file with the name displayed in the File Name field. Non-editable.

File Name field Displays the name of the file from which the current frame is being read. Non-editable.

Clip Information tabs

Available in the Basic and Extended menus of the Read File clip.

The Clip Information tabs display non-editable information about imported clip.

Clip Info tab The Clip Info tab displays the name of the original media, file format, resolution and FCM, as well as the number of tracks in the clip.

Metadata tab The Metadata tab displays metadata information about the imported media, including but not limited to: path to the sources, camera settings (RED and ARRI), file creator.

Versions tab The Versions tab lists all the versions available for the selected clip. Available to open clips and Maya .precomp imports.

Extended Settings

Extended button Opens the Extended menu where you set the channel options, from the channel displayed in the node proxy to the available outputs.

NOTE With a Read File clip selected in the schematic, press `Shift+C` to expand the node and display its channels in the schematic.

Type	Name	Icon	Proxy	Outputs
BEAUTY	MasterBeauty			
BEAUTY	Light1BeautyNoShadowNoReflections			
REFL	Light1Reflection			
SHD	Light1Shadow			
BEAUTY	Light2BeautyNoShadowNoReflections			
REFL	Light2Reflection			
SHD	Light2Shadow			

(a)Media output (b)Alpha output (c) Displayed and disconnected outputs (d)Hidden and disconnected outputs (e) Displayed and connected outputs (f) Hidden but connected outputs

Type field Displays the type of channel. Non-editable.

Name field Displays the name of the channel. Non-editable.

Icon field Enable to display the channel in the schematic; disable to hide the channel. The Read File clip must be expanded (press `Shift+C`) to view the channels in the schematic. Hiding a channel does not break its link to a node.

Proxy field Enable to use a particular channel as the Read File clip proxy in the schematic.

Outputs fields Click to display or hide the outputs available for each channel from the Read File clip in the schematic. Hiding an output does not break its link to a node. There is one output each for RGB and its alpha (if any).

Resize Settings

The Resize settings are the same as when you are using the Resize node in Batch or Batch FX. Click the Active button to activate the Resize settings.

RGB LUT Settings

The RGB LUT settings are the same as when you are using the LUT Editor node in Batch or Batch FX. Click the Active button to activate the RGB LUT settings.

Clip Settings

In Batch, you can also double-click a clip in the schematic to switch to the Timeline with the selected clip available as a source clip. You can apply any timeline editing operation on your clip, and when you return to Batch, your clip is updated.

The following settings are available when selecting a clip in the schematic. You can also right-click a clip node in the schematic to reveal a contextual menu of operations, such as Render options.

Basic Settings

Basic button Opens the Basic menu where you set timeline and timewarp options, control clip locking and slipping, and define how missing media is displayed and rendered.

Head Media box Select to substitute missing media at the beginning of a clip with black frames, the first frame of media, or leave as is.

Gap Media box Select to substitute missing media in gaps with black frames or leave as is.

Tail Media box Select to substitute missing media at the end of a clip with black frames, the last frame of media, or leave as is.

Offset field Displays the number of frames by which selected clips and/or segments are offset. This same setting can be found in the Timing View as well as the Clip Settings. Editable.

Lock Frame button Enable to display the current frame for the duration of the clip.

Explode All Timeline SFX button Click to explode all Timeline FX in the clip into a process tree.

NOTE If a clip proxy is black after exploding, right-click the clip and select Reset to reset the timing offset of the clip.

Explode History button Click to access pre-processing settings for the clip.

Explode One button Click to explode one level of the clip's BFX setup.

Explode All button Click to explode all levels of the clip's BFX setup.

Alpha Active button Enable to generate an alpha or matte from a clip.

Alpha Colour box Select whether to output a white or black alpha of your clip.

Resize Settings

Most of the Resize menu is the same as when using the Resize node in Batch or Batch FX. The following settings are specific to the Resize tab for a clip:

Resize button Opens the Resize menu where you change the size of a clip, as well as its aspect ratio.

Active button Enable to activate the Resize settings.

Load button Loads a Resize setup from the library.

Save button Saves the current resize setup.

RGB LUT Settings

Most of the RGB LUT menu is the same as when using the LUT Editor node in Batch or Batch FX. The following settings are specific to the RGB LUT tab for a clip:

RGB LUT button Opens the LUT Editor for the selected clip.

Active button Enable to activate the LUT settings.

Back Clip Settings

These settings are available for a Batch FX Back Clip created for a timeline adjustment segment.

Head Media box Select what media is available before the In Point of the adjustment segment. Select Timeline Level to have the Back Clip read the head media from the segments preceding (and below) the adjustment segment.

Tail Media box Select what media is available after the Out Point of the adjustment segment. Select Timeline Level to have the Back Clip read the tail media from the segments following (and below) the adjustment segment.

Adding and Connecting Nodes to the Process Tree

To add a node from the node bin to the schematic, double-click a node, or drag a node directly to the schematic. There are several ways of connecting clips or nodes together. You can connect them manually or automatically.

To insert a node between connected nodes:

- 1 Do one of the following:
 - If Auto Insert is enabled in the Prefs menu Schematic settings, drag a node and navigate to the link between two connected nodes. The link is highlighted in orange.
 - If Auto Insert is disabled in the Prefs menu Schematic settings (this is the default), press and hold **Shift**, then drag a node and navigate to the link between two connected nodes. The link is highlighted in orange.
- 2 Release the node.

The node is inserted, while retaining the input and output connections.

To connect nodes automatically with autolink:

- 1 Use the Autolink feature by pressing **Shift** and dragging a node to another node so their tabs touch.
Action: Press and hold **Shift** while dragging the Negative node to the Keyer node

Result: The Keyer output is the front for the Negative node

To connect nodes using the advanced autolink:

- 1 To distinguish between the various source tabs, use the Advanced Autolink feature by pressing **Alt** repeatedly while still holding **Shift** to extend a similarly coloured arm from each source tab (starting with the topmost source tab, and cycling counter-clockwise with each press of **Alt**). The name of the tab is also displayed above the node. You can then touch the extended arm to the tab you want to connect to.

Approaching a node with multiple outputs, such as a multi-channel clip imported with a Read File node, automatically expands that node.

Hold **Shift** and press **Alt** to extend the Front tab.

While still holding **Shift**, press **Alt** again to extend the **Back** tab.

While still holding **Shift**, press **Alt** a third time to extend the **Matte** tab.

You can also retain connections using this method by releasing the node over an existing connection (when it turns orange).

To create a node connection using tap-tap linking:

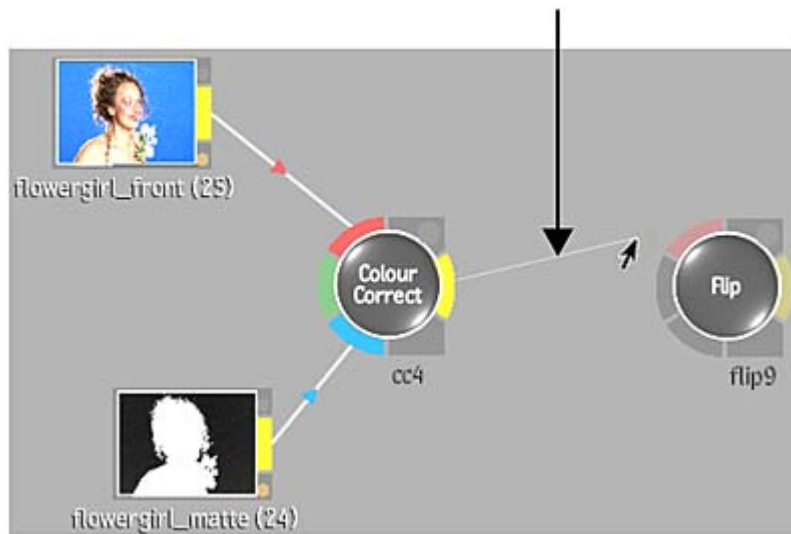

- 1 Click the tab of the first node or clip you want to connect.
 - 2 Click the tab of the node you want to connect the first node to.
- The nodes are connected.

NOTE If the first node you click is an Output node, you can add as many subsequent input tab connections as you like. To finish selecting, click anywhere in the schematic work area.

To connect nodes manually:

- 1 Click the Result tab of a node whose result you want to use and drag the cursor to one of the source tabs of the next node in the process tree.

An arrowed line is drawn from the node to the source tab. For example, click the Result tab of the Colour Correct node and drag the cursor to the front tab of the Flip node to flip the result of the colour-corrected clip.

To extract a linked node while maintaining connections:

- 1 Press **Alt+Win** and drag a linked node away from the link.
The node is disconnected and connections between existing nodes are reformed.

To disconnect nodes or clips:

- 1 Drag the cursor across the connecting line between a clip and a node or between two nodes.
The arrowed line is cut and the source tab is dimmed.
- 2 You can cut multiple connections in a single stroke by clicking and dragging over several connecting lines in the schematic.

To delete a node:

- 1 Do one of the following:
 - Right-click a node and choose **Delete**.
 - Drag a node towards the bottom of the screen, and release once you see the garbage can icon.

TIP You can combine the extract **Alt+Win** and dragging a node to delete it and maintain connections.

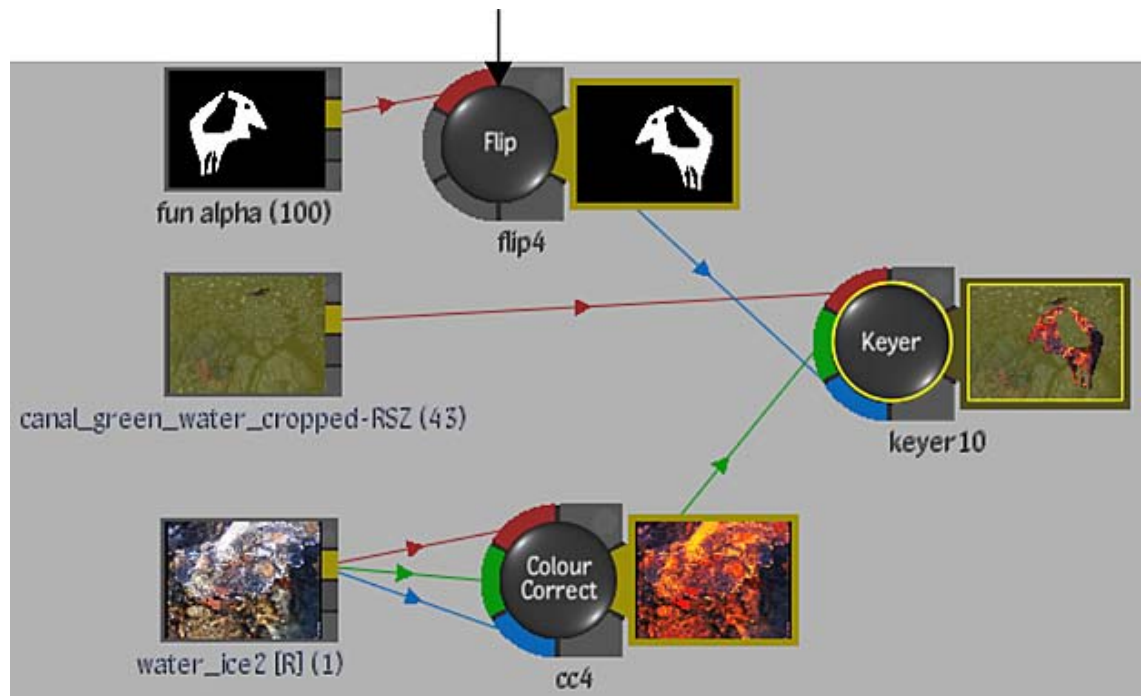

Bypassing Node Inputs

You can improve your workflow in Batch or Batch FX by deactivating certain nodes and rendering only the nodes that you want to process right away.

For any node, you can pass the Front, Back, Matte, or Key-in clip—depending on the type of node you select and its source tab inputs—as the input to the next node in a branch. If you bypass a node with multiple outputs (such as Action and Modular Keyer), the matte output will be the same as the result output (depending on the current selection in the Bypass box).

To bypass a node input:

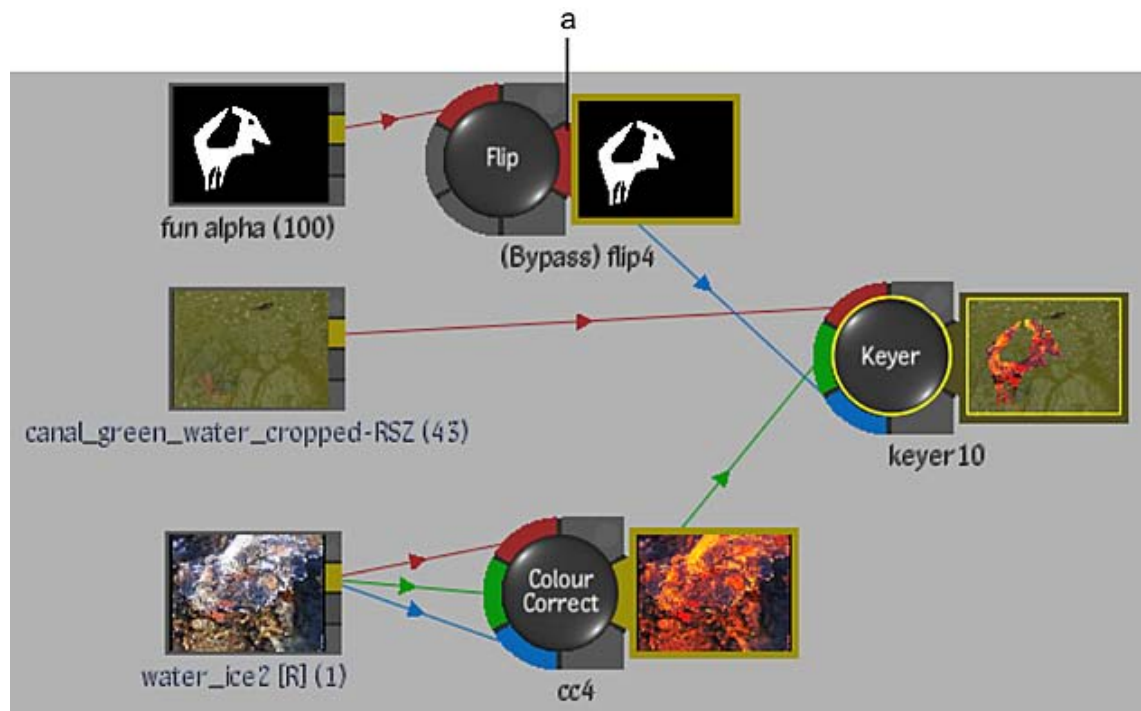

- 1 In the schematic, select the node whose input you want to bypass.

- 2 Enable Bypass.
The Bypass box becomes active.
- 3 Select the clip that you want to pass as the input to the next node from the Bypass box.

NOTE The Flip node, which was selected in step 1 of this example, has input tabs for a front source. Therefore Front is the only option in the Bypass box.

The output tab of the bypass node changes colour. In the following example, the tab turns red indicating that the Front input is passed to the next node in the tree. As well “(Bypass)” is added to the node name.

(a) Output tab of bypassed Front input

To unbypass nodes:

- 1 Do any of the following:
 - Select the node with the bypassed input and disable the Bypass button.
 - If the bypassed node is part of a multi-selection in the schematic, click Disable Bypass On Selection.

NOTE Click Restore Bypass On Selection to redo the bypass.

Adding Notes to the Schematic

You can add notes to the Batch or Batch FX schematic, or to a specific clip, node, or group. Notes are useful when collaborating on an effect or project with other users. Notes are saved with the setup so they are visible to all. You can copy and paste content between notes.

To create a freeform schematic note:

- 1 Drag the note icon from the All Nodes bin to the schematic.

- 2 Double-click the note icon.
The Note text editor appears.
- 3 Click the editor window to activate it, and type your note text.

- 4 Click the upper-left corner of the text editor to close the editor.

To create a note on a clip, node, or group:

- 1 In the schematic, select the clip, node, or group to which you want to add the note.
- 2 Press `Shift+V`.
The Note text editor appears.
- 3 Type text into the Note field.
- 4 Click the upper-left corner of the text editor to close the editor. The note icon appears to the right of the clip, node, or group.

This note is attached to the clip, node, or group.

Viewing Schematic Notes

You can modify how notes are displayed in the schematic.

To display an existing note:

- 1 Use one of the following commands with the cursor over the note (for freeform notes), or over a clip, node, or group that has a note.

Press:	To:
V	Temporarily display a note.
Ctrl+Shift+V	Expand a note for display.
Shift+V	Expand a note for editing.

Selecting Nodes in the Schematic

Use the following keyboard shortcuts to help you select and work with nodes in the schematic.

To:	Do this:
Select a node.	Click node.
Select multiple nodes.	Press <code>Ctrl</code> , then click and drag a rectangular selection around the nodes.
Deselect everything.	Click on an empty space in the schematic, or press <code>Ctrl</code> and click-drag on an empty space in the schematic.
Add or remove nodes from a selection.	Press <code>Ctrl</code> and click the nodes you want to add or remove.
Select all the nodes before the current node (ascendants).	Press <code>Alt</code> and click the node.
Select all the nodes after the current node (descendants).	Press <code>Alt+Spacebar</code> and click the node.

To:	Do this:
Remove a branch from a selection.	Press Ctrl+Alt and click the branch.
Add or remove the branch after a node (descendants) to the selection.	Press Ctrl+Alt+spacebar and click the node.
Select the entire tree.	Press Alt+Win+Spacebar and click any node in the tree.
Add or remove a tree to or from the selection.	Press Ctrl+Alt+Win+Spacebar and click a node in the tree.
Select the entire setup.	Press Ctrl+A.
Move only one node in a selection.	Press Shift and move the node in the selection.

Adding Media to an Action Node

To add indirect media to an Action node:

- 1 In the Batch or Batch FX schematic, double-click the Action node and then click Media in the Action menu.
- 2 From the Media List box, select New Input.
A Media node is added to the Action node.
Notice that the Media list is empty. Although you have added a Media node to the Action node, you have not yet added any media.
- 3 Connect front and matte clips (image clips, or the output of another node in the Batch or Batch FX process tree) to the red and blue input tabs of the Media node, respectively.
The Media list is updated with the indirect media. Brackets (“[]”) around the clip names indicate the media is indirect.
When you select a Media node in the schematic, the corresponding media in the Media list is highlighted. Conversely, selecting media in the Media list highlights the corresponding Media node and the link to the Action node.

To add direct media to Action using Clip Select:

- 1 In the Batch or Batch FX schematic, double-click the Action node and then click Media in the Action menu.
- 2 From the Media List box, select New Media.
- 3 From the workspace, select a front and matte clip to load as media.

NOTE You can select any number of front and matte clips by holding the Ctrl key while selecting clips. Each front/matte selection is added to its own line in the Media list, and image nodes are automatically added to the schematic if Auto Image is selected in the Node Prefs menu.

To add direct media to Action gesturally:

- 1 From the Workspace Media panel, drag a clip to the Action schematic or Media list.
An image node and axis are added to the Action schematic (if Auto Image is selected in the Node Prefs menu), and the Media list is updated with the front media.

- 2 To replace the media in an image node, drag a new clip from the workspace Media panel onto an existing image node in the Action schematic. Release the clip when you see the red replace arrow. The image is replaced in the schematic, and the Media list is updated with a new entry for the media. The replaced media remains as a Media list entry in case you are using it elsewhere in your Action scene.

To convert direct media to indirect media:

- 1 Select the media that you want to convert from the Media list.
- 2 Click Extract.

A Media node is added to the Batch or Batch FX Action node and the selected media is automatically connected to the respective input tabs. In the Media list, brackets appear around the media name, indicating the media is indirect.

About Action in a Batch or Batch FX Workflow

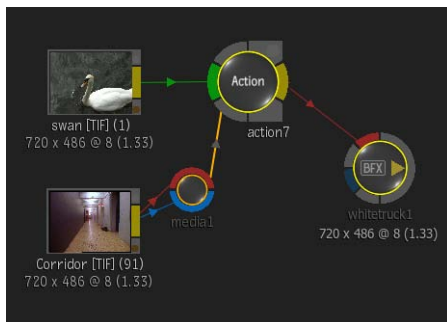

Action is a multilayer compositing tool for creating complex visual effects, with its own distinct schematic and node bin. The Action node supports direct media and indirect media.

Indirect media is connected directly to an Action Media node and appears in the Batch or Batch FX schematic. With indirect media, you can connect any source (such as images, or the output of another node in the Batch or Batch FX process tree) to an Action node. Media nodes are permanently parented to the Action node (you cannot sever the process lines). You can add multiple Media nodes to an Action node.

Direct media appears directly inside an Action node, and in the Batch or Batch FX Sources folder in the Workspace Media panel, as well as in the Batch or Batch FX Timing View. Although direct media does not appear in the Batch FX schematic, media and all related settings are saved with the Batch or Batch FX setup.

TIP You can also parent a back clip to the Action node. Although doing so is not necessary, a parented back clip node provides a good visual reference for identifying the Action composite in the process tree.

The following example displays indirect media in Action. The *swan* clip is attached to the Action node as the back clip, whereas the *Corridor* clip is attached to an Action media node as the front and matte media.

The Action node supports multiple outputs. For example, you can set up your scene to output your entire composition or just the mattes and then select the type of output you want to process. You can also output stereo results of your scene.

About Action Node Output Tabs

The Action node's output tab changes depending on the number and type of outputs it has, as shown in the following example.

(a) One output (b) Two outputs (c) Multiple outputs (more than two)

NOTE The colours of a dual-output tab are based on the type of output (for example, yellow for composite, blue for matte).

The number of outputs is determined by the outputs set up in the Output list. See [About Rendering Outputs from Action](#) (page 450).

Setting Stereo Startup Mode for Action

When dragging an Action node to the Batch or Batch FX schematic, you can automatically set the node to stereo startup mode. If you change any of the stereo startup settings, you can revert back to the default stereo startup settings. You can also change the settings of an existing Action mono node to the stereo startup settings.

For information on the settings that are affected by the stereo startup mode, see [Rendering Tab](#) (page 441).

To set the stereo startup mode for a new Action node:

- 1 Enable the Stereo Mode button below the node bin.

The node is renamed to Action_STEREO, the output tabs display the left eye and right eye outputs, and all stereo settings are automatically set.

(a) Left eye output tab (b) Right eye output tab (c) Stereo node name

To apply the stereo startup setting to an existing Action node:

- 1 Select the Action node.
- 2 In the Node Prefs menu for the Action node, click Reset To Stereo Mode in the Rendering section.

Once confirmed, the current setup is replaced by the stereo setup and all media is deleted.

Viewing Nodes in Context

View a node in context with another node to compare intermediate results throughout the process tree. By working with context points, you can modify nodes in the process tree and immediately view the impact those changes have on the nodes further along in the process tree. You can set two context points in a process tree.

You can set a context on a node or on any of its output tabs. You can also set a context on any node output in a group as well as on any output of an Action multiple output node.

To view nodes in context:

- 1 In the schematic, select the node you want as the context (for example, an Action node).
- 2 Right-click the node, and select Set as Context.
A dotted green line appears around the node, and (C1) appears next to the node name in the schematic.

- 3 In the schematic, select the node you want to edit. For example, select a Colour Correct node and modify the setup.
- 4 View your colour correction changes in the context of Action by selecting Context 1 from the View box.
In this way, you are colour correcting “in context” of the intermediate result. Furthermore, as you move to different frames in the tool, Context 1 also displays the result at the same frame. For instance, if you are at frame 15 in the Colour Corrector, Context 1 (Action) is also at frame 15. (Exceptions to this occur when using time-based nodes such as Pulldown, Interlace, and DeInterlace.)
- 5 If you want to set a second context, select another node in the schematic—such as a Keyer RGB node—right-click, and select Set as Context.
(C2) appears next to the Keyer RGB node name.
- 6 Repeat steps 3 and 4.

NOTE For group nodes, stereo nodes, or nodes with multiple output tabs, you can set the context on specific output tab instead of the complete node.

About Previewing Results in Batch or Batch FX

While creating your process tree, you can preview results at any time. If you do not like the result of one operation, you can modify or delete it without affecting the other operations in the sequence. You can preview your results in Batch or Batch FX by:

- Using proxies in the schematic.
Double-click the result tab on the node to display or hide the proxy. If Auto Update is enabled in the Schematic section of the Preferences menu, the proxy updates automatically as changes are made.
- Selecting one of the options in the View box to view results at the current pipeline level in the image window.

Select the node whose results you want to preview, then select an output or result view from the View box (use a 2-Up view to view the schematic and result at the same time). In Batch FX, you can select BFX Timeline Result to see your composite in the context of the timeline.

- Setting up to two context nodes in Schematic view and viewing the results in context in the image window.

Working with Audio Contexts

While working on one clip or branch of the process tree, you can listen to the audio of another clip. Audio contexts work in much the same way as video contexts. You can set up to two audio contexts in Batch or Batch FX.

To set an audio context:

- 1 In the schematic, select a clip that contains audio.
- 2 Right-click the clip, and select Set as Audio Context.
Clips with an audio context are labelled A1 or A2 and are outlined by a pink dotted line.
- 3 To hear an audio context, select Context1 or Context2 from the Audio Source box in the Batch or Batch FX Preferences menu.

NOTE Playback of audio is only available when playing a clip. However, you can scrub audio anytime in Batch or Batch FX. You can scrub your audio context by using **Ctrl** (quick scrub) or **Shift+Ctrl** (real-time scrub) on any node.

About Batch Rendering

When you are ready to generate final clips or intermediate results, define the settings for each Render and Write File node that you want to process.

Use the Render node to output clips to the Desktop or Media Library. Use the Write File node to export open clip files or image sequences in any supported format. With the Render node, metadata is kept; with the Write File node, metadata is not kept, unless you enable Create Clip Data.

Render and Write File nodes support RGB, RGB-A, and Stereo processing modes.

When you work with multiple resolutions, the Render or Write File node's resolution is determined by the clip or node feeding it. However, you can resize your output to any resolution.

You can also set up the Render List to manage multiple Render and Write File processes.

Naming Output Nodes

To help you organize outputs, you can automatically name an Output node with the name of any output socket in the process tree. With the Output node selected in the schematic, press **N** and click a node output—the name of the Output node is updated. If you want to change the Output node name, or if you change the name of the original output socket, simply redo the naming process.

Exporting With Open Clip Data

Open clip files can be created using a Write File node with Create Clip Data enabled. This gives you the ability to save a copy of the active setup with the exported material, allowing you to package exports with the setups that created them, or to version your exports.

NOTE An open clip file is an XML file which describes channels, media, and versions. You can also create your own open clip files to be used inside Batch, with the Read File node; you might want to do this within a context of render passes interop between Flame Premium and a 3D application.

Advanced: Executing Batch from the Command Prompt

You can execute Batch directly from a command shell so that you can render complex process trees while the machine is not in use, such as overnight. The following command starts Flame Premium for a specified user, and renders a specified Batch setup:

flame -b batchsetup -U user -J project

NOTE The specified user and project name must be valid.

About Open Clip Files

Open .clip files are files created using the Write File node in Batch or by a third party application.

How to Create an Open Clip?

Three ways to create an open clip:

- Using the Batch Write File node with Create Clip Data is enabled.
- Using a third party application or utility.
- Creating one by hand

What Is an Open .Clip File?

In its simplest form, an open .clip file consists of two parts:

- A .clip file
- Media files

The media is any supported media files, from DPX sequences to RED clips, including multi-channel OpenEXR renders. The other component, the .clip file, is written in a human-readable format, the XML format; you can open a .clip in any word processor (kedit, notepad, TextEdit) and decipher its content.

In essence, the .clip files contains all the metadata and references to media that are required to define a source and its versions. The .clip file does nothing by itself, but is essential to recreate the sources.

One of the strengths of the open .clip is that anyone can create .clip files. With one, you can organize media outside of your applications for later use.

Using an open .clip file, you can define many aspects of a clip, including:

- Source Information
- Versioning
- Multiple channels of media
- Paths to media

Why Use an Open Clip?

For open clip history and data exchange.

Open clip history Open clip history provides you with the ability to save with a processed clip the Batch setup used to create that clip. Later on, to open that clip in Batch and edit previous nodes and their settings.

Data exchange Data exchange requirements with a facility's shot management system. In such a case, the .clip is a file created by a third party system, allowing something else to define a source using instructions contained within the file. In this case, the clip can contain a list of render passes for you to composite in Flame Premium. Using of the Read File node, you can easily navigate a source's versions.

Open Clip Example

```
<?xml version="1.0" encoding="UTF-8"?>
<clip type="clip" version="3">
  <name type="string">ClipExport</name>
  <userData type="dict">
    <appName type="string">flame</appName>
    <appVersion type="string">2012</appVersion>
  </userData>

    </version>
</versions>
</clip>

```

Render Node Settings

Use node settings to define how individual Render nodes are processed and to specify a destination for each rendered result.

To access Render Node settings, double-click a Render node in the schematic. If you have multiple Render nodes and Write File nodes in your Batch pipeline, you can manage them in the Render List.

Basic Settings

Basic button Opens the Basic menu where you set Render Node formatting and destination settings.

Export Format box Select the type of clip rendered by the node. RGB-A sets one red RGB input tab and one blue matte tab. Stereo sets two RGB input tabs (one for each eye) as well as two blue matte tabs (one for each eye). Stereo requires a <polarity> token in the Naming field; if there is no <polarity> token, the application automatically adds it to the name of the exported files.

Framerate box Select the framerate of the output clip.

Output Depth box Select the bit-depth of the output clip.

Storage box Select a 12-bit storage option. Select Packed to save image data so that it requires less space on the framestore. Select Unpacked to save an image that can be retrieved without an intermediate step. Active when the Output Depth option is set to 12-bit.

Offset Timecode button Enable to apply any timecode offsets made in the Render List. For example, if you specify a timecode of 00:00:00:00 and render from frame 10, the first frame of the render is TC 00:00:00:09.

Source Timecode field Displays the source timecode for the output. Editable.

Record Timecode field Displays the record timecode for the output. Editable.

Renders Destination box Select whether the render is written to the Desktop or Media Library.

Range From field Displays the first impacted frame. Editable.

Range To field Displays the last impacted frame. Editable.

Render Range button Click to output based on the ranges in the To and From fields.

Burn Range button Click to burn based on the ranges in the To and From fields.

Resize Settings

The Resize settings are the same as when you are using the Resize node in Batch. Click the Active button to activate the Resize settings.

RGB LUT Settings

The RGB LUT settings are the same as when you are using the LUT Editor node in Batch. Click the Active button to activate the RGB LUT settings.

Write File Node Settings

Use these settings to define how individual Write File nodes are processed and to specify a destination for each processed result.

To access Write File Node settings, double-click a Write File node in the schematic. If you have multiple Render nodes and Write File nodes in your Batch pipeline, you can manage them in the Render List.

Basic Settings

Basic button Opens the Basic menu where you set Write File formatting, rendering, and naming settings.

Export Format box Select the type of clip rendered by the node. RGB-A sets one red RGB input tab and one blue matte tab. Stereo sets two RGB input tabs (one for each eye) as well as two blue matte tabs (one for each eye). Stereo requires a <polarity> token in the Naming field; if there is no <polarity> token, the application automatically adds it to the name of the exported files.

Framerate box Select the framerate of the output clip.

File Format box Select the file format of the images to export.

File Extension field Select the extension for the file type selected in the File Format box. Editable.

Output Depth box Select the bit-depth of the output clip.

Source Timecode field Displays the source timecode for the output. Editable.

Record Timecode field Displays the record timecode for the output. Editable.

Frame Pad field Displays the padding of the frame ID appended to the file name. "4" indicates that up to four zeros are prefixed to the file name for each frame; frame 1 is written as 0001, frame 22 as 0022, frame 555 as 0555.

Offset field Displays any timecode offsets that you made in the Render List. For example, if you specify a timecode of 00:00:00:00 and render from frame 10, the first frame of the render has TC 00:00:00:09.

Transfer Characteristics box Select an option to identify the attributes associated with a particular film or video format, such as resolution, frame rate, or colour space. Active when File Format is set to DPX.

Compress button Enable to apply compression to the exported file. This results in smaller file size but lower image quality. Available for Tiff, Sgi, and OpenEXR format types.

JPEG Quality field Displays the degree of quality versus compression for the Jpeg format type. 0 gives the lowest quality (and highest compression). 100 gives the best quality (but applies no compression). Editable.

Create Clip Data button Enable to create an open clip file, which includes extended clip data with the exported files.

Include Setup button Enable to include the Batch setup information with the rendered media. This allows someone accessing the open clip file to view and modify the original Batch setup, similar to how you can edit Clip History.

Version button Enable to version the rendered exports, using an open clip. The resulting open clip has versions accessible through the Clip Versions box in the Read File node. If enabled, it requires a <version> token in the Naming field; if there is no <version> token, the application adds the value of the Version field to the name of the exported files, prefixed by "v_".

Version field Displays the version identifier, which automatically increases at each subsequently rendered export. Or set the version value manually. Ctrl+click to display the next available value. Using a previously used version value overwrites that version with the new export. Editable.

Version Pad field Displays the number of zeroes to left-pad the version number with. Editable.

Range From field Displays the first impacted frame. Editable.

Range To field Displays the last impacted frame. Editable.

Render Range button Click to output based on the ranges in the To and From fields.

Burn Range button Click to burn based on the ranges in the To and From fields.

Name field Displays how to name the exported media files. Build a dynamic naming scheme using the Add Token menu, as well as use any of the characters allowed in a Linux file name. Create folders using the slash (/) character. The application always appends the file ID and the extension of the file format selected for the export. Editable.

Destination Path field Displays where the exported files are created. The path in bold characters is created by editing the Path field. The text in grey is the content of the Name field. The open clip file (Create Clip Data enabled) is always created in the path in bold. Polarity and Version are automatically added unless specified in the Name field. Editable.

Add Token menu Inserts in the Name field one of four tokens. <name> for the name of the Write File node. <date> token for the current date, formatted as YYYY_MM_DD. <version> for the value of the Version field; ignored if either Version or Create Clip Data are disabled. <polarity> to differentiate left eye and right eye files in Stereo exports; ignored if Export Format is set to RGB-A.

Load Name button Click to load a previously saved naming pattern to the Name field.

Save Name button Click to save the content of the Name field, to be loaded at a later time.

Resize Settings

The Resize settings are the same as when you are using the Resize node in Batch. Click the Active button to activate the Resize settings.

RGB LUT Settings

The RGB LUT settings are the same as when you are using the LUT Editor node in Batch. Click the Active button to activate the RGB LUT settings.

Matte LUT Settings

The Matte LUT settings are the same as when you are using the LUT Editor node in Batch. Click the Active button to activate the Matte LUT settings.

Render List Settings

Use the Render List to manage output and export processes. You can set up several output or export processes, specify the frames at which to start and end a process, as well as set job priorities.

You can execute jobs immediately or at a later time using a Batch script. You can attach scripts that convert processed images to a movie file (*.mpg*) or that send messages about the status of Batch processes. The jobs that appear in the Render List are saved in the Batch setup file.

The Render List also displays some settings you defined for a specific Render or Write File node. For example, it lists the destination you specified for a processed output as well as the type of output.

To access the Render List, click the Render List button. You can switch between the Render Node or Write File node menu and the Render List as needed.

List Filtering Settings

Nodes box Select whether to activate or deactivate all Render and Write File nodes in the Render List.

List box Select whether to render only visible Render and Write File nodes in the current Render List view, or include Render and Write File nodes nested in groups.

Render List Columns

Process Indicator column Activate individual Render and Write File nodes for processing. Click an indicator to activate or disable one job at a time.

The arrow in the P column is yellow when a job is active, grey when disabled, and red when there is a processing error.

Node Name column Displays the name for the processed clip. Click a Node Name field to rename the clip.

Start and End frames columns Specify the range of frames you want rendered in a processed result. Corresponds to the Range From and To fields in the Render or Write File node settings.

For example, one node could be set to process the first 30 frames of a 60-frame clip, and another node could process the remaining 30 frames.

NOTE The Start and End fields override the total number of frames in the timebar. For example, if the timebar shows a 60-frame clip and a node is set to start at frame 20 and end at frame 100, then 80 frames are processed.

Destination column Displays the destination for the output or exported result. Use the Output Destination box in the Render or Write File node settings to change the destination.

Priority column Displays the priority of the jobs to be processed. If two processing nodes are connected to the same process tree, they have the same priority.

If there is a processing error, for example, if the Render or Write File node is not connected to a process tree, the job is deactivated and the priority is automatically set to 0.

Script column Attach a script file whose content is executed when the Render or Write File node is finished rendering. Scripts must have the file extension *.bscript*.

Click this field to load an existing script from the file browser. See the Script Reference section below for more information.

Source column Generate your output with a source timecode. Corresponds to the Source Timecode field in the Render or Write File node settings. To edit the timecode, double-click the field and enter a new value.

Record column Generate your output with a record timecode. Corresponds to the Record Timecode field in the Render or Write File node settings. To edit the timecode, double-click the field and enter a new value.

FCM column Displays the framecode mode. Change this value using the Framerate box in the Render or Write File node settings.

Output Type column Displays the type of clip to be processed: RGB, RGB-A, or Stereo. Corresponds to the Export Format box in the Render or Write File node settings.

Script Reference

Batch scripts are ASCII files that contain instructions related to a Batch job. They must have the file extension *.bscript* for Batch to recognize them. A Batch script is executed after the Render or Write File node to which the script is associated has finished rendering.

NOTE Use the *imgview* and *movie* scripts with the Read File node, and use the *listVariables* script with the Render or Write File nodes.

You should consult with your system administrator when creating scripts. Scripts are created using either C shell, Korn shell, or Perl. Also, Batch scripts must have the proper file access, directory access, and execution permissions for the files, directories, and applications in the script.

When the script is executed, Flame Premium continues with its own processes and does not wait for the script to terminate. Flame Premium imposes no restrictions with executing scripts; however, make sure that no one else is using the system when a script is executed and that the script is approved by your system administrator.

Script variables that you can set are defined in the following table.

Variable	Description
BATCH_NODE_NAME	Corresponds to the name of the Render or Write File node. This is the same name that you provide in the Render List Node Name field.
BATCH_FIRST_FRAME	Corresponds to the first frame displayed in the Render List for the selected node name.
BATCH_LAST_FRAME	Corresponds to the last frame displayed in the Render List for the selected node name.
BATCH_ASPECT_RATIO	Corresponds to the framestore aspect ratio.
BATCH_FRAME_RATE	Applies only to scripts associated with Write File nodes. This is the framerate of the final clip result.
BATCH_FRAME_WIDTH	Applies only to scripts associated with Write File nodes. Corresponds to the width of the final clip result.
BATCH_FRAME_HEIGHT	Applies only to scripts associated with Write File nodes. Corresponds to the height of the final clip result.

Variable	Description
BATCH_OUTPUT_DST	Applies only to scripts associated with Render nodes. Indicates the destination of the final clip result as either the Desktop or Media Library.
BATCH_BIT_DEPTH	Applies only to scripts associated with Write File nodes. Specify the bit depth of the final clip result.
BATCH_CROP_WIDTH	Applies only to scripts associated with Write File nodes. Specify the crop width of the final clip result.
BATCH_CROP_HEIGHT	Applies only to scripts associated with Write File nodes. Specify the crop height of the final clip result.
BATCH_FILE_FORMAT	Applies only to scripts associated with Write File nodes. Indicates the numbering format of a sequence of exported images in the final clip result. This numbering sequence ensures that the order of frames in the clip is intact when you import the clip.
BATCH_FILE_EXT	Applies only to scripts associated with Write File nodes. Specifies the format to which the final clip result is being exported: Alias (<i>.als</i>), Cineon, Dpx (Spirit), Jpeg (<i>.jpg</i>), Pict (<i>.pict</i>), Pixar (<i>.picio</i>), Sgi (<i>.sgi</i>), SoftImage (<i>.pic</i>), Targa (<i>.tga</i>), Tdi/Maya (<i>.iff</i>), Tiff (<i>.tif</i>), or Wavefront (<i>.rla</i>).
BATCH_FILE_DIR	Applies only to scripts associated with Write File nodes. Indicates the file location of the final clip result.

About BFX Output Nodes

A Batch FX pipeline always terminates with a BFX Output node. This node is created automatically when you enter Batch FX from the timeline, and can't be deleted.

You can generate both RGB and alpha results from a BFX Output node to the timeline.

Since an effect you create in Batch FX is a setup applied directly to one or more timeline segments, you can choose to render your BFX directly in Batch FX, or wait until you return to the timeline.

Naming Output Nodes

To help you organize outputs, you can automatically name an Output node with the name of any output socket in the process tree. With the Output node selected in the schematic, press **N** and click a node output—the name of the Output node is updated. If you want to change the Output node name, or if you change the name of the original output socket, simply redo the naming process.

Outputting an Alpha to the Timeline

You can output alpha results in addition to the RGB result from a BFX Output node. You connect the RGB result to the front input of the BFX Output node, and the alpha result to the matte input of the BFX Output node (The output node now displays BFXa). Both results are fed directly to the timeline.

A Comp Timeline FX is automatically added on output, provided that the Add Comp On Matte Output button in the Batch FX section of the Preferences menu is enabled (this is the default).

Output Node Settings

Double-click the BFX Output node in the schematic to see its settings.

Basic Settings

The settings in the Basic menu are non-editable, and are available so you can see the output resolution and timecode of the timeline segment you entered Batch FX with.

Width field Displays the width resolution of the output clip. Non-editable.

Height field Displays the height resolution of the output clip. Non-editable.

Frame Depth field Displays the output frame depth. Non-editable.

Aspect Ratio field Displays the output aspect ratio. Non-editable.

In Timecode field Displays the in point timecode of the output clip. Non-editable.

Out Timecode field Displays the out point timecode of the output clip. Non-editable.

Duration Timecode field Displays the timecode duration of the output clip. Non-editable.

Resize Settings

The Resize settings for the BFX Output node are only available if you attach a clip to the pipeline that is a different resolution than the original BFX output. In this case, the Resize settings are active, but you are not able to change the Destination settings (these must remain the same as when you entered BFX from the timeline).

RGB LUT Settings

Similar to the Resize settings, The RGB LUT settings for the BFX Output node are only available if you attach a clip to the pipeline that is a different resolution than the original BFX output.

Saving and Loading Batch or Batch FX Setups

You can save and load Batch or Batch FX setups. When saving a setup, you have the option of saving the complete Batch or Batch FX setup, or only the selected items in the schematic. Use the drop-down list beside the Save button to make a selection before clicking Save. When loading a saved setup, you have the choice of loading (replacing any existing nodes), or load and append.

In Batch or Batch FX, you can also save and load specific node setups. The node load and save buttons appear next to the node name field when a node is selected in the schematic.

Saving Sources with Batch Snapshots

In Batch, instead of saving and loading setups, you also have the option of saving or restoring snapshots. The benefit of using Batch Snapshots is that along with the setup, you also save the sources used by the setup. Batch Snapshots work in a similar manner to Desktop Snapshots, in that they reside in the Workspace Library section of the Media Panel, and you can manage (create, open, or close) multiple snapshots. There are also multiple ways to replace or append a saved snapshot.

To create a Batch snapshot:

- 1 Enter a name in the name field.

- 2 Click Snapshot.

A closed snapshot folder is created and can be seen in the Batch Snapshots area in the Workspace Media panel. If you right-click, and select Open Snapshot, you can see a Sources subfolder under the Snapshot entry containing the sources saved with the snapshot.

TIP You can also create your own folders in the Batch Snapshots area to organize snapshots (right-click Batch Snapshots and choose New Folder).

- 3 The Batch area in the Workspace Media panel also displays the name of the snapshot in parentheses. If you make any changes to the schematic, an asterisk appears next to the name in the Batch area. You can click Snapshot again to overwrite your snapshot with the changes, or create a new snapshot with a different name.

NOTE Saving a Batch snapshot with the same name as an existing saved snapshot allows you to replace the existing snapshot, or bump the snapshot version. Bumping creates a new snapshot, with an incremental version number appended to the name (for example, *comp_V01*). Multiple snapshot versions are automatically grouped into a folder under Batch Snapshots.

As with Media Libraries and Desktop snapshots, you can close Batch snapshots as a memory-saving operation. The contents of a closed snapshot are flushed from memory, but you are able to open a snapshot at any time to view all the sources contained in it. The Open Snapshot and Close Snapshot options are available in the right-click menu for each Batch snapshot in the Workspace Media panel.

TIP You also have the option of creating and saving a Batch setup when you save a Batch Snapshot. Enable Also Save Batch File in the Preferences Timeline FX / BFX section. In this case, the setup is saved in the default Batch folder *~/batch/flame* in a snapshots subfolder. Note that these setup files are not managed by Flame Premium. Therefore, if you delete a Snapshot, the corresponding setup file is not deleted automatically.

Restoring a Batch Snapshot

You can replace or append a batch snapshot in a number a different ways (a snapshot does not need to be in an open state to restore it):

- While in Batch, drag and drop a snapshot to the schematic, and choose whether to replace or append.
- From anywhere in Flame Premium where you can access the Workspace Media panel, drag and drop a snapshot to the Batch Sources folder in the Workspace Media Panel. In this case, a replace is performed once you confirm the operation, and you are switched to the Batch tab automatically.

- From anywhere in Flame Premium where you can access the Workspace Media panel, right-click a Batch snapshot, and select Replace Batch Setup or Append Batch Setup. In this case, you are switched to the Batch tab automatically.
- From anywhere in Flame Premium where you can access the Workspace Media panel, double-click a Batch snapshot, and confirm to replace the current setup. In this case, you are switched to the Batch tab automatically.

NOTE Using any of the above methods while in Batch FX only allows you to append to your existing Batch FX setup. Any Write File or Render nodes in the snapshot are displayed as greyed out nodes in the Batch FX schematic.

Using a Create BFX Clip for Caching or Versioning

Use Create BFX within Batch or Batch FX to create a BFX clip that can be useful for disk caching and give you flexibility for re-use or versioning of complex pipelines.

A BFX clip is a nested group or container that has benefits over Group nodes in Batch or Batch FX.

Creating a BFX Clip

To create a BFX clip, right-click a node in the schematic, and select Create BFX. A new clip node is created that included the node you selected, and all downstream inputs to the node (that is, everything connected to the left of the node). At this point, you can delete the old nodes, and connect the new BFX clip into your pipeline.

Disk Caching Capabilities

You can switch to the Batch or Batch FX Timing view, select your BFX clip in the timeline, and click Render. Working in Batch or Batch FX is now faster, since all the nodes that make up the BFX clip are now rendered. Once you are ready to render your complete Batch or Batch FX pipeline, the BFX clip does not need to be re-rendered if you haven't modified it.

Flexibility

Another benefit of using a BFX clip is the flexibility it offers for versioning or re-using the clip. You can use the offset feature in the Timing view to offset the start time of the BFX clip, or even slide or trim the media and animation keyframes contained within the clip. When you create a BFX clip, it resides in the Batch or BFX Sources folder in the Workspace Media panel. You can copy this clip into another folder in the Media Library, and re-use it in another timeline segment, or even another project.

Exploding BFX Clips

To return a BFX clip to its original separate nodes, right-click the clip, and select Explode BFX. This action is non-destructive, but it does delete the rendered frames (if you had rendered the BFX clip).

Since you can nest a BFX clip inside another BFX clip, the explode operation only explodes to one level. In the Basic menu for the BFX clip, you have an option to Explode All levels of the clip back to its original nodes.

Using the Timing View to Offset Clips

When you offset a clip, you simultaneously offset all its segments on each track. You can also offset multiple clips simultaneously, including all clips in a group.

To offset clips:

- 1 To access the Batch or Batch FX Timing view, click the Timing button.
- 2 Select the clips and/or segments to offset. If you are offsetting all clips in a group, select one clip or segment in the group and then click Select All Clips in Group. To select all clips on a track, click the clip proxy to the left of the track.
- 3 Drag left or right in the Offset field, or enter the number of frames by which to offset the clip.

All selections are offset by the same amount.

NOTE If you offset multiple clips simultaneously, the value in the Offset field resets to 0 when the offset is complete.

About the Timing View

The Timing View displays the timeline of all Batch or Batch FX clips in one view. This view is especially useful for edits where you want to see the relative position of all clips in time. For example, offset multiple clips or edit one clip in relation to the others.

You can adjust the timing of any number of clips as well as perform basic editing operations such as slipping, sliding, or trimming. You cannot perform editing operations that involve combining clips or inserting frames from one clip into another.

Edit a clip gesturally, or use same buttons and keyboard shortcuts as you would on the timeline.

To access the Timing View, click the Timing button. All clips in the current schematic, including clips that are part of a group node, are represented by a clip proxy and primary video track. Gaps are displayed based on Media settings, which are set in the clip's Basic menu.

You can select multiple clips on different tracks to perform timing operations at the same time. Selected clip proxies and tracks are highlighted by an orange bounding box.

Timing View Settings

Some Timing View settings relating to trimming, slipping, or sliding clips (such as the Ripple and Snap buttons), or to the actual timeline itself (such as the Timeline Options menu) are exactly the same as the main Flame Premium timeline.

The following settings are specific to the Timing View:

Use Start Frame button Click to offset the selected Batch clip so that its source frame matches the timeline's timecode. This allows you to also offset based on header timecode. Not available in Batch FX.

Offset field Displays the number of frames by which selected clips and/or segments are offset. This same setting can be found in the Timing View as well as the Clip Settings. Editable.

Filter box Select the type of clips to display in the Timing View.

Select:	To display:
Show All	All clips in the schematic.
Show Tree	All clips in the selected processing tree.
Show Branch	All clips in the current node branch.
Show Selected	All clips and nodes selected in the schematic.

Select All Clips in Group button Click to select all clips that are part of a group. First select one clip or segment in the group.

Timing View Render box Select an option and click to render selected Timing View clips. Also available as a contextual option when right-clicking a clip node.

Caching Frames

You can avoid reprocessing the same nodes and clips as you navigate in the timebar by specifying which nodes and clips should be cached. Cached frames are stored on the system framestore, increasing system performance and efficiency. Stored cache clips are contained in a `_Cache_` library and correspond to the clip IDs in the setups. These cache library files are named according to setup and project name.

Node and clip caching is enabled in the Cache section of the Batch or Batch FX Preferences menu. The Cache menu also displays the number of rendered frames in the cache for the selected nodes or clips, and the remaining space on the framestore.

Any clip node can be cached as long as it is edited, resized, or has had a LUT conversion applied. Batch setup files include the location of any cached frames, which are stored with the clip ID until removed. The history associated with a clip can also be cached, but not if the clip was rendered in Proxy mode.

Each node and clip has a cache tab on the lower-right corner.

The following steps are not required to actually cache frames. Typically, you use intelligent caching, which automatically caches frames as you move through the timebar. Caching occurs as the frame is displayed and the node operation is applied. A cached node automatically saves frames as you display—or visit—they and then reloads them each time you visit the frame again. Your workflow speed is increased.

Read and write mode Cache enabled

Read-only mode Frames already cached are accessible

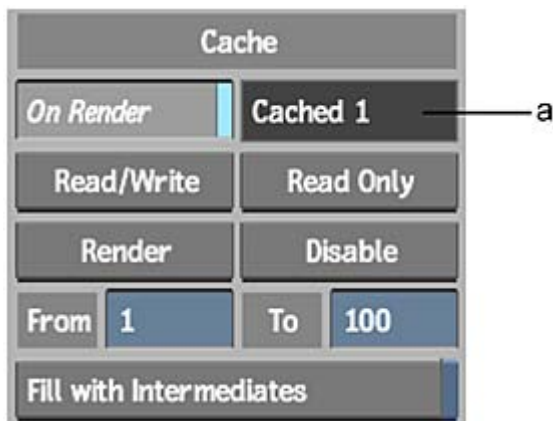

Cache disabled

Click the cache tab to activate any of the following modes.

Mode	Colour	Description
Disabled	Grey	Disables the cache. You can also Alt -click to disable and remove cached frames for the selected node.
Read and write	Yellow	Saves and loads data to and from the cache.
Read-only	Amber	Is shown with a yellow outline. No data can be saved to the cache, but rendered frames remain stored. Use this mode to prevent the framestore from getting full.

Changing or cutting an input or any node further along the process tree that has cached frames clears the cache buffer. The Cache section of the Batch or Batch FX Preferences menu (Rendering tab) shows how many frames are cached for the selected node and the number of frames available on the framestore. This allows you to clear the cache of the selected node or all cached frames.

(a) Cached frame counter

To cache frames:

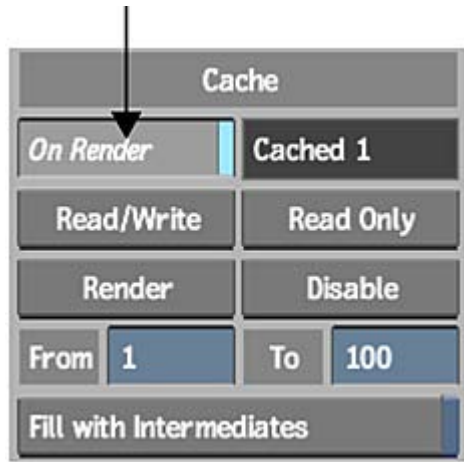

- 1 Specify the frames you want to render and store in cache using the From and To fields.
- 2 Click Render.

The cached frames are stored in the framestore and added to the cached frame counter.

To turn off the cache and remove cached frames, **Alt**-click the cache indicator for the selected node.

To render node caches while rendering:

- 1 Enable the cache for any nodes or clips whose frames you want to cache.
- 2 Enable On Render.

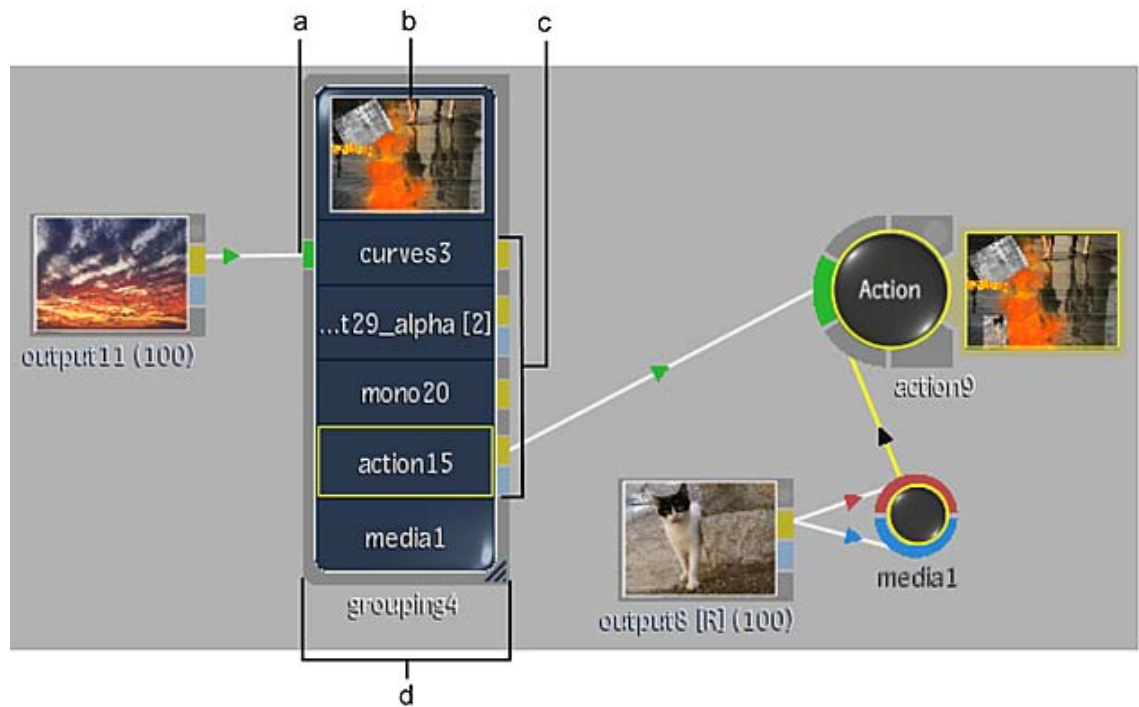

- 3 When you are satisfied with current settings in your process tree, click Render.
The clip is rendered, and all node caches are rendered. While rendering, the message bar displays the number of frames in the node and the time remaining until the render is complete.

Grouping Nodes

To group nodes:

- 1 **Ctrl**-drag to select the nodes you want to group.
Selected nodes are outlined in white.
 - 2 Right-click the selection, and select Group.
The selected nodes collapse into a Group node. The Group node lists the nodes contained in the group, as well as the non-hidden input tabs and output tabs.
- TIP** You can also create a group inside a group.

(a) Input connection (b) Proxy window (c) Output connections (d) Group icon

- 3 To rename the group, enter a name in the Node Name field.
- 4 Click the group node to display group display and editing settings.

To display a proxy of an output in the proxy window in the group node:

- 1 Do any of the following:
 - Click the field in the Proxy list that corresponds to the node whose output you want to display.
 - Press the `Shift+up` or `down` arrow as you navigate through the node's Group List.
 - If a node has multiple outputs, press `Ctrl+Shift+up` or `down` arrow as you navigate through the node's Group List to display all the outputs of a node.

To change the size of the group icon:

- 1 Drag the lower-right corner of the icon to make it wider or narrower.

Editing a Group

Use the Edit Group controls to edit the contents of a group.

To edit a group:

- 1 Select the group you want to edit.
- 2 In the Group settings, click Edit.

The nodes in the group appear in the schematic ungrouped, with other schematic nodes grayed out.

TIP Instead of editing the group, you can access a single node's menu by selecting the node's name from the Node List box. Click the Return to Group button to return to the Group List menu.
- 3 Modify the nodes as required.
- 4 Click Exit Group to return to the previous schematic.

NOTE Click Ungroup to expand the group of nodes to their pre-grouped positions in the schematic.

About Group Nodes

A group node is a selection of nodes and clips that are collapsed into one node icon. Each node icon displays the group's contents, inputs, and outputs. You can create groups for different branches of your process tree and work on each separately. Groups are useful for simplifying cluttered schematics.

(a) Group node

You can create several groups and work on each group separately. For example, group a Keying and Colour Correction branch separately from an Action and a filtering branch, and then work on each branch independently. If you need to edit the nodes in a group, you can expand the group and make the necessary modifications.

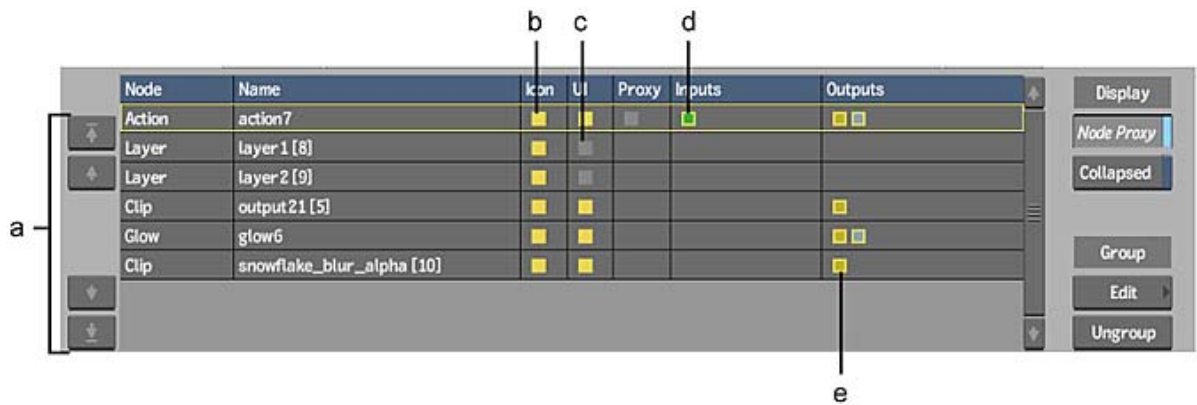

A clip with multiple outputs, (a stereo clip with left and right matte outputs, for example) can be displayed as a group node, allowing all output tabs to be displayed for connection.

Stereo nodes are displayed as group nodes, with inputs and outputs for the left eye and right eye.

Group Settings

Customize the group node using the Group List menu. The Group List menu lists all the nodes and connections contained in a group. You can rename and hide the contents of the group, as well as define which input and output connection sockets are visible and available for connection in the schematic.

You can select a node in the Group List menu to display the group at the selected node's stage. The View box must be set to Result, Front, or Back to use this display option. You can also display a preview proxy of a node in the group.

(a) Sort Order buttons **(b)** Enabled icon visibility **(c)** Disabled UI visibility **(d)** Enabled input visibility **(e)** Enabled output visibility

Use the Group List menu as follows:

Click:	To:
Sort Order buttons	Move the selected node one position up or down (click the single-arrow buttons). To move the selected node to the first or last position in a group, click the arrow-line buttons.
Name	Change the node's name.
Icon	Toggle the node's visibility in the group. Icons in the Group List are yellow when the node is visible and grey when hidden.
UI	Toggle the node's availability in the Node List box. Icons in the Group List are yellow when the node is displayed in the box and grey when hidden.
Proxy	Display a proxy of the corresponding node in the proxy window. Icons in the Proxy list are white when locked and grey when unlocked. Lock an icon when you do not want its proxy in the window to change as you navigate the Group List.
Inputs	Hide or unhide the selected node's input sockets. Sockets are colour-coded with the same scheme as nodes that are not part of a group. Icons in the Group List have a yellow border when the input socket is visible.
Outputs	Hide or unhide the selected node's output sockets. Sockets are colour-coded with the same scheme as nodes that are not part of a group. Icons in the Group List have a yellow border when the output socket is visible.

Node Proxy button Enable to display a preview proxy of a node in the group icon. To change the proxy, press Shift + up arrow or down arrow as you navigate through the Group List.

Collapsed button Enable to collapse the group icon so that only the preview proxy is displayed.

Edit button Click to display the schematic of the group contents, with all other nodes greyed out. To return to the Group List menu, click EXIT Group.

EXIT Group button Click to return to the Group List menu after editing.

Ungroup button Click to expand the group of nodes to their original positions in the schematic.

Node List box Displays the menu of the selected option. Select List or click the Return to Group button to return to the Group List menu.

Return to Group button Displays the Group List menu.

Mimicking, Copying, and Duplicating Nodes

When working in the Batch or Batch FX schematic, you have a few options to help you quickly get settings, or even complete nodes, to and from similar nodes. See the procedures below for information on how to access each of these options, but as a quick summary, here are the reasons for using each option:

- **Mimic Link:** You can keep two nodes in the schematic in sync by creating a Mimic Link between them. When you change the settings of one node, they are automatically mimicked in the other node.

NOTE To mimic nodes, the nodes must be of the same type. For example, you can link between Flip nodes but not between a Flip node and a Colour Correct node. Some nodes, such as Action or Modular Keyer do not support the Mimic Link option. In this case, you can see an error message in the message bar.

- **Duplicate:** Create another instance of a node or group of nodes within the same Batch or Batch FX schematic. All node information is duplicated as well.
- **Copy:** Copy is similar to Duplicate, except that the selected nodes or group of nodes is copied into the clipboard, so you can paste exactly where you want in the schematic. An added bonus of using Copy and Paste instead of Duplicate, is that you can paste a copied node or nodes into a different Batch or Batch FX schematic. You can even copy a Batch node and paste it into a Batch FX schematic or vice-versa.

Using Mimic Link

To create a Mimic link between nodes connected to mono clips:

- 1 From the Tools box, select Mimic Link.
- 2 In the schematic, drag between nodes of the same type.

A green-arrowed dotted line indicates that the nodes are linked as duplicates. The direction of the arrow indicates which node is the master.

(a) Duplicate link (b) Master node (b) Duplicate link (d) Duplicated nodes

- 3 Connect each node to a mono clip.
- 4 Change the settings of any node.

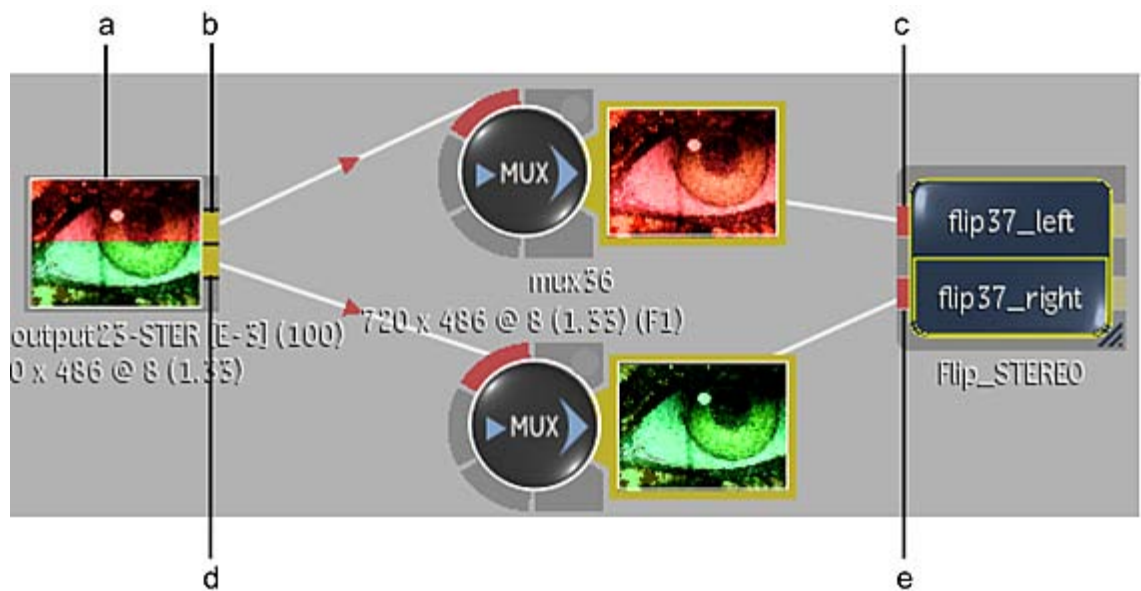

To work with Mimic link using a stereo group node:

- 1 With Stereo Mode selected, drag a node from the node bin to the schematic.
A stereo group node containing left eye and right eye inputs appears in the schematic.

(a) Left eye input (b) Right eye input

- 2 Connect the left and right eye inputs of the stereo group node to the clip node's left and right eye outputs, as shown in the following example.

(a) Clip containing stereo track (b) Left eye output tab (c) Left eye input tab (d) Right eye input tab (e) Right eye output tab

- 3 Double-click the stereo group node or click Edit in the Group List menu.
The schematic is dimmed except for the two nodes of the same type as the one you dragged from the node bin. A green-arrowed dotted line indicates that the nodes are linked as mimics.

(a) Master node (b) Mimic link (c) Mimicked node

- 4 Change the settings of either node.
Notice that the changes made to one node are mimicked on the other node so that both the left and right eye clips are affected simultaneously.

(a) Flip node connected to left eye is edited (b) Settings are automatically mimicked on Flip node connected to right eye

- 5 Click Exit Group.

Duplicating Nodes

To duplicate nodes:

- 1 In the schematic, select a node, or group of nodes.
- 2 Right-click the selection, and choose Duplicate.

A duplicate of the node or nodes (with all node settings) appears in the schematic.

Copying Nodes

To copy nodes:

- 1 In the schematic, select a node, or group of nodes.
- 2 Right-click the selection, and choose Copy.

A copy of the node or nodes (with all node settings) is added to the clipboard.

- 3 Navigate to the location in the schematic (or another Batch or Batch FX schematic) where you want the copied node or nodes to reside, right-click and choose Paste.

A copy of the node or nodes (with all node settings) appears in the schematic.

Customizing the Tools Bin

Create custom bins and populate them with your most commonly used nodes to optimize your workflow. As well, change the order of the tabs along the top of the bin and rename them to reflect the contents of a bin.

You can customize any bin in the Tools bin except the All Nodes bin and its tab.

To create a tab:

- 1 Click the plus sign tab.

- 2 Name the tab in the keyboard that appears.

NOTE You can create a maximum of 6 new tabs.

To copy a node to another bin:

- 1 Drag the node on top of the destination tab.

- 2 Release the cursor.

- 3 Click the destination tab.

The copied node appears in the bin. Nodes are added to the end of a bin in the order copied.

NOTE Nodes cannot be duplicated within the same bin.

To move a node to another bin:

- 1 Press **Ctrl+Alt** and drag the node on top of the destination tab.

- 2 Release the cursor when it changes to a green crosshair.
 - 3 Click the destination tab when the standard yellow cursor reappears.
- The node is moved from its original location to the destination bin. Nodes are placed at the end of a bin in the order moved.

NOTE Nodes cannot be duplicated within the same bin.

To reorder a node within a bin:

- 1 Press **Ctrl+Alt** and drag the node to a new location. You can move nodes from one row to another as well as reorganize nodes within a row.

In the following example, the AutoMatte node is dragged on top of the Degrain node.

- 2 Release the cursor when it appears where you want the node moved.

If you dragged the node on top of an existing node, the existing node shifts to the right and the moved node is inserted in its place. In the following example, the AutoMatte node is inserted in the place of the Degrain node, and the Degrain and Regrain node shift to the right.

(a) Reordered node

NOTE Click Sort to reset a tab to alphabetical layout

To delete a bin:

- 1 Press **Alt+Win** and drag the tab to the bottom of the screen.
- 2 Release the cursor when it changes to a delete cursor.

WARNING There is no undo capability when deleting a bin.

The entire contents of the bin, including the tab, are deleted.

To delete a node from a bin:

- 1 Press **Alt+Win** and drag the node to the bottom of the screen.
- 2 Release the cursor when it changes to a delete cursor.

WARNING There is no undo capability when deleting a node.

To reorder a tab:

- 1 Press **Alt+Win** and slide the tab to its new location.
- 2 Release the cursor when it changes to a green crosshair at the new location for the tab.
If you dragged the tab on top of an existing tab, the existing tab shifts to the right and the moved tab is inserted in its place.

About Batch and Batch FX Node Bins

In Batch and Batch FX, a node is a graphical representation of a function or effect that affects a clip or another node in the process tree. The available nodes are organized in bins that contain all nodes required for building a process tree. The nodes are divided into the following three groups, classified by tabs.

To access the Batch or Batch FX node bins, click the FX Nodes button. To add a node from the node bin to the schematic, double-click a node, or drag a node directly to the schematic. Enable Stereo Mode to add stereo nodes to the schematic.

I/O Bin

Use the nodes in the I/O bin to load clips into Batch or to output rendered clips. Available nodes are Read File, Write File, Render, and MUX.

In Batch FX, the I/O bin includes nodes for importing and working with source files. Available nodes are Read File, MUX, and Back Clip. By default, a BFX Output node is automatically connected to a Batch FX process tree.

Node	Description
Read File	Import clips in any supported formats from any available location. Use to import multi-channel clips such as OpenEXR, or metadata rich clips such as RED clips.
Render	Output clips to the Desktop; metadata such as clip history and timecode is kept.
Write File	Export image sequences in any supported format.
MUX	The MUX (multiplexer) node is a tool that helps you create cleaner schematics by allowing you to have multiple RGBA inputs feeding your outputs. The selection of the active input can be changed over time, therefore MUX also acts as an animated switcher.

Node	Description
Back Clip	The Back clip node enables you to create composites and effects in Batch FX, when using the Generate Adjustment Segment option from the timeline.

You cannot customize the I/O bin.

Tools Bin

The Tools bin contains effects and formatting nodes classified by tabs. The All Nodes tab contains all nodes except the nodes found in the I/O bin. The other tabs in the Tools bin allow you to create and customize bins.

Some of the nodes in the All Nodes bin are duplicated in other bins according to a preset tab classification. For example, the Gradient node is found in both the Colour and Comp bins.

The nodes in the Tools bin are listed in alphabetical order from top to bottom of each row. You can customize any of the bins and preset tabs in the Tools bin except the All Nodes bin.

Enable the Stereo Mode button below the Tools bin to access only stereo nodes (nodes not available as stereo nodes are greyed out).

TIP Use the scroll bar under the applicable bin to scroll through all available nodes. You can also frame and highlight all the nodes starting with the same letter by pressing the key corresponding to this first letter on your keyboard while the cursor is sitting over a node bin. For example: pressing "K" while hovering the cursor above the All Nodes bin automatically highlights all of the Keyer nodes.

User/Project Bin

The User/Project bin contains custom nodes classified by a User tab and a Project tab. Use this bin to save custom setups per user or project.

Creating Custom Nodes

Create custom nodes of specific setups that you often use. A custom node can consist of a single node with specific settings or multiple nodes that create a particular effect.

You create custom nodes by dragging individual nodes, groups, branches, or entire trees into the User/Project bin.

To create a custom node:

- 1 In the schematic, select a node or group of nodes.
- 2 Drag the selection on top of the User or Project tab.
The selection is copied to the bin. The original selection remains in the schematic.

To use a custom node:

- 1 Select a custom node from the User or Project bin. If necessary, scroll through the bin to find the node.
- 2 Drag the node to the schematic, or double-click the node.
The same configuration of nodes and clips that was used to create the custom node appears in the schematic.

You can use custom nodes as often as you like. Each time you drag a custom node to the schematic, a new number is appended to its name.

To manage the custom node bins:

- 1 Select any of the following from the dropdown lists.

Select:	To:
Load Project Bin or Load User Bin from the Load dropdown list	Load custom nodes from another project or user. NOTE If you load unsupported nodes, the unsupported nodes appear greyed out when dragged to the schematic.
Save Project Bin or Save User Bin from the Save dropdown list	Save the current custom nodes so they can be loaded by another project or user.
Clear Project Bin or Clear User Bin from the Clear dropdown list	Delete all custom nodes in the Project or User bin.

To delete a custom node from the User/Project bin:

- 1 Press **Alt+Win** and drag the node to the bottom of the screen.
- 2 Release the cursor when it changes to a delete cursor.

WARNING There is no undo capability when deleting a custom node.

Batch and Batch FX Preferences

Click the Batch Prefs or BFX Prefs button to access settings to customize rendering, preferences, and adaptive degradation in Batch or Batch FX.

NOTE Some Batch or Batch FX nodes also have specific preferences related to the functionality of the node. Click Node Prefs to access the preferences for a selected node.

Rendering Tab

Free Frames field Displays the space remaining on the framestore. Non-editable.

Use Proxies button Enable to replace clips with proxies. When enabled, the image window is outlined in amber.

Hardware Anti-aliasing Sample box Select a hardware anti-aliasing sampling level to accelerate edge anti-aliasing with no performance penalty. Available values are dependent on your graphics card.

On Render button Enable to allow node and clip caching.

Current Frame Cache field Displays the current number of cached frames. Non-editable.

Read/Write button Click to set cache to read and write status.

Read Only button Click to set cache to read-only status.

Render Cache button Click to render the cache of selected nodes for the frames defined in the From and To fields.

Disable button Click to turn the caching of selected nodes on or off.

From field Displays the lower limit in the range of frames that can be cached. Editable.

To field Displays the upper limit in the range of frames that can be cached. Editable.

Fill with Intermediates button Enable to fill each node's cache with the intermediate clips contained in the history. If a clip was rendered in proxy mode, the history is not cached.

Preferences Tab

Audio Source box Select the audio context you want to hear when working with another clip. This same setting appears in the Timing View menu.

Text Log button Enable to save rendering status information in a text file, located in /usr/discreet/project/<project home>/batch/log.

Status Webpage button Enable to create three status HTML files, located in /usr/discreet/html.

Update Numerics button Enable to update numerics in fields as the timebar is scrubbed.

Show Negative Frame button Enable to displays negative frame numbers in the Current Frame field when a segment is offset before frame 1. Disable to display only frames from frame 1 onward.

Set to In/Out button Click to have the timebar display frames as defined by the in and out points set on the clip's timeline.

Set to Media Range button Click to have the timebar display the head and tail frames brought in from the clip's timeline.

Clip Info box Select an option to display resolution, frame rate, size, or any combination of information in the schematic.

Transparency field Displays the transparency of currently unselected nodes in the schematic. Editable.

Auto Parent button Enable to allow Parent and Cut options in the schematic while using the Select edit mode.

Auto Insert button Enable to automatically insert a node when dragged between two connected nodes. When disabled, press Shift to auto insert.

Highlight Path button Enable to highlight the path of the currently selected node in the schematic.

Auto Update button Enable to update a node's result proxy automatically.

Update Clip box Choose whether to automatically update all clips or only selected clips.

Clear Buffer button Click to clear the Undo buffer of all previous undo operations.

Check for Updated Versions button Checks each imported Read File .clip file to see if it is the latest version, and updates it if that is not the case. Asks for confirmation before updating the version. Only available when a Read File node is used to import .clip files in the schematic.

Adaptive Degradation Tab

Use these settings to temporarily deactivate taxing operations during interactive manipulations. These settings do not affect the final renders.

Degrade Mode box Select how to propagate display degradation in the image, according to settings for supported nodes. Nodes in the pipeline respect this degraded image. In this case, press Preview to see your results with full settings on.

Change Node Degradation box Select whether to enable or disable adaptive degradation before clicking Apply To Selected.

Apply To Selected button Click to set the selected nodes to the chosen option in the Change Node Degradation box.

The following two settings appear in the Node Prefs menu for specific nodes that support adaptive degradation:

Active button Enable to activate adaptive degradation display settings. Use to prevent slowdowns in displaying your results when changing supported settings.

Synchronize All button Enable to synchronize all nodes of the same type with the Adaptive Degradation settings of the current node.

Compositing in 3D Space with Action

16

About Action

Action is a multilayer compositing tool for creating complex visual effects. Use Action to animate clips in 3D and add camera, lighting, and shadow effects.

You create effects and animations by manipulating objects in the scene. Objects you work with include surfaces, light sources, axes, particles, shadows, and the camera.

Action Concepts

The following concepts are used throughout the Action topics to describe the workflow and user interface.

Scene The scene is Action's representation of 3D world space. It is where objects are placed and animated. World space has three directions: X (left/right), Y (up/down), and Z (in/out).

Object An object is any element in a scene. An axis, a camera, a surface, a light, or a model can also be referred to as an object.

Media Media consists of a front and matte clip only.

Surface A surface is a special type of 3D geometry onto which media is mapped.

Geometric Object (Models) A 3D geometric object can be something as simple as a cube, sphere, or cone, or as complex as a character. Although some basic geometric objects are included with Flame Premium, most geometry is imported from a 3D application such as Maya and 3ds Max. A model is another way to refer to a geometric object.

3D Models and Text You can import 3ds Max files, FBX format files, Alembic format files, Wavefront files, Inventor files, and Paint geometry into Action. Also, you can create 3D text with custom beveling.

Camera The camera represents the 'eye' you are using to see the scene. The camera is used to “record” the scene in Action. By default, the camera consists of two objects: the camera eye and the point of interest (the coordinates the camera is 'looking' at).

Axis An axis is the element of an object or media that can be manipulated to determine the object's 2D or 3D space, position, and movement.

Schematic The Action schematic is an icon representation of the scene. It shows all the objects in the scene and their relationship with each other. The Action schematic is different from the Batch or Batch FX schematic (which is more of a process tree view).

Particles Action contains a particle system that can simulate environmental effects such as rain, snow, and many other user-defined effects.

Accessing Action from the Timeline

To access Action from the timeline:

- 1 Select the Timeline tab.
- 2 Do one of the following:
 - Click the FX button.
 - Right-click on a segment in the timeline and choose Add Effect.

The Effects ribbon appears.

NOTE Effects that are enabled have already been added to the current Timeline FX pipeline.

- 3 Enable AC (Action).
- 4 You can adjust the effect's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

Accessing Action From the Tools Tab

You can access Action from Batch or Batch FX, allowing you to be able to use the Workspace Media panel to add or organize clips and setups; or from the timeline, allowing you to apply the Action effect directly to your ongoing edit. But you can also access Action through the Tools tab, allowing you to create modified clips that you can use as a rendered result in the workspace.

To access Action from the Tools tab:

- 1 From the Tools tab, click Action.
- 2 Select an option from the Input Mode box.

Select:	To:
Front Back Matte	Select source clips from the workspace. The clips are selected in the order front, back, and then matte.
MultiVersion	Select a multiversion clip. The first frame of the first segment is used to fill the beginning, and the last frame of the last segment is used to fill the end.
MultiVersion Fill Gap	Select a multiversion clip. Each gap is filled with black frames.
MultiVersion SelfKey	Select a multiversion clip. The last version is loaded into the background and the other versions are loaded as fronts. The mattes are created based on each front. Gaps are filled with the last frame from the preceding segment.
MultiVersion Self Gap	Select a multiversion clip with gaps. Each gap is filled with the last frame from the preceding segment. Mattes are created based on each front.
None	Enter Action with no media or back clip. From the Resolution menu that appears, choose a resolution, width, height, pixel aspect ratio, bit depth, scan mode, and frame depth.

Select:	To:
	<p>If Action already contains a setup, entering with the None option keeps the objects present in the scene and creates empty media placeholders in the Media list for each object.</p> <p>Press the Alt key when you click the Action button to automatically select the None option. Press Alt when you select your destination to open Action with all media and nodes deleted and all parameters (except for resolution) set to default.</p>
Clear All	<p>To reset all parameters (except for resolution), delete all nodes and media, and prompt you to select front, back, and matte clips.</p> <p>Press the Ctrl+Alt key when you click the Action button to automatically select the Clear All option.</p>

Although you can use differing resolutions per media, you cannot specify clips of different resolutions to act as the front and matte clip of media (except for 10-bit, 12-bit, and 12-bit unpacked clips, which are interchangeable). An error appears in the message bar if the specified clips are not able to be loaded to the same media.

TIP To standardize some of your clip resolutions, you can resize them before entering .

- 3 Select the Action front, back, and matte clip or the multiversion video clip. If you selected None from the Input Mode box, proceed to the next step.

If you are selecting clips and not a multiversion clip, you can press **Ctrl** to load multiple fronts and mattes. The **Ctrl** key changes the order of clips to front and matte of media 1, front and matte of media 2, and so on. The back clip and destination are selected after the last media is filled or when the **Ctrl** key is released.

TIP Pay attention to the cursor colours to know which clips you are selecting (front = red cursor, matte = blue cursor, background = green cursor, and destination = white cursor).

- 4 Select the destination.

Action appears and the selected clips or tracks are loaded into the appropriate media. If Auto Image is enabled in the Action Setup menu, objects are automatically added to the schematic.

The composite of the front, matte, and back clips appear in the image window and their names are listed in the Media list. The Total Frames field defaults to the length of the longest clip loaded.

Loading from a Multiversion Clip

When you load from a multiversion clip, the versions from the selected multiversion clip are loaded from the bottom version to the top version. The last version is loaded as the background and subsequent versions are loaded as matte and front pairs. This means that the last version is loaded as the common back clip, the second to last version is loaded as the matte clip of media 1, the third to last version is loaded as the front clip of media 1, the fourth to last version is the matte clip of media 2, and so on.

NOTE If you select an even number of versions when loading from a multiversion clip, the second to last version selected is loaded as the front clip for its media, and the matte for this media is set to an internal white frame (of the same resolution as the front clip).

Loading from a Multiversion Clip with Selfkey or Self Gaps

When you load from a multiversion clip with Selfkey or Self Gaps, the versions from the selected multiversion clip are loaded from the bottom track to the top version. The last version is the background or back clip and

subsequent versions are loaded as front clips for each media. The matte of each media is generated from the front clip. This means that the last version is loaded as the common back clip, the second to last version is loaded as the front clip of media 1, the third to last version is loaded as the front clip of media 2, and so on.

Gaps that are located at the start and end of a version are treated in two ways depending on which multiversion option you choose. If you select MultiVersion, each gap is filled with its preceding non-gap frame. If you select MultiVersion with Gap, each gap is filled with black frames.

Action Interface Overview

Action is divided into a number of menus and sections designed to help you quickly create your composites.

Changing Views

You can change the orientation to view a scene from many angles. This can help you set up motion paths, light sources, and camera angles more easily.

From the View box, select an option to set the view in the image window.

(a) View box

Most of the View box options have keyboard shortcuts displayed in the expanded list. Some of these keyboard shortcut options are also cycle options. For example, pressing F5 repeatedly cycles through the animation channels, tracks, and info views.

You can also toggle ` (on the Tilde key) to alternate between the Schematic view and the previous view.

Accessing Action Menus

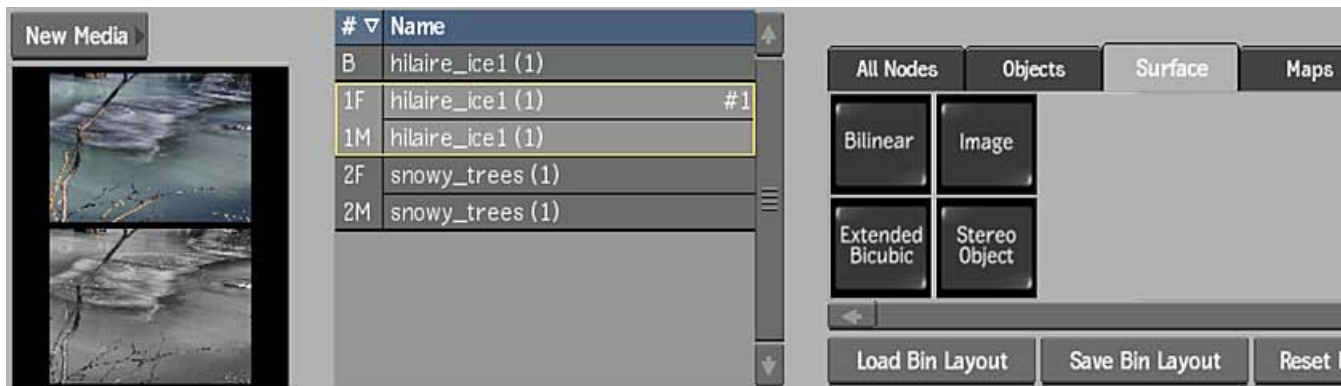

The left side of the Action menu houses a number of buttons that allow you to switch between the various Action sections and menus. Clicking any of these buttons opens the specific Action section, such as the Action Bin or Output menu.

Using the Node Bin

The Action node bin contains nodes classified by tabs. The All Nodes tab contains all Action nodes. The other tabs in the node bin allow you to create and customize bins. The node bin also contains an image proxy that displays a proxy of the currently selected media, as well as a mini Media list.

To access the node bin, click the Action Bin button.

Some nodes are duplicated in other bins according to a preset tab classification. For example, the Light node is found in both the Objects and ReLighting tabs.

Nodes are listed in alphabetical order from top to bottom of each row. You can customize any of the bins and preset tabs except the All Nodes bin.

To add a node from the node bin:

- 1 If applicable, select media from the mini Media list.
- 2 Do one of the following:
 - Drag the selected node (or image proxy) from the node bin and place it in the schematic. If the node is an image type node, an axis and an image are created and linked together.

- Drag the node (or image proxy) from the node bin and place it where you want it in Result view. For example, as you drag a Light node into Result view, it becomes active, so you can see its effect on the scene before placing it exactly where you want.
- Double-click a node (or image proxy). Depending on the node, it appears next to the last added object, or is attached to a selected node in the schematic. You do not need to be in Schematic view to add a node in this manner.

TIP You can frame and highlight all the nodes starting with the same letter by pressing the key corresponding to this first letter on your keyboard, while the cursor is sitting over a node bin. For example, pressing "L" while hovering the cursor above the All Nodes bin automatically highlights Lens Flare, Lens Texture, and Light nodes.

Customizing the Node Bin

Create custom tabs and populate them with your most commonly used nodes to optimize your workflow. As well, change the order of the tabs along the top of the bin and rename them to reflect the contents of a tab.

You can customize any tab except the All Nodes tab.

To create a tab:

- 1 Click the plus sign tab.

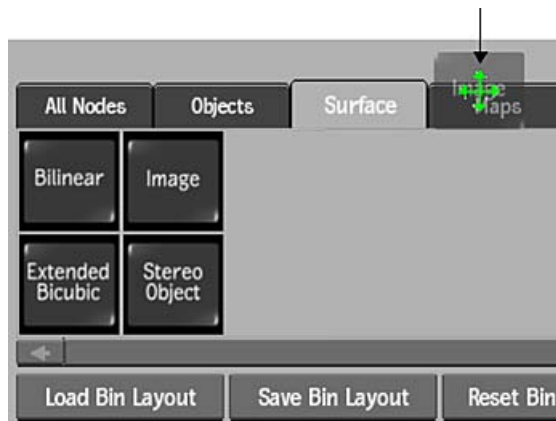

- 2 Name the tab in the keyboard that appears.

NOTE You can create a maximum of 6 new tabs.

To copy a node to another tab:

- 1 Drag the node on top of the destination tab.
- 2 Release the cursor when it changes to a green crosshair.

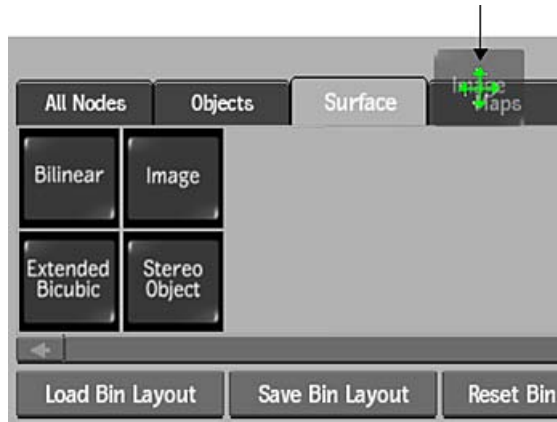

- 3 Click the destination tab when the standard yellow cursor reappears.

The copied node appears in the new tab. Nodes are added to the end of a tab in the order copied (following the same alphabetical node order of the rows, from top to bottom of each row).

NOTE Nodes cannot be duplicated within the same tab.

To move a node to another tab:

- 1 Press **Ctrl+Alt** and drag the node on top of the destination tab.
- 2 Release the cursor when it changes to a green crosshair.

- 3 Click the destination tab when the standard yellow cursor reappears.
The node is moved from its original location to the destination tab. Nodes are placed at the end of a tab in the order moved (following the same alphabetical node order of the rows, from top to bottom of each row).

NOTE Nodes cannot be duplicated within the same tab.

To reorder a node within a tab:

- 1 Press **Ctrl+Alt** and drag the node to a new location. You can move nodes from one row to another as well as reorganize nodes within a row.
- 2 Release the cursor when it changes to a green crosshair at the location where you want the node moved.
If you dragged the node on top of an existing node, the existing node shifts to the right and the moved node is inserted in its place.

To reset a bin to alphabetical layout:

- 1 With the applicable tab active, click **Sort**.
The nodes in the bin are reset to their alphabetical layout.

To delete a tab:

- 1 Press **Ctrl+Alt** and drag the tab to the bottom of the screen.
- 2 Release the cursor when it changes to a delete cursor.

WARNING There is no undo capability when deleting a tab.

The entire contents of the tab are deleted.

To delete a node from a tab:

- 1 Press **Ctrl+Alt** and drag the node to the bottom of the screen.
- 2 Release the cursor when it changes to a delete cursor.

WARNING There is no undo capability when deleting a node.

To rename a tab:

- 1 Click the Rename Tab button.
- 2 Enter a new tab name in the keyboard that appears.

To reorder a tab:

- 1 Press **Ctrl+Alt** and slide the tab to its new location.
- 2 Release the cursor when it changes to a green crosshair at the new location for the tab.
If you dragged the tab on top of an existing tab, the existing tab shifts to the right and the moved tab is inserted in its place.

To save a bin layout:

- 1 Click Save Bin Layout.
- 2 Name the layout.
The layout of the entire node bin is saved, including all new and customized tabs. You cannot save only select tabs.
Layouts are saved per user, not by project.

To load a bin layout:

- 1 Click Load Bin Layout.
- 2 Select the layout you want to load.

NOTE If you load a bin layout containing unsupported nodes, the unsupported nodes do not appear.

Animating with the Channel Editor

Use the Channel Editor to animate the media, axis, surface, light, camera, and other properties of every object in the scene.

To open the Channel Editor and display the Action channels:

- 1 In Action, click Animation.
- 2 In the Animation menu, select Channel from the View box.
The top-level folder in the hierarchy is the Scene, which provides the overall view of the animation. The Scene folder contains the Result Camera and folders of objects in the Action scene. Initially these are the media, motion blur, camera, axis, and image folders.
If you add an object to the scene, the Channel Editor adds a folder to the channel hierarchy for the new object. For example, if you add a light, a Light folder is added in the channel hierarchy.

Action Channel Editor Reference

Some of the Action folders in the Channel Editor are described as follows.

Camera Animates the camera position and point of interest. It also contains channels for animating camera roll, field of view, and the near and far clipping planes.

When Free Camera is selected, the point of interest channels are replaced by rotation channels in the Channel Editor.

Media Animates media properties such as blur, crop, shadow softness. A Media folder is listed for each media in the scene.

Axis Animates axis properties such as position, rotation, scaling, and shearing.

Image, Bilinear, Perspective, or Extended bicubic Animates surface properties such as material, offset, and displacement. The Material folder contains a shininess channel and folders for the specular highlight, diffuse, and ambient lighting.

Shadow Animates the shadow colour and shadow transparency.

Light Animates light properties such as intensity, falloff, spread, position, rotation, and colour.

TIP Selecting nodes in the schematic will automatically select the associated channels in the Channel Editor.

Most of the settings in the Animation menu are standard for all tools that support animation, but there are a few animation settings specific to Action, available from any Action menu (on the right side).

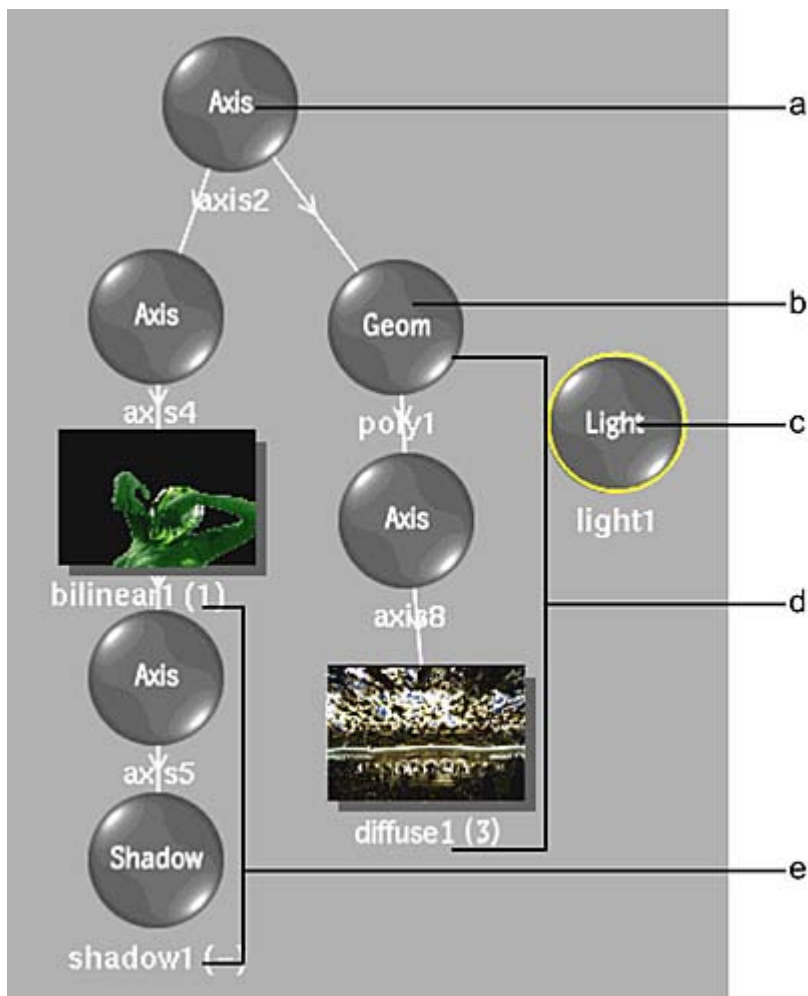

Auto Key button Enable to set a keyframe automatically each time you change a value at any frame.

Set Key button Click to set the current values for the selected channels in the current frame (when Auto Key is disabled).

Delete Key button Click to delete the selected keyframe.

About the Schematic and Menu Tabs

In Action Schematic view, a node exists for all objects in the scene, for example, shadows, lights, and texture maps.

(a) Axis object is the parent of axis 4 and poly1 (b) 3D model (c) Light source (d) Diffuse texture applied to the 3D model (e) Drop shadow of bilinear1

Here are some hints when working in the schematic with some of the various node types.

Surface Nodes When you add a surface node to the schematic, the node name is displayed with a number in parentheses. The number indicates the media applied to the surface. For example, a bilinear object labeled (1) shows that the bilinear uses the clips from Media 1.

For more information on the relationship between media and surfaces, see [Adding Surfaces](#) (page 473).

Camera Node The camera node appears in Schematic view by default and you can link it to any image. Use the camera node to rotate the camera about its own axis, and parent other nodes including shadow, texture, and geometry nodes.

Shadow and Texture Nodes Shadow and texture nodes each display a single number in parentheses beside the name that indicates the media used for the shadow or texture. For example, a shadow labeled (2) shows that the shadow uses the matte from Media 2.

Source Nodes Source nodes are used as part of an advanced schematic structure that separates the media's matte and front so that each clip can be animated individually. You can also use sources to create complex compositing effects such as nesting.

TIP Adding many nodes and connections can quickly make for a disorganized schematic. To solve this, press **Alt+T** to clean up the schematic.

Node Settings

Object Node Name field Displays the selected object node name. Editable.

Previous Node button Scrolls to the previous similar node.

Next Node button Scrolls to the next similar node.

The right side of Action also includes other settings to help you work with nodes in the schematic.

Solo button Enable to solo an object or a branch (object and its children), depending on what is selected in the Selection Mode box. See [Soloing Objects](#) (page 438).

Selection Mode box Make a selection to copy, delete, hide, or reset.

Clear All button Available in the Action Setup menu. Resets all parameters, and deletes nodes and media as well. Press Alt to bypass confirmation

Reset All button Available in the Action Setup menu. Resets all parameters but does not delete nodes or media. Press Alt to bypass confirmation.

Populating Menu Tabs of Selected Objects

Depending on what type of object is selected in the schematic, the tabs in the Object menu are populated based on different rules, as illustrated in the following examples.

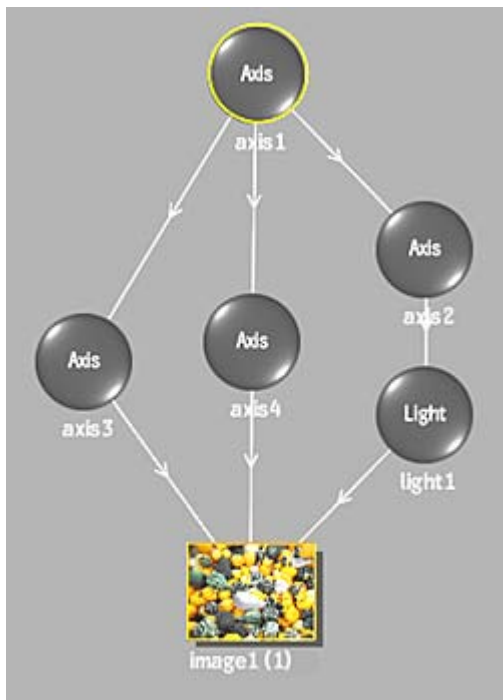

An object's name appears on the Object menu tab as well as beneath its node in the schematic and as a folder in the Channel Editor.

Axis selected

The Axis menu of the selected axis appears on the left side of the Object menu, and a limited number of the children objects' menus appear on the right side of the Object menu. The children objects are identified by scanning the hierarchy of the schematic from top-to-bottom (starting at the selected axis). The hierarchical scanning stops for any given branch when a non-axis object is encountered.

The order of tabs is determined on a per branch basis; that is, all of the tabs of one branch are listed before moving to another branch, starting with the highest levels in the parenting hierarchy (lowest index levels).

For example, in the following schematic, Axis 1 is selected.

The tabs in the Object menu appear as follows. The image1 tab appears in light blue to signify that multiple objects are connected down to it. Use the tabs to switch between menus within the Object menu. The Camera tab appears in orange as the first tab on the right side of the Object menu, and is exempt from the tab population rules.

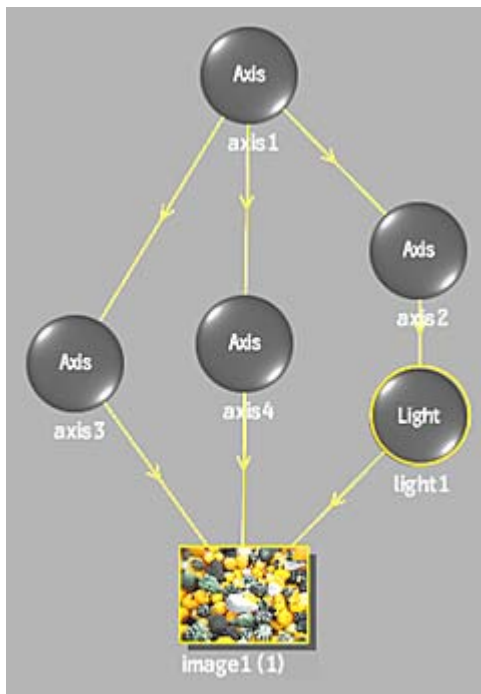

NOTE If there are more than five tabs on either side of the Object menu, use the arrows beside the tab names to navigate to the desired tab.

Other object selected (no “axis attributes”)

These objects include generators, bouncers, deformations, surfaces, texture maps, shadows, geometries, and 3D text. When one of these objects is selected in the schematic, an ascending (bottom-to-top) scanning of branches is performed. The hierarchical scanning stops for any given branch when an axis or object with axis attributes is encountered.

The menu of the selected object appears on the right side of the Object menu, and a limited number of the parent objects' menus appear on the left side of the Object menu.

For example, in the following schematic, Image 1 is selected.

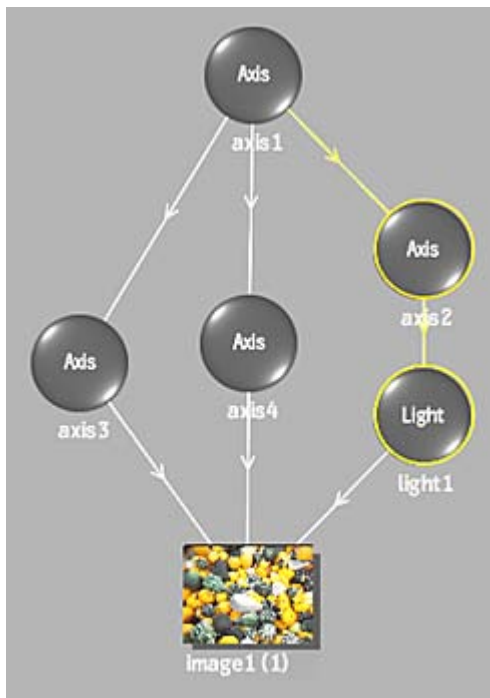

The tabs in the Object menu appear as follows. The image1 tab appears in light blue to signify that multiple objects are connected down to it. Use the tabs to switch between menus within the Object menu. The Camera tab appears in orange as the first tab on the right side of the Object menu, and is exempt from the tab population rules.

Object with “axis attributes” selected

These types of objects include lights, animators, projectors, and cameras. These objects trigger a different scanning behaviour depending on their position within the schematic hierarchy. If the selected object is the first of its branch (top of the hierarchy), it inherits the tab population rules of an axis, that is, descending branch scanning. If the selected object is not the top object of its branch, it inherits the tab population rules of other objects, that is, ascending branch scanning.

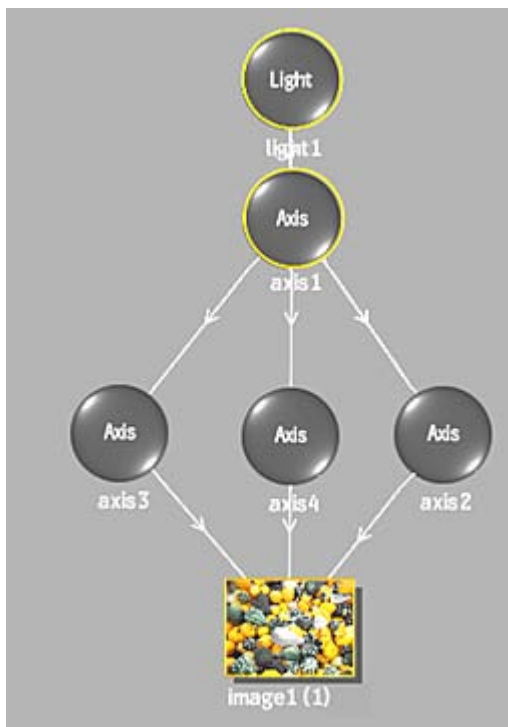

For example, in the following schematic, light 1 is selected.

Since Light 1 is not the top object in its branch, the tabs in the Object menu appear as follows.

In the following schematic, light 1 is moved to the top of the branch.

The tabs in the Object menu appear as follows. The image1 tab appears in light blue to signify that multiple objects are connected down to it. Use the tabs to switch between menus within the Object menu.

NOTE The Camera tab appears in orange as the first tab on the right side of the Object menu, and is exempt from the tab population rules. If a camera node is selected in the schematic, the special Camera tab does not appear, and the normal tab population rules apply.

Using the Object Menu for Multiple Selections

You can select multiple nodes to change some of the settings in the Object menu for all objects of the same type.

Objects that support multiple selection and changing of field settings are axes, images, shadows, and lights. For example, in the following schematic, you can select all of the nodes.

The tabs in the Object menu reflect the multiple selections.

In the Object menu, you can relatively change any of the available fields. For example, if the X Position for Axis1 and Axis2 was originally 100, and for Axis3 was 200, and you drag the X Position slider under the Mult-axes tab to 50, Axis1 and Axis2 are now set to 150 and Axis3 is set to 250.

NOTE Because the field values for individual objects can be different, the values in the multiple selected fields display as default values in the Object menu. When you select an individual object and view its Object menu, you can see the true field values.

Connecting Action Nodes

In Action, you can create complex animations where movements applied to one node are passed down to all connecting nodes.

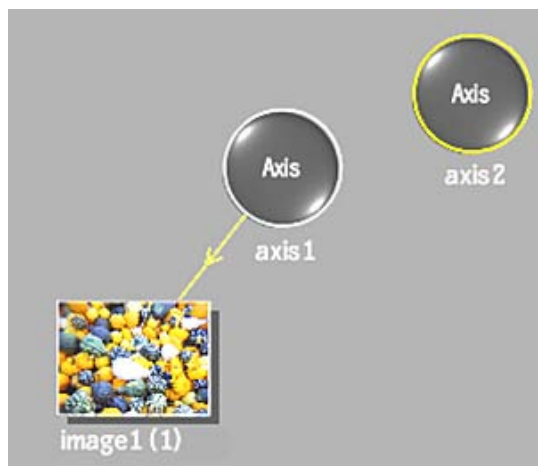

You can add an axis to the scene by itself, then make it the parent of another node. Use this method of parenting additional axes to create complex animations.

For example, create a cube of surfaces by parenting three additional axes to the same surface. Each axis that is parented to a surface places an additional surface in the scene. By changing the position and rotation of each axis, you can create a cube. If you parent the axes with another axis, you can control the position, rotation, scale, and shear of the cube.

To create a branch:

- 1 Add an axis (axis2) to the scene.
- 2 From the View box, select Schematic. The Schematic view should be similar to the *Before* figure.
- 3 Do one of the following:
 - In the Tools box, select Connect and drag the cursor from the edge of the parent node to the node that will be its child.
 - Press **Shift** and drag a parent node over another node that will be its child. With this method, the Tools box does not have to be set to Connect mode, and can remain in Select mode, for example.
 - In the Action Setup menu, enable Auto Parent in the Schematic section, and then in the schematic, drag the cursor from the edge of the parent node to the node that will be its child. With this method, the Tools box does not have to be set to Connect mode, and can remain in Select mode, for example.

Axis2 becomes the parent of axis1, as shown in the *After* figure.

Before: The schematic shows axis1 as the parent of image1

After: Axis2 is made the parent of Axis1 using Connect mode

Any transformations applied to axis2 are applied to axis1 and its surface (image1). If axis1 has any transformations, they are added to the transformations from axis2. For example, if axis2 is set to 500, 100, 0 and axis1 is set to -50, 20, -30, the positions are accumulated and applied to the surface. In this case, Image1 is positioned at 450, 120, -30.

TIP You can override the transformations passed from a parent to a child by enabling the Free button in the Axis menu.

Inserting a Node Between Connected Nodes

- 1 Do one of the following:
 - If Auto Insert is enabled in the Setup menu Schematic settings, drag a node and navigate to the link between two connected nodes. The link is highlighted in orange.
 - If Auto Insert is disabled in the Setup menu Schematic settings (this is the default), press **Shift** then drag a node and navigate to the link between two connected nodes. The link is highlighted in orange.
- 2 Release the node.
The node is inserted, and linked to the two previously connected nodes.

Mimicking, Copying, and Duplicating Objects

Similar to working in the Batch or Batch FX schematic, you can mimic, copy, or duplicate objects of the same type in the Action schematic.

Using Mimic Link

To create a Mimic link between Action objects:

- 1 From the Tools box, select Mimic Link.
- 2 In the schematic, drag between two similar object types, for example Axis to Axis. You can also link different map types, such as from a diffuse map to a reflection map.

A green arrowed dotted line indicates that the objects are linked as duplicates. The direction of the arrow indicates which object is the master.

(a) Originating object (b) Mimic link (c) Linked object

- 3 Change the settings of any node.

All of the settings applied to the original object are automatically applied to the linked object. Once objects are linked, any settings applied to either object are applied to both. When linking different map types, only the settings found in the Texture tab are mimicked.

The originating object can link to multiple objects, but only one object can be the originating link.

NOTE To remove the link between mimicked objects, drag the cursor across the green line that joins the two objects. Each object keeps the settings that were applied while they were linked.

Duplicating Objects

To duplicate objects:

- 1 In the schematic, select a node, or group of nodes.
- 2 Right-click the selection, and choose Duplicate.
A duplicate of the node or nodes (with all node settings) appears in the schematic.

Copying Objects

To copy objects:

- 1 In the schematic, select a node, or group of nodes.
- 2 Right-click the selection, and choose Copy.
A copy of the node or nodes (with all node settings) is added to the clipboard.
- 3 Navigate to the location in the schematic (or another Action schematic) where you want the copied node or nodes to reside, right-click and choose Paste.
A copy of the node or nodes (with all node settings) appears in the schematic.

Soloing Objects

Use the Solo button to hide all other objects except the selected object. Using Solo is useful for identifying an object in a scene with many objects, without having to hide all of the other objects.

To solo an object:

- 1 In the schematic, select the object that you want to solo.
- 2 From the Selection Mode box, choose Selected.
- 3 Enable Solo.
All other objects in the scene are hidden, regardless of whether they are set to Hide or not. When Solo is disabled, the Hide settings are restored.

TIP You can leave Solo enabled and select different objects in the schematic to view each object separately.

To solo a branch:

- 1 In the schematic, select the parent of the branch that you want to solo.
- 2 From the Selection Mode box, choose Branch.
- 3 Enable Solo.
All other objects in the scene are hidden, regardless of whether they are set to Hide or not. When Solo is disabled, the Hide settings are restored.

Grouping or Hiding Objects

You can collapse branches in the schematic into a group to reduce clutter in the schematic. You can also temporarily hide an object or objects in the schematic to see different results, for example.

To group a branch:

- 1 Select an object with children in the schematic view.
- 2 Right-click the parent object, and choose Group to collapse the selected object and all its children into a group.

A blue group node appears in the schematic to represent the entire group.

NOTE Collapsed groups cannot act as parents, but you can parent nodes to a group.

- 3 To uncollapse the group, right-click the Group node, and select Ungroup.

NOTE Groups created in the Schematic view are not related to groups created in the Priority Editor.

To hide and object or objects:

- 1 Select an object or multiple objects in the schematic view.
- 2 Right-click the object, and choose Hide.
(hidden) appears after the object name in the schematic.
- 3 To unhide the object, right-click the object, and select Show.

Setup and Processing Options

When accessing Action from Batch or Batch FX, use the Action Node Prefs menu to customize your Action display and to access tools and guides.

When accessing Action through the timeline or the Tools tab, these options are available from the Setup button in Action.

Use the tabs in the menu to switch between the different options.

Rendering Tab

Certain settings in this menu, such as the Resolution settings, are unavailable if you accessed Action from the timeline.

Resolution Settings

You can set the rendering resolution of clips that are output in Action. For example, if you are working in an NTSC 8-bit project, the default output is NTSC 8 bits. However, if you want to change the output resolution to HD (1920x1080), use the Resolution menu to change the values so the final outcome will be 1920x1080.

You can choose between progressive or interlaced when rendering at video resolution. Action media automatically adjust the rendering mode of each clip. This inherent awareness also makes it possible for Action to properly mix field-based HD / PAL with NTSC and not have dominance problems.

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution. Once you make a selection from the Apply and Scale box, the resolution is set for processing clips, and is remembered between Action sessions.

TIP Select Background Resolution to set the resolution to that of the background clip. The settings in the Resolution section change automatically to reflect the background clip resolution. If there is no background clip, the settings revert to the project resolution.

Width field Displays the custom width resolution of the clip. Editable.

Height field Displays the custom width resolution of the clip. Editable.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the custom render/output aspect ratio. Editable

Bit Depth box Select the render/output bit depth of clips.

Scan Mode box Select the scan mode of clips.

Apply and Scale box Select whether to apply or apply and scale the defined resolution settings. All subsequent processes will use the new render settings.

Select:	To:
Apply	Specify the output resolution.
Apply + Scale	Specify the output resolution and scale a scene to the defined resolution. Use this option if you are working with a low resolution of an Action setup from a previous version of Flame Premium. The scaling is applied to geometries, axes, lights, and cameras as well as their coordinates. Their positions are scaled accordingly. Flame Premium automatically scales textures and images.

NOTE If you do not change the Resolution settings, rendered results and camera settings default to the values set for the current project (set when you created a new project).

Stereo Settings

Reset To Stereo Mode button Enable to clear any previous stereo settings in Action, and reset all stereo settings to their defaults.

In the Stereo mode, these are the default settings when you enter Action with the Front/Back/Matte input option using stereo clips:

- A 3D camera (stereo camera) is created and the default camera is hidden.
- In the 3D Camera menu, the Result Camera is set to the stereo camera.
- In the Output menu, the Mode is set to Stereo and the Camera is set to Result Cam.
- A stereo object is created with the clips you selected.

NOTE If you enter Action using mono clips, the default camera is automatically created. If you need a stereo camera, you must add it manually.

Rendering Settings

Use the Rendering settings to improve the final output quality of your image.

Z-Buffer box Select an option to determine whether the distance from the camera eye is considered to determine the order in which objects are rendered.

Wireframe button Enable to display each surface and 3D model as a wireframe.

This is useful if interaction with Action becomes slow because of many surfaces and 3D models. Convert objects to wireframe when you want to speed up processing or rendering times. Because lighting and textures are not computed in wireframe mode, interaction time and rendering times are reduced.

Shading button Enable to light up the scene using added light sources. When Shading is disabled, no lighting effects appear in the scene; surfaces and 3D models appear flat.

Enable Shading for:

- Light sources
- Ambient or diffuse lighting for surfaces
- Specular highlights for surfaces and 3D models

Clamp Colours button Enable to clamp colour and luminance in the 16-bit floating point processing pipeline.

Anti-Aliasing Settings

Software Anti-Aliasing Sample box Select a software anti-aliasing sampling level.

The jagged lines that often occur along the edges of diagonal or curved lines when processing high-frequency images such as text are the result of aliasing. You can increase or decrease the anti-aliasing sampling level (up to 64 samples). Higher values yield smoother results at the expense of processing time.

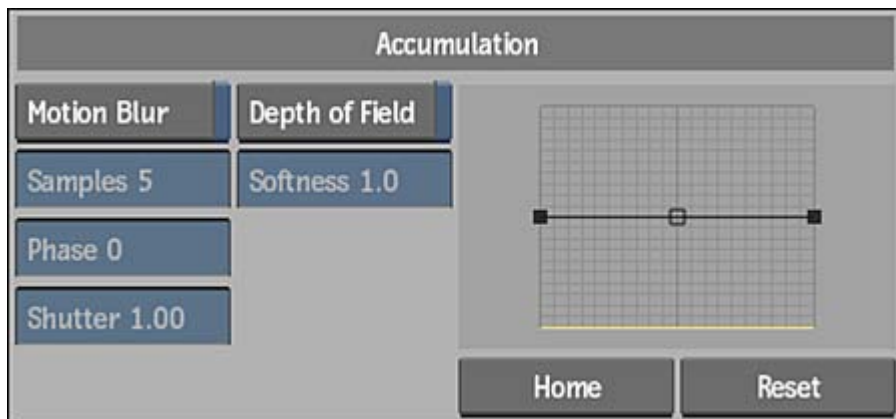

Anti-Aliasing Softness field Displays the softness value of the software anti-aliasing sample. Editable.

Hardware Anti-aliasing Sample box Select a hardware anti-aliasing sampling level to accelerate edge anti-aliasing with no performance penalty. Available values are dependent on graphics card and project graphic bit depth. Hardware anti-aliasing also gives anti-aliasing during normal interaction instead of only while rendering.

You can combine hardware anti-aliasing level with software anti-aliasing to obtain the desired level of image quality. For example, with hardware anti-aliasing set to 4 samples, and with 4 samples of software anti-aliasing selected, your results should be similar to selecting 16 samples of software anti-aliasing, but with a processing time much closer to that of 4 samples. You should experiment with different combinations to determine what works best for you.

Accumulation Settings

Use the Accumulation settings to define motion blur properties.

Global Motion Blur button Enable to use motion blur. Once enabled, specific Action object Motion Blur buttons can be enabled or disabled. See [About Motion Blur](#) (page 667) for specific examples of creating motion blurs.

Samples field Displays the quality of motion blur and the depth of field produced by the number of samples taken at each frame. Editable.

Increasing this value causes the processing time to increase linearly and affects the quality of the depth of field. The number of motion blur samples is multiplied by the number of anti-aliasing samples. To reduce the total number of passes made for each frame, reduce the level of anti-aliasing when motion blur is enabled.

Phase field Displays the frame that motion blur is based on (before or after the current frame). Editable.

A value of -100 places the motion blur before while a value of 100 places the motion blur after. A value of 0 is centred, which evenly distributes the motion blur. The default value is 0.

Shutter field Displays the duration of motion blur at each frame (essentially the number of frames that the shutter is open). Increasing this value does not increase the processing time. Editable

TIP You can animate the Global Motion blur button, as well as the Phase, Shutter, and Samples fields. They can be found in the Channel Editor under the *motion_blur* folder.

Depth of Field button Enable to use the camera's depth of field.

Depth of Field Softness field Defines the softness of the depth of field. A low value yields a sharp falloff between focused and unfocused regions. Editable.

Motion Blur curve Controls the sample weight over the scope of the motion blur.

Home button Resets the position of the motion blur curve after panning.

Reset button Resets the motion blur curve.

Preferences Tab

Surfaces Settings

Default Resolution field Displays the default geometry resolution (number of polygons) of surfaces. You can also change the geometry resolution of specific surfaces in the Surface menu. Editable.

The lower the value, the better the resolution and the greater the processing time required to interact with the image. A value of 1 creates one polygon per pixel on a surface, affording accurate displacement and lighting.

Use this field when [Exploding Objects and Surfaces](#) (page 773) with a particle generator and when using hardware texture mapping.

Apply Resolution To All button Click to apply the geometry resolution in the Resolution field to all surfaces. Since you can change the resolution of specific surfaces in the Surface menu, you can use this button to re-apply the default resolution to all surfaces.

Filtering Settings

Default Filter box Select the type of filtering to be set as the default when creating surfaces and maps.

Apply To All button Click to apply the default filter to all existing surfaces and maps.

Miscellaneous Settings

Animation Update button Enable to update properties such as position, rotation, and colour in the scene. When disabled, animated objects do not move, but keep the position of their current value. Disable to copy keyframe values from one frame to another.

Play Lock button Enable to update the animation settings according to the frame or timebar position as you move through the clip while keeping it locked at the current frame.

When Play Lock is disabled and you use > or < to play the resulting clip, each frame is loaded and displayed in sequence in the image window.

Front Only button Enable to display only the front media in the Media menu. Disable to display both the front and matte media.

Auto Image button Enable to add an image node and axis automatically in the schematic when new media is added.

Shift-Snap button Enable to use the Shift key as a snap-to-surface modifier key. Hold the `Shift` key when selecting an axis to snap the selected axis to the surface of the underlying geometry. Not available when in Top, Front, or Side views.

Matte Channel box Select which channel is displayed as transparent by default. This can be useful for a multichannel clip to display only the Red channel matte, for example.

Display Settings

Icons box Select object icon (axes, borders, control points) display options. The selected option displays icons only for the object currently selected in the scene.

Icon Transparency field Displays the transparency level for icons in the scene. Editable.

Ruler button Enable to display the ruler in the scene area. Use the arrows at each extremity of the ruler to place the beginning and end of the ruler anywhere in your scene view.

TIP Use the `Shift` key to snap the ruler into place either horizontally or vertically.

Ruler Define button Enable to define real unit measurements, such as feet, metres, or inches, instead of pixels. All camera distance or axes measurements thereafter use the defined scale.

Ruler Length field Displays the length and measuring unit (feet, metres) to use in Action. When you enter a length, click Define again to apply the new scale to the ruler and all pertinent fields, such as position, rotation, and scale. Editable.

TIP Hold the `Ctrl` key and click Define to reset the ruler's scale.

Grid Colour pot Displays the custom colour for the grid. Editable.

Grid box Select the type of grid to display in the scene. Use to position objects in the scene more accurately.

Select:	To:
Grid Off	Disable the grid.
Grid XY	Use a grid constructed on the X and Y planes.
Grid XZ	Use a grid constructed on the X and Z planes. The XZ grid is visible only when the camera is moved from its default position.
Grid YZ	Use a grid constructed on the Y and Z planes. The YZ grid is visible only when the camera is moved from its default position.

NOTE The Action grid is independent from the global grid in the Grids and Guides menu.

Ortho Near field Displays the value of the near view in the image window when using Camera or an orthographic view. Editable.

Ortho Far field Displays the value of the far view in the image window when using Camera or an orthographic view. Editable.

Schematic Settings

Auto Parent button Enable to automatically parent nodes in the schematic. Press Alt and drag a node in the schematic to disable Auto Parent temporarily.

Auto Insert button Enable to automatically insert a node when dragged between two connected nodes. When disabled, press Shift to auto insert.

Snap To Grid button Enable to position objects with precision in the scene. When you move an object in the scene, the object is automatically aligned to the snap grid.

NOTE When enabled, this snap only applies to the grid defined in Action. The grid defined from the Grid & Guides menu remains visible, but its snap is overridden as long as the Action Snap is enabled.

Schematic Transparency field Displays the level of transparency of unselected nodes in the schematic. Editable.

Display Information box Select what clip information is displayed in the schematic.

Proxy Update button Enable to automatically update proxies in the schematic. Interaction is slower when enabled. When disabled, Action updates proxies when you switch views. You can also update proxies by clicking Update.

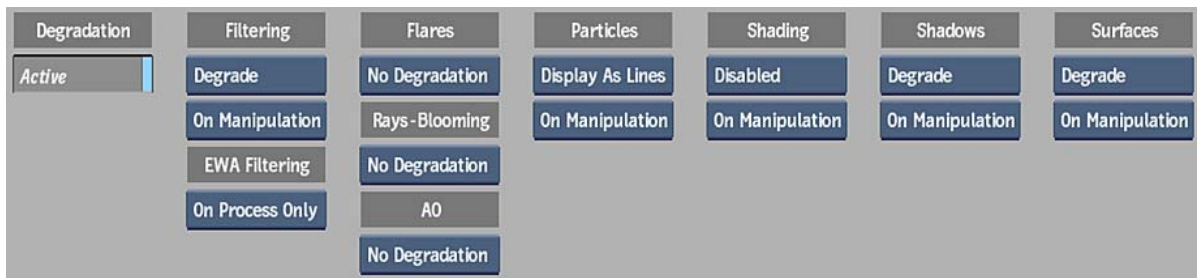

Output Naming Settings

Action Name button Enable to allow newly created outputs in the Output List to inherit the name of the Action node. If disabled, it will use a default output [number] for additional outputs. You also can rename any output manually by clicking the Rename button below the Output List. Once a setup is saved, the output will use the setup name when processed.

Append Type button Enable to append the type of output to the name of a processed file.

Adaptive Degradation Tab

Use these settings to temporarily deactivate taxing operations during interactive manipulations. These settings do not affect the final renders.

Active button Enable to activate adaptive degradation display settings. Use to prevent slowdowns of the image window display when changing Action settings. Press Ctrl+D to activate or deactivate degradation settings.

You'll see an icon

displayed at the bottom right corner of the image window when degradation is active in Action.

Synchronize All button Enable to synchronize all Batch FX Action nodes with the Adaptive Degradation settings of the current Action node.

Filtering Degradate box Select whether to degrade filtering selections in the image window when changing any Action settings.

Filtering Update box Select whether to always degrade filtering selections, or on manipulation only.

EWA Filtering box Select whether to apply EWA or EWA+Linear filtering on maps (if selected in the Filter box) only when processing (On Process Only), or all the time when working in Action (Degradate).

Flares Degradate box Select whether or not to degrade Lens Flares.

Rays Degradate box Select whether or not to degrade Rays.

Blooming Degradate box Select whether or not to degrade Blooming.

Particles Degradate box Select a particle quality display setting.

Particles Update box Select whether to always degrade particles selections, or on manipulation only.

AO Degradate box Select an ambient occlusion quality display setting.

Shading Degradate box Select whether to degrade shading selections in the image window when changing any Action settings.

Shading Update box Select whether to always degrade shading selections, or on manipulation only.

Shadows Degradate box Select a shadow quality display setting.

Shadows Update box Select whether to always degrade shadows selections, or on manipulation only.

Surfaces Degradate box Select a surface quality display setting.

Surfaces Update box Select whether to always degrade surfaces selections, or on manipulation only.

Motion Blur Degradate box Select whether or not to degrade Action motion blurs in the pipeline.

Software AA Degradate box Select whether or not to degrade Action software anti-aliasing in the pipeline.

Depth of Field Degrade box Select whether or not to degrade Action depth of field in the pipeline.

NOTE When Adaptive Degradation is active for a Batch FX Action node, you'll see an icon

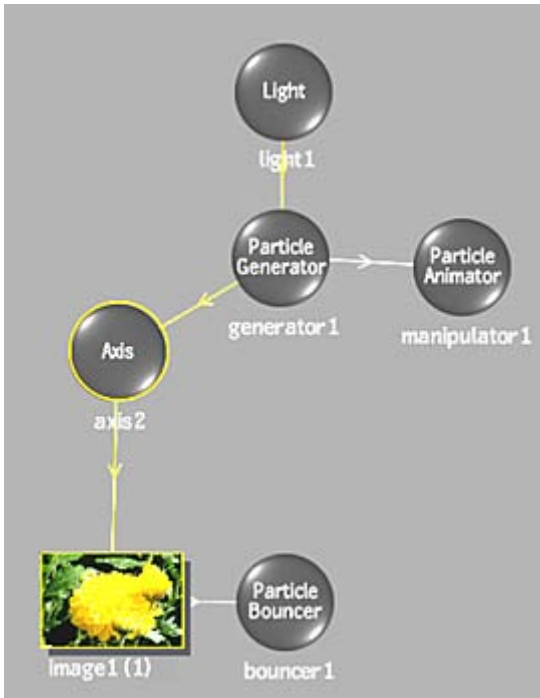

over the node in the schematic, and in the bottom right corner of the image window in result view.

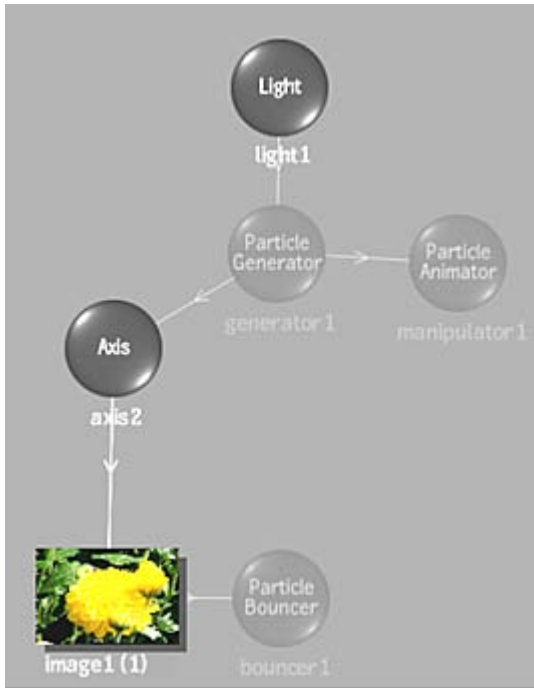

Saving and Loading Action Setups

You can save, load, and delete Action setups.

When importing a setup that contains non-supported objects (such as particles and deformations in Smoke), these objects are displayed as greyed out nodes in the schematic, and greyed out menus in the Object menu. These greyed out objects are read-only objects that can be viewed (in the image window and the Object menu), but not modified or linked to or from. In Channels view, you can view the parent channel for the non-supported object, and in Tracks view, you can slide or stretch the parent channel. If you modify the setup and resave it, you can then open it in the application that supports the objects, and modify all objects.

Schematic of Flame setup

Schematic of same setup opened in Smoke

To save an Action setup:

- 1 In Batch or Batch FX, select the Action node. Click Save Node (found next to the node name field). If you entered Action through the timeline or Tools tab, you can click Save directly in the Action menu. The file browser and Save menu appear.
- 2 From the Save Action box, select the format for saving the setup.

Select:	To save:
All	References to all clips in the Media list.

Select:	To save:
Selected Objects	The selected objects, their media and media settings. Any expressions on channels of selected nodes are baked to the channels before saving, and any Mimic links to or from non-selected nodes are removed before saving. If a node is selected that is mimicked from a non-selected node, though, the animation channels are copied from the node before saving.
Raw	Selected animation channels as a user-readable ASCII file. In the file, each line corresponds to one frame, and each column consists of one frame number and the value of the animation curve at that frame. All saved information starts at frame one. A file with the extension <i>.raw</i> is saved in the <i>.../action</i> directory by default. At least one channel must be selected in the Channel Editor.
Text	The current text settings, including font, character size, kerning, italics, depth, beveling curve, and text string properties, all of which can be loaded in another Action session. A file with the extension <i>.atext</i> is saved in the <i>.../action</i> directory by default. A 3D text node must be selected in the schematic.
Preferences	The current Action settings as user preferences. A file with the extension <i>.pref</i> is saved in the <i>/usr/discreet/user/<product_name>/<user_name>/action/pref</i> directory.
Defaults	The current Action preferences as Action's new default settings. To restore Action's factory default settings, select Factory Defaults in the Load menu.
MultiVersion	A multilayer setup for all Action media and save a multiversion clip in the current library.

- 3 Type a name for the setup file and click Enter.

The name appears in the Name field.

By default, the setup is saved in the */usr/discreet/project/<project_name>/action* directory. Using the file browser, you can save setups to the directory of your choice.

- 4 Once you have saved an Action setup, you can quickly resave it by clicking Save again.

TIP If you accessed Action from the Tools tab, you can click Revert to revert to the last saved setup. All changes made since the previous Save operation are undone.

To load a setup in Action:

- 1 In Batch or Batch FX, select an Action node. Click Load Node (found next to the node name field). If you entered Action through the timeline or Tools tab, you can click Load directly in the Action menu. The file browser and Load menu appear.

NOTE When you access the file browser through Load, you also have the option of deleting existing setups.

- 2 In the Load box, select the format for loading the setup.

Select:	To:
All	Load the clips in the selected setup into their corresponding media. The media in the Media list is replaced with the loaded clips. If a clip cannot be found, Action searches for it and loads it automatically to Action. If the clip still cannot be found, Action displays

Select:	To:
	the missing clip name in red in the Media list. A surface that uses a missing clip appears as an outline in the image area and is shown in red in Schematic view.
No Clips	Load a setup without its clips. The current media in the Media list remains the same.
Add Nodes+Media	Add nodes and media from the setup file. This option appends the schematic from the setup file to the current schematic, and wherever possible, media from the setup file fills empty slots in the Media list. Remaining media from the setup file is appended to the end of the Media list. Enable Load Cameras if you want to include the cameras saved with the setup.
Add Nodes	Add only the nodes from the setup file. This option appends the schematic from the setup file to the current schematic. Enable Load Cameras if you want to include the cameras saved with the setup.
MultiVersion	Load a multiversion setup. Loads front, matte, back, and background video versions from an entire clip. Replaces all media.
Raw	Load raw animation data to a selected channel in the Channel Editor.
Text	Load the text setup files. The text settings are loaded into Action's Text menu.
Preferences	Load a file containing Action preferences.
Factory Defaults	Load original Action default settings. Selecting this option prompts you to confirm that you want to restore factory defaults and returns you to the Action menu.

- 3 Select the setup you want to load.

NOTE Sample Action setups are provided in the *~/examples/action* directory.

About Rendering Outputs from Action

Use the multi-pass rendering capabilities of Action's Output menu to manage your outputs. Options are available to help you set up and prepare many different types of outputs, much as you would with render passes in a 3D application. You can process multiple outputs at once, from your complete Action scene, to specific Shadow or Z-Depth outputs, for example.

NOTE If you accessed Action from the timeline, you are limited to Comp and Matte outputs.

Action Output Workflow

When using the Action Output menu, you usually follow the options from left to right.

Step:	Action:
1	Use the Outputs List (page 451) to add, copy, delete, and rename outputs.
2	Set Output (page 452) and Render (page 454) options per output in the Output List.
3	Select objects (page 455) to output.
4	Render your outputs from Action (using the options in the Render button and dropdown list).

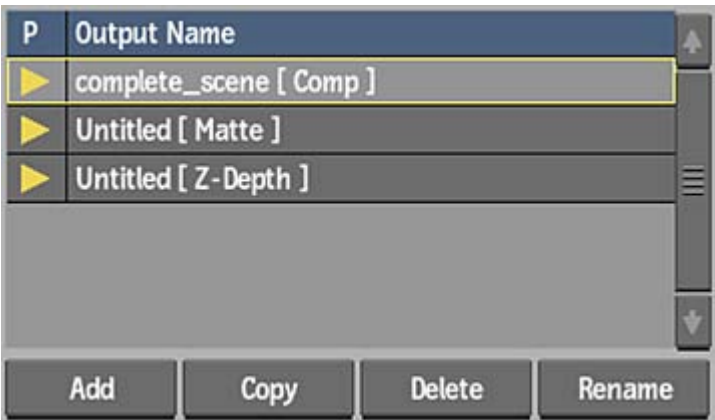

To access the Output menu, click the Output button.

Outputs List Settings

Use the Outputs List to organize the outputs you want to process. You must have at least one output in the Outputs List. By default, a Comp output exists, which is set to process the entire comp and result camera.

NOTE If you accessed Action from the timeline, you are limited to Comp and Matte outputs, and certain settings in the Outputs List are unavailable.

When you save an Action setup, your outputs are also saved.

Output List Lists all of the existing outputs. Use the buttons below the list to populate the list with the outputs you want. To select an output to process, click the yellow arrow beside the output (you can click as many outputs as needed).

Add button Adds a new output to the Outputs list. Use the Rename button to change the name to something more meaningful.

TIP Use the Output Naming settings in the Action Setup [Preferences](#) (page 443) menu to set default naming conventions for your outputs.

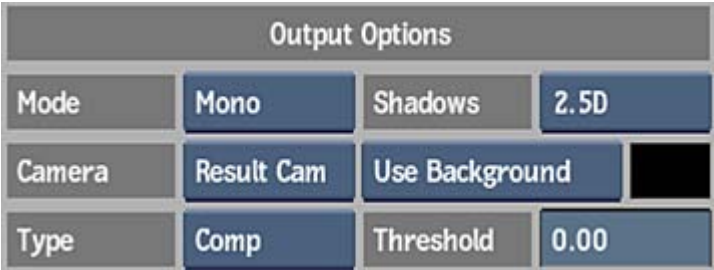

Copy button Creates a copy of a selected output.

Delete button Deletes the selected output from the Outputs list.

Rename button Opens the onscreen keyboard to rename the selected output in the Outputs list.

Output Options

For each output in the Outputs List, you can refine the output parameters.

Mode box Select a render mode: Stereo, Left, Right, or Mono.

NOTE Selecting the Stereo mode and a stereo camera results in left and right clips when processed. Selecting Stereo mode and any monoscopic camera results in two identical clips. Selecting Left, Right, or Mono results in a single output, regardless of the camera selected.

Camera box Select a camera or stereo rig to output for the selected output.

Type box Select an output type. Output and Render options change based on the Output Type.

Select:	To render:
Comp	Selected objects in the scene with their parameters.
Matte	The matte of the selected objects in the scene.
Media Matte	The matte of the media specified in the Media field.
Z-Depth	The Z-depth of selected objects in the scene.
Normal	The normals of selected objects in the scene.
Emissive	The colours of selected objects in the scene.
Shadow	A white image with greyscale regions that represent the shadow cast coverage.
Specularity	The specular map settings of selected objects in the scene.
Reflection	The reflection map settings of selected objects in the scene.
UV	The UV map settings of selected objects in the scene.
AO (Ambient Occlusion)	A grayscale output that is dark in areas that light cannot reach and bright in areas where it can.

Select:	To render:
Position	World absolute pixel coordinates of a scene or a selection of objects.

NOTE If you accessed Action from the timeline, you are limited to Comp and Matte outputs.

Shadow Output Type box Select the type of shadow cast to output.

Comp box Select whether to render the scene over a background or over a colour you choose using the colour picker.

Comp colour pot Displays the colour that the comp is rendered over. Editable.

Threshold field Displays the value at which the alpha is included in the depth of the output.

Matte Background box Not shown. Select whether the object's matte is rendered on top of a black (default) or white background.

Media field Not shown. Displays the number that corresponds to the media in the Media list. Editable.

Light box Not shown. Select which light to include in a shadow output.

Filtering field Not shown. Displays the amount of smoothing in a shadow output. Editable.

Maximum Z Difference field Not shown. Displays the maximum amount of Z depth information to take into account for smoothing a shadow output. Editable.

Bit Depth field Not shown. This locked field displays that this output type is locked to a 16-bit floating point output. Non-editable.

Ambient Occlusion Output Options

Ambient occlusion refers to the blocking of indirect or diffuse light on an object. Ambient occlusion is caused by indirect light's inability to bounce around and illuminate areas that are blocked by a nearby object that absorbs the light rays. These subtle variations in lighting are visual clues for our eyes to detect surface details and distinctions that would otherwise be washed out and unnoticeable. Ambient occlusion adds realism to your scene by adding shadows in crevices, nooks and crannies, and so on. For each surface point, it calculates how much light is blocked by other geometry.

Ambient Occlusion			Regen
Density 1.0	Spread 100	Falloff 100%	1 Sample
Tolerance 30	Blur 8	Precision 10	Soft 1.0

These settings are available for the AO type, and for the Comp type, if Use AO is enabled in Render Options.

Density field Displays the amount of darker areas to include in the ambient occlusion output. Editable.

Tolerance field Displays the starting point at which darker areas are included in the ambient occlusion output. Editable.

Spread field Displays the width of the ambient occlusion effect. Editable.

Blur field Displays the amount of blur applied to the ambient occlusion. Editable.

Falloff field Displays the amount of falloff around the edge of the ambient occlusion effect. Editable.

Precision field Displays the number of steps to take into account on rays cast from the surface of the object. Editable.

Samples box Select an ambient occlusion sampling level. Press Preview to see the result.

Softness field Displays the softness value of the ambient occlusion sample. Press Preview to see the result. Editable.

Regen button Enable to dynamically refresh the image as changes are made to the ambient occlusion settings.

Render Options

Use the Render Options to further refine your output. Different options are available or greyed out depending on the output type you choose in Output Options.

Anti-Aliasing button Enable to include anti-aliasing processing in the output.

Motion Blur button Enable to include motion blur processing in the output.

Transparency button Enable to include the alpha transparency of the objects in the Output when processing this output.

Depth of Field button Enable to process the selected output with the Depth of Field settings defined in the Action Setup menu.

Use Emissive button Enable to process an output with the effect of an emissive map in the scene. An emissive map uses colours to simulate a glowing effect within the texture.

Use Ambient button Enable to process an output with the ambient effect.

Use GMask button Enable to process the output with garbage mask effects. Available for all output types except Matte and Media Matte.

Use Gmask box Not shown. Select whether to use the garbage mask transparency or render the GMask colour. Available for Matte and Media Matte output types.

Blending box Not shown. Select whether to use a master blend option (Change Blend) or to use the blend set in the Blending Mode box (Keep Blend). Available for Matte and Media Matte output types.

Blend Mode box Not shown. Select an option to determine the blending mode of the mask when it overlaps with another mask. Available for Matte and Media Matte output types.

Use Specularity button Enable to process an output with the specularity effect.

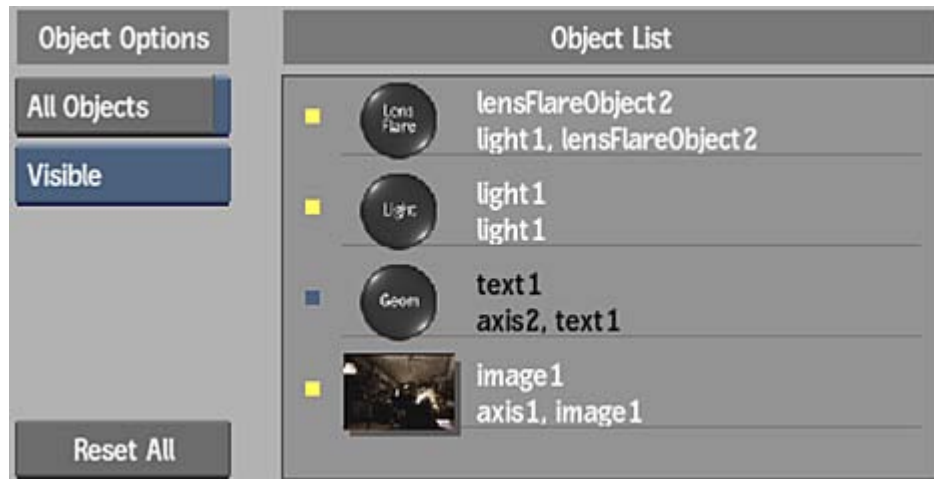

Use Reflection button Enable to process an output with the reflection effect.

Use **AO button** Enable to process an output with the ambient occlusion effect.

Selecting Objects to Output

You can select objects to include in your output by using the Object Options and Object List, or the Edit Output mode. Objects that are part of an output are displayed in the Object List. For each selected object, you can decide if you want it to be visible in the final render or not. Non-renderable objects, such as cameras, are always included in outputs.

TIP When you create a new output in the Outputs list, it is empty by default. Enable All Objects to display all objects in the scene.

To select an object:

- 1 In the Object List, click an object.
Selected objects are highlighted in the Object List, schematic, and image window.
- 2 To select additional objects, **Ctrl**-click another object.

NOTE When you select multiple objects with different visibility settings (Visible or Occluded), Mixed is indicated in the Visibility box.

To output all objects:

- 1 In the Object Options, enable All Objects.
All objects in the scene, as well as any object you subsequently create, are included in the selected output.

To set the visibility of an object:

- 1 Select an object from the Object List.
- 2 From the Visibility box, select one of the following:

Occlude Only Renders the object as black, excluding it from the shading effect. The result is a perceptual hole where the object was originally located.

Visible Renders the object in the final render.

NOTE When the Output type is set to Normal or Z-Depth, the objects in Occlude Only mode are rendered normally; it will be part of the Normal or Z-Depth output. The Visibility mode is ignored.

To add or remove an object from the Object List:

- 1 From the Tools box, select Edit Output.

NOTE In Edit Output mode, All Objects in the Object Options is disabled when you remove objects from the selected output.

- 2 Add or remove objects from the output by doing one of the following in the schematic:
 - Click an object. The complete tree of the object in the schematic must either be selected or grayed out for it to be included or excluded from the output.
 - Press **Ctrl** and drag in the schematic to add or remove multiple objects (or trees) from the output. This acts as a toggle between selected or greyed out (included or excluded from the output).

To set all objects to Visible mode:

- 1 Click Reset All.
All objects in the selected output are set to the Visible mode.

Object Options

All Objects button Enable to output all objects in the Object List.

Visibility box Select a visibility option for the selected object.

Reset All button Click to set all objects to Visible mode in the Object List.

About Media

You should have a working understanding of Action media and the relationship between media and surfaces to be successful in using Action. Media has the following characteristics:

- Each front and matte clip combination that you load into Action is called *media*.
- The clips you load into Action are listed in the Media list.
- When you first open Action, you load the front clip and matte clip for the first media and a common back clip for all media.
- Media must have a front and matte of the same resolution, but each media can have a different resolution from the other.
- You can work with front only or matte only media. In this case, the empty front or matte is replaced with an internal white frame of the same resolution.
- The same media can be applied to multiple surfaces. Any cropping, blurring, or recolouring that you apply to one instance of media is applied to all the surfaces for that media. For example, if you blur media, all of the surfaces using that media are blurred.

NOTE If you access Action from the timeline, you are limited to one front/matte media. Therefore, some Media menu settings are not available.

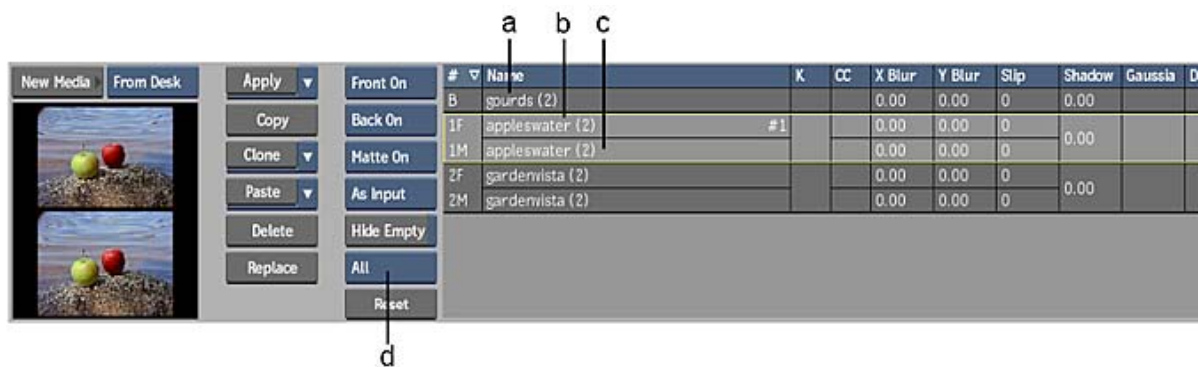

Working With Media in the Media Menu

When you open Action, you load the front and matte clips for the first media. You can then load any additional media.

The clips you load for each media appear in the Media list. The back clip you selected to access Action appears in the first row of the Media list and is assigned the letter B in the # column. The second row in the Media list contains the first front and matte clips you selected when accessing Action. The length of each clip appears in parentheses beside the clip name. A new line is added to the Media list each time you add media. For stereoscopic projects, you can apply media to the left and right eye.

You can sort the Media list by list number, front clip name, or matte clip name. As you view clips, you can look at the original front, back, or matte clip individually, as well as the results of colour correcting and keying a matte.

To access the Media menu, click Media in the Action menu. To help identify media, **Alt+click** a surface in the schematic, result, or camera view to automatically select the media in the Media list. If the Media menu is not selected, press **Alt** and double-click the surface to switch to the Media menu, and automatically select the media in the Media list. Also, when you select multiple surfaces, you can press **Alt** to select all associated media in the Media list. In this case, the first item selected is framed in yellow in the Media list as the current selection.

(a) Back media (b) Front media (c) Matte media (d) Reset box

Media Menu Tips

Use these tips when working with clips and media in the Media menu.

- Different colours and shades are used as visual cues within the Media menu. The current media is outlined in yellow, and the selected media is highlighted in light grey. Selected fields of the media are highlighted in grey.
- **Ctrl-click** fields or media to add to a selection, or **Shift-click** to add a range to a selection. If you **Ctrl-click** a field that is already selected, all selected fields of this type in other selected media become deselected. However, if you continue to press **Ctrl**, you can then click any field, and all fields of the same type in other selected media become selected.
- Click a numeric field to display the calculator, or click and drag to increase or decrease the value in a field.
- **Ctrl+Alt-click** a field to reset the field.
- Double-click the Gaussian, Divide, or Crop field to toggle the effect on or off. Press **Shift** while double-clicking to apply the toggle to all selected media.
- Double-click The K or CC to enter its menu.
- Click a front or matte media to select all the displayed fields.
- Use the **F** keyboard shortcut to toggle the matte media display in the Media list on or off. You can also set this behaviour with the Show Front Only button in the Action Setup menu.

- Resize the column widths in the Media menu by dragging the column dividers.
- **Ctrl**-click to multiselect media for applying to the left or right eye of a stereo object. The media you select first (odd numbers) are applied to the left eye. Even numbered media apply to the right eye.

Adding Media

As the complexity of your effects grows, so will the amount of media you use. You can add unlimited media; media is added to the Media list as they are created. If Auto Image is enabled in the Action Setup menu, an image node and axis are also created in the schematic when new media is added.

NOTE If you accessed Action from the timeline, you are limited to one front/matte media. Therefore, some Media menu settings are not available.

If you accessed Action through the Tools tab, the Workspace Media panel is not directly available from within Action. In this case, you'll need to follow these steps to add new media.

To add media from the workspace:

- 1 Click New Media.
- 2 From the workspace, select a front and matte clip of the same resolution to load as media.

TIP You can select any number of front and matte clips by holding the **Ctrl** key while selecting clips. Each front/matte pair must have the same resolution, and is added to its own line in the Media list.

NOTE After adding media, if the front or matte can no longer be found in the workspace, the name of the front or matte media is displayed in red in the Media list, and the missing front or matte acts as a white frame in Action.

Media Menu Settings

The Media controls are described as follows.

NOTE If you access Action from the timeline, you are limited to one front/matte media. Therefore, some Media menu settings are not available.

New Media button Click to open the workspace to add new media. Available when Action is accessed from the Tools tab.

Media List box To add media directly to the Media list, select New Media. To add an indirect layer to the Action node, select New Input. Available when Action is accessed from Batch or Batch FX.

Image Proxy Displays a proxy of the currently selected media.

Apply button Applies the selected media in the Media list to the selected surface in the scene.

Apply dropdown list For stereoscopic clips, select how the selected media in the Media list is applied to the selected surface in the scene.

Copy button Copies media and effects (for example, Blur and Crop settings) of the selected media in the Media list. Use the Paste options to decide how you want to use the copy/paste operation.

Clone button Clones the selected media, or media and effects onto a new media entry in the Media list.

Clone dropdown list Select whether the clone operation clones just selected media, or media and effects.

Paste button Pastes the copied parameters onto the selected media or media entry in the Media list.

Paste dropdown list Select how the paste operation is applied in the Media list.

Select:	To:
Paste Media Only	Paste the copied media onto a selected empty media entry, without any effects (such as Blur or Crop settings).
Paste FX/Media+FX	If pasting onto an existing media entry, pastes only the copied effects. If pasting on an empty media entry, pastes both the copied media and effects.

Delete button Deletes the selected media from the Media list.

Replace button Click to open the area selected in the Media From box to choose media to replace the selected media in the Media list.

Extract button Click to convert the selected media in the Media list from direct to indirect media.

Front Clip box Select an option to edit the front clip's visibility.

Select:	To:
Front On	Display the front clip for the selected media.
Front Off	Hide the front clip for the selected media.
Front Lock	Lock the selected front clip at the current frame in the timebar.

Back Clip box Select an option to edit the back clip's visibility.

Select:	To:
Back On	Display the back clip.
Back Off	Hide the back clip.
Back Lock	Lock the back clip at the current frame in the timebar.

Matte Clip box Select an option to edit the matte clip's visibility.

Select:	To:
Matte On	Display the matte clip for the selected media.
Matte Off	Hide the matte clip for the selected media.
Matte Invert	<div>Invert a matte. Black areas will be made white, and white areas will become black.</div> <div>TIP To invert multiple matte clips, Ctrl-click the matte media and select Invert in the Matte Clip box.</div>

TIP Use options in the View box to display selected media in the image window: Media Front (or press **F1**), Media Back (**F2**), and Media Matte (**F3**).

Media Rendering box Select a rendering option per media.

Reset Choice box Select the Media list properties to reset.

Reset button Resets the properties selected in the Reset Choice box.

Keyer field Loads the back, front, and matte clips for the selected media into the Modular Keyer. See [Accessing the Colour Corrector and the Modular Keyer from Action](#) (page 463).

NOTE The back clip is loaded into the Modular Keyer for reference only. Any modifications you make to the back clip, such as colour correction, are not applied in Action.

CC field Loads the clip for the selected media into the Colour Corrector. See [Accessing the Colour Corrector and the Modular Keyer from Action](#) (page 463).

X blur field Displays the amount of surface blur along the X axis. Editable.

Y blur field Displays the amount of surface blur along the Y axis. Editable.

Slip field Slips the back, front, or matte clip.

Shadow field Adjusts the softness of a shadow. If the scene contains more than one shadow using the selected media, all shadows are softened by the same amount you specify in this field. See [Adding Drop Shadows](#) (page 494).

Gaussian field Uses Gaussian blur on a selected media.

Divide field Divides the front media by its associated matte media.

Crop and Crop Softness fields Crops a front clip or a matte clip for a selected media. Use the Top, Bottom, Left, and Right fields to crop the selected sides. You can also add crop softness.

NOTE For more information on slipping, blurring, dividing, and cropping in the Media list, see [Adding Effects to Media](#) (page 460)

Adding Effects to Media

The Media list allows you to easily add and edit effects to your clips, such as blurs and crops.

Blurring a Clip

To blur the front, matte clip, or back clip for the selected media, use the Xblur and Yblur fields. The Xblur field controls the amount of blurring on the horizontal (X) axis, and the Yblur field controls the amount of blurring on the vertical (Y) axis.

NOTE If you apply the media to more than one surface, all the surfaces are blurred.

				a		b		c	
#	▽ Name	K	CC	X Blur	Y Blur	Slip	Shadow	Gaussia	Divide
B	gourds (2)			0.00	0.00	0	0.00		
1F	appleswater (2) #1			0.00	0.00	0	0.00		
1M	appleswater (2)			0.00	0.00	0			
2F	gardenvista (2)			0.00	0.00	0	0.00		
2M	gardenvista (2)			0.00	0.00	0			

(a) Xblur (b) Yblur (c) Gaussian Blur

You can use a Gaussian (Gaussian enabled) or a Box blur (Gaussian disabled):

- Gaussian blur has rounded, smoother edges. It is a better blur for animation because it can be blurred on a subpixel level (0.00).
- Box blur has rectangular, rougher edges.

To blur the front clip of media:

- 1 In Action, click Media.
- 2 Select the front media.
- 3 To use a Gaussian blur, double-click the Gaussian field (otherwise a Box blur is applied).
- 4 Set the blur using the Xblur and Yblur values, and then negate the values for the Blur fields on the matte media. For example, to blur only the front clip 10 pixels on both axes, set the front Xblur and Yblur fields to 10 and the matte Xblur and Yblur fields to -10.

TIP Alt-drag over the XBlur or YBlur field to change both values proportionally.

To blur the matte clip of media:

- 1 In Action, click Media.
- 2 Select the matte media.
- 3 To use a Gaussian blur, double-click the Gaussian field (otherwise a Box blur is applied).
- 4 Set the matte Xblur and Yblur fields. Blurring only the matte clip produces a softer edge on the surface of the front clip.

TIP Alt-drag over the Xblur or Yblur field to change both values proportionally.

Cropping a Clip

When you crop media, the front and matte clips are cropped together. You cannot crop the back clip. If you applied the media to more than one surface, all the surfaces are cropped.

You can animate a crop by changing the size and shape of the Crop box at different keyframes. You can also animate the softness of the Crop box.

NOTE Animating a crop in the Channel Editor does not enable the Crop field in the Media list.

To crop a clip with the Media list:

- 1 In Action, click Media.
- 2 Set values for cropping and softness in the Top, Bottom, Left, and Right fields. Once you set a value in one of the Crop or Softness fields, white checkmarks indicate that Crop and Softness are enabled.

Crop		Top	Bottom	Left	Right
		0	0	0	0
b	C ✓	5	5	10	10
a	S ✓	0	0	85	52
C		0	0	0	0
S		0	0	0	0

(a) Softness area of Crop field (b) Crop area of Crop field

TIP Alt-drag over one of the fields to change all four values proportionally.

To crop gesturally in the image window:

- 1 Double-click the Crop field to enable Crop and Softness.
- 2 In the View box, select Media Front or Media Matte.

The clip appears in the image window with a red outline, which indicates the Crop box, and a green outline, which indicates the Softness box.

(a) Crop box (b) Softness box

TIP You can use two viewports to view the crop interactively on both the front and the matte clips.

- 3 Set the corners of the Crop box and Softness box by dragging either the corners or edges of the red and green outlines.
The crop and softness values in the Media list are updated as you drag.
- 4 Click Result.
The cropped media appears in the image window, and the front and matte clip share the same crop.
- 5 To mute the Crop and Softness values, double-click the Crop field. To mute only the Softness, double-click the Softness area of the Crop field. When muted, a black checkmark appears in the Crop field.

Eliminating Unwanted Black in Areas of Media Transparency

When compositing with images generated by rendering 3D objects over a black background, unwanted black often appears on translucent or anti-aliased areas of the media. Use the Divide tool to divide the front media by its associated matte media, which eliminates the black edges in the composite.

To remove unwanted black in media transparency:

- 1 In Action, click Media.
- 2 In the Media list, select the media containing the unwanted black.
- 3 Double-click the Divide field of the media containing the unwanted black.

# ▾	Name	K	CC	Xblur	Yblur	Slip	Shado	Gaussi	Divide
B	elderberries (2)			0.00	0.00	0	0.00		
1F	appleswater (2) (A)			7.00	6.00	3	5.00	✓	✓
1M	gourds (2) (A)			3.00	5.00	7			
2F	A586 (2)			0.00	0.00	0	5.00		
2M	A586 (2)			0.00	0.00	0			

The selected media's front is divided by its matte, resulting in correct colour in areas of transparency.

Slipping Media

You can animate the Slip value of a media's front, matte or background clip. Do this to begin a clip at a specified frame number, or to produce a freeze frame effect where the first frame is held for a specified number of frames. In addition, Slip values are animatable for all types of clips.

If you want to animate the Slip values, or control the Front Slip and Matte Slip separately, use the Channel Editor. The channels are found in their respective media and are named Slip and slip_matte. The Background Slip channel is found in **Scene > Media > Background > Slip**.

To slip media:

- 1 In Action, click Media.
- 2 Change the value of Slip for either the Front or Matte fields, or both, of the media you want to slip.

TIP Alt-drag over the Front or Matte slip field to change both while maintaining the same offset.

# ▾	Name	K	CC	Xblur	Yblur	Slip	Shado	Gaussi	Divide
B	elderberries (2)			0.00	0.00	0	0.00		
1F	appleswater (2) (A)			7.00	6.00	3	5.00	✓	✓
1M	gourds (2) (A)			3.00	5.00	7			
2F	A586 (2)			0.00	0.00	0	5.00		
2M	A586 (2)			0.00	0.00	0			

A positive value starts the clip at the specified frame. A negative value creates a freeze frame effect where the first frame of the clip is held by the specified number of frames.

To slip a background clip:

- 1 Change the value of the B (background) Slip field.

Accessing the Colour Corrector and the Modular Keyer from Action

By accessing the Modular Keyer and the Colour Corrector directly from Action, you can key any media or colour correct any front, matte, or back clip without having to exit Action.

When you enter the Colour Corrector or Modular Keyer from Action, you can view the result of your colour correction or key as it would appear in Action by selecting Context from the View box. The Context view is interactive; as you make changes, the Action result is updated in the image window.

Use Result view while keying or colour correcting. In this way, the number of Action media has no impact on system performance. You can tweak the keying and colour correction setup using Context view.

While you work in the Colour Corrector or Modular Keyer, you do not have to click Render; the modifications are automatically applied to the media in Action. If you enter the Colour Corrector from Action, scrub the timebar to view the Result.

When loading Action setups that contain CC or Keyer effects from a previous version, you may experience a slight loss of quality when viewing proxies. To avoid this loss of quality, select Proxy Full from the Action Setup menu.

Also, when loading Action setups through Batch or Batch FX that contain CC or Keyer effects from a previous version, consider the following:

- If you enabled the Flame Reactor rendering engine when you created your project, make sure the media in the Setup is 8 or 16 bit, as the Flame Reactor engine only supports 8-bit and 16-bit floating point media.
- If you enabled the Classic Rendering engine when you created your project, the media in the Setup can be 8, 10, or 12 bit, but not 16-bit floating point, as the classic keyer and colour corrector do not support 16-bit floating point media.

To access other tools from Action:

- 1 In Action, click Media.
- 2 Double-click the corresponding field for your chosen media and tool. For example, to colour correct the matte clip, double-click the matte CC field.

# ▾	Name	K	CC	X Blur	Y Blur
B	gourds (2)			0.00	0.00
1F	appleswater (2) #1			0.00	0.00
1M	appleswater (2)			0.00	0.00
2F	gardenvista (2)			0.00	0.00
2M	gardenvista (2)			0.00	0.00

(a) Modular Keyer (b) Colour Corrector

- 3 As you work in the tool, select Context from the View box to preview the result.
- 4 Click Return to return to Action.

Muting Media Effects

You can mute Keyer and Colour Corrector media effects in the Action Media menu. Muting effect media can be helpful when you want to see what your Action setup looks like without the Keyer or Colour Corrector settings, but not lose any of the settings of the muted media effect.

To mute an effect, press **Alt** and click the K or CC media. The check mark in the field turns black to signify the media effect is muted. To unmute the media effect, press **Alt** and click the field again.

# ▾	Name	K	CC
B	elderberries (2)		
1F	appleswater (2) (A)		✓ a
1M	gourds (2) (A)		
2F	A586 (2)		✓ b
2M	A586 (2)		

(a) Active media effect (b) Muted media effect

About Using the Modular Keyer from Action

There are some minor differences when you access the Modular Keyer from Action instead of from the Batch or Batch FX, or from the Tools tab. This section describes features specific to using the Modular Keyer in Action.

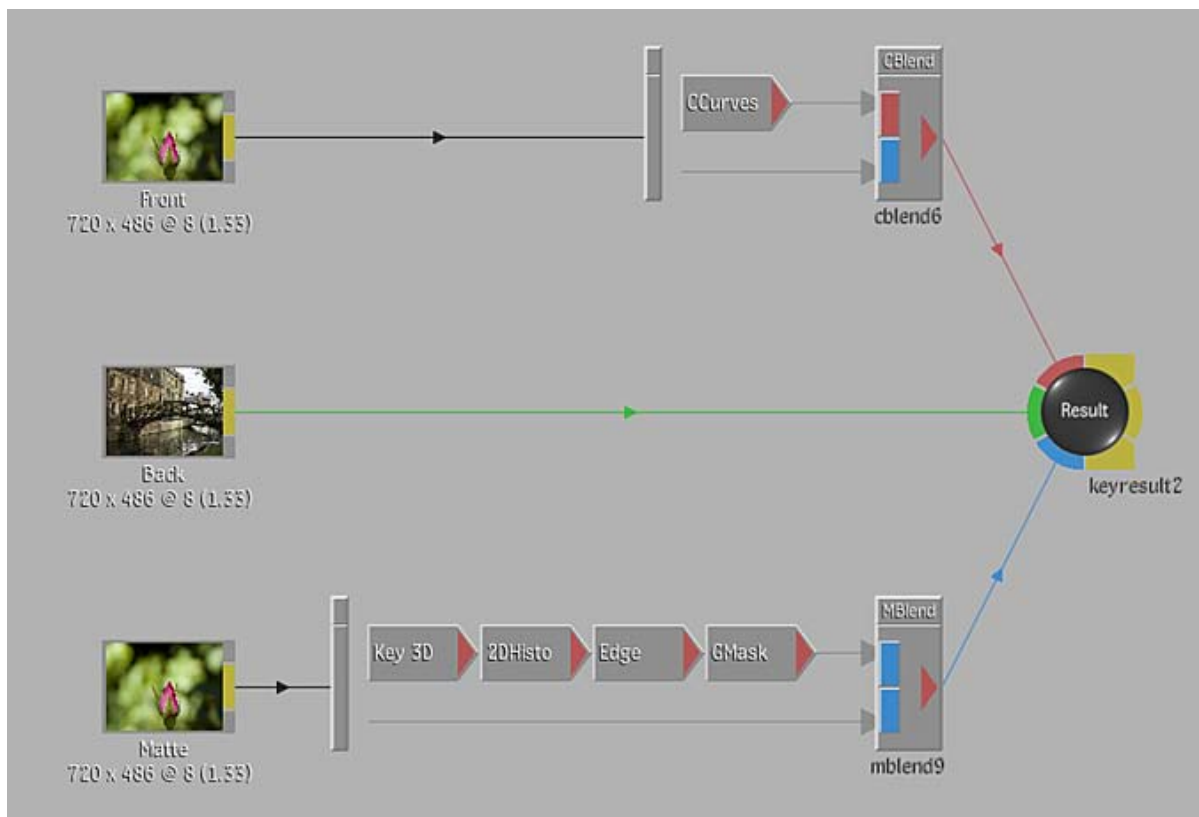

When you load media into the Modular Keyer, the front and matte clips for the selected media are loaded with the back clip and appear at the beginning of the processing pipeline. The front clip is used as the Front clip and the matte clip is used as the Key In clip for the processing pipeline.

The back clip is used as the Back clip in the processing pipeline and is loaded as a reference only. Any modifications you make to the Back clip in the Modular Keyer are not used when you return to Action.

NOTE If the Action back clip is a different resolution than the front clip, a Resize node is added to the Back pipeline when entering the Modular Keyer.

To view the results of your Modular Keyer work as it would appear in Action, select ActionRes from the View box.

The following example shows media loaded into the Modular Keyer from Action.

All branches in the processing pipeline are connected to the Result node. When you return to Action from the Modular Keyer, the following information is used:

- The colour-corrected front clip (attached to the red tab of the Result node)
- The matte clip (attached to the blue tab of the Result node)
- The matte curves for the Result node (To access the matte curves, click the Result node.)

NOTE The back clip is for reference only. Any modifications you make to the back clip, such as colour correction, are not applied in Action.

About Axes

An axis is the element of an object or media that can be manipulated to determine the object's 2D or 3D space, position, and movement.

Use the scene's X,Y, and Z coordinate system to place each surface in the scene, or to rotate, scale, and shear surfaces. You move, rotate, and animate objects directly in the scene and use the camera to record the scene. The part of the scene that the camera, or frustum, looks at is what gets rendered.

Manipulating an Object's Axis

When you add certain objects to the scene, such as models or images, they are added with their own axes. Each axis is used to place its respective object in the scene. An axis is represented by the following icon.

All transformations that you apply to the selected axis are applied to the objects connected to the axis. For example, if the position of a surface's axis is set to 500, 100, 0, then its surface is placed at 500 on the X-axis, 100 on the Y-axis, and 0 on the Z-axis.

(a) Surface is placed in the scene at 500, 100, 0

You can also add an axis manually to the scene from the node bin.

Action Views

Front, top, and side view are orthographic views used to position an object's axis in the scene. These views are useful for viewing the scene from another angle than the camera's.

Selecting an Axis

You can select an axis in any of the following ways:

- Click directly on the axis in the scene.

TIP If you have numerous overlapping axes in the scene, press and hold **Q** while clicking to cycle through each axis until the axis you need is selected.

- Go to Schematic view and click the node for the axis.
- Display the Channel Editor and select the Axis folder or one of its channels.
- Use the Prev and Next buttons in the Axis menu to select the previous or next axis.

Moving and Rotating Axes in the Scene

You can move and rotate an axis directly in the scene. You can do this when viewing the scene in Camera, Top, Side, or Front view.

The selected mode remains in effect until you select a different mode. To select a mode, use the Tools box.

Moving an Axis in the Scene

You can move an axis in the scene, as well as objects that do not have exclusive axes, such as lights, particle generators, and manipulators.

To move an axis directly in the scene:

- 1 In the Tools box, choose Select.
- 2 Select the axis you want to move and drag it to a new position.

If the Axis menu is displayed while you move an axis, you can see the Position X, Y, and Z fields update after the axis is placed in its new position. You can also change the X, Y, and Z position by dragging any of the position fields in the Axis menu to move the axis.

TIP Enable Shift-Snap (in the Action Setup menu Preferences section), and then hold the `Shift` key when selecting an axis to snap the selected axis to the surface of the underlying geometry. Not available when in Top, Front, or Side views.

Rotating an Axis in the Scene

You can rotate an axis in the scene, as well as objects that do not have exclusive axes such as lights, particle generators, and manipulators.

To rotate an axis directly in the scene:

- 1 From the Tools box, select Rotate.
- 2 Select the axis or the object you want to rotate.

A trackball appears in the scene. The trackball consists of three concentric rings. Each ring is used to rotate the object and its axis around one of the three axes.

- 3 Click and drag one of the trackball rings.

The axis and its object rotate in the image window. If the Axis menu is displayed while you rotate, you can see the Rotation fields update after the axis is rotated to its new position. You can also rotate the axis by dragging any of the Rotation fields in the Axis menu.

Changing the Plane

When you move an object in the scene, the object moves on a 2D plane. By default, an axis is moved gesturally on all three planes. You can change the orientation of the plane by selecting an option in the Plane box.

For example, if the camera is pointed toward the Y plane and you want to move an axis along the X and Z planes, change the orientation to Plane XZ.

Select:	To move objects:
Plane XY	On the X or Y plane, but not on the Z plane.
Plane XZ	On the X or Z plane, but not on the Y plane.
Plane YZ	On the Y or Z plane, but not on the X plane.
Plane Off	On the X, Y, or Z plane. The plane is oriented to face the camera.

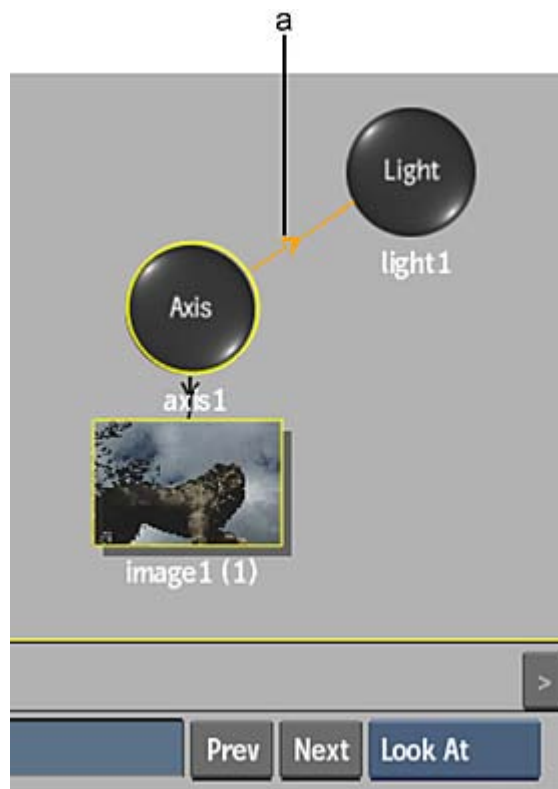

NOTE The different planes can only be used in Camera view. You see the change in the orientation of the plane only when you move the camera away from its default position.

Applying an Axis Look-at Connection

You can attach a look-at connection between the axis and another object in your scene. The axis then rotates to face the look-at object, no matter where it is positioned. You attach a look-at connection in the schematic between the Axis node and any object with axis characteristics (Axis, Camera, Light ,Projector, Particle Animator).

To apply a look-at connection:

- 1 Select Look At in the Tools box.
- 2 In the schematic, drag from the Axis node to an object with axis characteristics.
The selected object is connected to the Axis node by an orange dotted line with an arrow.

(a) Look-at connection

- 3 In the Axis menu, select which axis looks at the attached object in the Point Axis box.

Applying Tracking Data to an Axis

To remove jitter, or track the movement of a feature in the back clip, you can apply tracking data to an axis using the Stabilizer. You can access the Stabilizer directly from the Axis menu in Action.

Stabilizing an Axis

You can import stabilizing data from the Stabilizer to lock the position of the selected axis to a reference point on the front clip in Action. Any movement in the front clip is matched by the axis. See [Stabilizing a Clip from Action](#) (page 879).

Tracking a Feature in the Back Clip

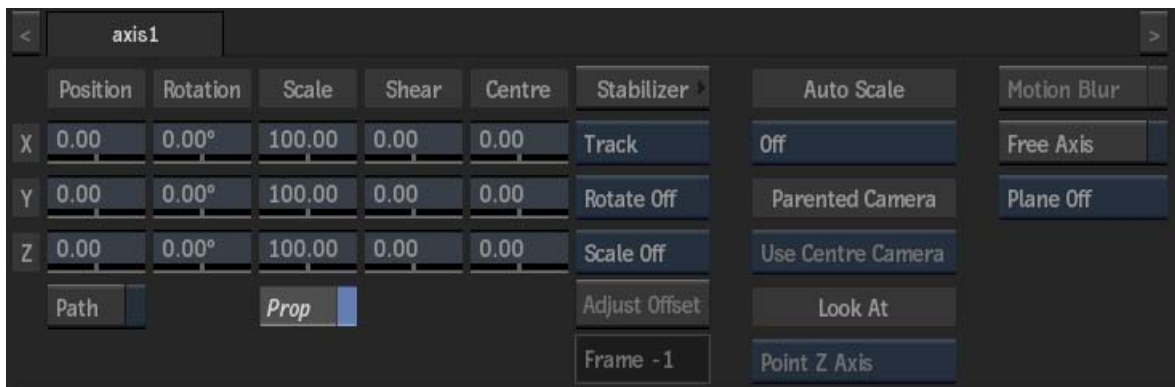

You can track the movement of a feature in the back clip and apply the tracking data to the selected axis in Action. The axis follows the movement of the feature in the back clip. You can also track the rotation or change in size of the feature. See [One-Point and Two-Point Tracking](#) (page 883).

After stabilizing or tracking, you can set a reference frame that has no transformations by enabling the Adjust Offset button at the selected frame.

TIP To help you view your tracking result without any objects blocking the view, enable the Context button in the Stabilizer menu. While similar to a result view, the context view allows you to see all of the Action scene, except for the selected node (and any children of the selected node).

Axis Menu Settings

When accessing Action as a Timeline FX, you have access to a quick menu with some of these Axis settings. To see the full Axis menu, click the Editor button to enter Action.

X Position field Displays the position of the X axis. Editable.

Y Position field Displays the position of the Y axis. Editable.

Z Position field Displays the position of the Z axis. Editable.

Motion Path button Enable to animate the position of the axis using a spline drawn in the scene. Disable to animate the position of the axis using explicit animation.

X Rotation field Displays the rotation of the X axis. Editable.

Y Rotation field Displays the rotation of the Y axis. Editable.

Z Rotation field Displays the rotation of the Z axis. Editable.

X Scale field Displays the scale of the X axis. Editable.

Y Scale field Displays the scale of the Y axis. Editable.

Z Scale field Displays the scale of the Z axis. Editable.

Proportional button Enable to change the fields proportionally.

X Shear field Displays the shear of the X axis. Editable.

Y Shear field Displays the shear of the Y axis. Editable.

Z Shear field Displays the shear of the Z axis. Editable.

X Centre field Displays the centre of the X axis. Editable.

Y Centre field Displays the centre of the Y axis. Editable.

Z Centre field Displays the centre of the Z axis. Editable.

Stabilizer button Opens the Stabilizer menu to apply stabilizing data to an axis. See [Applying Tracking Data to an Axis](#) (page 470).

Stabilizer box Select Track or Stabilize, then click the Stabilizer button.

Tracking Rotation box Select whether tracking rotation is On, Off, or Inverted.

Tracking Scale box Select whether tracking scaling is On, Off, or Inverted.

Adjust Offset button Enable to set the current frame as a reference frame that has no transformation data.

Reference Frame field Displays the frame number of the reference frame that has no transformation data. Non-editable.

Autoscale option box Select whether to autoscale when Position settings are changed relative to the camera (On Position Changes), or when Position, Rotation, Shear, or Centre settings are changed (On All Transforms).

Select:	To:
Off	Not use autoscaling on the image.
On Position Changes	Preserve the projected size of the image by automatically scaling when changing any Position parameters that affect the depth of the image relative to the camera.
On All Transforms	Preserve the projected size of the image by automatically changing Position, Scale, and Centre parameters (when any Position, Rotation, Shear, or Centre parameters are changed).

Parented Camera box Select which camera is used for the parenting offset when the immediate parent is a stereo camera. Choose left, right, or center camera. Active only when there is exactly one parent that is a stereo camera, or if a look-at connection is attached between the axis and the stereo camera.

Point Axis box Select which axis is pointed to the attached look-at object. Available only when objects are attached with a Look At connection. See [Applying an Axis Look-at Connection](#) (page 469).

Motion Blur button Enable to use a motion blur effect for the selected axis (can only be used once the global Motion Blur is enabled in the Setup menu).

Free Axis button Enable to ignore transformations from parent axes.

Plane box Select an orientation for the plane (in Camera view). See [Changing the Plane](#) (page 469).

About Surfaces

You use surfaces to display media in the scene and then composite front and matte clips with a common back clip.

You should have a working understanding of Action media and the relationship between media and surfaces to be successful in using Action.

A surface is used to place a media in the scene. To use media that you load into Action, you must add a surface to the scene for that media. A surface has the following characteristics:

- A surface type can be flat, bilinear, perspective, or extended bicubic.
- The same media can be applied to multiple surfaces. Any cropping, blurring, or re-colouring that you apply to one media is applied to all the surfaces for that media. For example, if you blur a media, all of the surfaces using that media are blurred.

The first time you open Action during a session, an image surface is added to the scene using the first media (if Auto Image is enabled in the Action Setup menu). You must add a surface for each additional media before its clips can be used in the scene. You can then add textures and lighting effects, or change the surface's properties such as its shape, transparency, and specular highlight. Once added, the media appears in the Media list.

By default, a Flat surface is added. You can change the surface type in the Shape box of the Surface menu. See [Changing the Shape of a Surface](#) (page 483).

You control the position of the surface using axis, rotation, scale, shear, and other attributes related to its placement. See [Manipulating an Object's Axis](#) (page 466).

Adding Surfaces

To add a surface:

- 1 In the Media list, select the media containing the back or front/matte that you want to add to the scene.
- 2 Do one of the following:
 - Drag an image node from the node bin and place it in the schematic. An axis and an image are created and linked together.
 - Drag an image node from the node bin to the Result view, so you can see its effect on the scene before placing it exactly where you want.
 - Double-click an image node. The node appears next to the last added object. You do not need to be in Schematic view to add a node in this manner.

The surface is added to the scene with its own axis. The selected media in the Media list is automatically applied to the surface.

Notice that when front/matte media is applied to the image surface, the front and matte clip are combined. You can turn off the matte in the Matte Clip box in the Media menu to show the entire front clip.

- 3 If you later decide to change the media on the surface, select the surface in the schematic, then select the new media in the Media list and click Apply.

Modifying Surfaces

The Surface menu includes properties common to all surfaces, and specific controls for bilinear, perspective, and extended bicubic surfaces. You can change a surface's shape, position, and transparency, as well as apply lighting effects. You can also apply tracking data to, and access the UV points of bilinear, perspective, and extended bicubic surfaces.

To access the Surface menu:

- 1 Double-click the selected surface in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

The Object Image menu appears with the Image controls for the selected surface displayed on the right side of the menu. Some of the tabs for the Surface menu are contextual, and are available depending on the circumstance.

NOTE When accessing Action as a Timeline FX, you have access to a quick menu with some of Surface settings. To see the full Surface menu, click the Editor button to enter Action.

Surface Tools

From the Tools drop down menu, you can select additional tools to modify surfaces.

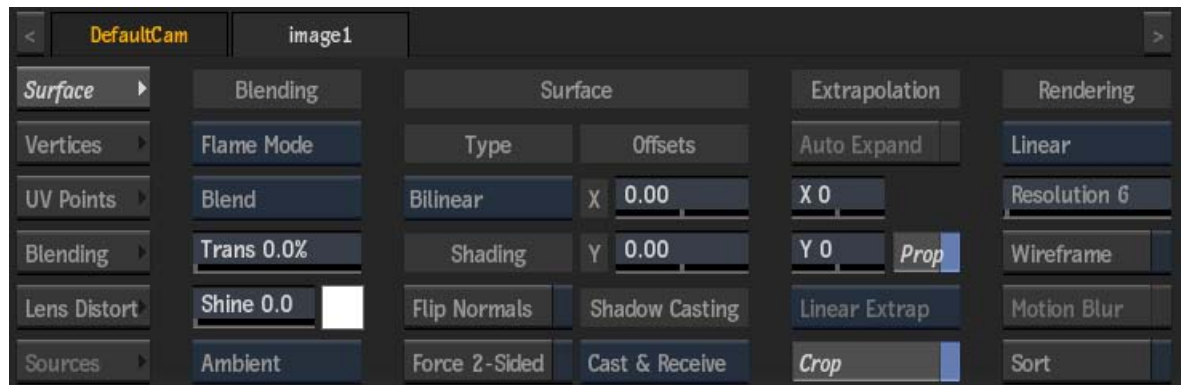

Slide Texture Enables you to slide the texture under the vertices, without moving the vertices, effectively moving the UV points behind the scene.

Move UV/Vertex Enables you to move the UV points and the vertices simultaneously and does not introduce any deformation.

NOTE If the UV points and Vertices grids are already in different positions, the relative position offset is kept when moving the UV points and vertices in this mode.

Surface Settings

The Surface tab is available at all times, and is divided into a number of sections.

Blending Section

Blend Type box Select whether to use Flame or Photoshop blend modes.

Blend Mode box Select how the front and matte clips or the front and back clips are combined.

See [Surface Blending Modes](#) (page 484).

Transparency field Displays the transparency of the image. Enter 0 for a completely opaque image, or 100 for a completely transparent image.

Shine field Displays the level of shine for the specular highlights (there are no specular highlights when Shine is set to 0). Editable.

Specular Highlights colour pot Displays the colour of the surface highlights. The specular highlight is visible only if Shading is enabled in the Setup menu and if shine is greater than 0. Editable.

See [Specular Highlights](#) (page 516).

Lighting box Select Ambient or Diffuse lighting so that the surface can reflect incidental light.

See [Incidental Light Reflection](#) (page 516).

Surface Section

Shape box Select a shape for the selected surface. For Stereo Objects, you are limited to using a Flat surface. For shapes other than flat, you have access to the Vertices and UV Points settings.

Shape	Description
Flat	This is the simplest surface. It is added to the scene by default the first time you enter Action with a Front, Back, and Matte. When working with a Stereo Object, Flat is the only shape available. You cannot change its shape because a flat image does not have vertices. You can, however, scale and shear a flat image using its axis.
Bilinear	A bilinear surface has four vertices: one for each corner. The vertices are joined using linear interpolation (straight lines). You can animate the shape of a bilinear surface by changing the position of the corners.
Perspective	A perspective surface has four vertices similar to a bilinear surface. The vertices form a perspective plane of the surface. You can animate the shape of a perspective surface by changing the position of the corners.
Extended Bicubic	An extended bicubic surface has vertices in sections that can be subdivided up to eight times to increase the number of vertices. The vertices are joined using bicubic interpolation (curved lines). You can animate the shape of a bicubic surface by changing the position of the corners and moving the tangent handles to adjust the curve between corners.

Flip Normals button Enable to flip the selected surface normals to light the back side of a surface.

Force 2-Sided button Enable to have lights in the scene light both sides of the surface (when shading is turned on).

Surface Offset X field Displays the level of offset for a surface along the X axis. Editable.

Surface Offset Y field Displays the level of offset for a surface along the Y axis. Editable.

See [Offsetting a Surface](#) (page 484).

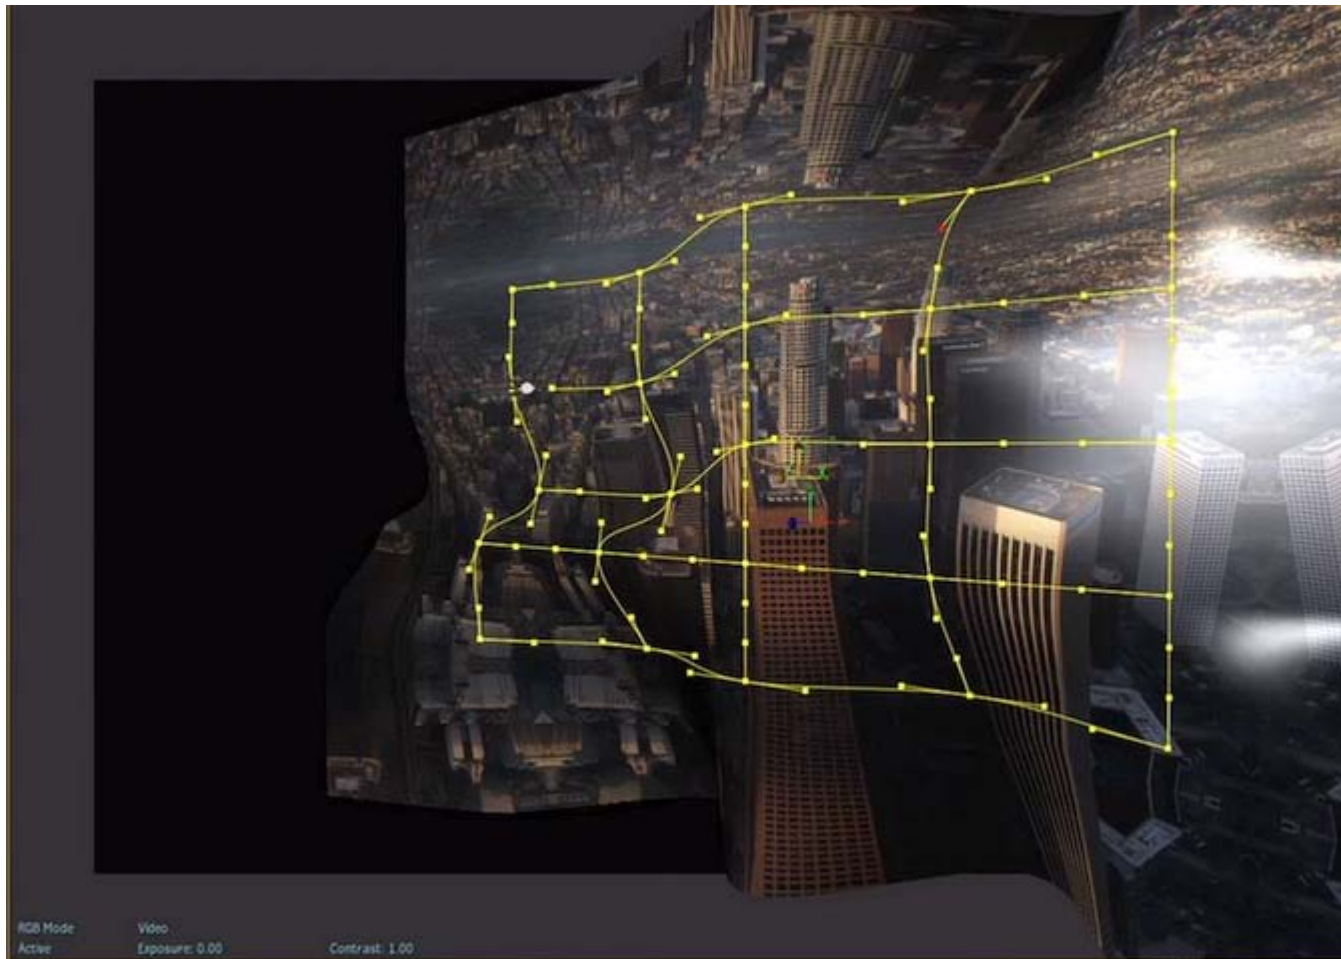

Shadow Casting box Select how the selected image object will be affected by a Shadow Cast object in the scene.

See [Surface and Geometry Shadow Casters](#) (page 521).

Extrapolation Section

Using the extrapolation sliders, you can extrapolate the texture beyond the geometry, in X and Y. You can assign negative extrapolation values and effectively crop the texture. The extrapolation is in mirror mode,

by default. You can change this by adding a Diffuse node in the Action schematic. When working with an Extended Bicubic surface, you can choose between Linear Extrapolation and Smooth Extrapolation. Smooth extrapolation produces a more organic deformation, extrapolating the deformation created by the vertices and tangents, while Linear extrapolates the surface in a straight line after the last vertices, in the direction of the tangents.

Linear extrapolation

Smooth extrapolation

Auto Expand button Enable to automatically resize the surface when an attached diffuse map's Axis settings are changed. Only available for Flat surfaces, and when a diffuse map is a child of the surface. Always available for stereo objects.

Vertical Size Offset field Displays the vertical size offset (expansion or restriction) of the surface while respecting the surface shape. Editable.

Horizontal Size Offset field Displays the horizontal size offset (expansion or restriction) of the surface while respecting the surface shape. Editable.

Proportional button Enable to change the size offset fields proportionally.

Extrapolation box Available for extended bicubic surfaces only, and when the size offset fields are not at 0. Select Linear to extrapolate the surface in a straight direction. Select Smooth to extrapolate smoothly based on the position of the vertices of the surfaces.

Crop button Enable to restrict a bilinear or perspective surface to the dimensions of the UV points.

You can crop the parts of the image that are outside of the geometry, or let the texture go beyond the surface wireframe, by enabling the Crop button.

Rendering Section

Filter box Select the type of filtering to apply to the surface. For example, to be able to mix various ratios in an Action setup, such as a PAL image in a 1080 HD setup, requires filtering.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.
EWA	A high-quality elliptical weighted average filter that determines the proportions of an elliptical area around every pixel to perform a weighted sampling of the colours (slower to process than other filters). EWA is always calculated in screen space, so you should always view the result with a 100% zoom factor.
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

EWA and Anisotropic filtering are especially useful to deal with rotations and perspective effects.

The majority of the filters do not alter the image in any way if you have not moved it, or if you move it in actual pixel increments. The only exception is the EWA+Linear filter which always filters the image, even if you have not moved it (inherent to this type of filtering).

Surface Resolution field Displays the geometry resolution of the selected surface. By default, the value is equal to the default Action Resolution setting (in the Rendering section of the Setup menu).

The lower the value, the better the resolution and the greater the processing time required to interact with the image. For example, a value of 1 on an NTSC image creates a mesh with 720 horizontal and 486 vertical subdivisions on the selected surface, affording accurate displacement, normals, and lighting.

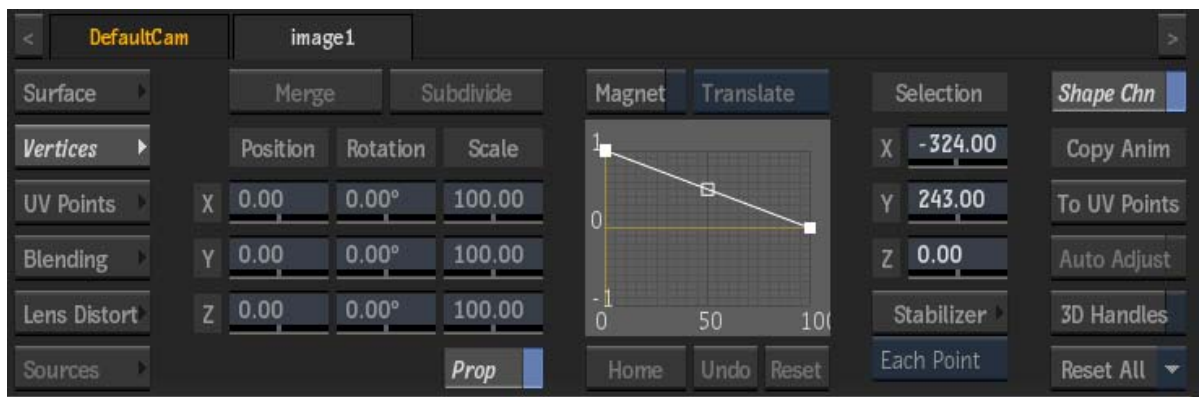

Wireframe button Enable to convert the selected surface to a wireframe representation (lighting and transparency properties are kept).

Motion Blur button Enable to use motion blur for the selected surface (can only be used if the global Motion Blur is enabled in the Action Setup menu).

Sort button Enable to sort non-flat surfaces where overlapping transparent regions are causing artefacts.

Vertices Settings

Vertices settings are available for all surface shapes, except for flat.

Merge button Click to merge the extended bicubic surface sections (can be clicked multiple times).

Subdivide button Click to subdivide the extended bicubic surface into more sections (can be clicked multiple times). See [Subdividing an Extended Bicubic](#) (page 490).

X Position field Displays the position of the selected surface points along the X axis. Editable.

Y Position field Displays the position of the selected surface points along the Y axis. Editable.

Z Position field Displays the position of the selected surface points along the Z axis. Editable.

X Rotation field Displays the rotation of the selected surface points along the X axis. Editable.

Y Rotation field Displays the rotation of the selected surface points along the Y axis. Editable.

Z Rotation field Displays the rotation of the selected surface points along the Z axis. Editable.

X Scale field Displays the scale of the selected surface points along the X axis. Editable.

Y Scale field Displays the scale of the selected surface points along the Y axis. Editable.

Z Scale field Displays the scale of the selected surface points along the Z axis. Editable.

Proportional Scale button Enable to scale the surface points proportionally.

Magnet button Enable to transform a range of surface points. Use in conjunction with the Magnet Transformation box. See [Transforming Multiple Points](#) (page 491).

Magnet Transformation box Select a transformation type to use when Magnet is enabled.

Magnet Curve Editor Displays the weighted polarity from the centre to the edge of the magnet.

Magnet Curve Home button Resets the position of the magnet curve after panning.

Magnet Curve Undo button Undoes a change to the Magnet Curve Editor.

Magnet Curve Reset button Resets the Magnet Curve Editor.

Vertex Position X field Displays the position of the vertices on the X axis. Editable.

Vertex Position Y field Displays the position of the vertices on the Y axis. Editable.

Vertex Position Z field Displays the position of the vertices on the Z axis. Editable.

Stabilizer button Opens the Stabilizer menu to apply stabilizing data to selected surface vertices.

Tracking Mode box Select whether to track each selected vertex or UV point individually (Each Point) or grouped via two proxy trackers, and from which parameters from the proxy trackers extrapolate the movement (Pos/Scale, Pos/Rot, Pos/Rot/Scale). With Perspective tracking, you can further select whether to enter the

Stabilizer with four trackers associated to the 4 Corners of the perspective surface (4 Corners), or use an unlimited number of trackers to track the Perspective transformation of the vertices or UV points (Perspective).

- **Each Point:** Perform the tracking using a tracker for each selected vertex or UV point.
- **Pos/Rot:** Perform the tracking using two proxy trackers that extrapolate the position of the selected vertices or UV points, based on the detected position and rotation motion.
- **Pos/Scale:** Perform the tracking using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on the detected position and scale motion.
- **Pos/Rot/Scale:** Perform the tracking using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on the detected position, scale and rotation motion.
- **4 Corners:** Associates a tracker to each corner of your image (equivalent to a four-point track on a bilinear surface).
- **Perspective:** Allows you to add as many trackers as you want and position them in the same plane as your surface, to cover as much of the perspective transformation as possible.

Shape Channel button Enable to use the Shape channel in the Channel Editor. Disable to use individual channels in the Channel Editor. See [Reshaping Using the Channel Editor](#) (page 485).

Copy To UV Points button Click to copy vertex data to the UV point animation channels.

Auto Adjust button Enable to scale adjacent tangents automatically. Auto Adjust creates a smooth curve between points in the deformation. If you want to work on a specific area of the image without affecting other tangents, disable Auto Adjust.

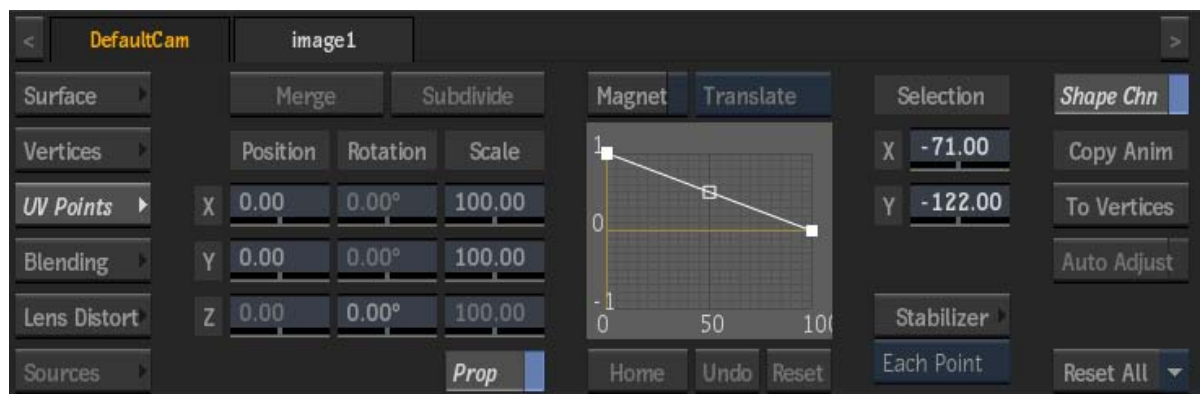

NOTE If you move a tangent explicitly, it is not affected by Auto Adjust. Click Reset Points or Reset Shape so that the tangents will be affected by the Auto Adjust mode.

3D Handles button Enable to allow Z buffering of the vertices. By default, the vertices are always visible, regardless of their position in Z space in relation to other media.

Reset Selection box Select whether to reset selected points, tracking data, or the shape of the surface. Click Reset All to reset all data.

UV Points Settings

UV Points settings are available for all surface shapes, except for flat.

Merge button Click to merge the extended bicubic surface sections (can be clicked multiple times).

Subdivide button Click to subdivide the extended bicubic surface into more sections (can be clicked multiple times). See [Subdividing an Extended Bicubic](#) (page 490).

X Position field Displays the position of the selected surface points along the X axis. Editable.

Y Position field Displays the position of the selected surface points along the Y axis. Editable.

Z Rotation field Displays the rotation of the selected surface points along the Z axis. Editable.

X Scale field Displays the scale of the selected surface points along the X axis. Editable.

Y Scale field Displays the scale of the selected surface points along the Y axis. Editable.

Proportional Scale button Enable to scale the surface points proportionally.

Magnet button Enable to transform a range of surface points. Use in conjunction with the Magnet Transformation box. See [Transforming Multiple Points](#) (page 491).

Magnet Transformation box Select a transformation type to use when Magnet is enabled.

Magnet Curve Editor Displays the weighted polarity from the centre to the edge of the magnet.

Magnet Curve Home button Resets the position of the magnet curve after panning.

Magnet Curve Undo button Undoes a change to the Magnet Curve Editor.

Magnet Curve Reset button Resets the Magnet Curve Editor.

UV Point Position X field Displays the position of the selected UV points along the X axis. Editable.

UV Point Position Y field Displays the position of the selected UV points along the Y axis. Editable.

Stabilizer button Opens the Stabilizer menu to apply stabilizing data to the selected UV points.

Tracking Mode box Select whether to track each selected vertex or UV point individually (Each Point) or grouped via two proxy trackers, and from which parameters the proxy trackers extrapolate the movement (Pos/Scale, Pos/Rot, Pos/Rot/Scale). With Perspective tracking, you can further select whether to enter the Stabilizer with four trackers associated to the 4 Corners of the perspective surface (4 Corners), or use an unlimited number of trackers to track the Perspective transformation of the vertices or UV points (Perspective).

- **Each Point:** Perform the tracking using a tracker for each selected vertex or UV point.
- **Pos/Rot:** Perform the tracking using two proxy trackers that extrapolate the position of the selected vertices or UV points, based on the detected position and rotation motion.
- **Pos/Scale:** Perform the tracking using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on the detected position and scale motion.
- **Pos/Rot/Scale:** Perform the tracking using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on the detected position, scale and rotation motion.
- **4 Corners:** Associates a tracker to each corner of your image (equivalent to a four-point track on a bilinear surface).
- **Perspective:** Allows you to add as many trackers as you want and position them in the same plane as your surface, to cover as much of the perspective transformation as possible.

Shape Channel button Enable to use the Shape channel in the Channel Editor. Disable to use individual channels in the Channel Editor. See [Reshaping Using the Channel Editor](#) (page 485).

Copy To Vertices button Click to copy UV point data to vertex animation channels.

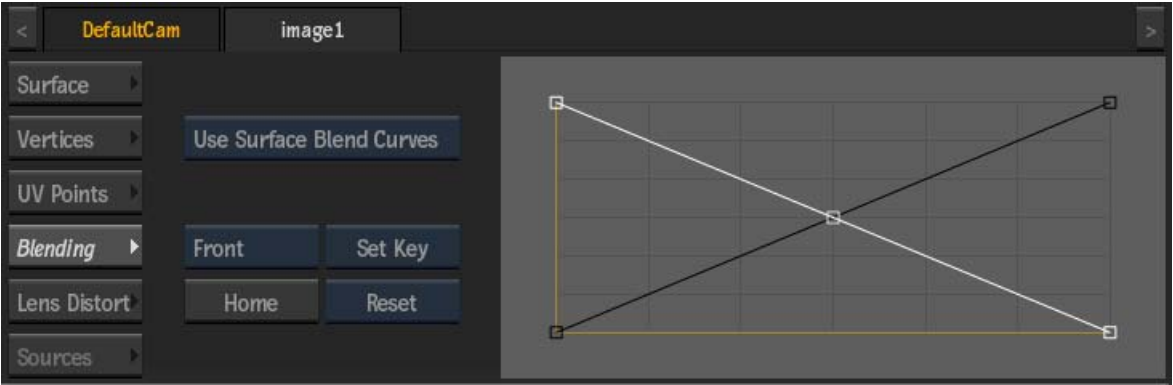

Auto Adjust button Enable to scale adjacent tangents automatically. Auto Adjust creates a smooth curve between points in the deformation. If you want to work on a specific area of the image without affecting other tangents, disable Auto Adjust.

NOTE If you move a tangent explicitly, it is not affected by Auto Adjust. Click Reset Points or Reset Shape so that the tangents will be affected by the Auto Adjust mode.

Reset Selection box Select whether to reset selected points, tracking data, or the shape of the surface. Click Reset All to reset all data.

Blending Settings

Use the settings in the Blending tab to adjust blending curve for each surface.

Blend Curves option box Select whether to work with the surface blend curves or view the existing keyer blend curves.

Matte box Select the matte curve you want to adjust. Selecting a curve in the curve editor automatically sets the correct curve in this box.

Keyframe Option box Select an option to Set, Delete, or Reset keyframes. If Auto Key is enabled, a keyframe is added automatically when you adjust the blending curve.

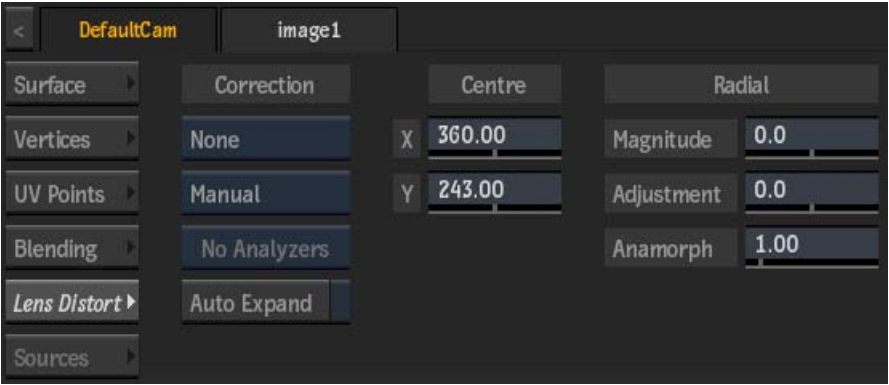

Home button Click to reset the curve view.

Reset Selection box Select whether to reset the selected curve (Reset) or all curves (Reset All) to their default settings.

For more information on using the blending curves, see [Applying Blending Curves per Surface](#) (page 487).

Lens Distort Settings

Differences in camera lenses or perspective irregularities cause lens distortion that results in skewed angles. Use the settings in the Lens Distort tab to rectify or simulate these types of distortions in your images.

Distortion box Specify whether you want perform a lens distortion or rectification.

Distort Corrections box Select whether to apply radial corrections manually in this menu, or use the automatic settings derived from the selected analyzer.

Distort Analyzer box Select which analyzer is used to provide automatic radial corrections.

Auto Expand button Enable to automatically resize the surface when an attached diffuse map's Axis settings are changed. This same button appears in the Surface tab.

Centre X field Displays the horizontal position of the centre of the lens. Editable.

Centre Y field Displays the vertical position of the centre of the lens. Editable.

Magnitude field Displays the magnitude of radial distortion or rectification. Editable.

Adjustment field Displays the level of secondary adjustment of radial distortion or rectification. Editable.

Anamorph field Displays the ratio of radial distortion or rectification along the X or Y axis. Editable.

Sources Settings

If a source node is parented above a surface node in the schematic, the Source tab is available. These settings allow you to change source settings on a per surface basis, independent of the source type set in the Source menu for the parent source node or nodes. See [Replacing the Front or Matte Clip](#) (page 713).

Changing the Shape of a Surface

When you first activate media or access Action, the media's surface is set to Flat by default. In Action, you can also represent a clip using custom bilinear, perspective, or extended bicubic surfaces.

To change the shape of a surface:

- 1 Double-click the surface in the Schematic view.
- 2 Select the shape of the surface from the Shape box.
- 3 Click the vertex you want to edit and drag it to its new position.

You use the vertices—or handles—on surfaces to change a surface's shape. You can move, rotate, shear, and scale a surface using the [Axis](#) (page 471) menu.

(a) Vertices on a bilinear surface

(a) Vertices and tangent handles on an extended bicubic surface

To move a handle on a bilinear or extended bicubic surface, click the handle that you want to edit. The selected handle appears in red. Use the cursor to drag the handle to its new position.

Each corner has two tangent handles. Lengthen or move the tangents to change the shape of the bicubic between corners.

All of the animation modifications you make to a shape are saved. If you decide to change a shape, then change it back to the original shape, your modifications are not lost.

Surface Blending Modes

Use the Blend Mode box to select how the front and matte clips or the front and back clips are combined. For example, use Screen for blending a fire or a lightning bolt shot on black that you want to composite with a different background.

You can select between a number of Flame or Photoshop blend modes by making a selection in the Blend Type box. Some of the blend modes are similar (or identical) between the different types, but are repeated with the mode names you are used to working with.

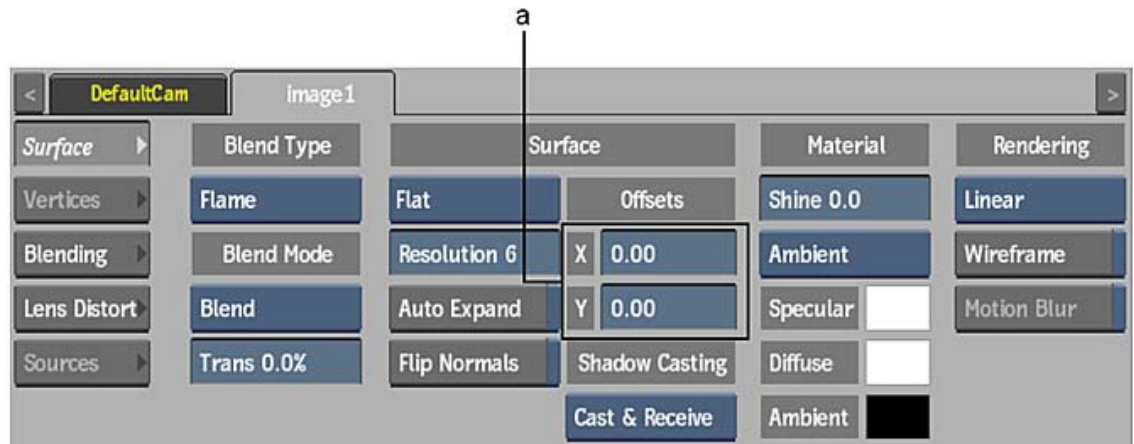

Offsetting a Surface

By default, a surface's axis is at the centre of the surface. Use the Surface Offset X and Y fields to offset a surface along the X-axis or Y-axis. All rotations, scaling, and shearing applied to a surface are applied about its axis. The location of the axis is indicated by the axis icon in the scene.

To offset a surface:

- 1 Select the surface you want to offset.

- 2 In the Surface menu, change the Surface Offset X and Surface Offset Y fields accordingly.

(a) Surface Offset fields

The following figure illustrates the difference between rotating a surface that has not been offset and a surface offset using the Surface Offset X field.

Rotated image with no offset. Notice that the axis is in the centre of the image.

Rotated image with an offset along the X-axis. Notice that the axis is offset from the image centre.

Reshaping Using the Channel Editor

You can select whether you want to create an animation for bilinear, perspective, or extended bicubic surfaces using the Shape channel or individual Vertex channels in the Channel Editor. The Shape channel shows when the shape of the surface changes during the animation. Each time you move a surface handle, a shape key is added at the current frame, provided that Auto Key is enabled.

Vertex channels correspond to the vertices—or handles—that appear on the four corners of bilinear, perspective, and extended bicubic surfaces. The channel names for each corner are: `upper_left`, `upper_right`, `lower_left`, and `lower_right`, and are listed in the channel hierarchy each with a position `x,y,z`. To use the vertex channels in the Animation editor, make sure that Shape Channel is disabled in the Vertices or UV Points menu.

Each corner vertex has two tangent handles—the tangent handles for `upper_left` are named `horz_tan_right` and `vert_tan_down`.

(a) upper_left (b) horz_tan_right (c) horz_tan_left (d) upper_right (e) vert_tan_down (f) vert_tan_up (g) lower_right (h) lower_left

Extended bicubics have additional vertex channels that appear in the Channel Editor for subdivided vertex channels. These channels appear only when you create a keyframe for the channel and its value changes. These vertex channels are named vertex_0.1, vertex_1.0, vertex_2.1, and so on, according to their position on the surface. Click the vertex on the surface to highlight its channel in the channel hierarchy. See [Warping an Extended Bicubic Surface](#) (page 488).

Blending Curves

You can adjust the blending curves of each surface separately. The blending curve is similar to the Keyer luminance blending curve, but you can adjust it per surface.

When you create a matte for the front clip, a matte for the back clip is automatically created to specify which part of the back clip is used for the composite. By default, the back matte is the inverse of the front matte.

You can adjust the luminance of the front matte and back matte separately in the Action blending curve. For example, increase the luminance of the back matte so that more of the back clip shows through at the edges of the key. This creates a better blend at the edges.

The following calculation is applied to each pixel of the image to create the composite. The calculation is applied in three passes, one each for the R, G, and B values of the front and back images, and the pixel is given the resulting R, G, and B values.

$$\text{Result} = F * \text{FrontLUT} + B * \text{BackLUT}$$

where:

- F = the R, G, and B values of the front image
- B = the R, G, and B values of the back image
- FrontLUT is the front matte pixel value, re-mapped according to any luminance curve change made in the blending curve. The value is expressed as a decimal, where, for example:
 - in 8-bit mode, 0 = 0, 127.5 = 0.5, and 255 = 1
 - in 12-bit mode, 0 = 0, 2047.5 = 0.5, and 4095 = 1
 - 16-bit floating point images, the values are represented on a logarithmic scale between 0 and 1.
- BackLUT is the back matte pixel value, re-mapped according to any luminance curve change made in the blending curve. The value is expressed as a decimal, as is the FrontLUT.

Applying Blending Curves per Surface

To adjust the blending curve:

- 1 In the Surface menu, click the Blending tab.
- 2 Select Result view from the View box. This allows you to view a particular image as you adjust the curve.
- 3 To adjust the luminance curve for the front matte, select Front from the Matte box. To adjust the back matte curve, select Back. Alternatively, click a curve to select it.

(a) 255 (White) (b) Output (remapping of luminance values) (c) 0 (Black) (d) 0 (Black) (e) Input (current luminance values) (f) 255 (White)

In Select edit mode, click a point to display its tangent handle and drag the handle to adjust the curve. Use other modes in the Tools box (Add Points or Break Tangent, for example) to further adjust the curve, adding or deleting points, or breaking tangent handles as needed.

- 4 Use the options in the Keyframe option box to Set, Delete, or Reset keyframes. If Auto Key is enabled, a keyframe is added automatically when you adjust the blending curve.
- 5 Use the Blend Curves option box to switch between the surface blend curves and the keyer blend curves. This gives you a good comparison to luminance curve work you have already done in the Keyer. When Use Keyer Blend Curves is selected, all of the other Action blend curve settings are unavailable.

Warping an Extended Bicubic Surface

Use an extended bicubic surface to warp specific areas of a surface. An extended bicubic surface can be subdivided into many sections, which are controlled by vertices. The vertices allow you to bend and contort the surface. The vertices are joined using bicubic interpolation—curved lines.

You can animate the shape of a bicubic surface by changing the position of the vertices and moving the vertex tangent handles. See [Reshaping Using the Channel Editor](#) (page 485).

By default, the extended bicubic surface has four vertices and eight tangents. You can translate, scale, or rotate these points and tangents individually or as a group. Subdividing the bicubic surface increases the number of vertices in the image and allows for more precision.

(a) vertex 1 (b) tangents of vertex 1 (c) tangents of vertex 2 (d) vertex 2 (e) Reference point

Image courtesy of Topix

Extended bicubics have three types of points: vertices, tangents, and the reference point. Vertices and tangents are collectively called *surface points*.

Vertices lie on the surface and its tangents determine the curvature of the deformation at each vertex. The reference point indicates the axis of origin for applying rotation and scaling to surface points.

Use the surface points to control the deformation of the surface. Each vertex has tangent handles. By moving the tangents and their handles, you can warp specific areas of the surface. You can translate, scale, or rotate these points and tangents individually or as a group.

TIP If a tangent point is hidden behind a vertex or reference point, press **Q** and click the point in the image window to select the tangent.

Tangent handles have three modes.

This mode:	Indicates:
	The handles are not broken. If you move this handle, the adjacent handle will move in the opposite direction and by the same magnitude (length).
	The handles are broken. If you move this handle, no other handles are affected.
	The handles are geometrically continuous. If you move this tangent, the adjacent handles will move in the opposite directions but maintain its magnitude (length).

Subdividing an Extended Bicubic

Subdivide the bicubic surface up to eight times to increase the number of vertices and tangents. Then translate the vertices for a smaller region of the image for more precision. You should warp the surface with a small number of subdivisions to obtain the best results. After applying some deformations to a large portion of the surface, subdivide the surface further and perform deformations on a more localized region of the surface.

To subdivide extended bicubics:

- 1 From the Vertices menu, click Subdivide.
You can click the subdivide button up to eight times to further subdivide the surface. Click Merge to undo subdivide operations.
- 2 Transform the tangents to achieve the effect you want.

To move the reference point:

- 1 Select the reference point.
The reference point turns red when selected.
- 2 Drag the reference point to a new location, or use the X, Y and Z vertex fields to assign a new coordinate for the reference point.

To rotate multiple surface points:

- 1 Set the reference point values you want to use as the axis of origin using the X, Y, Z Vertex Position fields.
- 2 Select multiple surface points by pressing `Ctrl` and dragging to select the surface points.
- 3 From the Tools box, select Rotate.
A 3D trackball appears on the reference point.
- 4 Use the 3D trackball to rotate the reference point and selected points.
All selected points rotate around the reference point.

To scale multiple surface points:

- 1 Set the reference point values you want to use as the axis of origin using the X, Y, Z Vertex Position fields.
- 2 Select multiple surface points by pressing `Ctrl` and dragging to select the surface points.
- 3 From the Tools box, select Scale.
- 4 Drag in a direction in the image window to scale accordingly.

About Transforming Multiple Points

Use the magnet to transform a range of extended bicubic points. Use the magnet when there are many surface points as a result of more than one subdivision. In the Vertices or UV Points menu, the magnet controls include the Magnet button, the Magnet Transformation box, and the Magnet Curve Editor.

There are two ways to transform points with the magnet. You can use the magnet to select a range of points and transform them gesturally. Or, you can use the invisible magnet in conjunction with the Translation, Rotation, and Scale fields to transform selected points numerically.

Before you can use the magnet, you must set the polarity of the magnet and the magnet area of focus. The magnet's area of focus is determined by where you click the surface and the polarity of the magnet is set by the Magnet Curve Editor. The radius is determined by the distance from the centre to the farthest selected point.

Using the Magnet

Setting the Magnet Polarity

Use the Magnet Curve Editor to define the weighted polarity from the centre to the edge of the magnet. Points are either attracted or repelled depending on their location in the magnet and the shape of the magnet curve.

The area of the magnet is plotted on the X-axis where 0 is the centre of the magnet and 100 is the edge of the magnet. The polarity is plotted on the Y-axis where 1 is maximum positive strength and -1 is maximum negative strength.

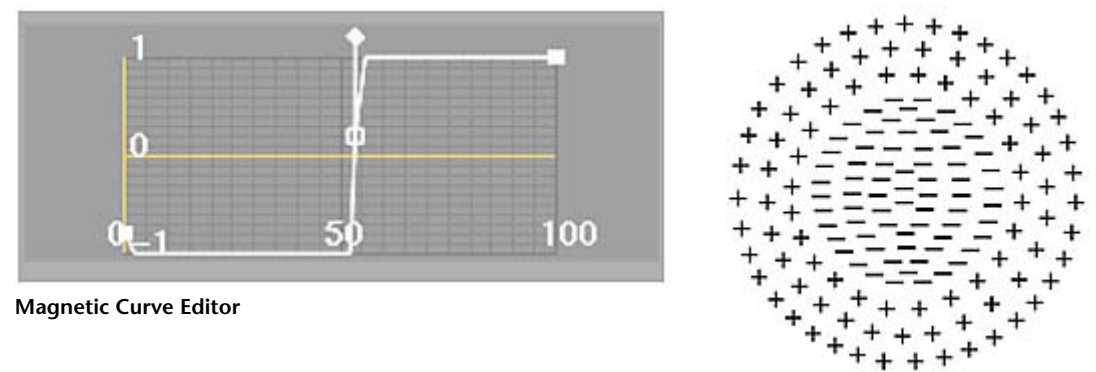

A positive polarity value attracts nearby points. A negative polarity value repels nearby points. The following example illustrates a magnet that has a strong positive polarity near the centre and strong negative polarity near the edges.

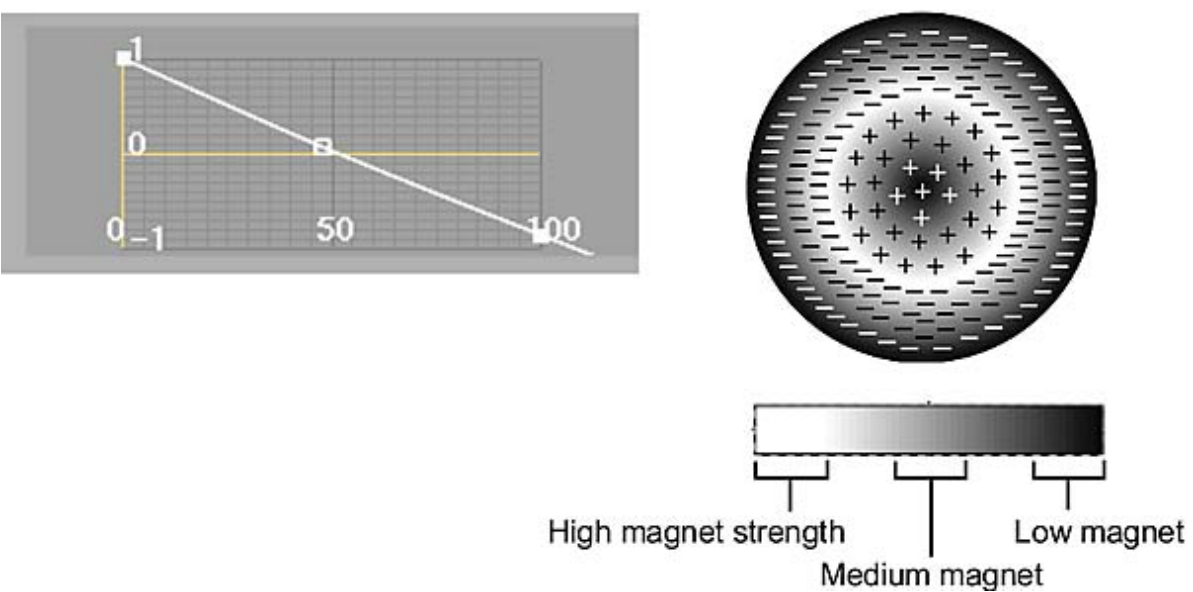

Magnetic Curve Editor

The following example illustrates a magnet that has a strong negative polarity near the centre and a strong positive polarity near the edges.

The following example illustrates a magnet whose positive polarity decreases from the centre and whose negative polarity increases toward the edges.

When you transform points, the direction and size of the transformation is determined by the weighted polarity of the magnet at the location of the points.

Using the first example, if you use the magnet to translate the points on the X-axis by +200, the points in the centre of the magnet move in the positive direction on the X-axis—they are attracted to the magnet—while the points near the edge of the magnet move in the negative direction on the X axis—they are repelled by the magnet.

To change the polarity of the magnet:

- 1 In the Vertices or UV Points menu, click Reset to return the magnet curve to its default.
- 2 Click the left-most handle on the curve and drag to define the polarity for the centre of the magnet.

Drag the point:	To:
Up	Increase the positive polarity.

Drag the point:	To:
Down	Increase the negative polarity.
To the middle	Assign no polarity.

- 3 Click the right-most handle on the curve and drag to define the polarity for the edge of the magnet.

Drag the point:	To:
Up	Increase the positive polarity.
Down	Increase the negative polarity.
To the middle	Assign no polarity.

- 4 Click the middle handle on the curve and drag to define the transition of polarity from the centre to the edge of the magnet.

Transforming Points

Use Magnet mode to transform points gesturally. The magnet's area of focus is determined by where you click the surface and the radius of the magnet is set by the Magnet Curve Editor. The radius is determined by the distance from the centre to the farthest selected point.

To transform points:

- 1 Use the Magnet Curve Editor to determine the polarity for the magnet.
- 2 From the Tools box, select Magnet.

The magnet appears as a red circular outline.

- 3 To resize the magnet, press **Ctrl+S** and drag left or right.
- 4 From the Magnet Transformation box, select the type of transformation.

Select:	To:
Translate	Translate the selected points along the X-, Y-, or Z-axis.
Rotate	Rotate the selected points about the centre of the magnet.
Scale	Scale the selected points about the centre of the magnet.

- 5 Click the points you want to transform in the image window.
- 6 Drag in the image window to apply the transformation to the selected points.

Transforming Unselectable Points

Use the invisible magnet to transform points you cannot select with the magnet. The centre of the magnet is determined by the centre of the selection and the radius is determined by the distance from the centre to the farthest selected point. Any transformations to the selected points are affected by the magnet.

To transform unselectable points:

- 1 Use the Magnet Curve Editor to determine the polarity for the magnet.
- 2 From the Tools box, choose Select.
- 3 Hold **Ctrl** and drag to select a range of points.
- 4 In the Vertices or UV Points menu, enable Magnet.

The magnet is not visible, but is illustrated here to show how the points will be affected when you transform them.

(a) Selected Points (b) Magnet (not visible)

- 5 From the Magnet Transformation box, select the transformation type.

Select:	To:
Translate	Translate the selected points along the X-, Y-, or Z- axis.
Rotate	Rotate the selected points about the centre of the magnet.
Scale	Scale the selected points about the centre of the magnet.

- 6 Change the values in the Translation, Rotation, or Scale fields.

Adding Drop Shadows

In Action, drop shadows are cutouts based on a surface's matte. A drop shadow can be fully opaque or slightly transparent to simulate a real shadow.

Shadows cast by lit objects are also supported in Action (see [Casting Shadows](#) (page 519)).

To add a drop shadow:

- 1 Select the surface that you want to use.
- 2 Do one of the following:
 - Drag the shadow node from the node bin and place it in the schematic. An axis and a shadow are created and linked together.
 - Drag the shadow node from the node bin to the Result view, so you can see its effect on the scene before placing it exactly where you want.
 - Double-click the shadow node. An axis and a shadow are created and linked together. You do not need to be in Schematic view to add a node in this manner.

If a surface node is selected in the schematic, the axis of the shadow node is automatically connected to the surface.

NOTE A shadow has its own parent axis. It can be moved, rotated, scaled, and sheared independently of its parent surface. Because a shadow is also the child of the surface, moving the surface axis also moves the shadow.

Adjusting Drop Shadows

To change drop shadow colour and transparency:

- 1 Double-click a shadow node to display the Shadow menu.

- 2 Make sure that the Shadow button is set to Shadow On.

NOTE You can turn the shadow on or off from the Shadow button. This button is independent of the Hide option.

- 3 To change the colour of the shadow, do one of the following:
 - Enter colour values in the three colour fields in the Shadow menu.
 - Click the colour pot below the fields. Use the colour picker to pick the shadow colour.
- 4 To adjust the transparency of the drop shadow, use the Transparency field. When this field is set to 100, the shadow is completely transparent. When set to 0, the shadow is completely opaque.

TIP You can lock the shadow's transparency to the transparency of its parent surface using the Transparency Lock button. Once a shadow transparency is locked to its parent surface, changes to the surface transparency also affect the shadow's transparency. You can then adjust transparency of the shadow as an offset of the surface's transparency.

Adjusting Shadow Softness

You can adjust the softness of a shadow using the Shadow field in the Media menu. Use a value of 0.00 to have a distinct shadow. Increase the value to soften the shadow.

Shadow softness is a property of the media. If you add more than one shadow for the same media, all shadows are softened by the same amount.

Using Shadow Mix

Use Shadow Mix to render shadows and surfaces according to their order in the Priority Editor, independently of their position in Z-space. This option makes it possible to have the shadow of one media on top of the shadow of another media. Shadow Mix is an option in the Z-Buffer box in the Rendering section of the Action Setup menu.

Shadow Menu Settings

Red Shadow field Displays the red shadow value. Editable.

Green Shadow field Displays the green shadow value. Editable.

Blue Shadow field Displays the blue shadow value. Editable.

Shadow colour Pot Displays the colour of the shadow. Editable.

Shadow Transparency Lock button Locks a shadow's transparency to the transparency of its parent surface.

Shadow Transparency field Displays the transparency level of the drop shadow. Editable.

Shadow button Toggles the shadow on or off.

Reordering Surfaces

When you add a surface (flat image, bilinear, or bicubic) or geometry (3D text or model), the surface or geometry appears in front of all other objects in the scene. These overlapping objects create a stack and an order of priority as one object is drawn in front of the other.

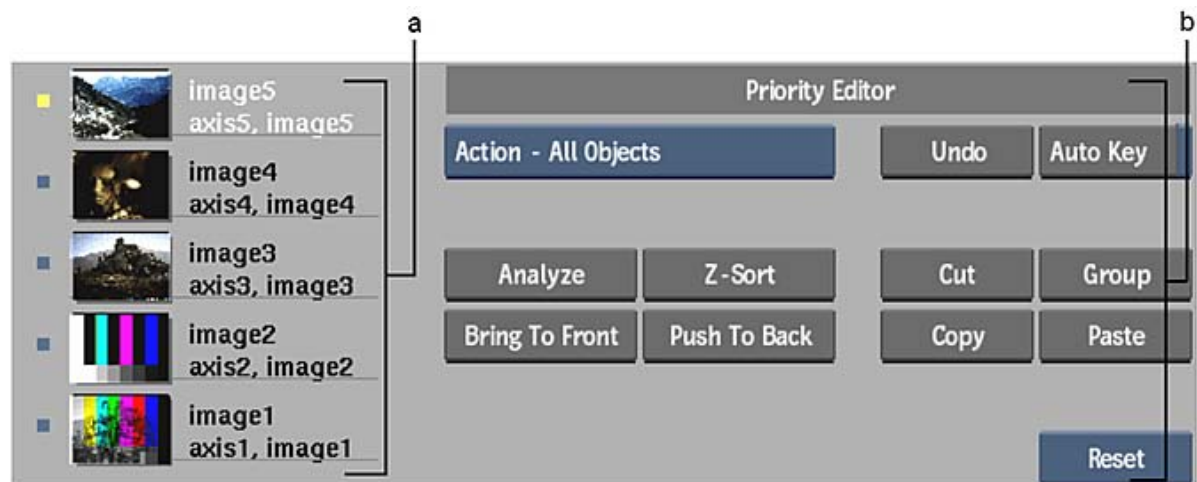

You can change the drawing order of surfaces, 3D models, and other objects using the Priority Editor.

Accessing the Priority Editor

Each entry in the Priority Editor indicates the object's name, the order of the object in the stack, and the location of the object in its branch. There is also a proxy showing what the object looks like in Schematic view.

To access the Priority Editor, click the Priority button, or swipe the bar at the bottom of the Media or Object menu.

NOTE If a source node is selected in the schematic, the Priority Editor that is displayed is that of the source node (the source node name is prepended to the branch name).

(a) Drawing order of objects in the scene (b) Priority Editor controls

Use the Priority Editor controls to analyse the scene for changes in rendering priority, to change the rendering priority, and to cut, copy, and paste priority information from one frame to another.

Changing the Drawing Order

The objects in the scene are shown according to z-depth, while still being drawn in the order of their priority: highest priority at the top of the list to the lowest priority at the bottom. The lowest level object is drawn first, the second to lowest level object is drawn next, and so on, until the top of the list.

To change the drawing order of objects:

- 1 In the Priority Editor, select the object.
The selected object name is highlighted in yellow.
- 2 Click the Push To Back button to move the selected object one position lower in the stack, or click the Bring To Front button to move the selected object one position higher in the stack.
When you move an object in the stack, a keyframe is added to the timebar.

- 3 Click Preview to ensure that the drawing order is correct.
Occasionally, a matte may obscure another object if the drawing order is unordered. If this happens, move the surface up and down in the stack until the drawing order is corrected, or click Z-Sort.

TIP You can also select and drag a media (or multiple media using `Ctrl`) while holding the `spacebar`.

Grouping Media

Select objects in the Priority Editor and group them to edit or affect several media at once. You can analyse or Z-Sort groups as you would single media.

Groups are named according to their contents. For example, if a group is created from Image 3 and Image 32, the Group's label will be "Image 2 Image 32".

It is not possible to add a scene object to an existing group. To do this, you must ungroup the objects, reselect those you want to include in the group, and click Group.

NOTE Single element groups cannot be created.

To create groups in the Priority Editor:

- 1 Select multiple scene objects in the Priority Editor using either `Alt`-click for individual objects or `Shift`-click to select a range.
- 2 Click Group in the Priority Editor menu.
Media is minimized to a single line in the Priority Editor. To expand the group and view its contents, click the arrow to the left of the group.

- 3 Scene objects can be ungrouped by clicking Group once again.

Analyze, Z-Sort, and the Z-Buffer

When you use Analyze or Z-Sort, the objects in the scene are compared using their position in the scene and not the individual pixels of a shape or model. The Priority Editor uses distance between the camera and the nearest and farthest points on the objects in the scene to determine the sorting order.

Since the Priority Editor is geometry based and not polygon based, you cannot properly order objects or groups that intersect due to their rotation, scale, or shear values. The Z-buffer uses the Z-value of each pixel for the sorting order. Use the Priority Editor in conjunction with the Z-Buffer box in the Setup menu Rendering section.

(a) Z-buffer box

When Z-buffer is on, objects and groups are arranged according to their distance from the camera eye. Since the camera is pointed towards the Z-axis by default, objects and groups are arranged according to their location on the Z-axis. In the following example, Image A is at Z position 200, Image B is at Z position 100, and Image C is at -50. When Z-buffer is on, Action draws these images as shown.

If you move the camera, objects are sorted according to the axis the camera is pointed towards.

When Z-buffer is off, the distance of objects from the camera eye is not considered. Objects are drawn in the order shown in the Priority Editor. To follow the previous example, you can turn off Z-buffer and change the priority of Image B so that it is drawn on top of both Image A and Image C. The Z position of these images is therefore ignored.

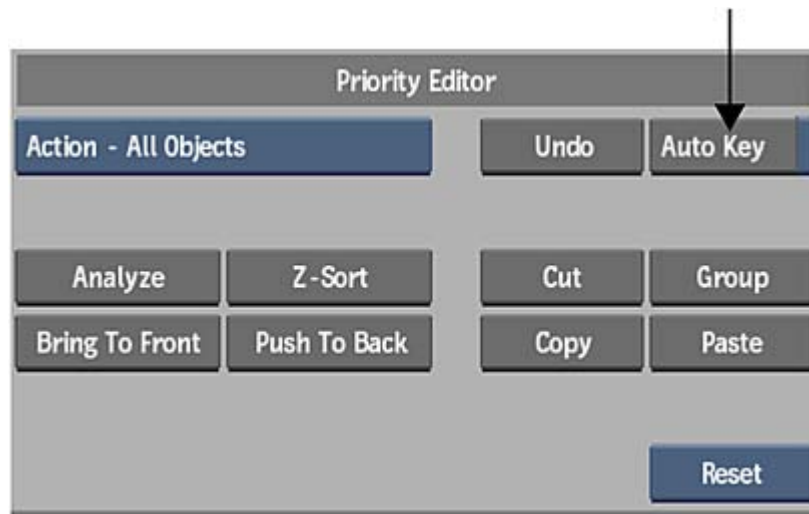

Shadow Mix, like Z-buffer, arranges objects according to their distance from the camera eye. Use Shadow Mix so that each shadow is rendered in the correct Z order with its corresponding surface.

Creating Keyframes Using the Priority Editor

When you edit media priorities in the Priority Editor, keyframes are not created by default. To create keyframes from the Priority Editor, the Auto Key button must be enabled. By default, the Auto Key button is set to off so as not to create keyframes when reordering media.

To create keyframes for a media priority change:

- 1 Display the Priority Editor by clicking the Priority button, or swipe the bar at the bottom of the Media or Object menu.
- 2 Click Auto Key to enable auto-keyframing.

- 3 Reorder priorities at different points in the timebar. Keyframes are automatically created as priorities are edited.

NOTE Stop all priority auto-keying anytime by disabling the Auto Key button.

Priority Editor Settings

Action Layers Selection box Based on the object selection in the Action scene, select an option to determine which Priority Editor to display.

Analyze button Click to analyze the entire scene for changes in rendering priority.

Z-Sort button Click to analyze the current frame for changes in rendering priority.

See [Analyze, Z-Sort, and the Z-Buffer](#) (page 498).

Bring To Front button Click to move the selected object one position higher in the stack, in front of the next higher object.

Push To Back button Click to move the selected object one position lower in the stack, behind the next lower object.

Undo button Undoes the last Priority Editor operation, except for Z-Sort or Analyze.

Use Action's Undo List to view a list of recent operations and revert to a prior state. Select an item in the list to return to that state. All actions that occurred after the selected item are undone.

Auto Key button Enable to create keyframes when reordering media. See [Creating Keyframes Using the Priority Editor](#) (page 500).

Group button Click to create groups of selected media (use this to analyze, Z-Sort, or manage several lines of media at once). See [Grouping Media](#) (page 498).

Cut button Click to cut priority information between frames.

Copy button Click to copy priority information between frames.

Paste button Click to paste priority information between frames.

NOTE A mark indicates when a change in priority occurs. If you copy and paste a mark that does not change the priority, no mark appears on the timebar.

Reset box Select whether to reset priority information for the current frame or for all frames.

About Stereoscopic Workflow in Action

A stereoscopic workflow in Action allows you to create stereo composites using 3D and stereo elements. With the stereo camera rig (the 3D camera), you can access stereo rigs and monoscopic cameras. With support for multiple outputs, you can experiment with any number of passes, including left and right scene output, as well as normals, Z-Depth, matte, media matte, and composition outputs.

When working in a stereoscopic compositing workflow in Action, there are three essential elements: a stereo camera, a stereo object for viewing and adjusting the result, and outputs. The following table outlines the stereoscopic workflow in Action.

Step:	Refer to:
1. Bring stereo clips into Action.	Starting a Stereoscopic Session (page 501).
2. Work with the stereo camera and stereo object to make any adjustments to the scene.	About the 3D Camera (page 671) and Working with the Stereo Scene (page 502).
3. Output various passes of your work.	About Rendering Outputs from Action (page 450).

NOTE Since Action as a timeline FX uses only one front/matte media, stereo clips are not supported. If you need to work with stereo clips, access Action from Batch or Batch FX, or from the Tools menu.

Starting a Stereoscopic Session

You can start a stereoscopic session in Action by loading stereo clips and using the Stereo Startup mode. This creates a stereo camera. The output is set to the stereo camera, a stereo object is created for visualizing the scene, and the clips are placed on separate lines in the Media list.

NOTE A stereo clip cannot be loaded in Action if it is selected as the Back or MultiVersion input, or if it is selected to replace a clip in the Media list. Also, since Action as a timeline FX uses only one front/matte media, stereo clips are not supported.

When using a stereo clip, its left and right eye tracks are automatically split and placed on individual lines in the Media list. Also, new clips appear in the workspace. They retain the name of the original clips, and are appended with a “_Left” or “_Right” suffix. It is important to save these clips, as they are used for loading an Action setup or loading the previous Action session.

NOTE It is not possible to select a mono clip as the Matte input if the Front input is stereo, and vice versa.

To start a stereo session from the Tools tab:

- 1 Click Action.
- 2 From the Input Mode box, select one of the following:
 - Clear All to delete all media and objects from the previous setup. Select stereo clips for the front and matte input. This is the Stereo Startup mode.
 - Front/Back/Matte to enter Action using the previous setup. Select stereo clips for the Front and Matte input, and a mono clip for the Back input.

NOTE If you enter Action using mono clips, the default camera is automatically created. If you need a stereo camera, you must add it manually.

- 3 Select the destination.

If you selected Clear All and selected stereo clips for the Front and Matte input before entering Action (Stereo Startup mode), the following is created:

 - In the schematic, a 3D camera (stereo camera) is created and the default camera is hidden.
 - In the Output menu, the Mode is set to Stereo and the Camera is set to Result Cam.
 - In the Camera menu, the result camera is set to the 3D stereo camera.
 - A stereo object is created with the clips you selected.
 - In the Media list, the Front and Matte inputs are split into separate lines for the right and left eye.

NOTE If you entered Action using the Front/Back/Matte option and want to clear all previous settings and use the Stereo Startup mode, click the Reset To Stereo Mode button in the Action Setup menu. You will now have to bring in new clips.

When you exit Action, the workspace contains left and right clips for the Front and Matte inputs for a total of four new clips.

Working with the Stereo Scene

When working in a stereoscopic workflow, the stereo object lets you visualize the scene. The stereo object lets you composite stereo sources in Action, ensuring the stereo effect of the stereo source is preserved during the compositing process. You can combine stereo objects with 3D geometry, such as 3D text or FBX models within the same scene.

The stereo object is a single image surface which contains two diffuse maps (left and right) for handling stereo sources. When working in a stereoscopic workflow in Action, you must handle the left and right eye as separate media in the Media list. When a stereo object is filmed by a stereo camera, a link is created between the left image of the object and the left camera of the stereo rig. This is the same for the right image and right camera. The link ensures that left-eye material is only visible through the left camera, and likewise, right-eye material is handled with the right camera.

NOTE Entering Action with a stereo clip will automatically create a stereo object with the stereo clip used as the left and right material.

To add a stereo object to a scene (not applicable if you accessed Action as a timeline FX):

- 1 In the Media list, select the media for the left eye. Press **Ctrl** and select media for the right eye.

NOTE By default, the first clip you select is the media for the left eye. You can select multiple pairs of left-right media. Odd numbered selections are considered as left media and even numbered selections are the right media when creating stereo objects.

- 2
- Create a stereo object for the media by doing one of the following:
- Drag the Stereo Object node from the node bin and place it in the schematic.
- Drag the Stereo Object node from the node bin and place it where you want it in the Result view.
- Double-click the Stereo Object node. You do not need to be in Schematic view to add a node in this manner.

The stereo object is added to the scene.

- 3
- To display a selected viewport in any of the stereo modes (Anaglyph Mono, Anaglyph Dubois, Blend or one of the Difference modes), select one from the Stereo mode button in the lower-left corner of the viewport.

NOTE The viewport must be set to Result.

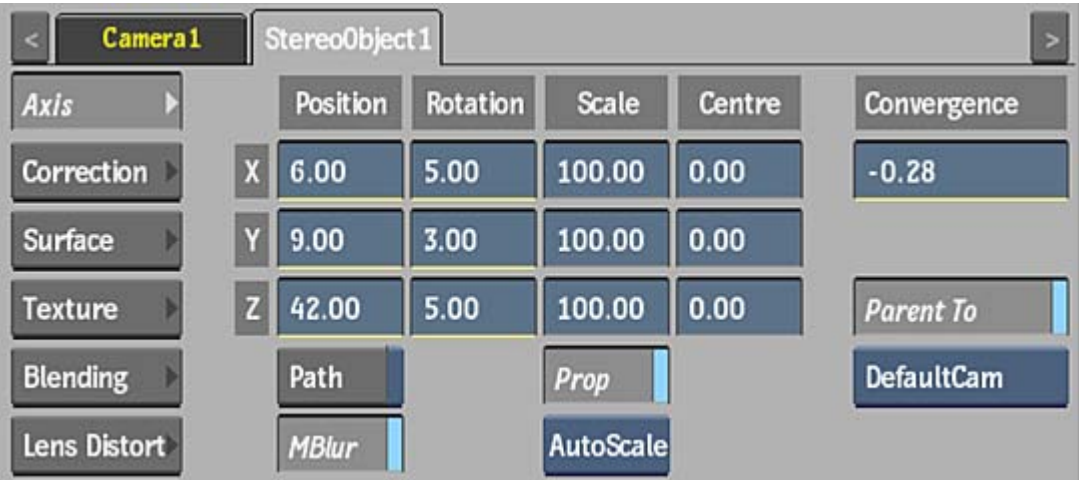

- 4
- To open the Stereo Object menu, double-click the StereoObject node in the schematic.

Stereo Object Settings

Since Action as a timeline FX uses only one front/matte media, stereo clips are not supported. If you need to work with stereo clips, access Action from Batch or Batch FX, or from the Tools menu.

Stereo Object Axis Settings

Use the Axis tab of the Stereo Object menu to position, rotate, scale, and shear an axis, as well as adjust the convergence, parenting, and autoscaling of stereo objects.

The Position, Rotation, Scale, and Centre settings are the same as in the Axis menu. The following Axis settings are specific to the Stereo Object:

Autoscale box Select whether to autoscale when settings are changed relative to the camera.

Select:	To:
Auto Off	Not use autoscaling on the image.

Select:	To:
Auto Z	<p>Link the Position Z parameter with Convergence. This allows you to see how a change in the Convergence value makes the object appear to move closer or farther from the camera. This preserves the same visual aspect while scaling the textures up or down accordingly.</p> <p>NOTE The result camera must be set to the stereo camera.</p>
AutoScale	<p>Change the left and right texture parameters when the Position Z or a Scale parameter is changed. When you create a stereo object, it is automatically oriented towards the camera and automatically scales. That is, the apparent size of the images scale to compensate when you move the stereo object along the Z axis. If you move a stereo object away from the camera, it grows, and vice versa.</p> <p>NOTE The result camera must be set to the stereo camera.</p>

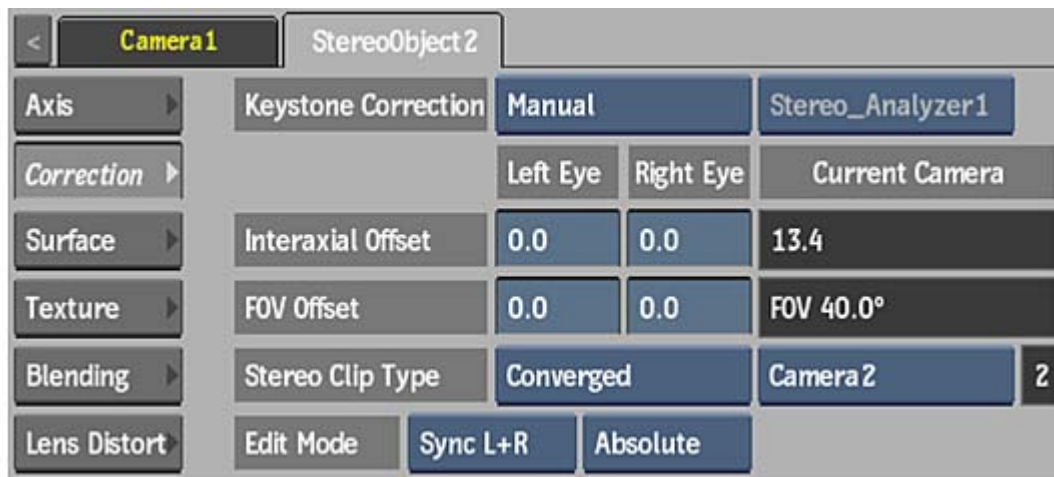

Convergence field Displays the equal amount of convergence in opposite directions horizontally, between left and right images. Positive values make the image appear farther from the camera. Editable.

Parent To button Enable to associate a stereo object with the camera selected in the Parent Camera box. Enabled by default to force the stereo object to face the 3D camera at all times when the camera is moved around.

Parent Camera box Select which camera in the scene is associated with the stereo object. Setting found in the Axis and Correction tabs.

Stereo Object Correction Settings

Use the Correction tab of the Stereo Object menu to indicate how the footage was shot, and make interaxial offset and FOV offset adjustments to the left/right images.

Keystone Correction box Select whether to apply keystone corrections manually in this menu, use the automatic settings derived from the selected analyzer, or inherit the Stereo Mode settings from the stereo camera (Pass Through).

In most cases, a keystone correction is needed if the stereo types of the camera and the stereo object do not match, but there may be cases when you want to sync the two.

Correction Analyzer box Select which analyzer is used to provide automatic keystone corrections.

Interaxial Offset Left Eye field Displays the offset distance between the left eye compared to the 3D camera. Editable.

Interaxial Offset Right Eye field Displays the offset distance between the right eye compared to the 3D camera. Editable.

Interaxial Offset Current Camera field Displays the interaxial offset of the selected camera. Non-editable.

FOV Offset Left field Displays the offset field of view between the left eye compared to the 3D camera. Editable.

FOV Offset Right field Displays the offset field of view between the right eye compared to the 3D camera. Editable.

FOV Offset Current Camera field Displays the offset field of view of the selected camera. Non-editable.

Stereo Clip Type box Specify how the footage was shot: Parallel, Off Axis, or Converged.

Parent Camera box Select which camera in the scene is associated with the stereo object. Setting found in the Axis and Correction tabs.

Camera Number field Displays the number of the selected camera. Non-editable.

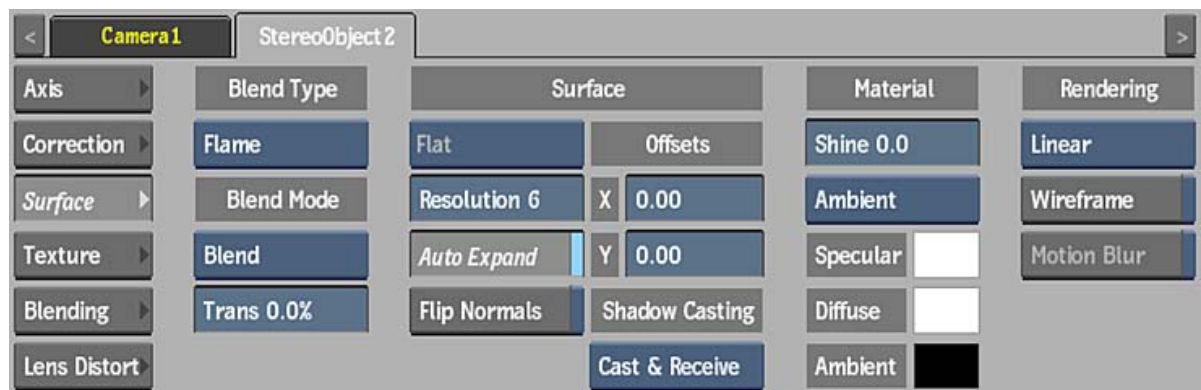

Tools box Select whether to sync the left and right eye correction values.

When synced, a change to one value affects the other value. The left eye position is a combination of the camera's left eye position and the left interaxial offset; the same applies for the right eye. The effective FOV for the correction is the sum of the camera's FOV and the FOV offset.

Sync Type box Select whether the relationship between the left and right eye correction values is absolute or relative. Available when Sync L+R is selected in the Tools box.

Stereo Object Surface Settings

Use the Surface tab of the Stereo Object menu to adjust surface and shading properties of the stereo object.

The Surface tab settings are the same as in the Object Image menu for non-stereo objects. See [Surface Settings](#) (page 474).

Stereo Object Texture Settings

Use the Texture tab of the Stereo Object menu to set the built-in diffuse maps (as well as any added texture maps) of a stereo object.

X Position field Displays the position of the X axis. Editable.

Y Position field Displays the position of the Y axis. Editable.

Z Position field Displays the position of the Z axis. Editable.

X Rotation field Displays the rotation of the X axis. Editable.

Y Rotation field Displays the rotation of the Y axis. Editable.

Z Rotation field Displays the rotation of the Z axis. Editable.

X Scale field Displays the scale of the X axis. Editable.

Y Scale field Displays the scale of the Y axis. Editable.

Z Scale field Displays the scale of the Z axis. Editable.

Proportional button Enable to change the fields proportionally.

X Shear field Displays the shear of the X axis. Editable.

Y Shear field Displays the shear of the Y axis. Editable.

Z Shear field Displays the shear of the Z axis. Editable.

X Centre field Displays the centre of the X axis. Editable.

Y Centre field Displays the centre of the Y axis. Editable.

Z Centre field Displays the centre of the Z axis. Editable.

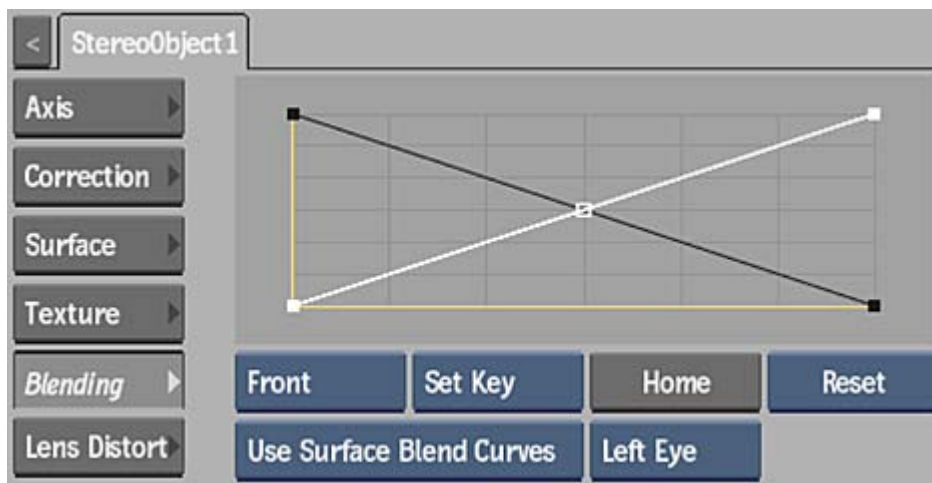

Tools box Select whether to sync the left and right eye texture values.

Sync Type box Select whether the relationship between the left and right eye texture values is absolute or relative. Available when Sync L+R is selected in the Tools box.

Texture Eye box Select whether to apply changes to the left or right eye and display the values of the left or right texture.

Stereo Object Blending Settings

Use the Blending tab of the Stereo Object menu to adjust the blending curves of each stereo surface separately. The blending curve is similar to the Keyer luminance blending curve, but you can adjust it per eye.

You can switch between the stereo surface blend curves and the keyer blend curves. This gives you a good comparison to luminance curve work you have already done in the Keyer.

The Blending tab settings are the same as in the Object Image menu for non-stereo objects. See [Applying Blending Curves per Surface](#) (page 487). One extra setting is available for stereo objects, allowing you to select which eye to apply blending curves.

Eye Selection box Select which eye to apply the blending curves. Select Both Eyes to apply the same blending settings to both eyes. In this case, the settings of the last selected eye apply to both eyes.

Stereo Object Lens Distort Settings

Differences in camera lenses or perspective irregularities cause lens distortion that results in skewed angles. Use the settings in the Lens Distort tab to rectify or simulate these types of distortions in your stereo images.

The Lens Distort tab settings are the same as in the Object Image menu for non-stereo objects. See [Lens Distort Settings](#) (page 482).

About the Perspective Grid

Use the Perspective Grid node to help you with perspective alignments in your Action scene. The perspective grid creates a rectangle on a plane within the perspective of the clip. The accuracy of the plane determines

whether any adjustments are properly scaled and oriented in your clip. Objects can be placed anywhere on this plane. Aligning objects to the perspective grid has multiple benefits:

- You can perform a 4-corner pin with a surface or geometry that respects the perspective.
- Aligning the grid establishes the orientation of the plane in 3D space and the Field of View (FOV) of the camera that shot the scene.
- Because the Perspective Grid node has an axis-like behaviour, objects attached to it inherit the grid's 3D transformations.

Aligning an Object with a Perspective Grid

To align an object with a perspective grid:

- 1 Click Media.
- 2 In the Media menu, select the media you want to use for the perspective grid (you can change the media later in the Perspective Grid menu).
This media becomes the reference for the perspective grid alignment.
- 3 Do one of the following:
 - Drag the Perspective Grid node from the node bin and place it in the schematic.
 - Drag the Perspective Grid node from the node bin and place it where you want it in Result view.
 - Double-click the Perspective Grid node. You do not need to be in Schematic view to add a node in this manner.

The Perspective Grid object is added to the schematic. In the Schematic view, the number in brackets next to the name of the node indicates the media used for the perspective grid reference.

To specify different perspective grid reference media, select the media in the Media menu, then click Apply, or enter a different media number in the Use Media field of the Perspective Grid menu.

- 4 With the Perspective Grid object selected in the schematic, select Action Object Solo view from the View box (or press F8) to see the grid and the selected media.

- 5 While in Action Object Solo view, drag each of the four corners of the rectangle to the desired location. The grid automatically aligns to the new perspective.

NOTE When dragging one of the corner points of the rectangle, if your desired location cannot be computed (for example, if a point goes past another point on the plane), the location is remembered with a dotted line and red circle. Once you move other corners, your original location may now become viable, and the rectangle and grid align properly.

- 6 Once you are satisfied with the alignment of the perspective grid rectangle, parent an object to the Perspective Grid node. The object inherits the perspective transformation of the Perspective Grid node. Switch to Result view (F4) to see the complete scene.

NOTE You can also manipulate the perspective grid in the Result view, provided that Lock Camera is not selected in the Camera Adjustment box of the Perspective Grid menu, or the perspective grid camera is the same as the Result camera.

Working with FOV

The Camera Adjustment box in the Perspective Grid menu allows you to animate the perspective grid by positioning corner points in other frames. To create an animated transform, place the grid in the first frame, then select Lock Camera in other key frames. You can also select Lock Camera if the camera FOV does not change over the length clip.

If you select Allow Adjustments in the Camera Adjustment box, Action will solve for the FOV in each frame on which you edit the corners. The target camera FOV and position adjusts to fit the perspective set by the perspective grid. If Lock Camera is selected, the perspective grid does not adjust the target camera. To use

the existing value in the camera and not solve for it, regardless if you animate the perspective grid, you should select Lock Camera before positioning in the first frame.

NOTE When the FOV of the camera is computed (not locked), the camera is repositioned in order to frame the media.

Perspective Grid Menu Settings

Camera Adjustment box Select Allow Adjustments to allow adjustments of the target camera FOV and position. Select Lock Camera to lock camera FOV and position.

Perspective Camera box Specify which camera to view the perspective grid in Object view, and for modifying its FOV when working with the perspective grid.

Perspective Camera field Displays the active perspective camera number. Non-editable.

Stereo Camera Perspective box Select whether to use the left or right camera from a stereo camera rig when working with the perspective grid.

FOV field Displays the field of view of the active perspective camera. When adjusting the perspective grid, the FOV of the target camera updates automatically (unless Lock Camera is enabled). Non-editable.

Width field Displays the width of the four-point perspective grid rectangle. Editable.

Height field Displays the height of the four-point perspective grid rectangle. Editable.

Size box Select whether to only affect the height or width of the grid when dragging directly in the image window. Select No Size Adjust Enable to lock the width and height of the perspective grid rectangle (in this case, only the Z Offset is updated when dragging).

Use Media field Displays the number of the media associated with the perspective grid. You can change the media number in this field, or select a media entry in the Media List and click Apply.

Z Offset field Displays the amount of offset to apply along the Z axis to make the grid larger or smaller while maintaining the visual result. Editable.

Display Grid button Enable to display the grid lines in Result or Object view.

Grid Colour pot Displays the colour of the grid lines. Click to change the colour.

Magnifier button Enable to display the magnifier while dragging a corner of the perspective grid rectangle.

Zoom field Displays the zoom factor of the magnifier. Editable up to 5x.

Reset button Click to reset the perspective grid settings (does not reset the active perspective camera settings).

About Lights and Lighting Effects

Objects are lit up in the scene according to the number, position, direction, and colour of light sources, as well as the rotation and spread of each light source.

You can add up to 64 active light sources to a scene. You can also control each light individually. By default, the light you add to the scene is applied to all surfaces. However, you can also apply a light source to specific surfaces.

Once lights are added to your scene, you can use them to add other effects to enhance the scene, such as cast shadows, lens flares, rays, and blooming effects.

You can also use image-based lighting (IBLs) to light objects in the scene.

Adding a Light Source

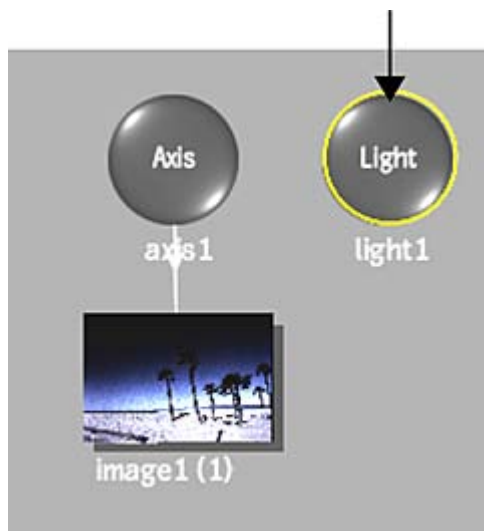

When you add a light to a scene, it is applied to all objects. Before adding another light, you may want to position the light and modify its attributes. In the Lights menu, you can set lighting properties such as position, orientation, spread, falloff, and colour.

NOTE When accessing Action as a Timeline FX, a light is automatically added to your Action scene.

To add a light to the scene:

- 1 Do one of the following:
 - Drag the light node from the node bin and place it in the schematic.
 - Drag the light node from the node bin to Result view, so you can see its effect on the scene before placing it exactly where you want.
 - Double-click the light node. The node appears next to the last added object. You do not need to be in Schematic view to add a node in this manner.

A light is added to the scene. An icon representing the light source is added to the schematic.

Unlike many objects, a light is added without an axis. To set the position and rotation of a light source, use the Position and Rotation fields in the Light menu.

- 2 To display the Light menu, double-click the selected light in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).
- 3 Enable the Active button in the Light menu to activate the light source.
The light icon appears in the scene.

(a) Light sources in the scene.

Importing Lights

In Action, you can import 3D data saved in the FBX format. FBX files may have lights and their data included, and you can use these same lights in Action. Supported light types from FBX files are Area, Directional, Ambient, Point, or Spot. See [Importing the FBX Format](#) (page 550).

Selecting a Light Source

You can select a light source in the following ways:

- Click the light source in the scene.
- In Schematic view, click the icon corresponding to the light source. All light sources initially appear at the same X, Y, and Z position in the scene (0, 0, 0). If you add two light sources, for example, you need to move one light source in order to see the other.
- Select a Light folder in the Channel Editor.
- Use the Prev and Next buttons to select the previous or next light source.

Using the Light Bevel Curve

The bevel curve allows you to create unique lighting effects in conjunction with the Spread field in the Light Basics tab. Since a spread value of 90 or less creates a spotlight, you can then create a bevel curve to act as a multiplier of the spotlight intensity.

For example, a curve such as this.

Results in a lighting ripple-like effect.

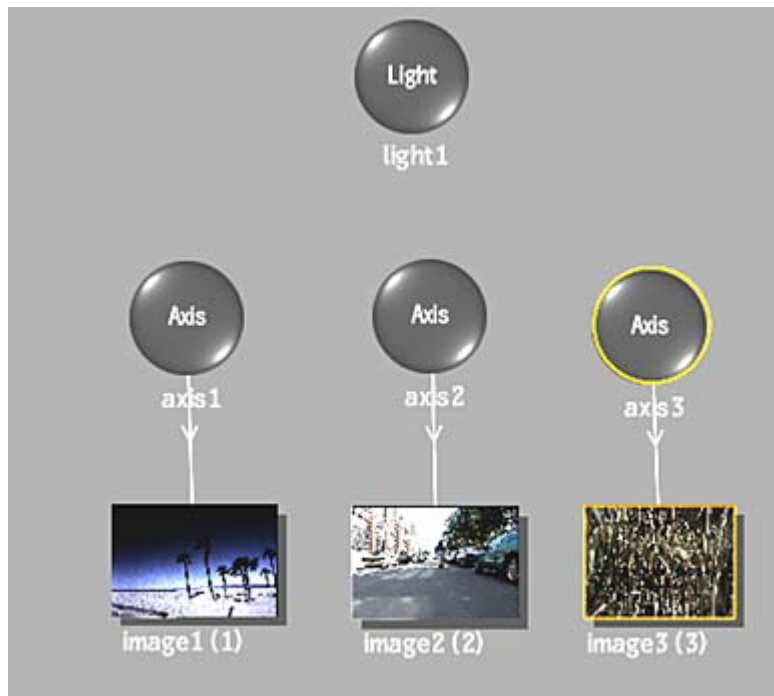

TIP To create black holes in your lighting effect, use values below zero on the Bevel curve.

Applying Selective Lighting

When you add a light source to a scene, the light is applied to all surfaces. You may want a light source to only illuminate an individual or specific group of surfaces, or prevent a light source from illuminating an individual or specific group of surfaces.

To apply selective lighting:

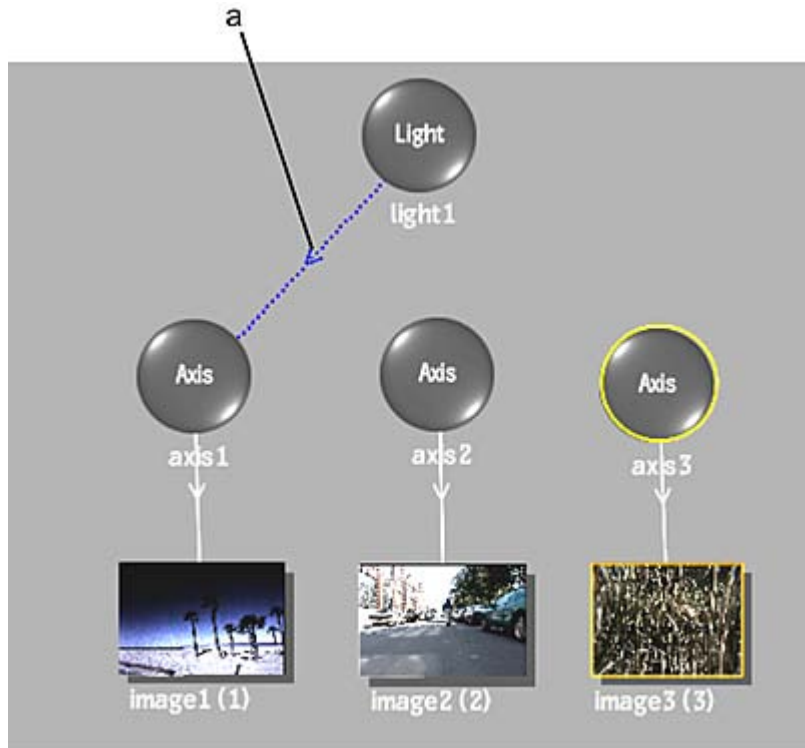

- 1 Add multiple surfaces to the scene.
- 2 Add a light to the scene.
All surfaces are illuminated.

3 Select Lighting from the Tools box.

4 To illuminate only a selected surface, click the light node, and drag it to an axis or image you want illuminated.

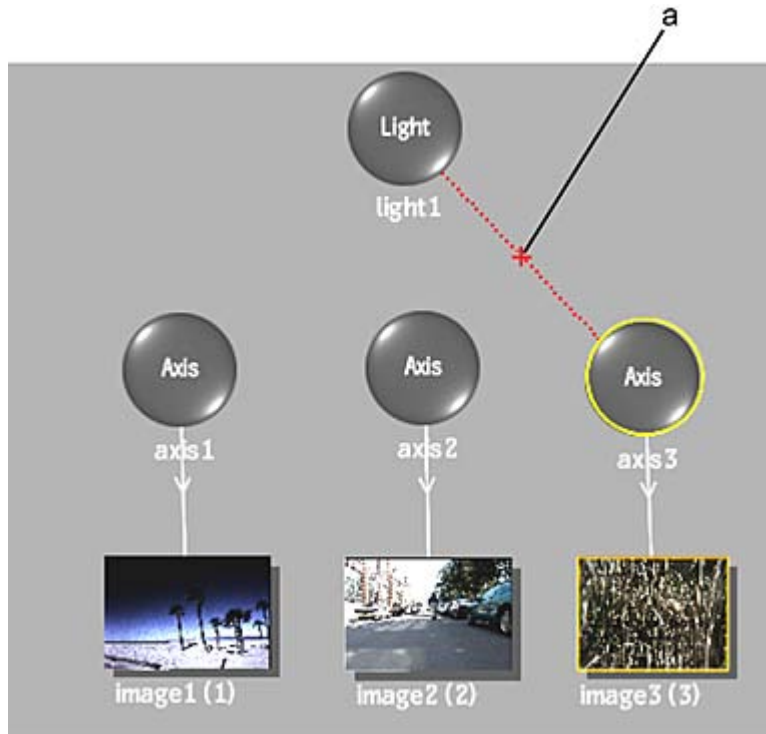

The selected object is connected to the light source by a blue dotted line with an arrow, and only the selected surfaces are illuminated.

(a) Light inclusion link

- 5 To exclude a surface, hold the **Alt** key while clicking and dragging from the light source to the surface you do not want illuminated.

Excluded surfaces are connected to the light source by a red dotted line with an “X”, and they are not illuminated. In the following example, all surfaces are illuminated, except for image3, which is excluded.

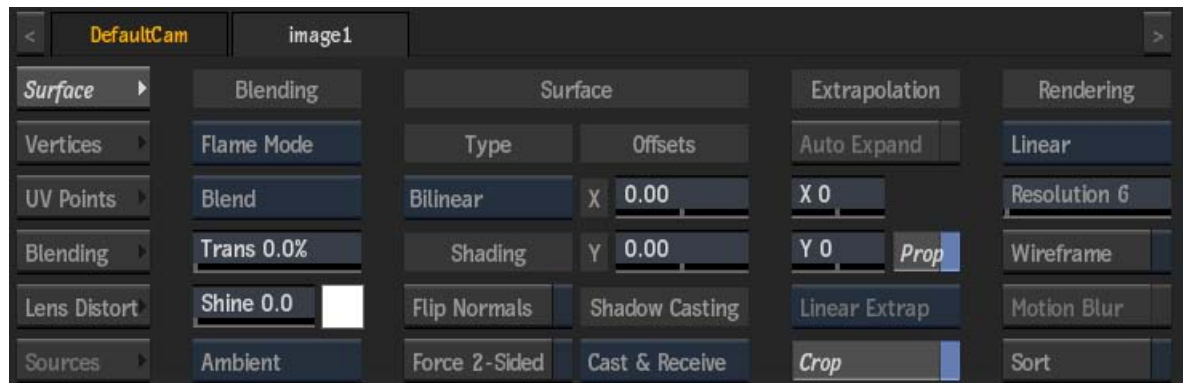

(a) Light exclusion link

NOTE To remove the inclusion or exclusion link, while still in Lighting mode, click and drag over the line that connects the light source to the axis or image.

Modifying Surface Lighting

After you set the parent-to-child relationships between lights and surfaces, you can set specific surface lighting properties. You control a surface's lighting and adjust the surface's specular highlight in the Surface menu. To access the Surface menu, double-click the selected surface in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).

The Surface settings that relate to lights are described as follows.

Specular Highlights

A specular highlight is a reflection of a light source. The position of the specular highlight depends on the position and number of light sources surrounding a surface and the angle of the camera.

Use the Shine field to change the intensity of the specular highlight. When the Shine value is set to 0, the specular highlight is disabled. To change the size of the specular highlight, use the Falloff field in the Light menu.

By default, the specular highlight is the same colour as the light source. You can change the colour of the specular highlight by changing the specular colour values.

The specular colour is the colour of light that is reflected by the surface. For example, if the specular colour is red and the light source is white, the specular highlight is red. If the specular colour is yellow and the light source is red, the highlight is orange.

Incidental Light Reflection

Set how a surface reflects incidental light by applying ambient or diffuse lighting. The actual colour of the reflection depends on both the colour value of each pixel and the colour of the incidental light. The intensity of the reflection depends on the orientation of the light source relative to the surface; it is greatest where the incident light strikes the object perpendicular to its surface. The intensity of the reflection is independent of the camera eye position.

When you turn shading on, you do not have to enable a light source to see the lighting effect, as a default infinite light source supplies ambient light at 20% intensity. The infinite light source is located behind the camera eye and cannot be moved. As soon as you add a light source, the infinite light source is replaced by the new light source.

In the Surface menu, make a selection in the Lighting box:

Select:	To reflect incidental light:
Ambient	To all parts of a surface that are not directly illuminated.
Diffuse	Equally in all directions, producing a flat reflection on the object.

TIP You can optionally adjust the colour of the incidental light using the ambient or diffuse RGB channels. To display the RGB channels, click Animation to display the Channel Editor. Expand the surface's folder (it should already be selected), expand its Material folder, then expand the Ambient or Diffuse folder.

Flipping a Surface's Normals

Flips the normals of the surface so that light is applied to the opposite side of the surface. Use to create a two-sided shaded surface. To control both surfaces, parent them by a new axis and use this axis to rotate, scale, shear, and move the two surfaces.

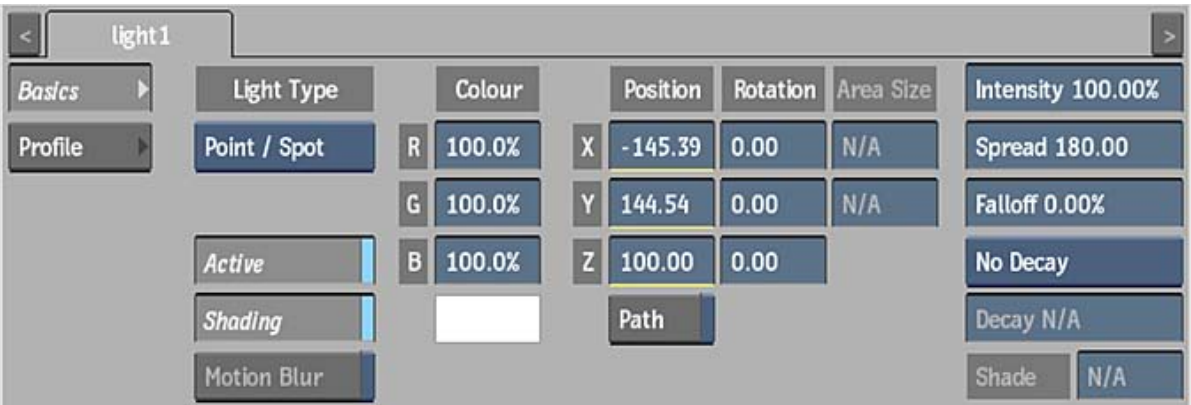

NOTE There may be a priority problem causing one surface to be drawn over the other. To correct this problem, use the [Priority Editor](#) (page 497) to animate the drawing priority of surfaces, or change the Z position of one surface by one pixel.

Converting to Wireframe

You can remove some lighting effects for a selected surface by converting surfaces to a wireframe depiction of the surface. When Wireframe is enabled, specular values and any applied textures are replaced with a wireframe view of the surface. When used on an image, the surface will adopt a screen-like look.

Light Menu Settings

When accessing Action as a Timeline FX, you have access to a quick menu with some of these Light settings. To see the full Light menu, click the Editor button to enter Action.

Light Type box Select the type of light to apply to the scene.

Light Type:	Description:	Example:
Point / Spot	A point light radiates light uniformly in all directions. A spotlight radiates a cone of light centred along the spotlight direction. Use the Spread field to change the spread angle. A spread of 90 or less creates a spotlight.	
Directional	A directional light shines evenly in one direction only. The light icon in the scene displays an arrow showing the direction of the light. Use a directional light to simulate a very distant point light source (for example, the sun as viewed from the surface of the Earth).	

Light Type:	Description:	Example:
Ambient	An ambient light shines in two ways—some of the light shines evenly in all directions from the location of the light (similar to a point light), and some of the light shines evenly in all directions from all directions (as if emitted from the inner surface of an infinitely large sphere). Use the Shade field to set the percentage on ambient light applied.	
Rectangle Area	A rectangle area light is similar to a point or spot light light except that it produces a hotspot based on the shape of the rectangle. Use the area size fields to set the size of the rectangle.	
Ellipse Area	An ellipse area light is similar to a point or spot light light except that it produces a hotspot based on the shape of the ellipse. Use the area size fields to set the size of the ellipse	

Active button Enable to turn the selected light source on.

Shading button Enable to light up the scene using added light sources. When Shading is disabled, no lighting effects appear in the scene; surfaces and 3D models appear flat.

Enable Shading for:

- Light sources
- Ambient or diffuse lighting for surfaces
- Specular highlights for surfaces and 3D models

This same button appears in the Rendering section of the Action Setup menu.

Motion Blur button Enable to use a motion blur effect for the selected light (can only be used if the global Motion Blur is enabled in the Setup menu).

Red Light field Displays the red value of the selected light. Editable.

Green Light field Displays the green value of the selected light. Editable.

Blue Light field Displays the blue value of the selected light. Editable.

Light colour pot Displays the colour of the light source. Editable.

X Position field Displays the position of the selected light along the X axis. Editable.

Y Position field Displays the position of the selected light along the Y axis. Editable.

Z Position field Displays the position of the selected light along the Z axis. Editable.

Path button Enable to animate the position of the light using a spline drawn in the scene. Disable to animate the position of a light using explicit animation.

X Rotation field Displays the rotation of the selected light along the X axis. Editable.

Y Rotation field Displays the rotation the selected light along the Y axis. Editable.

Z Rotation field Displays the rotation the selected light along the Z axis. Editable.

Width field Displays the width of an area or directional light. Editable.

Height field Displays the height of an area or directional light. Editable.

Light Intensity field Displays the intensity of the selected light. Editable.

Light Spread field Displays the spread angle. A value of 90 or less creates a spotlight. Editable

Light Falloff field Displays the amount of falloff around the edge of the light source (also changes the size of the specular highlight). Editable.

Decay Type box Select the type of decay to apply to the light source.

Decay field Displays the rate at which light decreases for the chosen decay type. Editable.

Shade field Displays the percentage of ambient light applied. Editable.

Light Profile Settings

Settings for controlling the light bevel curve are located in the Light Profile tab.

Light Bevel curve Adds a specific profile to the selected light. Use the options in the Tools box to add, select, delete, or move keyframes on the bevel curve. The bevel curve behaves in much the same way as an animation curve in the Channel Editor. See [Using the Light Bevel Curve](#) (page 512).

Home button Resets the Bevel curve viewer to show the whole curve.

Undo button Undoes the last set of Bevel curve operations.

Reset button Resets the Bevel curve.

Relighting: Casting Shadows

You can create realistic 2D and 3D shadows in your Action scene by using lights to cast and receive shadows, as well as self-shadow (an object can cast a shadow on itself).

After adding and setting up shadow casts in Action, you can output the shadow by itself, or as part of your overall composition. A shadow pass is a white image with greyscale regions that represent the shadow coverage. See [Output Options](#) (page 452) for information on the specific shadow output settings.

Action also supports drop shadows (see [Adding Drop Shadows](#) (page 494)).

Adding a Shadow Cast to a Light

Lights in the scene are able to cast shadows. You can parent a Shadow Cast object to multiple lights at once. This allows you to control the overall attributes of the shadow (for example, colour, softness, and transparency).

To add a shadow cast to the scene:

- 1 Add and position a light to your scene.
- 2 Do one of the following:
 - Drag the shadow cast node from the node bin and place it in the schematic.
 - Double-click the shadow cast node.

If there is only one light in the scene, the shadow cast node is automatically connected to it. If there are several lights in the scene, select the light in the schematic that you want parented to the shadow cast before added the shadow cast node. Otherwise, you can parent the shadow cast node to the light or lights manually in the schematic.

- 3 To display the Shadow Cast menu, double-click the shadow cast object in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

Surface and Geometry Shadow Casters

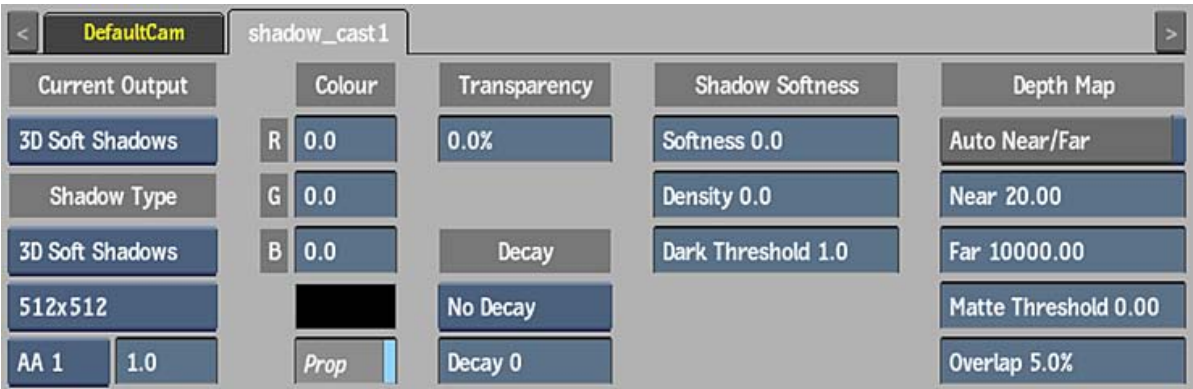

By default, all objects in the scene cast and receive shadows from a light attached to a Shadow Cast object. You can control this on a per object basis in the Object Surface or Geometry menu.

The Shadow Casting box in the Surface or Geometry menu allows you to select how the each image or geometry object is affected by a Shadow Cast object in the scene.

Select:	For the Surface or Geometry to:
Cast & Receive	Cast and receive a shadow (this is the default).
Receiver	Receive, but not cast a shadow.
Caster	Cast, but not receive a shadow.
Shadow Only	Not be displayed, but the shadow is displayed.
Off	Not cast or receive a shadow.

Shadow Cast Menu Settings

The Shadow Cast menu settings are described as follows. Shadow types are dependant on your graphics card, so you may not see all of these settings.

Shadow Output Type box Select the type of shadow to output. This setting is repeated in the Output Options section of the Output menu.

Source Shadow Type box Select the type of shadow cast for the source node. This setting is available in the Shadow Cast menu only if the shadow cast node is a child of a source node, and is repeated in the Source menu.

Shadow Type box Select a mapping type for the shadow.

Shadow Type:	Description:
3D Hard Shadows	Use 3D Hard Shadows for higher precision shadows when lights are close to the objects in the scene. These are best for hard edge shadows with penumbra effects, but can be slower.

Shadow Type:	Description:
3D Soft Shadows	Use 3D Soft Shadows if you want faster soft shadows with lights further away from your objects. These shadows offer explicit control over softness.
2.5D Shadows	2.5D Shadows work best on transparent or semi-transparent objects, for example a shadow projected on a wall by smoke.

NOTE Some of the settings in the Shadow Cast menu differ based on the shadow type you choose.

Resolution box Select a resolution to determine the quality of the selected mapping type.

Anti-Aliasing Sample box Select an anti-aliasing sampling level for the shadow cast.

NOTE Depending on your graphics card and the size of your Action scene, shadows may not appear or render properly with higher anti-aliasing sampling levels.

Anti-Aliasing Softness field Displays the softness value of the anti-aliasing sample for the shadow cast.

NOTE Jitter on 3D shadows is inherent to the shadow map technique. However, in most situations it can be go completely unnoticed. Some lighting situations which cause stretched shadows, such as lights close to the horizon, are very likely to create visible jittering. To alleviate jittering problems, you can try to use higher resolution, anti-aliasing, and anti-aliasing softness levels. In these cases, interactive manipulations in the image window may become taxing; therefore, you should activate [Adaptive Degradation](#) (page 446) for Shadows.

Red Colour field Displays the amount of red in the shadow (based on the colour of the attached light). Editable.

Green Colour field Displays the amount of green in the shadow (based on the colour of the attached light). Editable.

Blue Colour field Displays the amount of blue in the shadow (based on the colour of the attached light). Editable.

Shadow Colour pot Displays the colour of the shadow (based on the colour of the attached light). Editable.

Proportional button Enable to change the Red, Green, and Blue colour fields proportionally.

Transparency field Displays the transparency level of the shadow. Editable.

Decay Type box Select the type of decay to apply to the shadow.

Decay field Displays the rate at which the shadow decreases for the chosen decay type. Editable.

Softness field Displays the softness of a shadow. Editable.

Density field Displays the amount of dark values to include in the softness of a 3D soft shadow. Editable.

Dark Threshold field Displays the amount of light values to include in the softness of a 3D soft shadow. Editable.

Focus field Displays the softness of the 2.5D shadow based on the distance from the light. Objects closer to the focus distance are less blurred. Editable.

Colour Bleed field Displays the amount of colour bleed in the 2.5D shadow from semi-transparent objects in the scene. Editable.

Flattening Mode box Select a flattening mode for the 2.5D shadow. Most of the time, Best Fit gives the best quality, but if you see clipping artefacts in the shadow, try one of the other modes.

Penumbra field Displays the softness of a 3D hard shadow. Editable.

Sampling Mode box Select a softness sampling mode for the 3D hard shadow.

Filter Samples field Displays the amount of filter samples to take into account when creating softness (X xY) for a 3D hard shadow. Available when Regular sampling is chosen in the Sampling Mode box. Editable.

Caster Samples field Displays the amount of shadow caster samples to take into account when creating softness (X xY) for a 3D hard shadow. Editable.

Auto Near/Far button Enable to automatically set the near and far parameters for the 3D shadow based on the objects in the scene.

Near field Displays the near distance of the start of the 3D shadow. Editable.

Far field Displays the far distance of the end of the 3D shadow. Editable.

Matte Threshold field Displays the value at which the alpha casts a 3D shadow. Editable.

Overlap field Displays the amount of overlap from the light source. Increase to remove imperfections in the 3D shadow. Editable.

Relighting: Lens Flares

Use lights in your scene to generate procedural lens flares with built-in 3D occlusions.

With lens flares in Action, you can control:

- How lights change as they move behind 2D or 3D layers.
- How flares behave when a light exits or enters the camera field of view.

Lens Flares in Action are comprised of a Lens Flare object, attached to one or more Border FX objects, and any number of texture components, such as irises, streaks, and glows. To help you get accustomed to working with lens flares, a preset with typical settings is loaded when you first add a lens flare object to your scene.

You can attach multiple lens flares to a light, and multiple lights can attach to a lens flare.

TIP Use a GMask link to connect a GMask directly to the Lens Flare node in the schematic. If you then select Use As Occluder in the Post Processing box in the GMask menu, you can create interesting effects by having the GMask occlude only the Lens Flare effect.

Using Lens Flare Presets

A number of lens flare presets are included in Action, simulating the light refraction of certain camera lenses, as well as some creative flare effects, such as car lights. These presets can help you add complex lighting effects with just a few clicks.

To add a lens flare preset:

- 1 Do one of the following:
 - Drag the Presets node from the node bin and place it in the schematic.
 - Drag the Presets node from the node bin and place it where you want it in Result view.
 - Double-click the Presets node. You do not need to be in Schematic view to add a node in this manner.

The file browser opens.

- 2 From the Preset Type box, select Lens Flare.

The Lens Flare Preset file browser appears, pointing to the default location of the presets:
usr/discreet/<product home>/lensflare/presets.

- 3 Optional: Enable Scale to Action Resolution to load the preset in the current Action resolution.
- 4 Optional: Select which rendering settings to enable or disable in the preset (Z-Buffer, Shading, Polygon Resolution, and Colour Clamping).

NOTE These settings are enabled by default, and by disabling any of them, you may not see the intended results in the preset.

- 5 Select the lens flare preset you want to load. Hold **Ctrl** and click to select multiple presets.

TIP Switch to Proxies view to see a visual representation of the presets.

- 6 Click Load.

The lens flare preset is then appended to your Action scene. You may need to move the light in the image to see the full lens flare effect.

Presets Browser Settings

Preset Type box Select the category of presets to display in the browser.

Scale to Action Resolution button Enable to load the preset in the current Action resolution.

Z-Buffer button Enable to load the Z-buffer rendering settings of the preset.

Shading button Enable to load the shading rendering settings of the preset.

Polygon Resolution button Enable to load the rendering resolution settings of the preset.

Colour Clamping button Enable to load the resolution colour clamping settings of the preset.

Adding a Lens Flare to a Light

In Action, a lens flare is a child of a light. Multiple lights can be parented to the same Lens Flare object.

To add a lens flare to the scene.

- 1 Add and position a light to your scene.
- 2 Do one of the following:
 - Drag the lens flare node from the node bin and place it in the schematic.
 - Double-click the lens flare node.

A default lens flare (including a Lens Flare object, Border FX object, and multiple component texture objects) is added to the schematic. In Result view, you can see the lens flare (you may need to move the light in the scene to see the full lens flare effect).

If there is only one light in the scene, the lens flare node is automatically connected to it. If there are several lights in the scene, select the light in the schematic that you want parented to the lens flare before added the lens flare node. Otherwise, you can parent the lens flare node to the light or lights manually in the schematic.

- 3 To add a texture component to a lens flare, select the Border FX object in the schematic, then double-click a texture node in the Relighting tab of the node bin.
- 4 To display the Lens Flare menu, double-click the lens flare object in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

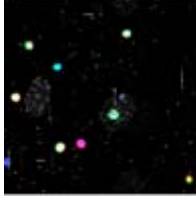

You can also add a Lens Flare using the Presets node. See [Using Lens Flare Presets](#) (page 525). In this case, a light is automatically added as part of the preset.

Using Texture Components With Lens Flares

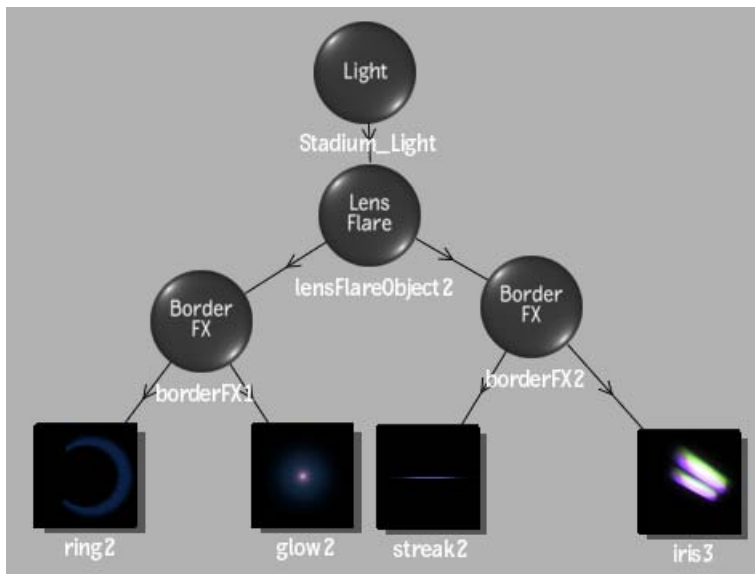

You must add texture components to the Border FX object of a lens flare to see a result. These components are textures that are attached to a Lens Flare Border FX object (or optionally, directly to a Rays or Blooming object). The Lens Flare Object menu has global settings for the complete lens flare, but each component texture has its own menu to control settings particular to it.

Each type of component can be added multiple times, each with its own settings. The following are the types of texture components you can add:

Component:	Description:	Example:
Glint Texture	Star-like texture.	

Component:	Description:	Example:
Glow Texture	Glowing loops of different colours.	
Iris Texture	Multiple shapes, such as polygons, discs, orbs, or caustics.	
Lens Texture	Lens "defects" such as hair, scratches, or fingerprints.	
Ring Texture	Rings with multi-coloured loops.	
Streak Texture	Lines streaking across the image.	

In the Action schematic, the components are attached to a Border FX object that is itself attached to the Lens Flare object. You can use multiple Border FX objects to achieve the lens flare look you want. For example, attach a ring and glow to one Border FX object, while a streak and iris are attached to another Border FX object. In this case, you can control how the lens flare behaves when it reaches the borders of your image differently for the components under each Border FX object.

TIP You can also attach multiple Border FX objects to the same texture component, to compare different Border FX settings, for example. In this case, you can use the Action Hide button to hide each selected Border FX node to see the different results.

Re-Texturing Components

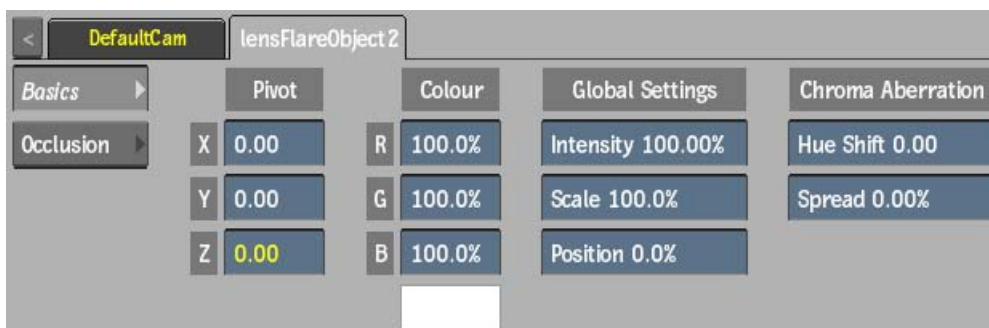

Since the components are textures, you can also re-texture a component using a Diffuse Map with your own texture media applied. To do so, select the component in the schematic, then select the media you want to use from the media list, and double-click the Diffuse Map node in the node bin. In this case, the Pattern settings in the component menu are not applicable, though you can still use the settings in the Basics and Border FX tabs of the component menu, as well as the Diffuse menu settings.

You can also use lens flare components on their own as Substance Texture presets, as a *LENSFLARE* subfolder is available in the preset browser. See [Substance Textures](#) (page 592) for more information.

Lens Flare Menu Settings

The Lens Flare Object menu lets you control settings for the complete lens flare effect. The Border FX object and each attached component texture also have their own specific menus.

Basics Tab

Position X field Displays the screen space position along the X axis of the Lens Flare pivot point. Editable.

Position Y field Displays the screen space position along the Y axis of the Lens Flare pivot point. Editable.

Position Z field Displays the screen space position along the Z axis of the Lens Flare pivot point. Editable.

Red Colour field Displays the amount of red in attached flare components (based on the colour of the attached light). Editable.

Green Colour field Displays the amount of green in attached flare components (based on the colour of the attached light). Editable.

Blue Colour field Displays the amount of blue in attached flare components (based on the colour of the attached light). Editable.

Flare Colour pot Displays the colour of the attached flare components (based on the colour of the attached light). Editable.

Global Intensity field Displays the intensity of the attached flare components (multiplied by the intensity of the attached light). Editable.

Global Scale field Displays the scale of the attached flare components. Editable.

Global Position field Displays the position of attached flare components in relation to the light (0%) and pivot point (100%). Editable.

Hue Shift field Displays the RGB offset applied to the edges of attached flare components. Editable.

Spread field Displays the amount of refractive distortion applied to the edges of attached flare components. Editable.

Occlusion Tab

Occlusion curve Displays the occlusion profile of the lens flare. Use to set the behaviour of the lens flare components when behind other objects in the scene.

Occluder Size field Displays the size of fade in/out of occluded lens flare components. Editable.

Z Threshold field Displays the transparency value at which objects start occluding the flare. Editable.

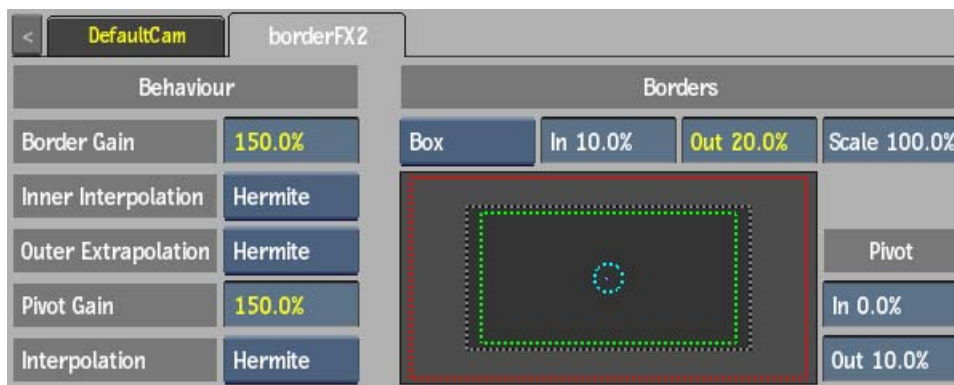

Home button Resets the bevel curve viewer to show the whole curve.

Undo button Undoes bevel curve operations.

Reset button Resets the bevel curve.

Border FX Menu Settings

Use the Border FX settings to control how the lens flare behaves when it reaches the borders of your image. A visual representation of the inner and outer borders, as well as the pivot area is displayed in the menu.

Border Gain field Displays the amount of gain to apply to the attached lens flare components when the light reaches the defined border. Editable.

Inner Interpolation box Select an interpolation type to define the transition between the border gain and the inner border.

Outer Extrapolation box Select an extrapolation type to define the transition between the border gain and the outer border.

Pivot Gain field Displays the amount of gain to apply to the attached lens flare components when the light reaches the defined pivot area. Editable.

Pivot Interpolation box Select an interpolation type to define the transition between the pivot gain and the pivot point.

Border Mode box Select whether Border FX settings are applied vertically, horizontally, or in both directions.

Inner Border Margin field Displays the position of the inner border. Editable.

Outer Border Margin field Displays the position of the outer border. Editable.

Border Scale field Displays the scale of the border that controls where the lens flare effect occurs. Editable.

Pivot Radius In field Displays the inner radius of the pivot point. Editable.

Pivot Radius Out field Displays the outer radius of the pivot point. Editable.

Component Menu Settings

Each flare component has its own menu to control settings particular to the component. Some of these settings are common among the different component types, while some are specific to the component type.

Basics 1 Tab

< DefaultCam iris4					
Basics 1		Value	Variance	Seed	Polygons
Basics 2	Intensity	0.0%	10.0%	0	Number 33
Border FX	Scale	60.0%	80.0%	10	Position 376.0%
Pattern	Spread	10.0%	0.0%	28	Negative Spread
	Rotation	0.0	0.0	0	Lock To Light
	Ratio	1.00	0.00	0	Ratio Before Rotation

Intensity Value field Displays the brightness of the component. Editable.

Intensity Variance field Displays how much the intensity varies. Available when the Number field value is greater than 1. Editable.

Intensity Seed field Displays the random intensity seed value. Available when the Number field value is greater than 1. Editable.

Scale Value field Displays the size of the component. Editable.

Scale Variance field Displays how much the scale varies. Available when the Number field value is greater than 1. Editable.

Scale Seed field Displays the random scale seed value. Available when the Number field value is greater than 1. Editable.

Spread Value field Displays the position of components in relation to each other. Available when the Number field value is greater than 1. Editable.

Spread Variance field Displays how much the spread varies. Available when the Number field value is greater than 1. Editable.

Spread Seed field Displays the random spread seed value. Available when the Number field value is greater than 1. Editable.

Spread option box Select a behaviour for the spread settings: Centre (equal), Positive (light to pivot direction), or Negative (pivot to light direction).

Rotation Value field Displays the level of rotation of the component. Editable.

Rotation Variance field Displays how much the rotation varies. Available when the Number field value is greater than 1. Editable.

Rotation Seed field Displays the random rotation seed value. Available when the Number field value is greater than 1. Editable.

Ratio Value field Displays the aspect ratio of the component. Editable.

Ratio Variance field Displays how much the ratio varies. Available when the Number field value is greater than 1. Editable.

Ratio Seed field Displays the random ratio seed value. Available when the Number field value is greater than 1. Editable.

Iris Shape box Select the shape of iris component. For other component types, this box is grayed out and displays the type of component.

Number field Displays the amount of components. Editable.

Position field Displays the offset applied to the component in relation to the light (0%) and pivot point (100%). Editable.

Lock To Light button Enable to lock the orientation of the component to the light.

Order box Select whether ratio is applied before rotation or vice-versa.

The Lens Texture component Basics 1 tab only has the following two settings (not shown):

Overall Brightness field Displays the brightness level of the Lens Texture component. Editable.

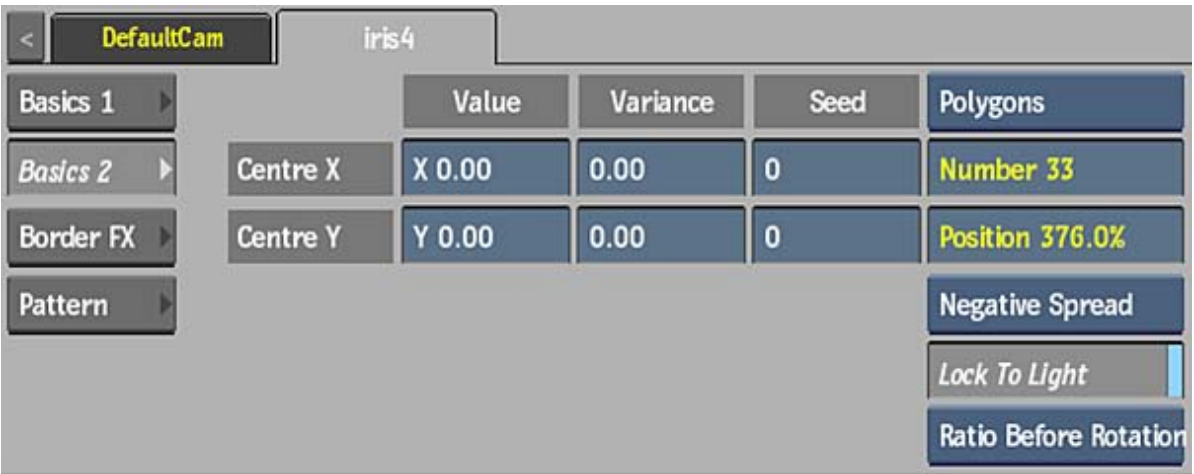

Inner Brightness field Displays how much of the lens is revealed. Editable.

The Glint component Basics tab also has the following two settings (not shown):

Overall Speed field Displays the rate at which the Glint animation plays.

Time Offset field Displays the start point of the Glint animation. With a value of 0, the animation starts at frame 1. With a value of 100, the animation begins as if it has been generating for 99 frames. You cannot animate this field.

Basics 2 Tab

Centre X Position field Displays the position of scaling and rotation of the component along the X axis. Editable.

Centre X Variance field Displays how much the centre position varies along the X axis. Available when the Number field value is greater than 1. Editable.

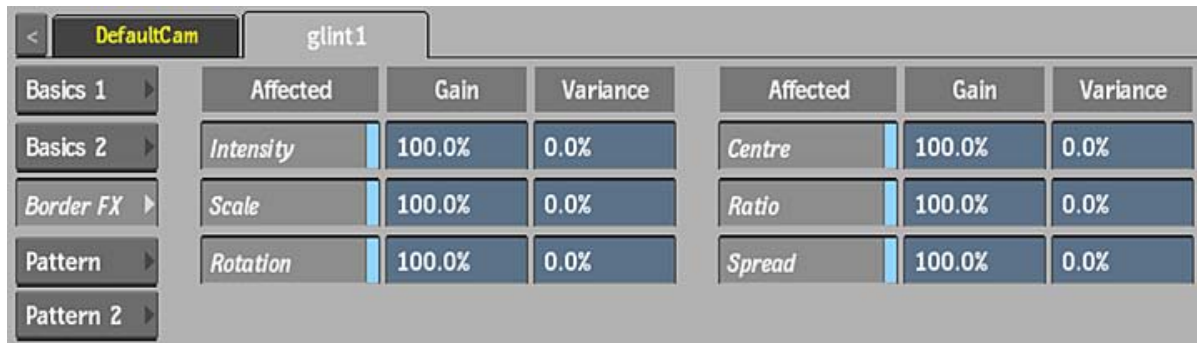

Centre X Seed field Displays the random centre X seed value. Available when the Number field value is greater than 1. Editable.

Centre Y Position field Displays the position of scaling and rotation of the component along the Y axis. Editable.

Centre Y Variance field Displays how much the centre position varies along the Y axis. Available when the Number field value is greater than 1. Editable.

Centre Y Seed field Displays the random centre Y seed value. Available when the Number field value is greater than 1. Editable.

Border FX Tab

The component Border FX settings allow you to choose which how the component interacts with the parent lens flare border settings.

Border Intensity button Enable to take into account intensity values of the parent relighting object.

Intensity Gain field Displays the amount of gain applied to the intensity. Editable.

Intensity Variance field Displays how much the intensity varies. Editable.

Border Scale button Enable to take into account scale values of the parent relighting object.

Scale Gain field Displays the amount of gain applied to the scale. Editable.

Scale Variance field Displays how much the scale varies. Editable.

Border Rotation button Enable to take into account rotation values of the parent relighting object.

Rotation Gain field Displays the amount of gain applied to the rotation. Editable.

Rotation Variance field Displays how much the rotation varies. Editable.

Border Centre button Enable to take into account centre values of the parent relighting object.

Centre Gain field Displays the amount of gain applied to the centre. Editable.

Centre Variance field Displays how much the centre varies. Editable.

Border Ratio button Enable to take into account ratio values of the parent relighting object.

Ratio Gain field Displays the amount of gain applied to the ratio. Editable.

Ratio Variance field Displays how much the ratio varies. Editable.

Border Spread button Enable to take into account spread values of the parent relighting object.

Spread Gain field Displays the amount of gain applied to the spread. Editable.

Spread Variance field Displays how much the spread varies. Editable.

Pattern Tab(s)

< DefaultCam		iris4		
Basics	Sides	6	Colour	
Border FX	Rounded	15.00	Border Colour	
Pattern	Border Size	3.00	Border Softness	0.00
	Gap	0	Blur	5.00
	Gap Softness	0.00	Softness	0.00
Regen	Gap Rotation	0		

Use the pattern settings to control the texture before it is applied to the lens flare or ray. The settings in the Pattern tabs vary depending on the component type. You can get a quick description of each setting by viewing its tooltip.

Relighting: Rays

Use rays to simulate volumetric effects. You can attach a Rays object to a light in Action.

You can position rays behind 2D or 3D objects to generate effects, although rays are still visible even without an object to outline them. When semi-transparent objects are positioned in front of the light, it is possible to generate volumetric rays that use the colour of the object.

TIP Use a GMask link to connect a GMask directly to the Rays node in the schematic. If you then select Use As Occluder in the Post Processing box in the GMask menu, you can create interesting effects by having the GMask occlude only the Rays effect.

Adding a Rays Object to a Light

In Action, a ray is a child of a light. Multiple lights can be parented to the same Rays object.

To add a ray to the scene.

- 1 Add and position a light to your scene.
- 2 Do one of the following:
 - Drag the rays node from the node bin and place it in the schematic.
 - Double-click the rays node.

A Rays object is added to the schematic. In Result view, you can see the ray.

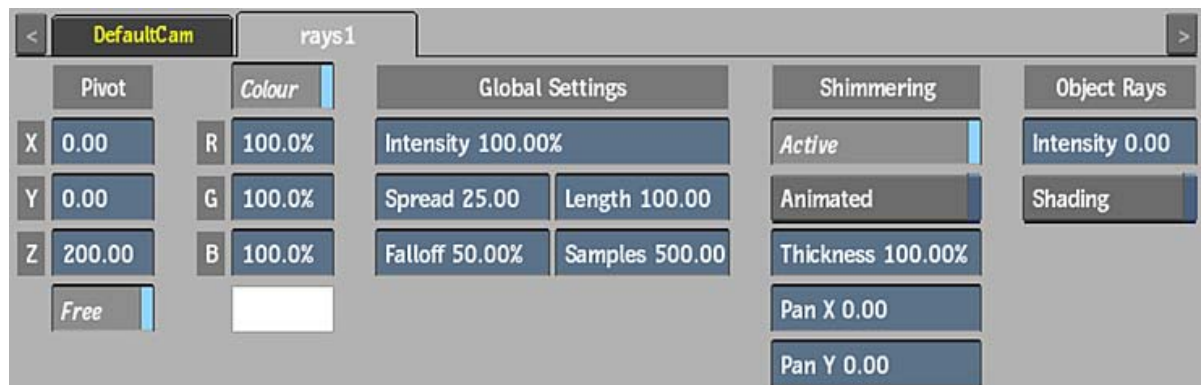

If there is only one light in the scene, the rays node is automatically connected to it. If there are several lights in the scene, select the light in the schematic that you want parented to the rays node before added the rays node. Otherwise, you can parent the rays node to the light or lights manually in the schematic.

- 3 To display the Rays menu, double-click the Rays object in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

Similar to the workflow of the Lens Flare, you can add [texture components](#) (page 526) to a rays node to enhance the effect.

Rays Menu Settings

The Rays Object menu lets you control settings for the complete rays effect. If you have added component textures to the Rays effect, each component texture also has its own menu that is specific to the component (see [Component Menu Settings](#) (page 530)).

Position X field Displays the screen space position along the X axis of the Rays point-of-interest. Unavailable if Free is disabled. Editable.

Position Y field Displays the screen space position along the Y axis of the Rays point-of-interest. Unavailable if Free is disabled. Editable.

Position Z field Displays the screen space position along the Z axis of the Rays point-of-interest. Editable.

Free button Enable to ignore transformations from the parent light object. When disabled, the ray is affected by the parent light's position, rotation, spread, and falloff settings.

Colour button Enable to add the ray colour to the colour bleed applied to semi-transparent 3D objects placed in front of the attached light.

Red Colour field Displays the amount of red in the effect and in any attached components (based on the colour of the attached light). Editable.

Green Colour field Displays the amount of green in the effect and in any attached components (based on the colour of the attached light). Editable.

Blue Colour field Displays the amount of blue in the effect and in any attached components (based on the colour of the attached light). Editable.

Colour pot Displays the colour of the effect and any attached components (based on the colour of the attached light). Editable.

Intensity field Displays the intensity of the effect and any attached components (multiplied by the intensity of the attached light). Editable.

Spread field Displays the shape of the ray cone. Editable.

Falloff field Displays the amount of smoothness applied to the borders of the ray cone. Editable.

Length field Displays the amount of softness applied to the ray. Editable.

Samples field Displays the quality of the ray based on the radial distance to the attached light. Editable.

Active button Enable to use shimmering settings to modulate the ray with noise particles.

Animated button Enable to automatically apply a noise effect to the shimmer at each frame.

Thickness field Displays the thickness of the shimmer noise particles. Editable.

Pan X field Displays the amount of movement of the shimmer noise particles along the X axis. Editable.

Pan Y field Displays the amount of movement of the shimmer noise particles along the Y axis. Editable.

Object Intensity field Displays the amount of ray colour bleed applied to semi-transparent 3D objects placed in front of the attached light. Editable.

Shading button Enable to allow the ray to inherit the shaded colours of a 3D object as it passes through the object.

Relighting: Blooming

Attach a Blooming node to a light in the scene to help define highlight areas that generate a glowing effect. You can add textures to stamp a blooming node with particular patterns, such as streaks and glints.

Blooming can affect surfaces and geometries in your Action scene, and you can also use lighting links from the attached lights to selectively include or exclude blooming from objects in the scene.

Since Blooming works in Action screen space, the effect is not limited to the surface or geometry in your scene. Note however, that while blooming can occur outside of the Action scene while you are viewing the effect in the image window, in this case you may not see the full blooming effect when you preview or process in Action. You may notice this also if you zoom in or out while viewing in the image window.

TIP Use a GMask link to connect a GMask directly to the Blooming node in the schematic. If you then select Use As Occluder in the Post Processing box in the GMask menu, you can create interesting effects by having the GMask occlude only the Blooming effect.

Adding a Blooming Object to a Light

In Action, a blooming node is a child of a light. Multiple lights can be parented to the same Blooming object.

To add a bloom to the scene.

- 1 Add and position a light to your scene.
- 2 Do one of the following:
 - Drag the blooming node from the node bin and place it in the schematic.
 - Double-click the blooming node.

A Blooming object is added to the schematic. In the Result view, you can see the bloom effect.

If there is only one light in the scene, the blooming node is automatically connected to it. If there are several lights in the scene, select the light in the schematic that you want parented to the blooming

node before adding the blooming node. Otherwise, you can parent the blooming node to the light or lights manually in the schematic.

- 3 Optional: To add a texture component, select the blooming object in the schematic, then double-click a texture node in the Relighting tab of the node bin.
- 4 To display the Blooming menu, double-click the Blooming object in the schematic, or follow the tab population rules for the Object menu.

Blooming with Texture Components

Similar to the workflow of the Lens Flare, you can add texture components to a blooming node to enhance the effect. When using blooming in Stamping mode, texture components must be attached to see any result.

The Stamping tab of the Blooming menu has global settings for all attached components, but each component texture has its own menu to control settings particular to it.

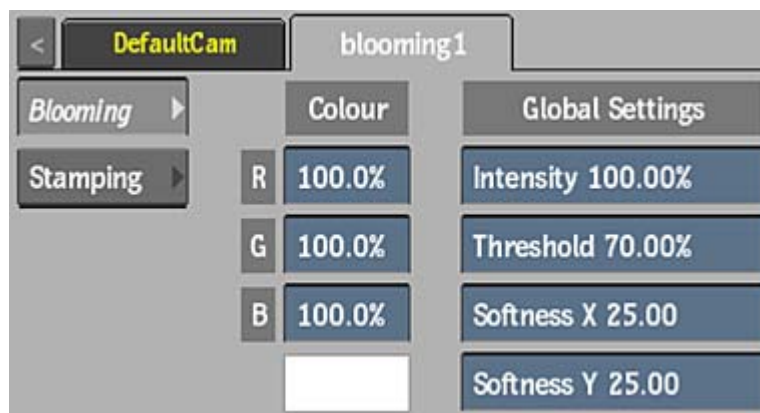

Be aware of the following when working with texture components attached to a blooming node:

- Each type of component can be added multiple times to a blooming object, each with its own settings.
- Some settings in the Basic tab of the component menu do not affect stamping, such as Number, Position, Variance, and Seed. Only one instance of the texture pattern is used for stamping, so these settings have no effect.
- You can use the Border FX settings for each component to decide how the luminance of the objects that the blooming is affecting modulates the Basics settings (Intensity, Scale, Rotation, and Ratio) of the texture pattern. Centre and Spread are not used for blooming.
- You can re-texture a component using a Diffuse Map with your own texture media applied. To do so, select the component in the schematic, then select the media you want to use from the media list, and double-click the Diffuse Map node in the node bin. In this case, the Pattern settings in the component menu are not applicable, though you can still use the settings in the Basics and Border FX tabs of the component menu, as well as the Diffuse menu settings.

Blooming Menu Settings

The Blooming menu is divided into two tabs, each with its own type of blooming effect, which can work independently, or in combination with each other.

Blooming Tab

Red Colour field Displays the amount of red in the effect and in any attached components (based on the colour of the attached light). Editable.

Green Colour field Displays the amount of green in the effect and in any attached components (based on the colour of the attached light). Editable.

Blue Colour field Displays the amount of blue in the effect and in any attached components (based on the colour of the attached light). Editable.

Rays Colour pot Displays the colour of the effect and any attached components (based on the colour of the attached light). Editable.

NOTE The same colour settings are also found in the Stamping tab.

Intensity field Displays the intensity of the effect and any attached components (multiplied by the intensity of the attached light). Editable.

Threshold field Displays the minimum luminance value at which blooming occurs. Editable.

Softness X field Displays the amount of softness along the X axis of the blooming effect. Editable.

Softness Y field Displays the amount of softness along the Y axis of the blooming effect. Editable.

Stamping Tab

For stamping settings to have any effect, you need to attach one or more texture components to the blooming node. In this case, stamping settings are global for all attached components, and each component texture has its own menu that is specific to the texture.

Red Colour field Displays the amount of red in the effect and in any attached components (based on the colour of the attached light). Editable.

Green Colour field Displays the amount of green in the effect and in any attached components (based on the colour of the attached light). Editable.

Blue Colour field Displays the amount of blue in the effect and in any attached components (based on the colour of the attached light). Editable.

Rays Colour pot Displays the colour of the effect and any attached components (based on the colour of the attached light). Editable.

NOTE The same colour settings are also found in the Blooming tab.

Stamping Intensity field Displays the global stamping intensity of all attached texture components. Editable.

Stamping Threshold field Displays the minimum value at which stamping occurs for all attached texture components. Editable.

Stamping Softness X field Displays the softness along the X axis for all attached texture components. Editable.

Stamping Softness Y field Displays the softness along the X axis for all attached texture components. Editable.

Stamping Attenuation field Displays the smoothing level of the blooming effect. Use to fade out regions that have too much blooming. Editable.

Texture Minimum Size field Displays the minimum size of all attached texture components. Editable.

Texture Scale field Displays the size of all attached texture components. Editable.

Texture Rotation field Displays the level of rotation of all attached texture components. Editable.

Texture Ratio field Displays the aspect ratio of all attached texture components. Editable.

Sampling X field Displays the size of the grid along the X axis to affect the number of samples taken to calculate the stamping effect. A higher value yields faster results, but may be less precise. Editable.

Sampling Y field Displays the size of the grid along the Y axis to affect the number of samples taken to calculate the stamping effect. A higher value yields faster results, but may be less precise. Editable.

Relighting: Image-Based Lighting (IBL)

Image-based lighting (IBL) is the process of illuminating scenes and objects (real or synthetic) using images of light from the real world. This is in contrast to using only direct light sources such as point lights or spotlights, which are more localized. A typical use of IBL is taking high-dynamic photos of a chrome ball placed in the original environment of a live-action shoot, then using the photos as an IBL map to simulate the lighting conditions of the shoot.

Light Probe Images courtesy of Paul Debevec, www.debevec.org

In Action, you can use IBL maps to:

- Colour blend images onto the backplate (the IBL map must be a shot of the environment that the backplate was taken from). This technique is useful for green screen work.
- Light 3D geometry or text objects from every direction using the colours in the environment.

You can use IBL maps to make surfaces perfectly reflective or perfectly diffuse. You can also make an IBL map act as a virtual spherical background plate.

Action supports angular, cubic, and cylindrical IBL mapping types. You can use the [Map Convert](#) (page 1395) tool to convert images to one of these types.

NOTE When accessing Action as a Timeline FX, IBL maps are not supported.

Adding an IBL Map

IBL maps behave differently than other Light FX nodes, such as Lens Flares, since you don't attach it to a light in the scene. The IBL performs lighting based on media as an environment texture.

NOTE When accessing Action as a Timeline FX, IBL maps are not supported.

To add an IBL map to the scene:

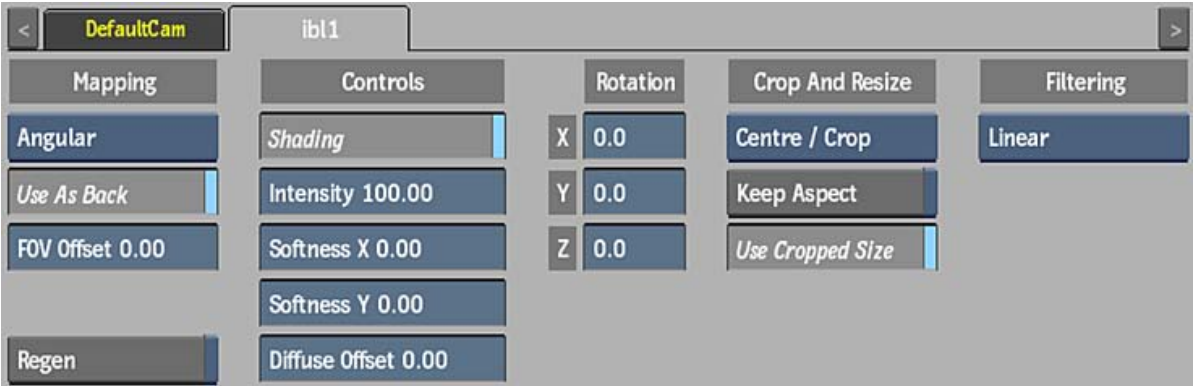

- 1 Select the media to be uses as the IBL in the image list. Any type of media can be used, including, but not limited to, *.hdr* images.
- 2 Select the node in the schematic that you want to attach the IBL map to.
- 3 Do one of the following:
 - Drag the IBL node from the node bin and place it in the schematic.
 - Double-click the IBL node.

To affect the entire scene, add an IBL map and make it a child of the Result camera (or any camera used for the comp output). To affect a specific object, make the IBL map a child of the object. You can use only one IBL to affect the entire scene, and only one IBL to affect an object.

- 4 To display the IBL menu, double-click the IBL object in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

IBL Menu Settings

The settings in the IBL menu are as follows.

Mapping box Select the type of IBL texture mapping. Use the [Map Convert](#) (page 1395) tool to convert different mapping types.

IBL Type:	Description:	Example:
Angular	Usually a high-dynamic picture of a mirrored ball.	
Cubic	A series of images shown as an unfolded cube displaying six sides of the image.	
Cylindrical	An image mapped onto an unfolded cylinder (also known as longitude and latitude maps).	

Light Probe Images courtesy of Paul Debevec, www.debevec.org

Use As Back button Enable to use the selected IBL map as the background in the scene.

FOV Offset field Displays the field of view offset applied to an IBL map that is used as a background. Use to simulate a zoom in or out of the background. Editable.

Regen button Enable to dynamically refresh the image as changes are made to the IBL settings.

Shading button Enable to light up the scene using added light sources. When Shading is disabled, no lighting effects appear in the scene; surfaces and 3D models appear flat.

Enable Shading for:

- Light sources
- Ambient or diffuse lighting for surfaces
- Specular highlights for surfaces and 3D models

This same button can be found in the Light and Action Setup menus.

Intensity field Displays the overall brightness of the IBL map. Editable.

Softness X field Displays the amount of X-axis blur applied to the IBL map (not available when Cubic is chosen as the mapping type). Editable.

Softness Y field Displays the amount of Y-axis blur applied to the IBL map (not available when Cubic is chosen as the mapping type). Editable.

Diffuse Offset field Displays the offset based on an attached diffuse map or the existing diffuse light in the image. Editable.

Rotation X field Displays the level of rotation of the IBL map along the X axis. Editable.

Rotation Y field Displays the level of rotation of the IBL map along the Y axis. Editable.

Rotation Z field Displays the level of rotation of the IBL map along the Z axis. Editable.

Fit Method box Select a fit method option to be applied to the IBL map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the IBL map with the cropped size of the IBL media. Disable to use the cropped IBL media as is.

Filter box Select the type of filtering to apply to the IBL map.

About 3D Geometry

A powerful feature of Action is its ability to import 3D models created in other applications and combine them with existing clips. Compositing 3D models and characters with other media or a background can be done quickly and with a finite level of control.

3D geometric objects are manipulated like an image or a clip: you can animate their position and shape, apply textures and media, and light objects to produce a variety of effects.

You can import 3D polygon objects such as 3ds Max files, FBX files, Alembic files, Wavefront files, Inventor files, garbage masks, and Paint geometry. 3ds Max files contain object data, specifically, texture and materials. The FBX format acts as the intermediary between different file types. Files can be exported from another product to the FBX or ABC format and then imported into Flame Premium.

Paint geometry files are created by the Flame Premium Paint tool. If you want to work with polygon geometry in Action, import Paint geometry. Action ignores its animation and attributes, such as its colour, outline, and gradient. For example, in Paint, if you create a blue polygon, animate its scale, and save it as geometry, it is imported in Action as a white polygon with no animation.

NOTE Sample 3ds Max and FBX model files are located in the *usr/discreet/<product_home>/models/(FBX or 3DS)* libraries. All models are textured with an identical image. The library consists mostly of geometric primitives such as cubes, cylinders, and spheres.

Importing 3D Models

You can import a 3D model into one or several geometry nodes. You can also import multiple 3D models into a single animated geometry node.

To import a 3D model:

- 1 Do one of the following:
 - Drag the Import node from the node bin and place it in the schematic.
 - Drag the Import node from the node bin and place it where you want it in Result view.
 - Double-click the Import node. You do not need to be in Schematic view to add a node in this manner.

The Import menu and file browser appear.

NOTE When selecting Paint, GMask, or Photoshop, the subsequent controls described in this section do not apply. When selecting FBX, other controls appear. See [Importing the FBX Format](#) (page 550).

- 2 From the Import Type box, select the import format.
- 3 If the file you want to import has a file extension different from the one specified, type a file extension.
- 4 Set any [Import Settings](#) (page 546), as needed.
- 5 Select the file to import from the file browser.
- 6 Click Load.

The 3D model (Geom node) and axis is added to the scene.

You can change the 3D model's colour, specular highlight, shine, and other material properties. See [3D Geometry Menu Settings](#) (page 552).

To import multiple 3D models into an animated sequence:

- 1 Follow the same steps for adding a single 3D model, but from the Import file browser, select multiple 3D models by holding the **Shift** or **Ctrl** key.
- 2 Once the models are selected, click Load.

The selected 3D models are loaded to the same line in the Media list.
- 3 Double-click the Geometry node in the schematic to access the Geometry menu, then click the Timing tab.

Importing Photoshop Files into Action

You can also import Adobe Photoshop® format files into Action without having to convert them into a TIFF or other format. Once imported, the PSD file keeps its inherent layer structure, which can be used or modified within Flame Premium.

NOTE This functionality is not available if you accessed Action from the timeline.

You also have the option of automatically importing all the layers at their native resolution. Each layer is parented by an axis that gives it the correct offset in the X and Y axes. Hidden layers are imported, but will remain hidden. Photoshop blend modes are maintained for each layer.

To import a PSD file into Action:

- 1 From the Action Node bin, double-click the Import node.

The file browser appears.
- 2 From the Import Type box, select the Photoshop format.

3 Select a *.psd* format file.

4 Click Load.

The Photoshop file is loaded into Action. Each layer is parented by an axis, and blend modes are maintained. The Photoshop files are added to the media list and to the Batch or Batch FX Sources folder (or to the desktop destination you set when entering Action through the Tools tab).

Import Settings

Geometry Import Settings

Depending on the type of import, some of the options differ.

Import Type box Select the 3D model type to import.

File Extension field Displays the default extension for the file type selected in the Import Type box.

Smooth button Enable to build normals for the 3D model. Enable if you are importing polygons that do not have normals.

Auto Fit In Scene button Enable to scale the imported model to fit into the current frame. When disabled, the imported model maintains the same size in which it was created.

Mesh Animations button Enable to import the Alembic scene animations and preserve complex geometry animations.

Cameras button Enable to import cameras from the Alembic format file.

Normal button Enable to import an Alembic model's normal information.

Separate Nodes button Enable to create individual nodes for all 3D models contained in a file. When disabled, the 3D model is added to the scene with its own axis.

Rotate Axis button Enable to rotate the 3D model by 90 degrees on the X-axis so that it is compatible with the target's coordinate system.

Create Media button Enable to load the textures of the geometry to the Media list. If a texture is used in multiple geometry maps, it is loaded only once in the Media list. Not available if Action is accessed as a Timeline FX.

Timing Settings

Animation Mode box Select the animation mode to use for multiple 3D geometries imported into a single animated geometry node.

Select:	To:
Loop	Play in a continuous loop.
Once	Play once. The 3D geometry is no longer displayed.
Last Still	Play once, and hold the last frame.
Timing	Animate according to the timing in the animation channel.

Hold field Displays the number of continuous frames for Loop, Once, or Last Still Animation modes. Editable.

Slip field Displays the offset to the start point for Loop, Once, or Last Still Animation modes. Editable.

Timing Range option box Select an option to determine how Frame Timing values outside the timing range of the animation are handled. Available when Timing is selected in the Animation Mode box.

Select:	To:
Roll	Roll over the Frame Timing value.
Cut	(Geometry is not displayed.)
Round	Display the first or last geometry (with this option, you can select the first and the last geometry of your animation).

Frame Timing field Displays the value for the frame in the timing curve. Available when Timing is selected in the Animation Mode box. Editable.

About 3D Data in the FBX Format

The FBX standard format provides a means for exchanging 3D data—3D polygonal models, cameras, lights, keyframe animation—for scene compositions between tools and packages developed by different manufacturers.

FBX support makes it possible to import Autodesk 3ds Max, Autodesk Maya, Autodesk MotionBuilder, Autodesk Mudbox, and Autodesk Softimage files. You can import models, scene compositions, lights, and camera data.

NOTE Flame Premium supports the import of most models, including polygonal, nurbs, and smooth bind skinning, while subdiv primitives are not supported. See the FBX [compatibility maps](#).

About Mesh Animation

Mesh animation (geometry caching) records the position of every vertex in an animated 3D scene over time. This allows character animations, animated geometry deformations, or physical simulations to be "baked" and transported in the FBX file without an understanding of the animation technique used to create the effect. By exporting FBX scenes with geometry caching, and then importing into Action with Mesh Animations enabled, you can preserve complex geometry animations, such as nCloth animations.

All imported cached geometry can still be manipulated in Action like a normal geometry. Deform meshes, texture maps, lighting, and axis manipulations are all supported on the animated geometry. Animations can also be re-timed within Action.

FBX Information Preserved at Import

Flame Premium supports the latest FBX SDK, in sync with Autodesk 3D applications. To ensure compatibility, all applications must use the same version of the FBX SDK.

The following FBX features are preserved in Action:

- Point lights, spotlights, area lights, ambient lights, and directional lights
- Shadow casting
- Object ID and material assignments
- Sub-materials, exposed explicitly in the Action schematic
- Bezier animation curves

Object Group and Material Nodes

FBX models are created with one or more faces, which leads to different representations in Action.

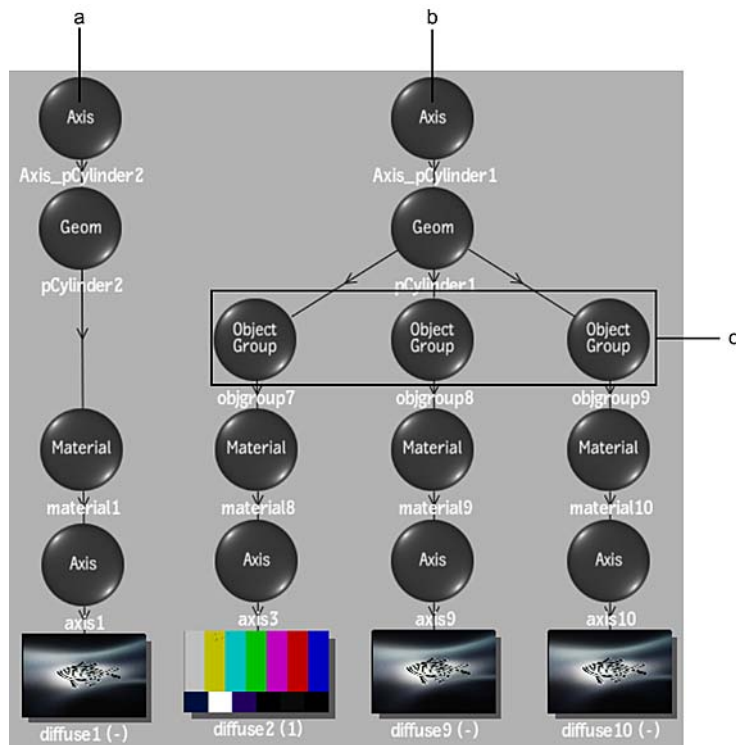

NOTE In this context, *face* actually means either a single face (such as one of six sides of a cube) or faces (such as a group consisting of 2 sides of a cube) that are grouped together to receive a single texture. How faces are grouped (if grouped at all) is decided when the model is created and cannot be modified in Flame Premium.

A model with a single face appears as a simple model, with a single Material node attached to the Geom node.

A model with multiple faces appears as a complex schematic where one Object Group node is created for each face. To each Object Group node is then attached the Material node. Having multiple Object Nodes allows you to modify, even replace, the textures applied to each shader.

You cannot create new Object Group nodes, and their link to the Geom node is unbreakable; they have no editable attributes. Object Group nodes details how faces were applied to the FBX model, and allow you to texture differently the components of the FBX model.

In the following examples, one imported FBX model has a single face, while the other has three faces, one for each sides of the cylinder.

(a) FBX model with a single face **(b)** FBX model with multiple faces **(c)** Added Object Group nodes, one for each face

The schematic above creates the image below. Note how having different Object Group nodes allows you to link different textures.

(a) FBX model with a single face: one texture map for the whole model (b) FBX model with multiple faces: a different texture for each face

Importing the FBX Format

To import FBX format data in Action:

- 1 Do one of the following:
 - Drag the Import node from the node bar and place it in the schematic.
 - Drag the Import node from the node bar and place it where you want it in Result view.
 - Double-click the Import node. You do not need to be in Schematic view to add a node in this manner.
- 2 In the Import menu, select FBX as your format type.
- 3 Use the FBX import settings, as needed.
- 4 Navigate to the location where the FBX files are located.

NOTE Make sure that you have write permissions to the folder where the FBX file is located, as Flame Premium decompresses the textures embedded in the FBX to an .fbm folder collocated with the FBX file.

- 5 Select a file from the file browser.
The FBX data is imported into Action.

FBX Import Settings

Auto Fit In Scene button Enable to scale the imported model to fit into the current frame. When disabled, the imported model maintains the same size in which it was created, or you can use the FBX Units to Pixels field to manually set a scaling factor.

FBX Units to Pixels field Displays the scaling factor used on the imported FBX file to fit the scaling used in the application. One unit in the FBX file (default is cm) is converted to the number of pixels (default is 10) that you specify.

FBX Import Type box Select an FBX import type. Select Link to Original File to keep a live link to the original FBX file, but without control over the components of the scene. Select Create Local Copy to have control over the elements of the scene, but lose the link.

Keep FBX Frame Rate button Enable to use the frame rate of the FBX file as the frame rate in Action.

TIP It might be useful to enable Keep FBX Frame Rate when importing an FBX file before starting to build your animation, otherwise the timing of your animation may be affected.

Bake FBX Animation button Enable to add a keyframe at every frame of the imported FBX file. When disabled, Action translates the FBX keyframes to a comparable animation curve for comparable channels.

Create Media button Enable to load the textures of the geometry to the Media list. If a texture is used in multiple geometry maps, it is loaded only once in the Media list. Not available if Action is accessed as a Timeline FX.

Lights button Enable to import lights from the FBX format file.

Cameras button Enable to import cameras from the FBX format file. Free cameras are imported as target cameras (with a point of interest).

Mesh Animations button Enable to import the FBX scene animations and preserve complex geometry animations, such as nCloth animations.

Normals button Enable to import the model's normal information.

Working with FBX Scenes Linked to the Original Files

When importing an FBX file in an Action schematic, setting the FBX Import Type to the option Link to Original File does not create a Geom node as the option Create Local Copy does, but rather creates an FBX Scene node.

You cannot perform the same operations on an FBX Scene node as on a Geom node.

- You can only parent Axis nodes.
- You cannot parent it to other nodes.
- You cannot select individual components; you always select the entire scene.
- There is only one node in the Priority Editor for the whole scene.

If the linked FBX file is updated, click Refresh in the FBX Scene menu to update the FBX Scene node in Action.

NOTE If the linked FBX file is moved or changes its file name, the FBX File Path field turns red to indicate that the original file cannot be found. If you click Refresh, the geometry in your scene is replaced with a "Missing FBX" text. In this case, click the FBX File Path field to open the browser and locate the moved or renamed FBX file.

FBX Scene Settings

FBX Scale field Displays the factor by which to scale the FBX scene. Does not scale the camera if it has already been extracted using the Extract Camera button. Editable.

Extract Camera button Click to extract the 3D camera from the FBX scene. It extracts and creates a new 3D camera node, scaled to the current FBX Scale. Once extracted, the camera is no longer linked to the FBX scale: changing the FBX scale does not affect the camera. If you need to edit then rescale the camera after changing the FBX Scale, delete the extracted camera and extract a new one.

Sort button Enable so the 3D models contained in the FBX Scene are drawn according to their normals. Consider using this option if the scene contains semi-transparent 3D models to ensure they are correctly drawn.

FBX File Path field Displays the path to the FBX file. This field is displayed in red if the linked FBX file can no longer be found. Click to open the browser to locate a moved FBX file, or to replace the currently displayed FBX scene with another one.

Refresh button Click to update the FBX Scene node with the content of the linked FBX file. Use this if the FBX file has been updated since its import.

3D Geometry Menu Settings

You can change and animate parameters such as the colour, specular highlight, shine, and transparency of 3D models. You set these parameters using the Geometry menu. To access this menu, double-click a Geometry node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).

Blending Settings

Blend Type box Select whether to use Flame or Photoshop blend modes.

Blend Mode box Select how the 3D model and the scene are combined. The available list of modes depends on the selection in the Blend Type box. See [Surface Blending Modes](#) (page 484).

Transparency field Displays the transparency level of the 3D model. Editable.

Shine field Displays the intensity value of the specular highlight. When this value is zero, the specular highlight is disabled. Shine affects both size and intensity. Editable.

See [Creating a Specular Highlight on a Model](#) (page 557).

Specular colour pot Displays the colour of light reflected by the 3D model's surface. To enable the specular highlight, the Shine value must be larger than 0. Editable.

Diffuse colour pot Displays the diffuse colour. Editable.

Surface Settings

Sort Order box Select the drawing priority of the 3D model normals.

Select:	To draw the polygons:
Shade Both	That are both facing and opposite the camera.
Shade Front	Facing the camera last.
Shade Back	Opposite the camera last. This option is especially useful for semi-transparent models

Force 2-Sided button Enable to have lights in the scene light both the inside and outside of the geometry (when shading is turned on).

Shadow Casting box Select how the selected geometry object will be affected by a Shadow Cast object in the scene. See [Surface and Geometry Shadow Casters](#) (page 521).

Polygons Settings

Polygons field Displays the number of polygons in the 3D model. Non-editable.

Subdivide button Enable to create high-quality shading for polygon models.

Resolution field Displays the geometry resolution of the 3D model. Active when Subdivide is enabled. Editable.

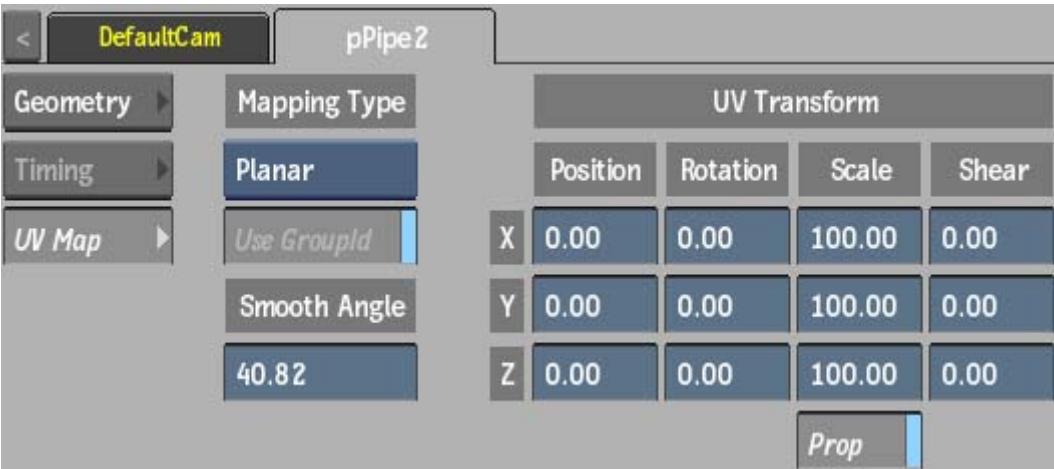

Wireframe box Select a wireframe option for the 3D model. When you render the 3D model with Wireframe or Original Wire selected, it retains its light, shading, and texture attributes.

Select:	To:
Solid	Disable wireframe for the 3D model (filled polygons are drawn).
Wireframe	Display the model as a wireframe outline (triangular polygons only).
Original Wire	Display the model as a wireframe outline (original mesh; any polygon type). May be useful for imported geometries.

Sort button Enable to determine how the 3D model is drawn according to its normals.

UV Map Settings

Use the UV Mapping settings to select how the UV coordinates of an attached displace, normal, or diffuse node are mapped to the 3D model. You can also apply axis transformations to the UV map. These transformations are different from the settings of the parent axis in that they transform the axes of the actual UV map coordinates.

UV Mapping Type box Select the type of UV mapping to apply to the attached node.

When a Displace or Normal node is attached to a geometry, you may need a UV mapping type other than Default for the displace or normal pattern to have any effect on the geometry.

NOTE When a Diffuse node is attached to a geometry, you must select Wrap from the Mapping box in the Diffuse menu to be able to use the UV mapping settings. See [Diffuse Mapping](#) (page 628).

Use GroupId button Enable to respect GroupId information in an FBX file created in 3ds Max.

Smooth Angle button Enable to override existing normals in the geometry, then use the Smooth Angle field to change the value.

Smooth Angle field Displays the angle at which the edges of normals become hard. Changes to this field only affect the shading of the displacement, and not the shape. Editable.

Position X field Displays the position of the X axis. Editable.

Position Y field Displays the position of the Y axis. Editable.

Position Z field Displays the position of the Z axis. Editable.

Rotation X field Displays the rotation of the X axis. Editable.

Rotation Y field Displays the rotation of the Y axis. Editable.

Rotation Z field Displays the rotation of the Z axis. Editable.

Scale X field Displays the scale of the X axis. Editable.

Scale Y field Displays the scale of the Y axis. Editable.

Scale Z field Displays the scale of the Z axis. Editable.

Prop Scale button Scales the X, Y, and Z UV axes proportionally.

Shear X field Displays the shear of the X axis. Editable.

Shear Y field Displays the shear of the Y axis. Editable.

Shear Z field Displays the shear of the Z axis. Editable.

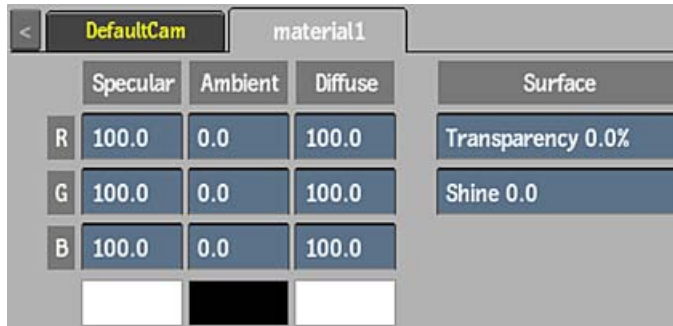

NOTE The UV Transform fields are only available if a Mapping Type other than Default is selected.

Material Node Settings

The Material node creates a central hub to control the specular, ambient, diffuse, transparency, and shininess of a geometry's children maps and substances.

Flame Premium automatically creates a Material node when you insert a Substance Texture or when you import 3ds Max or FBX models with textures. You can also manually add a material node to any geometry or surface in the Action schematic.

Material Node Menu Settings

Lighting Settings

Red Specular field Displays the red specular highlight value. Editable.

Green Specular field Displays the green specular highlight value. Editable.

Blue Specular field Displays the blue specular highlight value. Editable.

Specular colour pot Displays the colour of light reflected by the 3D model's surface. To enable the specular highlight, the Shine value must be larger than 0. Editable.

NOTE Specular lighting sets the colour of light reflected by the 3D model's surface. To enable the specular highlight, the Shine value must be larger than zero.

Red Ambient field Displays the red ambient colour value. Editable.

Green Ambient field Displays the green ambient colour value. Editable.

Blue Ambient field Displays the blue ambient colour value. Editable.

Ambient colour pot Displays the colour of the area of the 3D model that is not illuminated by a direct light source. Editable.

NOTE Ambient lighting sets colour to the area of the 3D model that is not illuminated by a direct light source. The edge of the ambient area mixes with the specular highlight colour and the diffuse colour.

Red Diffuse field Displays the red diffuse colour value. Editable.

Green Diffuse field Displays the green diffuse colour value. Editable.

Blue Diffuse field Displays the blue diffuse colour value. Editable.

Diffuse colour pot Displays the diffuse colour. Editable.

NOTE Diffuse lighting modifies the colour and illumination of the entire 3D model. Diffuse light mixes with the colour of the light sources used to illuminate the 3D model. The diffuse colour may also mix with the ambient colour and the colour of the specular highlight.

Surface Settings

Transparency field Displays the transparency level of the 3D model. Editable.

Shine field Displays the intensity value of the specular highlight. When this value is zero, the specular highlight is disabled. Shine affects both size and intensity. Editable.

See [Creating a Specular Highlight on a Model](#) (page 557).

Adjusting Normals

When using transparency with 3D models, you may sometimes see the back polygons, giving the model a shattered or broken look. This happens when the drawing priority of the normals is not sorted properly. Enable Sort and select an option from the Sort Order box to sort the drawing priority back to front or front to back.

Drawing order of the 3D model's polygons is incorrect. Back polygons are drawn through when the model is transparent.

Select Front to sort the polygons front to back. The transparency is drawn correctly.

Subdividing a Model

The Subdivide feature is useful for creating precise highlights and spotlights. The polygons in the 3D model are subdivided at the time of render according to the value you specify, resulting in smoother rendered surfaces.

Spotlight on a polygon model rendered with Subdivide off.

Spotlight on a polygon model rendered with Subdivide set to 2.

To subdivide a model:

- 1 Select the model or geometry you want to subdivide.
- 2 In the Geometry menu, click Subdivide to enable the Subdivide field.
- 3 Edit the Subdivide value. The default value is 5.

NOTE The smaller the value, the slower the rendering.

- 4 Click Process or Preview to see the subdivision effect.

You can animate the Subdivide channel in the Channel Editor; however, expect a longer rendering time when the Subdivide value changes over several keyframes.

Creating a Specular Highlight on a Model

Change the specular colour by entering values in the Specular red, green, and blue channel fields or using the colour picker. For example, if the specular colour is red and the light source is white, the specular highlight is also red. If the specular colour is yellow and the light source is red, the highlight is orange.

To use a specular highlight with a 3D model:

- 1 Add and position a light source in the scene.
- 2 In the scene, select the 3D model to which you want to add the highlight.
- 3 In the Action Setup menu, enable Shading.

- 4 In the Geometry menu, set a value in the Shine field.

A high Shine value produces a dimmer highlight while a low Shine value produces an intense highlight. When the Shine field is set to zero, the 3D model does not have a highlight. The following example shows the same 3D model using two different Shine values.

Shine is set to 1. The specular highlight is intense.

Shine is set to 20. The specular highlight is dimmer.

Deforming Models and Surfaces

Use a deformation mesh to deform a 3D model or surface. To use 3D deformations, attach a Deform node to the 3D model or surface, and then use the Deform menu to modify the mesh. You can animate individual

points on the deformation mesh, or move the entire mesh over the 3D model or surface to apply the deformation as the mesh passes over the object.

Adding a Deformation Mesh

When you add a Deform Mesh node, the deformation mesh appears over the 3D model or surface. You can view the source mesh, the destination mesh, or both to assist you as you deform the object. You can also turn both meshes off to view only the deformed object.

The deformation mesh consists of cells and lattices. You can divide the mesh into 1-100 lattices and each lattice can be divided by 1-3 cells. Increase the number of cells and lattices to deform specific areas of the object.

To add a deformation mesh:

- 1 In the schematic, select the axis for the image, 3D model, or 3D text.
- 2 Do one of the following:
 - Drag the Deform Mesh node from the node bar and place it in the schematic.
 - Drag the Deform Mesh node from the node bar and place it where you want it in Result view.
 - Double-click the Deform Mesh node in the node bar. You do not need to be in Schematic view to add a node in this manner.

The deformation mesh is added to the selected object.

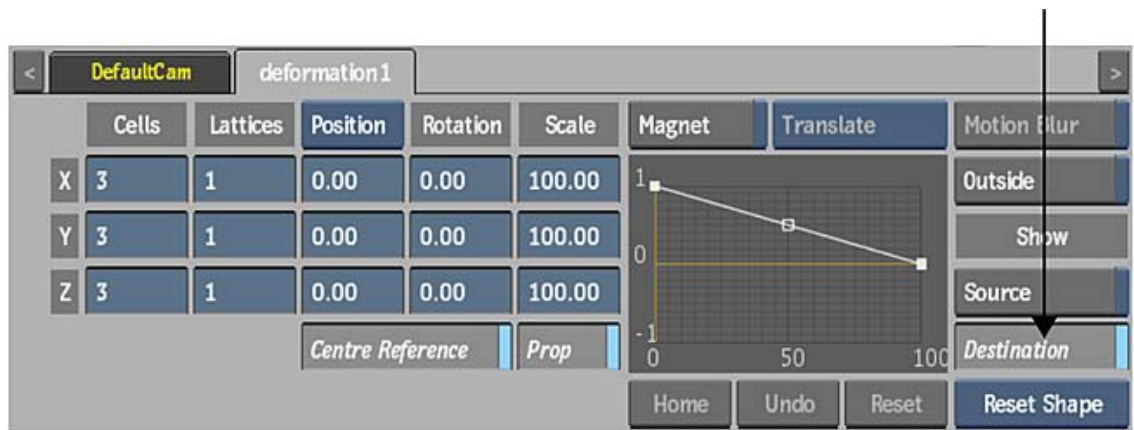

Image courtesy of Quietman

If you do not see the deformation mesh, follow the next steps.

- 3 Double-click the Deform Mesh node in the schematic.
The Deform Mesh menu appears.
- 4 In the Deform Mesh menu, enable the Show Destination button to view the deformation mesh in the image window.

Modifying a Deformation Mesh

By default, the deformation mesh has three X,Y, and Z cells and one X, Y, and Z lattice. You can change the number of cells (1-3) or lattices (0-100).

NOTE You can only change the number of cells or lattices before you modify the parameters of the mesh. If you modify a parameter, for example, translate a tangent, you cannot change the number of cells or lattices.

To change the number of cells or lattices:

- 1 In the image window, select the mesh.
- 2 In the Deform menu, change the number of cells in the Cells X, Y, and Z fields. By default they are set to 3, 3, 3.
- 3 In the Lattices X, Y, and Z field, change the number of vertices.
The cells or lattices are added to the deformation mesh.

Image courtesy of Quietman

- 4 To view the original mesh, enable Show Source.

- 5 Use the Outside button to apply the deformation outside of the mesh (enabled) or constrain the deformation within the mesh (disabled).

To select points:

- 1 From the Tools box, select Move or Select.
- 2 Select the point(s):
 - To select a single point, click the point.
 - To select multiple points, hold the **Shift** key and click the points you want to select.
 - To select a range of points, hold the **Ctrl** key and draw a box around the points you want to select.
 - To add a range of points to a selection, hold **Shift+Ctrl** and draw a box around the points you want to add to the selection.

When you move a point, all selected points also move.

Image courtesy of Quietman

To transform a point on the mesh, drag it in the image window, or change the value in one of the X,Y or Z Translation fields.

Passing a Deformation Mesh Over an Object

Animate the deformation mesh so that it passes over the object. If the Outside button is disabled, the deformation is only applied to the parts of the object within the mesh. To achieve this effect, you must move the mesh over the object. You cannot move the object through the mesh because the object axis parents the mesh axis.

You can also use the channel editor to animate individual or multiple points for the deformation mesh.

To pass a deformation mesh over an object:

- 1 Add the deformation mesh to the object.
- 2 In the Deform menu, disable Outside.
- 3 Modify the points on the mesh to achieve the deformation you want.
- 4 In Schematic view, select the deformation axis.
- 5 Click Axis to view the Axis menu.

- 6 Move the deformation mesh so that it is on one side of the object.
- 7 Set a new keyframe with the deformation mesh on the other side of the object.

Transforming a Range of Points

Use the magnet to transform a range of deform mesh surface points. In the Deform Mesh menu, the magnet controls include the Magnet button, the Magnet Transformation box, and the Magnet Curve Editor. The magnet controls work the same way as the magnet controls in the [Extended Bicubic](#) (page 491) menu.

Deform Mesh Menu Settings

X Cells field Defines the number of cells along the X axis. Editable.

Y Cells field Defines the number of cells along the Y axis. Editable.

Z Cells field Defines the number of cells along the Z axis. Editable.

X Lattices field Defines the number of lattices along the X axis. Editable.

Y Lattices field Defines the number of lattices along the Y axis. Editable.

Z Lattices field Defines the number of lattices along the Z axis. Editable.

Position/Current mode box Select to modify the Position or Current axis controls.

X Position field Positions the selected points along the X axis.

Y Position field Positions the selected points along the Y axis.

Z Position field Positions the selected points along the Z axis.

X Current field Positions the selected vertex along the X axis.

Y Current field Positions the selected vertex along the Y axis.

Z Current field Positions the selected vertex along the Z axis.

X Rotation field Rotates the selected points along the X axis.

Y Rotation field Rotates the selected points along the Y axis.

Z Rotation field Rotates the selected points along the Z axis.

X Scale field Scales the selected points along the X axis.

Y Scale field Scales the selected points along the Y axis.

Z Scale field Scales the selected points along the Z axis.

Proportional Scale button Enable to scale the points proportionally.

Centre Reference button Enable to create a centre reference axis for selected points.

Magnet button Enable to transform a range of deform mesh surface points.

Magnet Transformation box Select a transformation type to use when Magnet is enabled.

Magnet Curve Editor Defines the weighted polarity from the centre to the edge of the magnet.

Magnet Curve Home button Resets the position of the magnet curve after panning.

Magnet Curve Undo button Undoes a change to the Magnet Curve Editor.

Magnet Curve Reset button Resets the Magnet Curve Editor.

Motion Blur button Enable to use a motion blur effect for the selected deformation (can only be used if the global Motion Blur is enabled in the Action Setup menu).

Outside button Enable to apply the deformation outside of the mesh. Disable to constrain the deformation within the mesh.

Show Source button Enable to view the original mesh.

Show Destination button Enable to view the destination mesh.

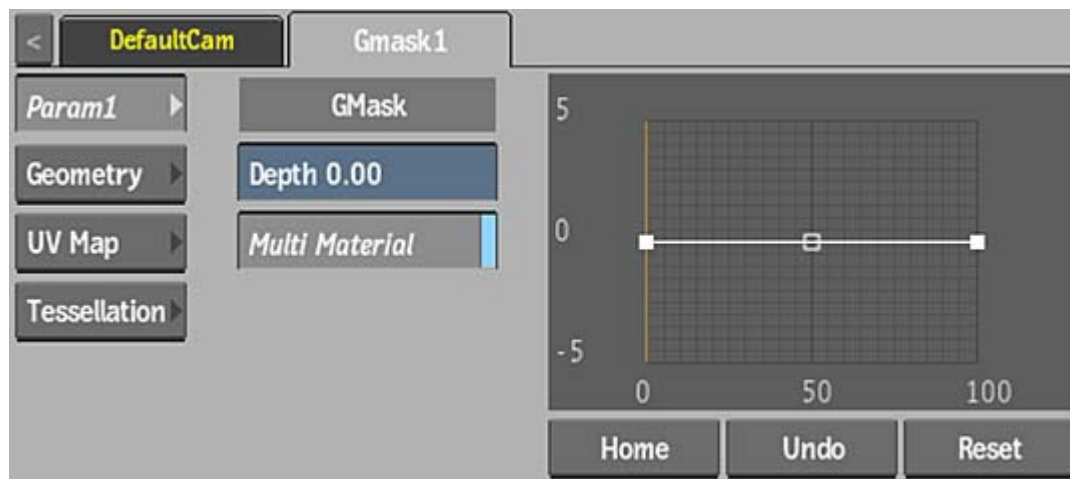

Reset box Select whether to resets the shape of the deformation mesh, or only the selected points.

Using Garbage Masks as 3D Geometry

Garbage mask files are created through the Keyer or by the GMask node in Batch. You can import a saved garbage mask setup into Action, and specify 3D properties, such as depth and geometry settings. If your garbage mask is animated, all shapes are imported into Action. Softness and offset settings in the imported garbage mask are not brought into Action. Any holes in the imported garbage mask are also holes in the 3D geometry. For help creating garbage masks, see [Drawing a Mask](#) (page 912).

TIP A library of preset garbage mask setups is available. To load a preset garbage mask, navigate to the `/usr/discreet/<product_name>/gmask` directory when importing your 3D model.

Once you import a garbage mask as a 3D geometry into Action, use the GMask menu to extrude the garbage mask.

GMask Menu Settings

Depth field Displays the level of depth (thus extruding the selection, making it three dimensional). Editable.

Multi Material button Enable to create an Object Group node for each of the front, back, and extrude of the 3D object. You can then attach a different texture map to apply to the different surfaces.

Bevel Curve Applies a bevel to the depth of the geometry when you manipulate the Bevel curve. You can move and add points to the curve, as well as adjust the tangent handles to produce different effects with the text string.

Home button Resets the Bevel curve viewer to show the whole curve.

Undo button Undoes the last set of Bevel curve operations.

Reset button Resets the Bevel curve.

Click the [Geometry](#) (page 552) and [UV Map](#) (page 553) tabs to apply any of the other geometry settings to your garbage mask.

Click the [Tessellation](#) (page 588) tab to control the tessellation of the garbage mask.

About 3D Text

You can create and manipulate 3D text strings in your Action scenes. With 3D text, you specify typical text properties such as font, font size, kerning, and italics. Since 3D text strings created in Action are also 3D geometries, you can extrude text, offset your text from a path, and apply other geometry settings.

Using 3D Text Presets

A number of 3d text presets are included in Action, such as rotating or fading text to add to your scene. These presets can help you add complex text effects with just a few clicks.

To add a 3d text preset:

- 1 Do one of the following:
 - Drag the Presets node from the node bin and place it in the schematic.
 - Drag the Presets node from the node bin and place it where you want it in Result view.
 - Double-click the Presets node. You do not need to be in Schematic view to add a node in this manner.
The file browser opens.
- 2 From the Preset Type box, select 3D Text.

The 3D Text Preset file browser appears, pointing to the default location of the presets:
usr/discreet/<product home>/3d_text_presets.

- 3 Optional: Enable Scale to Action Resolution to load the preset in the current Action resolution.
- 4 Optional: Select which rendering settings to enable or disable in the preset (Z-Buffer, Shading, Polygon Resolution, and Colour Clamping).

NOTE These settings are enabled by default, and by disabling any of them, you may not see the intended results in the preset.

- 5 Select the 3d text preset you want to load. Hold **Ctrl** and click to select multiple presets.

TIP Switch to Proxies view to see a visual representation of the presets.

- 6 Click Load.

The 3D text preset is then appended to your Action scene. In the 3D Text menu, you can change the default text string of the preset.

3D Text Presets Usage Tips

A number of 3D text presets are included in Action, such as fading or spinning 3D text effects to add to your scene. The presets are easily added to your scene from the Action node bar. For more information on the 3D Text node and its menu, see [About 3D Text](#) (page 563).

The 3D Text presets are designed for ease-of-use, so you should be able to easily identify the various schematic nodes and their corresponding menus. For example, the nodes in the schematic for each preset are renamed to give you an indication of the functionality of the node. Many of the presets include a *transition_ctrl* Axis node, that you can use to modify the timing of the text effect, as follows:

Rotation X=duration of the In effect; Y=start weight; Z=end weight. The Y and Z Rotation fields represent the shape of the “S” curve of the In effect, if applicable. The combined Y and Z values should equal 100.

Scale X=duration before the start of the In effect; Y=duration between the end of In effect and the start of the Out effect.

Shear X=duration of the Out effect; Y=start weight; Z=end weight. The Y and Z Shear fields represent the shape of the “S” curve of the Out effect, if applicable. The combined Y and Z values should equal 100.

Centre These fields include expressions to produce animation curves, and shouldn’t be altered.

When loading a 3D Text preset, with a few exceptions, you can replace the **Type Your Own Text** string in the Text field of the 3D Text menu. Some of the presets have multiple text entries. In these cases, replace the text string of each Text Geom node with your preferred text string.

Presets Browser Settings

Preset Type box Select the category of presets to display in the browser.

Scale to Action Resolution button Enable to load the preset in the current Action resolution.

Z-Buffer button Enable to load the Z-buffer rendering settings of the preset.

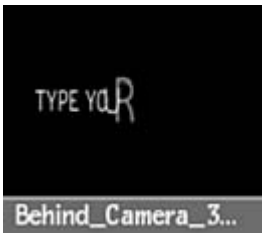

Shading button Enable to load the shading rendering settings of the preset.

Polygon Resolution button Enable to load the rendering resolution settings of the preset.

Colour Clamping button Enable to load the resolution colour clamping settings of the preset.

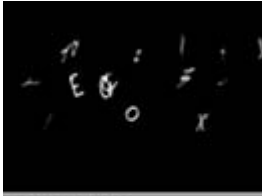

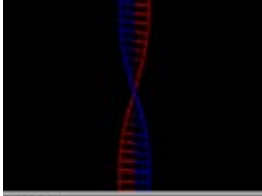

3D Text Preset List

Use the following table to get a quick overview of the 3D text presets available in this release, along with particular comments, if applicable.

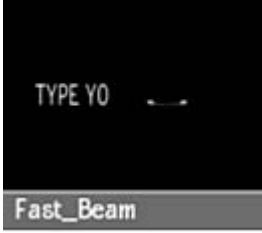

Proxy	Name/Description/Comments
	3DRotate Text on a rotating circular path. Edit timing using the Animation Track Editor.
	3DRotate_Shadow Text rotating on a circular path with a fake shadow. Edit timing using the Animation Track Editor.
	3DRotate_Transition Transition between two text strings rotating on a circular path. Edit timing using the Animation Track Editor.
	Behind_Camera_3D Characters coming from behind the camera. Edit timing using <i>transition_ctrl</i> settings.
	Bounce Characters falling and bouncing. Edit timing using <i>transition_ctrl</i> settings. Set duration and amplitude of the bouncing.

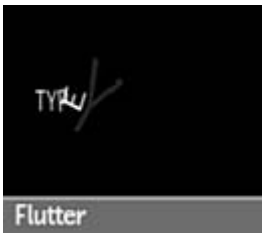

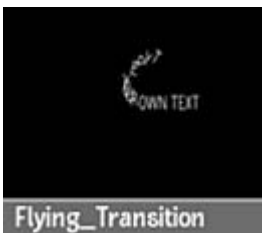

Proxy	Name/Description/Comments
	Break_and_Fall Characters breaking in two parts and falling down. Edit timing using the Animation Track Editor.
	Bubble_Pop Characters forming a bubble which pops. Edit timing using <i>transition_ctrl</i> settings.
	Chop_Sticks Characters arriving one after the other with a scale and rotation effect. Edit timing using <i>transition_ctrl</i> settings.
	Circle Characters moving along a circular path. Edit timing using the Animation Track Editor.
	Circle_Transition Transition between two text strings, in which characters are moving along a circular path with a banking effect. Edit timing using <i>transition_ctrl</i> settings.

Proxy	Name/Description/Comments
	<p>Climber Characters climbing from the bottom to the top of the frame. Edit timing using <i>transition_ctrl</i> settings. Use <i>offset.rotation.X</i> to set the displacement duration and <i>offset.rotation.Y</i> to set the rotation duration.</p>
	<p>Clock_Transition Transition between four text strings rotating like clock hands. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Colour_Flasher Moving coloured flashing text. Edit timing using <i>transition_ctrl</i> settings. <i>Colour_offset</i> sets the time offset between red, green, and blue channels.</p>
	<p>Counter Incremental counter with numbers 000 to 999.</p>
	<p>Diagonal Characters dispersing diagonally in the frame. Edit timing using <i>transition_ctrl</i> settings.</p>

Proxy	Name/Description/Comments
 Dispersion	Dispersion Characters dispersing randomly. Use <code>time_stretch.scaling.X</code> to slow down or speed up the effect.
 Dispersion_Transiti...	Dispersion_Transition Transition between two text strings using a dispersion movement. Edit timing using <code>transition_ctrl</code> settings.
 DNA	DNA Animated double helix structure using two text strings of the letter "T".
 Dominos	Dominos Characters falling one after the other. Edit timing using <code>transition_ctrl</code> settings.
 Fade_In_Flicker	Fade_In_Flicker Fade in of randomly flickering characters. Edit timing using <code>transition_ctrl</code> settings.

Proxy	Name/Description/Comments
	Fade_In_From_Centre Fade in from the centre to the extremities of the text. Edit timing using <i>transition_ctrl</i> settings. Set characters.rotation.X to the number of characters in the Text field.
	Fade_In_From_Left Fade in from the left to the right of the text. Edit timing using <i>transition_ctrl</i> settings.
	Fade_In_Out_By_Character Fade in and out one character after the other. Edit timing using <i>transition_ctrl</i> settings. Set characters.rotation.X to the number of characters in the Text field.
	Fade_In_Random Use time_stretch.scaling.X to slow down or speed up the effect.
	Fade_In_To_Centre Fade in from the extremities to the centre of the text. Edit timing using <i>transition_ctrl</i> settings.

Proxy	Name/Description/Comments
	Fade_Out_From_Centre Fade out from the centre to the extremities of the text. Edit timing using <i>transition_ctrl</i> settings. Set <i>characters.rotation.X</i> to the number of characters in the Text field.
	Fade_Out_From_Right Fade out from the right to the left of the text. Edit timing using <i>transition_ctrl</i> settings.
	Fade_Out_Random Use <i>time_stretch.scaling.X</i> to slow down or speed up the effect.
	Fade_Out_To_Centre Fade out from the extremities to the centre of the text. Edit timing using <i>transition_ctrl</i> settings.
	Fast_Beam Characters arriving from the right side of the frame, with scaling and flickering. Edit timing using <i>transition_ctrl</i> settings. Customize the flicker effect using <i>flicker</i> settings.

Proxy	Name/Description/Comments
	Flasher Customize the flashing using <i>period_offset</i> settings.
	Flicker Animate with <i>period.rotation.X</i> .
	Flip_Transition Transition between two text strings, with characters rotating on the Y axis. Edit timing using <i>transition_ctrl</i> settings.
	Flutter Characters arriving one after the other with a scale and rotation effect. Edit timing using <i>transition_ctrl</i> settings.
	Flying_Transition Transition between two text strings in which characters are flying out from the centre and coming back to it. Edit timing using <i>transition_ctrl</i> settings.

Proxy	Name/Description/Comments
	From_Back Characters arriving from behind the camera. Use <code>time_stretch.scaling.X</code> to slow down or speed up the effect.
	From_Bottom Characters arriving from the bottom of the frame, with rotation. Edit timing using <code>transition_ctrl</code> settings.
	From_Camera_3D Characters arriving from behind the camera and turning towards the camera. Edit timing using <code>transition_ctrl</code> settings.
	Ghost Text arriving toward the camera, reflecting, and fading. Edit timing using the Animation Track Editor.
	Ghost_Cascade Similar to Ghost, with a cascade applied. Edit timing using the Animation Track Editor.

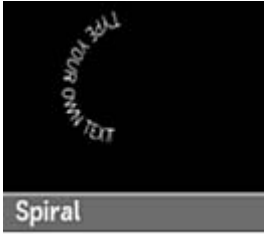

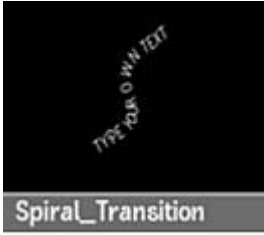

Proxy	Name/Description/Comments
	<p>Ghost_Rotation Similar to Ghost with an animated ParticleDraw axis. Edit timing using the Animation Track Editor.</p>
	<p>Helix_Transition Transition between two text strings in which characters are rotating on their X axis. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Insertion Text is revealed frame after frame in insert mode. Edit timing using <i>transition_ctrl</i> settings. Use <i>offset.rotation.X</i> to set the starting value of the path.</p>
	<p>Kern Characters arriving and leaving the frame with kerning and rotation. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Mirror Text on path with a mirror effect. Edit timing using the Animation Track Editor.</p>

Proxy	Name/Description/Comments
	<p>Negate Text revealed using a negate blending effect. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Ocean_Tide Text moving slowly as if characters were floating on the sea. Use period and amplitude axes to customize the wavy effect.</p>
	<p>Ocean_Tide_Transition Transition between two text strings moving slowly as if characters were floating on the sea. Edit timing using <i>transition_ctrl</i> settings. Use period and amplitude axes to customize the wavy effect.</p>
	<p>Path_Warp Text on animated path producing a warping effect. Edit timing using the Animation Track Editor.</p>
	<p>Pendulum Characters moving as if attached to a pendulum Edit timing using <i>transition_ctrl</i> settings. Use period and amplitude axes to customize the oscillating effect.</p>

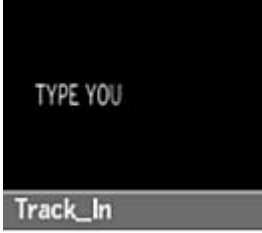

Proxy	Name/Description/Comments
	Pulse_Wave Characters moving vertically with a pulsating effect. Customize using period and amplitude settings.
	Quick_Rotate Characters rotating on their X axis. Edit timing using <i>transition_ctrl</i> settings.
	Quick_Twist Characters scaled on their Y axis. Edit timing using <i>transition_ctrl</i> settings.
	Random_Display Random letters with a specific starting and ending text string. Edit timing using <i>transition_ctrl</i> settings. Type the start text in text_1 and the stop text in text_2.
	Random_Hide Characters disappearing randomly. Clipping Plane modified. Use <i>time_stretch.scaling.X</i> to slow down or speed up the effect.

Proxy	Name/Description/Comments
	Random_Letters Letters displayed randomly.
	Random_Reveal Characters appearing randomly. Clipping Plane modified. Use <code>time_stretch.scaling.X</code> to slow down or speed up the effect.
	Replace_Transition Transition between two text strings with rotation. Edit timing using <code>transition_ctrl</code> settings.
	Reverse Transition between two text strings in which characters reverse direction. Edit timing using the Animation Track Editor.
	Rubber Characters are stretched and released like rubber. Edit timing using <code>transition_ctrl</code> settings. Set period and amplitude of the bouncing.

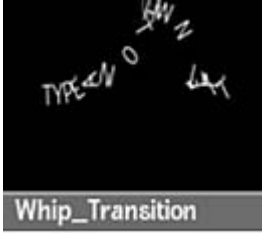

Proxy	Name/Description/Comments
	<p>Rubber_Transition Transition between two text strings using a rubber effect. Edit timing using <i>transition_ctrl</i> settings. Set period and amplitude of the bouncing.</p>
	<p>Scaling_Transition Transition between two text string using a scaling effect. Edit timing using <i>transition_ctrl</i> settings. Set characters.rotation.X to the number of characters in the Text field.</p>
	<p>Shiver_Transition Transition between two text strings with a shiver-like effect. Edit timing using <i>transition_ctrl</i> settings. Increase or decrease the turbulence using noise_amplitude.</p>
	<p>Shuffle_In_Out Characters arriving from the left, stopping in the centre, and leaving to the right. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Spin_Compress Characters revealed with rotation, and leaving with a compression effect. Edit timing using the Animation Track Editor.</p>

Proxy	Name/Description/Comments
	<p>Spin_In_Out Characters arriving and leaving with rotation. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Spin_Transition Transition between two spinning text strings. Edit timing using <i>transition_ctrl</i> settings.</p>
	<p>Spinning_Letters Characters thrown with a spinning effect. Edit timing using <i>transition_ctrl</i> settings. Experiment with <i>transition_ctrl.scaling.Y</i> and <i>transition_ctrl.scaling.Z</i>.</p>
	<p>Spiral Text on a spiral path. Edit timing using the Animation Track Editor.</p>
	<p>Spiral_Transition Transition between two text strings with a spiral effect. Edit timing using <i>transition_ctrl</i> settings.</p>

Proxy	Name/Description/Comments
	Spring_Transition Transition between two text strings with letters springing left and right. Edit timing using <i>transition_ctrl</i> settings. Customize the pulsing effect using period and amplitude settings
	Squash_Transition Transition from a text string with letters being squashed to reveal the other text string. Edit timing using <i>transition_ctrl</i> settings.
	Star Text moving along a star path. Edit timing using the Animation Track Editor.
	Stretch Text arriving from the left of the frame with a stretching effect. Edit timing using <i>transition_ctrl</i> settings.
	Subtract Text revealed using a subtract blending effect. Edit timing using <i>transition_ctrl</i> settings.

Proxy	Name/Description/Comments
	Text_Falling Characters moving along a line, then falling down. Edit timing using the Animation Track Editor.
	Titles Three text strings on a path arriving from the upper left. Edit timing using the Animation Track Editor.
	Titles_Stairs Three text strings revealed with a spinning effect. Edit timing using <i>transition_ctrl</i> settings.
	Track_In Characters appear and disappear with scaling. Edit timing using <i>transition_ctrl</i> settings.
	Tremor Characters appear as if shaking. Increase or decrease the turbulence effect using <i>noise_amplitude</i> .

Proxy	Name/Description/Comments
	Twist Characters arriving and leaving with a twisting effect. Edit timing using <i>transition_ctrl</i> settings.
	Typewriter Text revealed frame after frame with a typewriter effect. Edit timing using <i>transition_ctrl</i> settings. Use <i>transition_ctrl.rotation.X</i> and <i>transition_ctrl.shearing.X</i> to set the fade in duration of characters.
	Typewriter_Cursor Text is revealed frame after frame with a cursor preceding characters. Edit timing using <i>transition_ctrl</i> settings. Use <i>transition_ctrl.rotation.X</i> and <i>transition_ctrl.shearing.X</i> to set the fade in duration of characters. Set as many white squares as characters in the text node. Adapt cursor kerning if needed.
	Vertical_In_Out Characters arriving from the left side of the frame and moving vertically before going out to the right of the frame. Edit timing using <i>transition_ctrl</i> settings.
	Vertical_Rotation_Transition Transition between two text strings moving vertically. Edit timing using <i>transition_ctrl</i> settings.

Proxy	Name/Description/Comments
	Waveform Waveform using Cursor font. Link text.character_anim.scaling.Y to an audio file.
	Whip_Effect Characters whipped by a rotating effect. Edit timing using <i>transition_ctrl</i> settings.
	Whip_Transition Transition between two text string with characters whipped by a rotating effect. Edit timing using <i>transition_ctrl</i> settings.
	Whirlwind_Transition Transition between two text string with characters circulating by a rotating effect. Edit timing using <i>transition_ctrl</i> settings.
	White_Background Characters revealed on a white background. Edit timing using <i>transition_ctrl</i> settings. Change the background using <i>white_bkgd_ax</i> settings and <i>white_bkgd</i> kerning value.

Proxy	Name/Description/Comments
	Windy Characters moving as if by wind. Customize with period and amplitude axes.
	Zig_Zag Characters arriving and leaving following a zig-zag path. Edit timing using <i>transition_ctrl</i> settings. Change the path, if needed.

Adding a 3D Text Node

When you add a 3D Text node to your Action schematic, a special geometry node with an axis is added.

To add a 3D Text node to the scene:

- Do one of the following:
 - Drag the 3D Text node from the node bin and place it in the schematic.
 - Drag the 3D Text node from the node bin and place it where you want it in Result view.
 - Double-click the 3D Text node. You do not need to be in Schematic view to add a node in this manner.

A Geometry object, called Text1 by default, and parent axis appear in the schematic. In Result view, the default Text string appears.
- To open the 3D Text menu, double-click the 3D Text node in the schematic, or follow the tab population rules for the Object menu.

See [Populating Menu Tabs of Selected Objects](#) (page 431).

You can also add a 3D Text node using the Presets node. See [Using 3D Text Presets](#) (page 563).

Changing 3D Text Properties

When you add a 3D Text node to your scene, the default text string “Text” appears. You can easily change this text string.

To change a text string:

- Click the Text field.

The on-screen keyboard appears, representing the character set for the selected font. Enable Up ASCII to access the rest of the character set. If the selected font has special symbol characters, enable Symbols to see them.

- 2 Type your text string or use the on-screen keyboard.
- 3 Click Exit Keyboard. The text string is displayed in the Text field and automatically updated in the scene.
- 4 Use the settings in the 3D Text tab to change the font, size, depth, and other text properties.

Creating Bevelled Text

Use the Bevel curve to add a bevelled edge to your 3D text. Use the options in the Tools box to add, select, delete, or move keyframes on the Bevel curve. The Bevel curve behaves in much the same way as an animation curve in the Channel Editor. Experiment with different curves to create different effects.

Bevel curve

Resulting bevelled text

Separating Text

Rather than create a separate pivot point for each letter, you can separate words or sentences so that each letter can be individually manipulated by its own axis in the schematic.

To separate text:

- 1 Select the text to separate.
- 2 From the Text tab, click Separate.

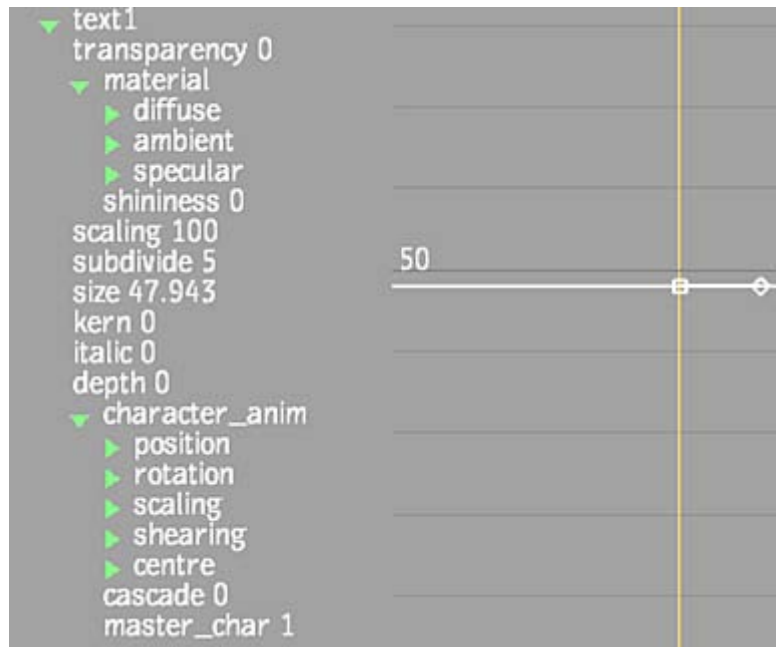

Each letter of the text geometry is now an independent geometric object, and has its own axis and offset (to separate the letters). Each word is also given its own axis. The original 3D Text node is hidden in the schematic.

(a) Root axis for word (b) Root axis for letter (c) Offset per letter (d) Letter geometry

Animating 3D Text

You can animate the 3D text property and geometry channels in the Channel Editor. However, you cannot animate the text string or its bevel curve. The 3D text channels are contained in the text folder.

3D Text Menu Settings

3D Text Tab

(a) Text field (b) Font field (c) Bevel curve

Text field Displays the current text string. Editable.

Font field Displays the current font. Click to open the font library to select a different font for the text.

You specify the default font in the Preferences menu. Also, you can install additional fonts for use with Flame Premium.

Kern field Displays the kerning value for the text string. Editable.

Size field Displays the font size for the text string. Editable.

Italic field Displays the level of italics for the characters in the text string. Editable.

Depth field Displays the level of depth (thus extruding the selection, making it three dimensional). Editable.

Rigid Text button Enable to gang the text string characters as a single geometry. Enabling this button is particularly noticeable when attaching the 3D Text node to a 3D path.

Show Pivots button Enable to display the pivot points for each individual text character in the 3D Text string (displayed in the image window in red). When disabled, only the master character pivot point is displayed (in green).

This setting can also be found in the Character Axis tab.

Separate button Click to separate selected text so that each letter has its own axis. See [Separating Text](#) (page 584).

Motion Blur button Enable to use a motion blur effect for the selected text (can only be used if the global Motion Blur is enabled in the Action Setup menu).

Bevel Curve Applies a bevel to the depth of the geometry when you manipulate the Bevel curve. You can move and add points to the curve, as well as adjust the tangent handles to produce different effects with the text string.

Home button Resets the Bevel curve viewer to show the whole curve.

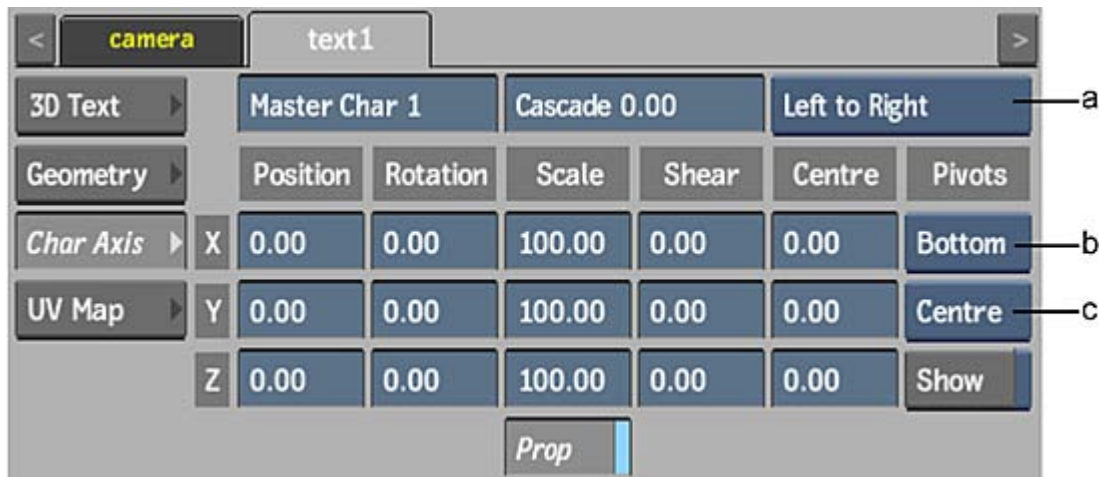

Undo button Undoes the last set of Bevel curve operations.

Reset button Resets the Bevel curve.

Multi Material button Enable to create an Object Group node for each of the front, back, and extrude of the 3D object. You can then attach a different texture map to apply to the different surfaces.

Character Axis Tab

You can change the axis properties of your 3D text string characters. This can be useful in offsetting your text from a 3D path.

(a) Cascade Alignment box (b) Vertical Pivot box (c) Horizontal Pivot box

Master Character field Displays the number of the character in the text string that is considered to be the master. All other text characters follow this character in any character axis settings. Editable.

Cascade field Displays the amount of frames to offset the animation of other characters from the master character. The animation that is offset includes all numeric fields in the Character Axis tab, as well as the Specular, Ambient, Diffuse, Transparency, and Shine fields in the Geometry tab. Editable.

For example, if Cascade is set to 0, all characters have the same animation as the master character. If Cascade is set to a positive number, all characters other than the master character have their animation offset forward in time.

Cascade Alignment box Select the flow of the cascade offset, with respect to the master character.

X Position field Displays the position of the offset along the X axis. Editable.

Y Position field Displays the position of the offset along the Y axis. Editable.

Z Position field Displays the position of the offset along the Z axis. Editable.

X Rotation field Displays the rotation of the offset along the X axis. Editable.

Y Rotation field Displays the rotation of the offset along the Y axis. Editable.

Z Rotation field Displays the rotation of the offset along the Z axis. Editable.

X Scale field Displays the scale of the offset along the X axis. Editable.

Y Scale field Displays the scale of the offset along the Y axis. Editable.

Z Scale field Displays the scale of the offset along the Z axis. Editable.

Proportional Scale button Enable to scale the X, Y, and Z axes proportionally.

X Shear field Displays the shear of the offset along the X axis. Editable.

Y Shear field Displays the shear of the offset along the Y axis. Editable.

Z Shear field Displays the shear of the offset along the Z axis. Editable.

X Centre field Displays the centre of the offset along the X axis. Editable.

Y Centre field Displays the centre of the offset along the Y axis. Editable.

Z Centre field Displays the centre of the offset along the Z axis. Editable.

Vertical Pivot box Select the vertical position of the pivot point for the selected text characters.

Horizontal Pivot box Select the horizontal position of the pivot point for the selected text characters.

Show Pivots button Enable to display the pivot point for each individual text character in the 3D text string, displayed in the image window in red. When disabled, only the master character pivot point is displayed (in green). This setting can also be found in the 3D Text tab.

Geometry and UV Map Tabs

Click the Geometry and UV Map tabs to apply any of the other geometry settings to your 3D text.

See [3D Geometry Menu Settings](#) (page 552) for definitions of the specific Geometry and UV Map controls.

Changing Tessellation Properties

Tessellation is the process of tiling the curves' shapes with polygons. Flame Premium offers three different tessellation methods:

Tessellation Type box Select the tessellation type you want to apply to the geometry. More settings appear if you select Delaunay or Medial Axis.

- **Standard (GLU)** is the least taxing tessellation option, although it is also the least efficient.
 - **Delaunay** generates a mesh composed entirely of triangular polygons. This method gives consistent and predictable results, and in particular, it will not give different results if the tessellated objects are rotated.
 - **Medial Axis** creates concentric contour lines along the medial axes (averages between the input boundary curves), morphing from one boundary shape to the next.
- The Wireframe box is also provided in the Tessellation menu. It is the same setting as in the Geometry tab, but repeated here for ease-of-use.

Each method has its own set of options, described in the sections that follow.

Standard (GLU)

The Standard (GLU) tessellation method is the legacy tessellation option; while being very light in its processing requirements, it is also the least efficient and precise. And compared to Delaunay and Medial Axis tessellation methods, it has no options to fine tune the resulting tessellation.

Delaunay

The Delaunay tessellation method (or more precisely, *constrained Delaunay tessellation*) generates a mesh composed entirely of triangular polygons. This method gives consistent and predictable results, and in particular, it does not give different results if the curves are rotated.

With this method, there are several options for fine-tuning the tessellation further.

Min Angle field Displays the smallest value of angle that the polygons can have. If a triangle contains an angle that is smaller than this value, it gets replaced by better-shaped ones. Eliminating small-angled triangles gives a more uniform shading and is more suited for deformations.

Min Angle = 20

Max Area field Displays the largest value of area that the polygons can have. If a triangle is larger than this value, it gets replaced by smaller ones. This allows the polygon mesh to be deformed more smoothly.

Max Area = 5

Max Vertices field Displays the total number of new vertices that can be added by the Minimum Angle and Maximum Area options. 0 by default.

Use this option as a precaution against accidentally setting the other options to values that would create huge amounts of geometry with long processing times.

It is not recommended that you rely on this option to control the final number of vertices because it can force the tessellation to stop before the process is completed, thereby giving an unpredictable combination of polygon shapes and sizes.

Boundary Split box Select an option to control tessellation along boundaries.

Select:	To:
Free	Allow the boundary edges along the outer contour and inner holes to be split further during tessellation. This is particularly useful for text and other shapes that may contain straight edges that need to be deformed smoothly.
None (Contour Only)	Allow boundary edges along inner holes to be split, but not boundary edges along the outer contour. Note that this may affect the uniformity of the mesh if you enabled Min Angle or Max Area.
None (Contour and Holes)	Prevent any boundary to be split. Note that this may affect the uniformity of the mesh if you enabled Min Angle or Max Area.

Medial Axis

The Medial Axis tessellation method creates concentric contour lines along the medial axes (averages between the input boundary curves), morphing from one boundary shape to the next. This method creates mainly quads with some triangles, so it is well-suited for subdivision surfaces.

With this method, there are several options for fine-tuning the tessellation further.

Loops field Displays the number of loops used in the tessellation, modified by the Adaptive toggle.

Loops = 2

Adaptive button Enable to set the Loops field as the average number of medial axes drawn and to keep the distance between them fairly constant. Disable to set the Loops field as the exact number of medial axes drawn per boundary (rounded to the nearest integer).

Backtrack Length field Displays the tessellation value at the extremities. Editable.

Set to:	To have:
0	The medial axis intersects boundaries at each point of concavity, which can often create many small triangles especially in sharp extremities.
Positive value	The medial axis does not extend completely to the boundary and the remaining area is tessellated with a fan shape.
Negative value	Sharper embossing effects

Split Edges to Enhance button Enable to add vertices to allow the contour lines to follow the medial axes more accurately. Turn this option off if there are no holes in the geometry; otherwise, there may be shading artifacts along internal curves.

Edge Tessellation box Select an option to control the shape of the polygons.

Select:	To:
None	Have long edges that are not split. This results in fewer polygons and lighter geometry, but the resulting long, thin polygons may not deform well.
Equal on Both Sides	Have a tessellation made of squarer polygons that deform better, at the cost of a heavier tessellation.

About Shading and Textures

Action uses shaders to compute the colour, lighting, shadows, and other attributes of each pixel or vertex of objects in the scene. Shaders use the processing pipeline of the GPU to accelerate object-specific rendering effects. You can use shaders to control the interaction between surfaces or models and the lights in the scene to contribute to the realism of a material simulated in a texture.

You can use any media to map textures to Action surfaces and geometries, thus adding detail such as depth and reflections to your 3D composites.

Substance Textures

Use the Substance Texture node to quickly create photorealistic procedural textures using a library of organic, fabric, and material presets. A loaded preset consists of a Material Node, a Substance node, as well as other texture maps and shaders, as needed.

TIP You can also create textures with your own input materials, such as photographs, using the [Substance Materialize](#) (page 598) node.

To add a Substance preset:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the Substance Texture.
- 2 Do one of the following:
 - Drag the Substance Texture node from the node bin and place it in the schematic.
 - Double-click the Substance Texture node.
The file browser appears, pointing to the default location of the presets: *usr/discreet/<product home>/substance_presets/TEXTURE*

TIP Switch to Proxies view to see a visual representation of the presets.

- 3 Navigate through the subfolders and select the Substance Texture preset you want to load.
The preset, with applicable maps and shaders, is automatically loaded into Action.

Using Third-Party Substance Textures

While Flame Premium comes with a selection of Substance Texture presets, you can also use Substance Textures available in Autodesk Maya, Autodesk 3ds Max, or created with the Substance Designer from Allegorithmic. In these cases, a Substance Texture file uses the *.sbsar* file extension.

To use an *.sbsar* Substance Texture file, simply select Interop Format from the Substance Format box in the preset file browser, then navigate to and select your *.sbsar* file. The Substance Texture, with applicable maps and shaders, is automatically loaded into Action.

Navigating the Schematic with a Substance Texture

When you load a Substance Texture preset into the Action schematic, multiple nodes are added and connected with different types of links, creating a type of Substance group. You can work with the menus of the various nodes (such as the Parallax node) as you would if you had added the object manually.

Keep in mind the following when working with Substance Texture presets in the schematic and menus:

- The Substance node is parented by an Axis node, itself parented by a Material node, and is the parent of some or all of the following map nodes:
 - Specular node — see [Specular Mapping](#) (page 620)
 - Normal node — see [Normal Mapping](#) (page 616)
 - Diffuse node — see [Diffuse Mapping](#) (page 628)
 - Parallax node — see [Parallax Mapping](#) (page 612)
 - Displacement node (locked to Hardware Displacement) — see [Displacement Mapping](#) (page 607)
 - Emissive node — see [Emissive Mapping](#) (page 624)

Media is automatically applied to these mapping nodes, and cannot be changed.

- The Substance node is also parented to a Reflection node, with its own axis. You can apply media to the Reflection node. See [Reflection Mapping](#) (page 632).
- A Shader node is parented from the Substance node. Lighting links (blue dotted lines) are applied from the Shader node to the Substance node and the originally selected surface or geometry. See [Using the Shader Node](#) (page 600).

- Some presets require you to add input media to feed into the Substance node and attached maps to create a plausible effect. For example, the *Broken_Glass* preset in the *Glass* category requires one input node. See [Substance Textures with Inputs](#) (page 594).
- All Map parameters are loaded with default values based on the loaded Preset. Reflection map parameters sometimes have an expression automatically set on its effect or softness values.
- The Diffuse node acts as an originating duplicate object to the present Specular, Normal, Emissive, and Parallax nodes (green dotted lines). Therefore, any common settings applied to one of these map nodes are applied to all map nodes. The common settings are found in the Texture tab of any of the map menus. See [Mimicking, Copying, and Duplicating Objects](#) (page 437).
- Since the Substance preset requires all of the loaded objects, and the parenting, lighting, and duplicate links to function correctly, you are unable to delete any of the objects separately, or break any of the links.
- Some presets load and use only the maps that are needed for that preset. For example, the *Defocused_Light* preset in the *Abstract* category includes only an Emissive map that blends in additive mode with the diffuse colour of the attached surface or geometry. In this case, the preset works best if the diffuse colour in the Geometry or Image menu is set to black.
- You cannot parent an object from any of the Substance objects. You can parent the Material node to another object to substitute for one of the Substance maps. For example, you can add a Diffuse map and connect it to the Material node, and then hide the Substance Diffuse map so that it is no longer applied to the Substance effect.
- If you select a surface or geometry before adding the Substance Texture preset, the connection to the Material node of the Substance node, and the lighting link from the Shader node are automatically applied. If you do not select a surface or geometry first, you have to make these connections manually for the Substance node to function correctly.

Substance Textures with Inputs

Some semi-transparent presets, such as those with water or glass, may require one or more media inputs to be added manually. This is done so that the Substance node and attached maps can correctly create a plausible effect. When you load a Substance Texture preset that requires media input, one or more input nodes are attached to the Substance node in the schematic.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

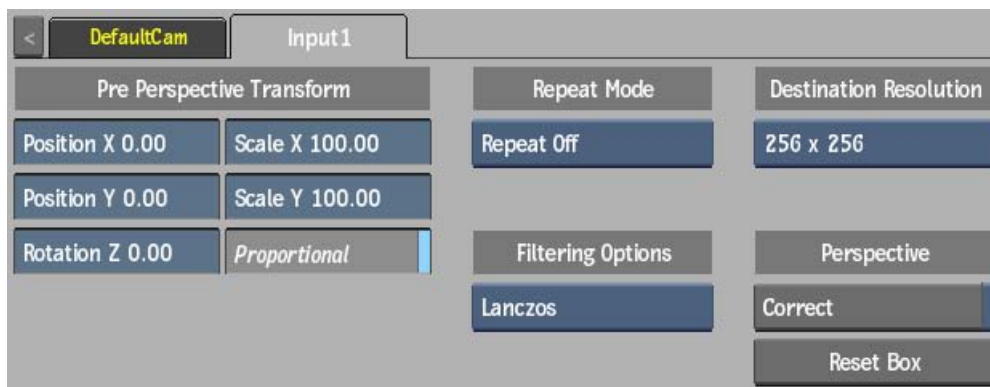

To specify media as the input source:

- 1 Select the Input node in the schematic.
- 2 Select the appropriate media in the Media list.
- 3 Click Apply.

NOTE If media is selected in the Media list prior to adding a Substance Texture preset that requires an input, the media is automatically added to the input. You can change the input by following the steps above. For presets with more than one input, only the first input is added automatically.

- 4 Double-click the Input node in the schematic to access the Input menu.

Input Menu Settings

Position X field Displays the X-axis offset applied to the clip. Editable.

Position Y field Displays the Y-axis offset applied to the clip. Editable.

Rotation field Displays the rotation offset applied to the clip. Editable.

Scale X field Displays the X-axis scaling offsets applied to the clip. Editable.

Scale Y field Displays the Y-axis scaling offsets applied to the clip. Editable.

Proportional button Enable to affect the Scale fields proportionally.

Repeat Mode box Select how the input media is repeated (after Transform settings are applied).

Filter box Select the type of filtering to apply to the input media.

Destination Resolution box Select the square destination resolution of the input media.

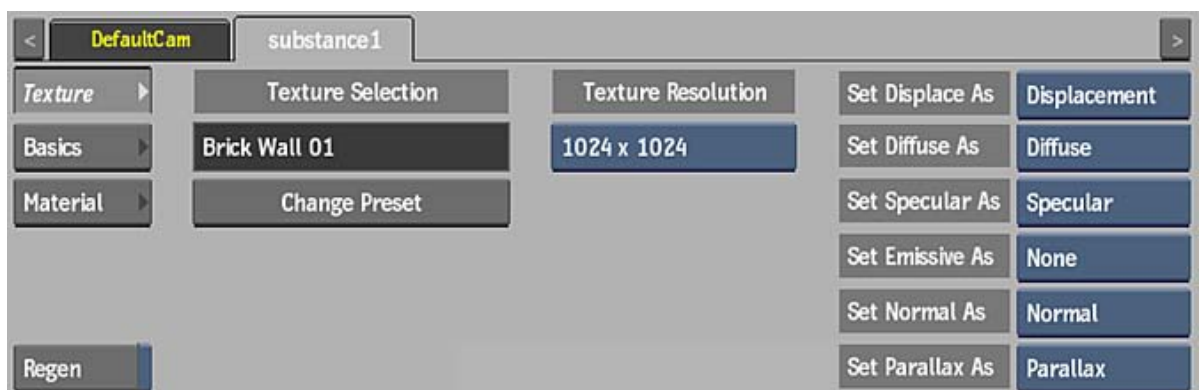

Perspective Correct box Enable to apply perspective transformations to the input. Switch to Object view (F8), and interactively align the perspective of what area you want to include in the input image.

Reset Box button Click to reset the Perspective box in the Object view.

Substance Menu Settings

Double-click the Substance node to access the Substance menu. The Substance menu is divided into three tabs.

The Texture tab contains settings related to the selection and resolution of the texture.

Preset Name field This locked field displays the name of the current preset.

Change Preset button Click to open the file browser to select a different preset.

Texture Resolution box Select the resolution of the pattern.

Lock Width and Height button Not shown. Enable to lock the texture resolution width and height. Disable to be able to select different width and height values. Available when using third-party Substance Textures or the Substance Materialize node.

Texture Resolution Width box Not shown. Select the width resolution of the pattern. Available if Lock Width And Height is disabled.

Texture Resolution Height box Not shown. Select the height resolution of the pattern. Available if Lock Width And Height is disabled.

Set Displace As box Select a map to be used as the Displace pass. This is useful if you want to rewire one of the maps in the substance (such as the Bump map), that might be invisible, to be seen explicitly.

Set Diffuse As box Select a map to be used as the Diffuse pass. This is useful if you want to rewire one of the maps in the substance (such as the Bump map), that might be invisible, to be seen explicitly.

Set Specular As box Select a map to be used as the Specular pass. This is useful if you want to rewire one of the maps in the preset (such as the Bump map), that might be invisible, to be seen explicitly.

Set Emissive As box Select a map to be used as the Emissive pass. This is useful if you want to rewire one of the maps in the preset (such as the Bump map), that might be invisible, to be seen explicitly.

Set Normal As box Select a map to be used as the Normal pass. This is useful if you want to rewire one of the maps in the preset (such as the Bump map), that might be invisible, to be seen explicitly.

Set Parallax As box Select a map to be used as the Parallax pass. This is useful if you want to rewire one of the maps in the preset (such as the Bump map), that might be invisible, to be seen explicitly.

TIP Use the Output Rewire boxes to define how the images making up the Substance are wired to each texture map. If a texture map is not used by the selected Substance, the Output Rewire box is set to None. You can also rewire a texture map to None to disable it and remove it from the Action Schematic (the map is not deleted, just disabled).

Regen button Enable to dynamically refresh the image as changes are made to the settings. If you notice a slowdown in interactivity, disable Regen.

NOTE The Regen button is available from all Substance menu tabs.

The Basics tab contains settings common to all Substance presets. Settings that are not applicable to a specific preset are greyed out.

< DefaultCam		substance1			
Texture ▶	Hue	0.000	Depth	0.000	
Basics ▶	Luminosity	0.500	Normal	0.500	
Material ▶	Saturation	0.500	Emboss	5.00	
	Contrast	0.000	Angle	45	
	Random	1	Relief	64.00	
Regen	Overall Speed	100.00%	Time Offset	0	

Hue field Displays the colour range of the texture. Editable.

Luminosity field Displays the brightness level of the texture. Editable.

Saturation field Displays the level of colour purity of the texture. Editable.

Contrast field Displays the gradations between the light and dark areas of the texture. Editable.

Random field Displays the random seed value of the generated texture. Editable.

Depth field Displays the attenuation of depth of the texture. Editable.

Normal field Displays the attenuation of the normals of the texture. Editable.

Emboss field Displays the level of enhanced details of the texture. Editable.

Angle field Displays the angle of diffuse in relation to the level of Emboss applied to the texture. Editable.

Relief field Displays the frequency of surface detail between attached Parallax and Displacement maps. Editable.

Overall Speed field Displays the rate at which the animation plays. Editable.

Time Offset field Displays the start point of the animation. With a value of 0, the animation starts at frame 1. With a value of 100, the animation begins as if it has been generating for 99 frames. You cannot animate this field. Editable.

The settings in the Material tab vary depending on the preset chosen.

< DefaultCam		substance1			
Texture ▶	Age	0.25			
Basics ▶	Bricks X	10			
Material ▶	Bricks Y	26			

For example, the Material settings for the BrickWall01 preset allow you to age the bricks, and alter the number of the bricks on the X and Y axes.

Some presets include a Flow field in the Material settings. Animate the Flow field to create a motion behaviour specific to the preset.

Substance Materialize

The Substance Materialize node allows you to easily create realistic material textures based on your own image inputs. When you add a Substance Materialize node to the Action schematic, you'll notice the familiar Substance tree of maps and shaders. Simply specify your input image, as well as optional Height and Details maps, and use the menu settings to fine-tune the results.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

Here is an example of the various inputs in a Substance Materialize:

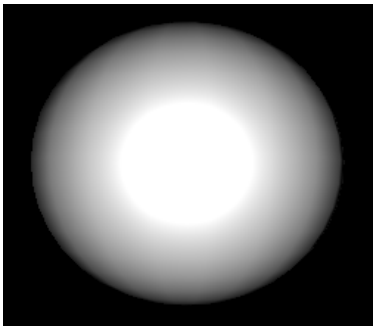

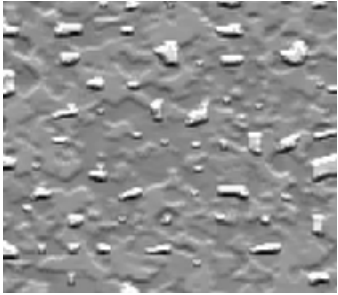

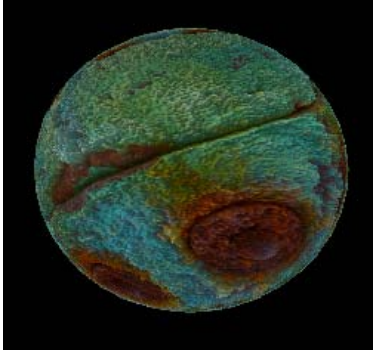

Image	Comments
	Initial sphere geometry
	Input image Single-frame .tif photo of rusty screws in a wall.
	Height Map An optional grayscale image file you can use to enhance elevation. Black represents the lowest elevation on the map, while white represents the highest.

Image	Comments
	<p>Details Map An optional image file allowing you to specify fine details in your result.</p>
	<p>Result After applying inputs and various Substance settings.</p>

Adding a Substance Materialize Node

To add a Substance Materialize node:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the Substance Materialize.
- 2 In the Media list, select the image that you want to use as the input. You can add this later, or even change the media.
- 3 Do one of the following:
 - Drag the Substance Materialize node from the node bin and place it in the schematic.
 - Double-click the Substance Materialize node.

The Substance tree, with applicable maps, shaders, and inputs appears in the Action schematic.
- 4 To specify different media as the input source, select the input node in the schematic, select the media in the Media menu, then click Apply.
- 5 Optional: If you have Height and Details maps, you can also use them to enhance your Substance material. Simply apply them from the Media list in the same manner as with the Input image.
- 6 Double-click any of the nodes in the schematic to access its menu.

Materialize Settings

Once you have added a Substance Materialize node (with your Input image and optional Height and Details maps), you have settings in various menus that you can use to tweak your result.

The Substance menu is different than if you added a Substance Texture preset. You have tabs in the Substance menu with settings to control the texture, inputs, normal, specular, ambient occlusion, and depth. See the tooltips for help with each setting.

For each input, you also can use the [Input menu](#) (page 595) (as with Substance Textures with inputs), and the Object view (F8). The Object view lets you visualize changes that you make to the Input menu settings. In the Object view, you can also interactively align the perspective of the area you want to include in the input image.

Using the Shader Node

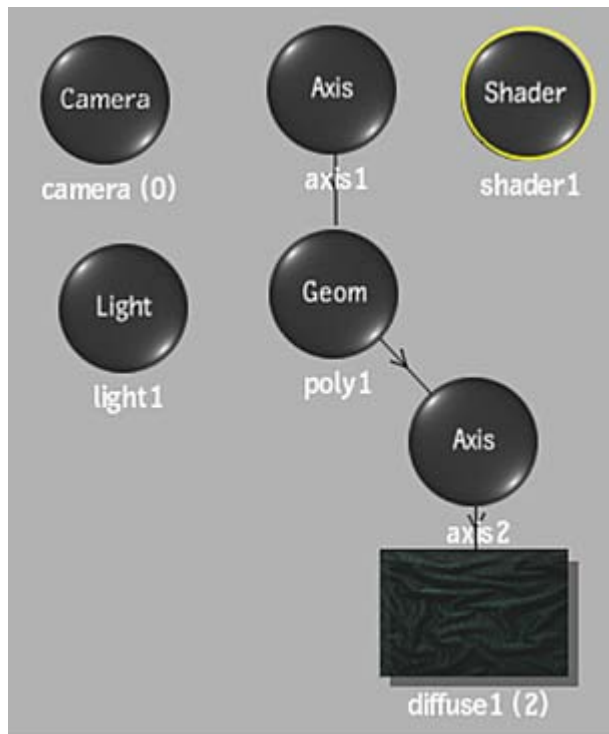

You can add a shader to your scene to apply to all objects in the scene. You also have the option of selectively applying a specific shading algorithm, or turning shading off completely. You can use multiple shaders in an Action scene, but only one shader can be applied to each object. Even if no shaders are present in the schematic, Action uses an implicit default shader that applies to the whole scene.

NOTE The shader node is not a typical Action object — its appearance in the schematic represents the ability to selectively include or exclude shading from objects in the scene.

To add a shader to the scene:

- 1 Do one of the following:
 - Drag the Shader node from the node bin and place it in the schematic.
 - Drag the Shader node from the node bin and place it in Result view.
 - Double-click the Shader node. You do not need to be in Schematic view to add a node in this manner.

A shader is added to the scene. If you select a surface or 3D geometry in the scene before adding the Shader node, a shader inclusion link is automatically applied. You can also apply inclusion and exclusion links manually. See [Applying a Selective Shader](#) (page 601).

Unlike many objects, a shader is not a confined object in the perspective space, and therefore is added without an axis.

- 2 To display the Shader menu, double-click the selected shader in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
- 3 From the Shader Type box, select a shading algorithm, or turn shading off.

See [Shader Types and Settings](#) (page 604) for more information on the shader algorithms, and their settings.

Applying a Selective Shader

If you select a surface or 3D geometry in the scene before adding a Shader node, a shader inclusion link is automatically applied; otherwise, the shader is applied to all objects. You can also apply inclusion and exclusion links manually. You may want a shader to only affect an individual or specific group of objects, or prevent a shader from affecting an individual or specific group of objects.

To apply selective shading:

- 1 Add a shader to the scene.
All objects are affected.

- 2 Select Lighting from the Tools box.
- 3 To affect only a selected object, click the Shader node, and drag it to an object you want affected.
The selected object is connected to the shader by a blue dotted line with an arrow, and only the selected objects are affected.

(a) Shader inclusion link

- 4 To exclude an object, hold the **Alt** key while clicking and dragging from the shader to the object you do not want affected.
Excluded surfaces are connected to the shader by a red dotted line with an "X", and they are not affected by the shader.

(a) Shader exclusion link

NOTE To remove the inclusion or exclusion link, click and drag over the line that connects the Shader node to the object (while in Lighting mode).

Shader Types and Settings

Depending on the look you are trying to apply to an object or the scene, you can select from among different shader algorithms. The differences between the shader types are sometimes subtle, as they build upon the same algorithms, such as Fresnel or the Oren-Nayar diffuse model.

Some of the settings in the Shader menu change depending on the shader type chosen. See the following sections for the specific settings for each shader type.

Shader Type box Select a shading algorithm, or turn shading off.

Anisotropic Shader

Use the anisotropic shader to control the specular effect of the highlights.

X Roughness field Displays the shape of specularity of the shader along the X axis. Editable.

Y Roughness field Displays the shape of specularity of the shader along the Y axis. Editable.

Fresnel Offset field Displays the total amount of specular light.

Fresnel Factor field Displays the amount of specular light at grazing angles.

TIP To cancel out the Fresnel effect altogether, set the Fresnel Offset to 0 and the Fresnel Factor to 100.

Cook-Torrance Shader

Use the Cook-Torrance shader for high specularity materials, such as metals or shiny plastics. This shader includes Fresnel controls for specularity.

Roughness field Displays the shape of specularity of the shader.

Fresnel Offset field Displays the total amount of specular light.

Fresnel Factor field Displays the amount of specular light at grazing angles.

TIP To cancel out the Fresnel effect altogether, set the Fresnel Offset to 0 and the Fresnel Factor to 100.

Fresnel Shader

The Fresnel shader contains only Fresnel controls for the specularity.

Roughness field Displays the shape of specularity of the shader.

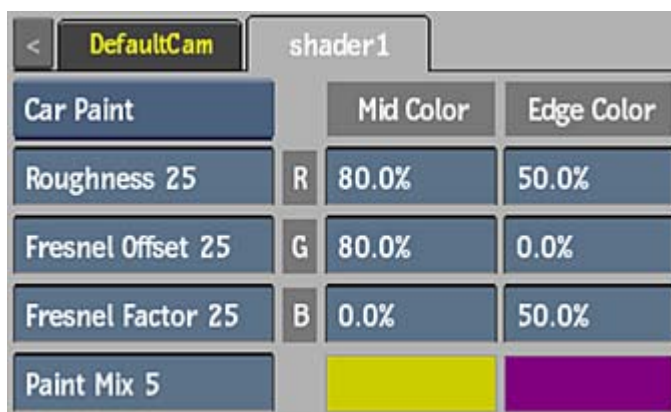

Fresnel Offset field Displays the total amount of specular light.

Fresnel Factor field Displays the amount of specular light at grazing angles.

TIP To cancel out the Fresnel effect altogether, set the Fresnel Offset to 0 and the Fresnel Factor to 100.

Car Paint Shader

Use the Car Paint shader to blend between two colour tones, based on the viewing angle and the normal of the object. This shader includes Cook-Torrance shaders and Fresnel controls for the specularity.

Roughness field Displays the shape of specularity of the shader.

Fresnel Offset field Displays the total amount of specular light.

Fresnel Factor field Displays the amount of specular light at grazing angles.

TIP To cancel out the Fresnel effect altogether, set the Fresnel Offset to 0 and the Fresnel Factor to 100.

Paint Mix field Displays the viewing angle of the normal that occurs between parallel (mid colour) and perpendicular (edge colour). Editable.

Red Mid Colour field Displays the red mid colour value. Editable.

Green Mid Colour field Displays the green mid colour value. Editable.

Blue Mid Colour field Displays the blue mid colour value. Editable.

Mid colour pot Displays the mid colour. Editable.

Red Edge Colour field Displays the red edge colour value. Editable.

Green Edge Colour field Displays the green edge colour value. Editable.

Blue Edge Colour field Displays the blue edge colour value. Editable.

Edge colour pot Displays the edge colour. Editable.

Displacement Mapping

Use displacement mapping to create a 3D model from a 2D surface. The values of a selected colour channel in the displacement source clip are used to create a displacement map. Displacement mapping uses the media's matte clip, so you can turn the matte on or off to get the desired effect.

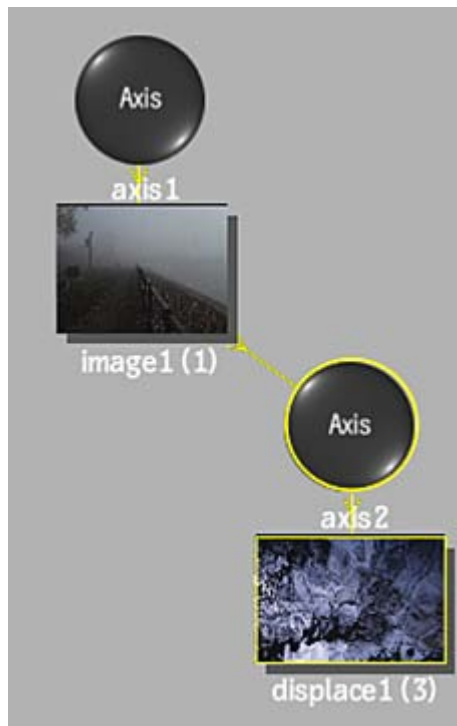

You have the choice of applying hardware or software displacement mapping. Hardware displacement mapping is GPU-accelerated and allows you to create a normal map if none exists. Software displacement mapping displaces the pixels of the surface along the positive or negative X, Y, and/or Z axes. Hardware Displacement is faster than software displacement, especially when using low resolution values in an image surface (high polygon count).

NOTE If the Displace node is attached to an imported 3D Geometry, you may need to select a UV Mapping mode other than Default in the Geometry menu for the displace pattern to have an effect on the geometry. See [UV Map Settings](#) (page 553).

To add a displacement map:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the displacement.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the displacement.
- 4 Do one of the following:
 - Drag the Displace Map node from the node bin and place it in the schematic.
 - Drag the Displace Map node from the node bin and place it where you want it in Result view.
 - Double-click the Displace Map node. You do not need to be in Schematic view to add a node in this manner.

The displace object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the displace node indicates the media used for the displacement.

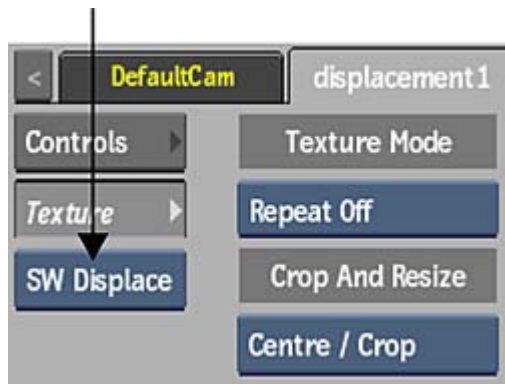

To specify different media as the displacement source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the Displace node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).

The Displacement menu appears. You can choose between Hardware Displacement or Software Displacement using the Displacement Type box.

Software Displacement Menu Settings

Displacement Type box Select whether to use hardware or software displacement mapping.

Regen button Enable to dynamically refresh the image as changes are made to the menu settings.

The Software Displacement menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Channel box Select a colour channel to calculate the displacement map.

Softness field Displays the level of rounding off, or softening of the spikes that result from colour values in the image that vary from pixel to pixel in the displacement map. Editable.

Softness rounds the edges of the displacement. The larger the softness, the smoother the displacement. Softness also affects rendering; the larger the softness, the longer it takes to render.

Displace Direction box Select the direction in which a displace occurs when a displacement map is attached to a surface. Geometries parented to a displacement map always use Normal Displace as the direction.

Select:	To Displace:
Flat Displace	In the X, Y, and Z directions.
Normal Displace	Bilinear and bicubic surfaces according to their normals.
Camera Displace	In the direction of the camera selected in the Displace Camera box.

Offset field Displays the offset to the displacement of X and Y. Editable.

Displace Camera box Active only when Camera Displace is selected in the Displace Direction box. Select which camera to take into account when using camera displacement.

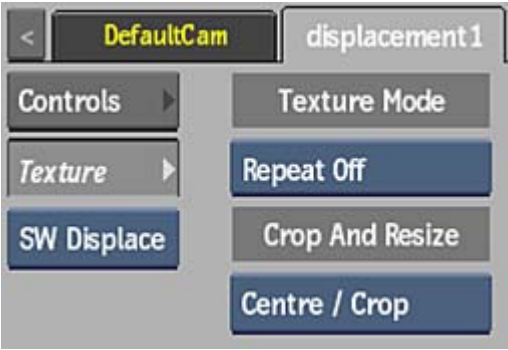

Displace Camera field Displays the active displace camera number. Non-editable.

Displacement X field Displays the amount of displacement in pixel units along the X axis. Editable.

Displacement Y field Displays the amount of displacement in pixel units along the Y axis. Editable.

Displacement Z field Displays the amount of displacement in pixel units along the Z axis. Editable.

Texture Tab

Repeat mode box Select how the map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the map.

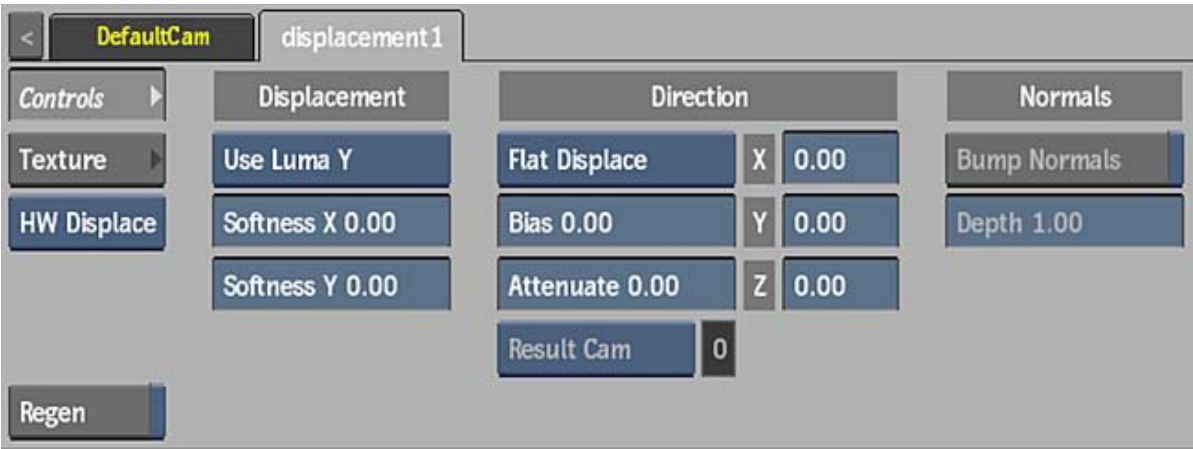

Hardware Displacement Menu Settings

Displacement Type box Select whether to use hardware or software displacement mapping.

Regen button Enable to dynamically refresh the image as changes are made to the menu settings.

The Hardware Displacement menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Channel box Select a colour channel to calculate the displacement map.

Softness X field Displays the amount of X-axis blur applied to the map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the map. Editable.

Displace Direction box Select the direction in which a displace occurs when a displacement map is attached to a surface. Geometries parented to a displacement map always use Normal Displace as the direction.

Select:	To Displace:
Flat Displace	In the X, Y, and Z directions.

Select:	To Displace:
Normal Displace	Bilinear and bicubic surfaces according to their normals.
Camera Displace	In the direction of the camera selected in the Displace Camera box.

Bias field Displays the distance between the real surface of the object and the perceptual ground (zero level) of the texture. Editable.

Attenuate field Displays the level of amplitude of the effect caused by the displacement map texture. Editable.

Displace Camera box Active only when Camera Displace is selected in the Displace Direction box. Select which camera to take into account when using camera displacement.

Displace Camera field Displays the active displace camera number. Non-editable.

Displacement X field Displays the amount of displacement in pixel units along the X axis. Editable.

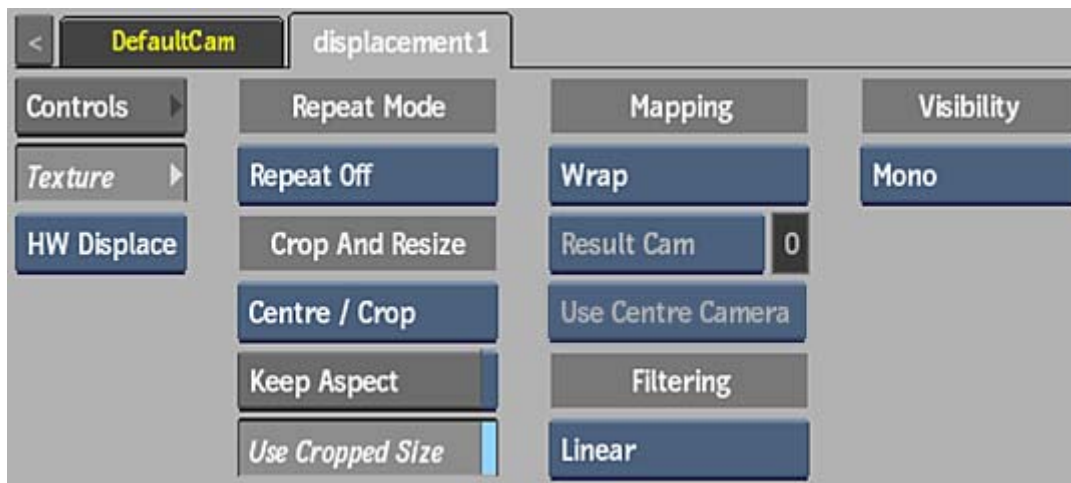

Displacement Y field Displays the amount of displacement in pixel units along the Y axis. Editable.

Displacement Z field Displays the amount of displacement in pixel units along the Z axis. Editable.

Bump Normals button Enable to allow the map to create a normal map for enhanced lighting effects. Used only if no normal map exists for the object using the displacement texture. The availability of this setting is dependant on your graphics card.

Depth field Displays the amount of Z scale applied to the generated normals. Higher values attenuate the effect toward the normals of the parent surface. Editable.

Texture Tab

Repeat mode box Select how the map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the map with the cropped size of the media. Disable to use the cropped media as is.

Mapping box Select the type of texture mapping.

Wrap Wrap mapping completely envelops the 3D model with the texture map according to the object's texture coordinates. To use this option, you must import a model that has its own texture coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu.

Plane Planar mapping applies the map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the texture values. Planar mapping positions the lower-left corner of the map on the 3D model's axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the "sides" of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the map based on the selected camera's field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the map.

Camera Type box Select the camera type visibility for the map.

Parallax Mapping

Parallax mapping can generate a visual result similar to that of a displacement map without actually displacing polygons. Parallax mapping uses the height map (similar to a displacement map) to determine how the object texture should be warped in order to simulate shading and occlusion effects, without actual polygonal displacement.

Because a parallax map does not actually change the polygons of the object, there are inherent limits to the illusion — looking at the object from the side will reveal the cheat. It is best used on surfaces and geometries where you do not see the angles or edges.

To add a parallax map:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the parallax.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the parallax.
- 4 Do one of the following:
 - Drag the Parallax Map node from the node bin and place it in the schematic.
 - Drag the Parallax Map node from the node bin and place it where you want it in Result view.

- Double-click the Parallax Map node. You do not need to be in Schematic view to add a node in this manner.

The parallax object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the Parallax node indicates the media used for the parallax.

To specify different media as the parallax source, select the media in the Media menu, then click Apply.

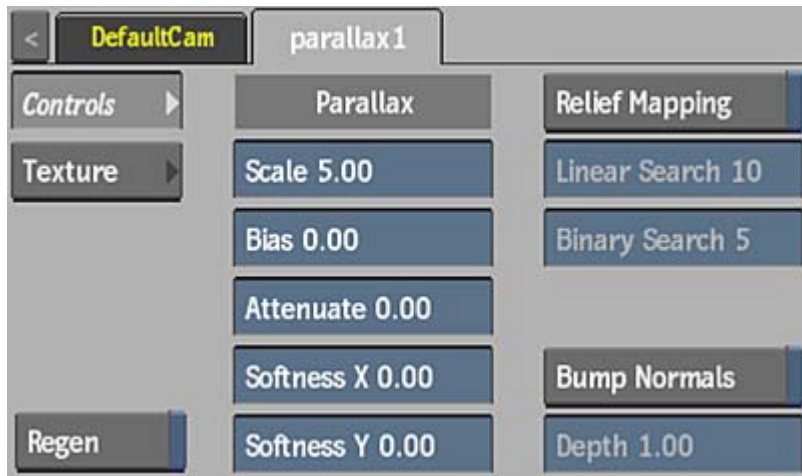

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the Parallax node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
The Parallax menu appears.

Parallax Menu Settings

The Parallax menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Regen button Enable to dynamically refresh the image as changes are made to the parallax settings.

Scale field Displays the perceptual height of the texture driven by the parallax map. Editable.

Bias field Displays the distance between the real surface of the object and the perceptual ground (zero level) of the texture. A value of half of the Scale field value should give the best results.

Attenuate field Displays the level of amplitude of the effect caused by the parallax map texture. Editable.

Softness X field Displays the amount of X-axis blur applied to the parallax map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the parallax map. Editable.

Relief Mapping button Enable to augment the 3D surface detail by creating occlusions where changes occur in the parallax map. Rendering is slower when enabled, but the results may be better.

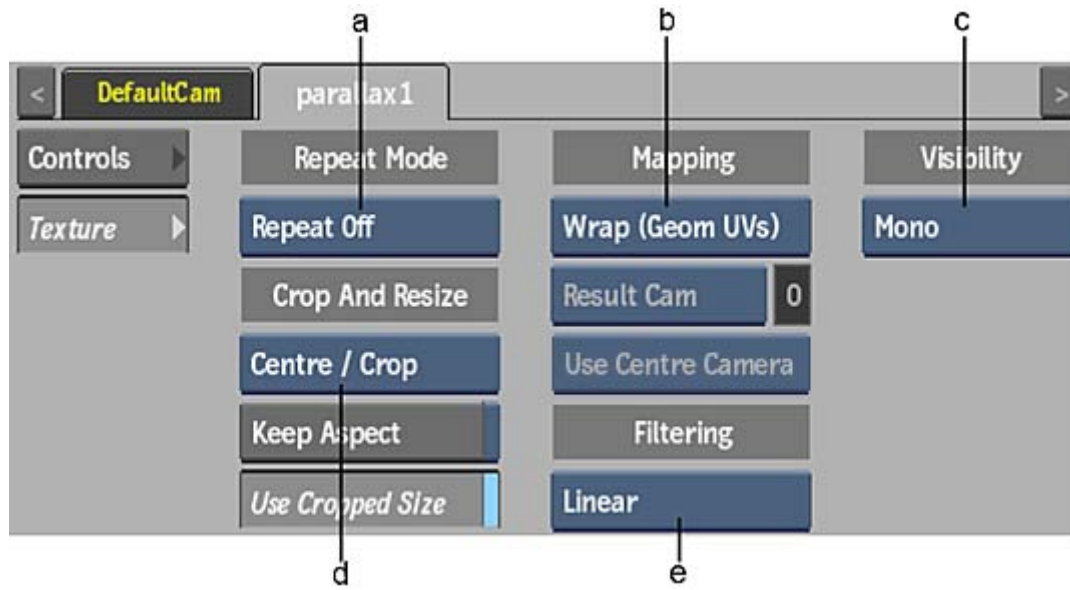

Linear Search field Displays the number of steps to search for the best depth in the relief map. Editable.

Binary Search field Displays the number of steps to refine the precision of the best depth found by the linear search. Editable.

Bump Normals button Enable to allow the parallax map to create a normal map for enhanced lighting effects. Used only if no normal map exists for object using the parallax texture. Enabling also affects the Normal output in Action.

Depth field Displays the amount of Z scale applied to the generated normals. Higher values increase the effect of normals. Editable.

Texture Tab

(a) Repeat Mode box (b) Mapping box (c) Camera Type box (d) Fit Method box (e) Filter box

Repeat Mode box Select how the parallax map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the parallax map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the parallax map with the cropped size of the parallax media. Disable to use the cropped parallax media as is.

Mapping box Select the type of texture mapping.

Wrap (Geom UVs) Wrap mapping completely envelops the 3D model with the texture map according to the object's texture coordinates. To use this option, you must import a model that has its own texture coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu. See [UV Map Settings](#) (page 553).

Plane Planar mapping applies the map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the texture values. Planar mapping positions the lower-left corner of the map on the 3D model's axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the "sides" of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the map based on the selected camera's field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Perspective Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Perspective Camera field Displays the active perspective or projection camera number. Non-editable.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the parallax map.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.
EWA	A high-quality elliptical weighted average filter to produce enhanced rendering results (slower to process than other filters).
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

TIP You can set the default filtering type in the Action Setup menu Preferences tab.

Camera Type box Select the camera type visibility for the parallax map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

Normal Mapping

A normal map is used to simulate bumps and lighting on a surface or geometry. You can apply a normal map to modify how a surface reacts to shading. You can manipulate a surface's normals based on X, Y, and Z offsets.

To add a normal map:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the normal.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the normal.
- 4 Do one of the following:
 - Drag the Normal Map node from the node bin and place it in the schematic.
 - Drag the Normal Map node from the node bin and place it where you want it in Result view.
 - Double-click the Normal Map node. You do not need to be in Schematic view to add a node in this manner.

The normal object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the normal node indicates the media used for the normal.

To specify different media as the normal source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the Normal node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).

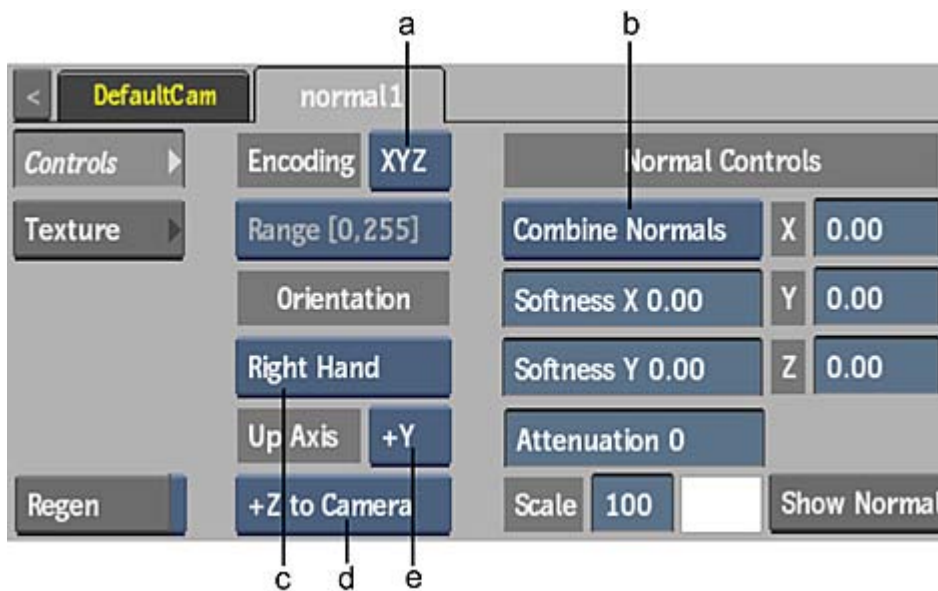

The Normal menu appears.

Normal Menu Settings

The Normal menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Use the Encoding and Orientation settings to help Action with information on how the normal map was encoded and rendered. Then use the Normal Controls to tweak the map in Action.

(a) Encoding box (b) Normals box (c) Orientation box (d) Camera box (e) Up Axis box

Encoding box Select the order that the normal map is encoded based on the interpretation of the RGB channels (XYZ or XZY).

Range box When working with floating point normal map media, select the range of the normal map media: [0, 1] or [-1, 1]. When working with 8-, 10-, or 12-bit images, the Range box displays the appropriate range for Action, but the box is greyed out.

Orientation box Select whether the orientation of the coordinate system of the map is Left Hand or Right Hand.

Up Axis box Select which axis is the up axis of the map.

Camera box Select which axis of the map corresponds to the Z axis in Action. The selection in the Up Axis box determines the available selections in this box.

Normals box Select whether to combine or replace the normal map with the surface normals.

Select:	To:
Combine Normals	Combine the normals map texture with the surface's normals.
Replace Normals	Apply only the normal map texture to the surface (ignoring the surface normal properties).

Softness X field Displays the amount of X-axis blur applied to the normal map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the normal map. Editable.

Attenuation field Displays the level of amplitude of the effect caused by the normal map texture. Editable.

X Normal axis Displays the amount of offset in pixel units along the X axis.

Y Normal axis Displays the amount of offset in pixel units along the Y axis.

Z Normal axis Displays the amount of offset in pixel units along the Z axis.

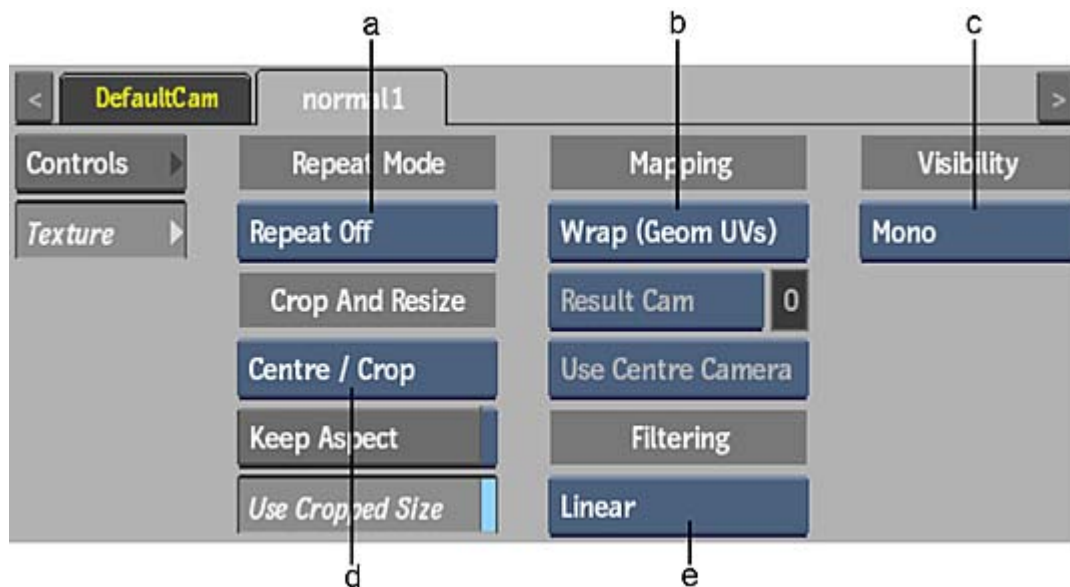

Show Normals button Enable to display normal vectors over the surface.

Normals colour pot Displays the normal vectors colour. Editable.

Scale field Displays the scale of the normal vectors. Editable.

Regen button Enable to dynamically refresh the image as changes are made to the normal settings.

Texture Tab

(a) Repeat Mode box (b) Mapping box (c) Camera Type box (d) Fit Method box (e) Filter box

Repeat mode box Select how the normal map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the normal map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the normal map with the cropped size of the normal media. Disable to use the cropped normal media as is.

Mapping box Select the type of texture mapping.

Wrap (Geom UVs) Wrap mapping completely envelops the 3D model with the texture map according to the object's texture coordinates. To use this option, you must import a model that has its own texture coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu.

Plane Planar mapping applies the map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the texture values. Planar mapping positions the lower-left corner of the map on the 3D model's axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the "sides" of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the map based on the selected camera's field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number. Non-editable.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the normal map.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.
EWA	A high-quality elliptical weighted average filter to produce enhanced rendering results (slower to process than other filters).
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

TIP You can set the default filtering type in the Action Setup menu Preferences tab.

Camera Type box Select the camera type visibility for the normal map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

NOTE If the Normal node is attached to a 3D Geometry node, you may need to select a UV Mapping mode other than Default in the Geometry menu for the normal pattern to have an effect on the geometry. See [UV Map Settings](#) (page 553).

Specular Mapping

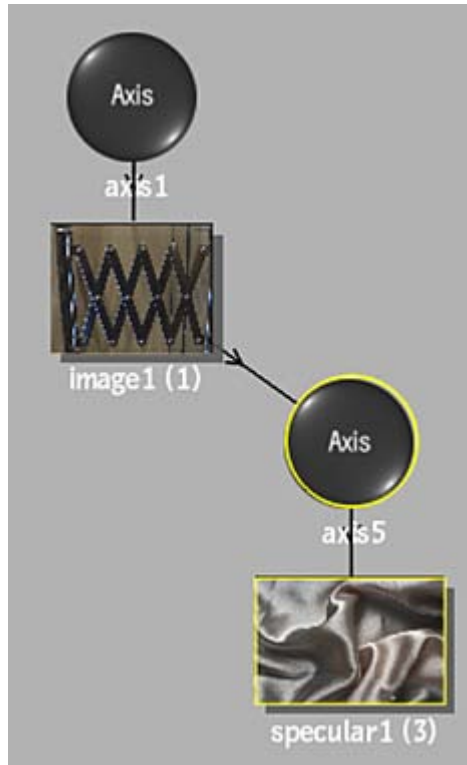

A specular map defines the shininess and highlight colour of a surface or geometry.

To add a specular map:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the specular.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the specular.

- 4 Do one of the following:
- Drag the Specular Map node from the node bin and place it in the schematic.
 - Drag the Specular Map node from the node bin and place it where you want it in Result view.
 - Double-click the Specular Map node. You do not need to be in Schematic view to add a node in this manner.

The specular object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the Specular node indicates the media used for the specular.

To specify different media as the specular source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the Specular node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
- The Specular menu appears.

Specular Menu Settings

The Specular menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Effect field Displays the amount of specular colour. Editable.

Softness X field Displays the amount of X-axis blur applied to the specular map. Editable.

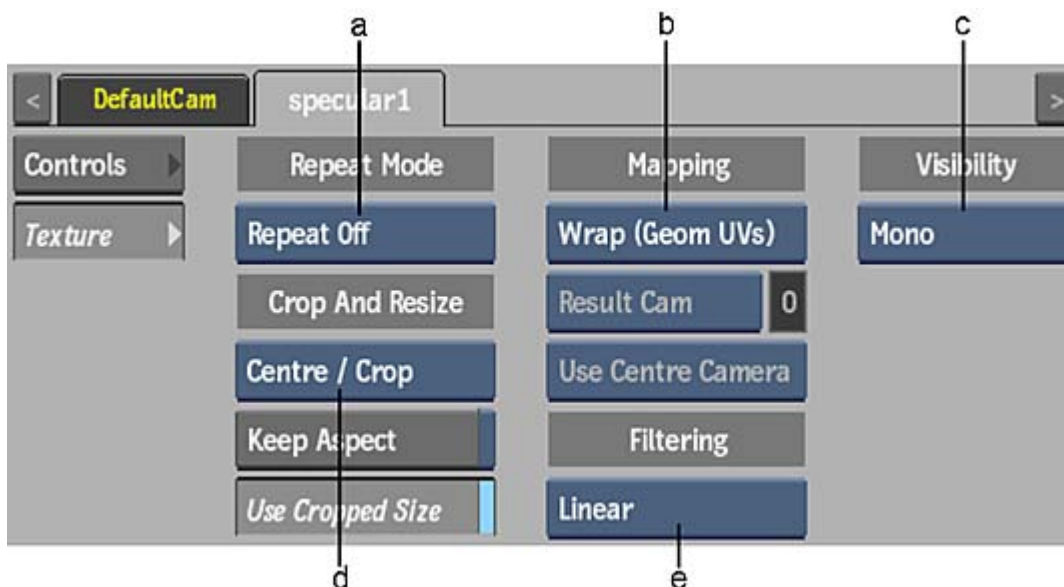

Softness Y field Displays the amount of Y-axis blur applied to the specular map. Editable.

Shininess field Displays the amount of shininess in the specular map. Editable.

NOTE To display proper results, the specular map also uses the value of the surface or geometry shine field. A shine value of 0.0 in the Surface or Geometry menu is interpreted as 1.0.

Regen button Enable to dynamically refresh the image as changes are made to the specular settings.

Texture Tab

(a) Repeat Mode box (b) Mapping box (c) Camera Type box (d) Fit Method box (e) Filter box

Repeat Mode box Select how the specular map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the specular map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the specular map with the cropped size of the specular media. Disable to use the cropped specular media as is.

Mapping box Select the type of texture mapping.

Wrap (Geom UVs) Wrap mapping completely envelops the 3D model with the texture map according to the object’s texture coordinates. To use this option, you must import a model that has its own texture coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu. See [UV Map Settings](#) (page 553).

Plane Planar mapping applies the map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the texture values. Planar mapping positions the lower-left corner of the map on the 3D model’s axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the “sides” of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the map based on the selected camera’s field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number. Non-editable.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the specular map.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.
EWA	A high-quality elliptical weighted average filter to produce enhanced rendering results (slower to process than other filters).

Select:	To apply:
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

TIP You can set the default filtering type in the Action Setup menu Preferences tab.

Camera Type box Select the camera type visibility for the specular map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

Emissive Mapping

An emissive map uses colours to simulate a glowing effect within the texture. The effect of an emissive map does not go beyond the limits of an object, and therefore cannot be used to generate glows around the rest of the scene or the surrounding objects.

To add an emissive map:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the emissive.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the emissive.
- 4 Do one of the following:
 - Drag the Emissive Map node from the node bin and place it in the schematic.
 - Drag the Emissive Map node from the node bin and place it where you want it in Result view.
 - Double-click the Emissive Map node. You do not need to be in Schematic view to add a node in this manner.

The emissive object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the Emissive node indicates the media used for the emission.

To specify different media as the emissive source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the Emissive node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
The Emissive menu appears.

Emissive Menu Settings

The Emissive menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

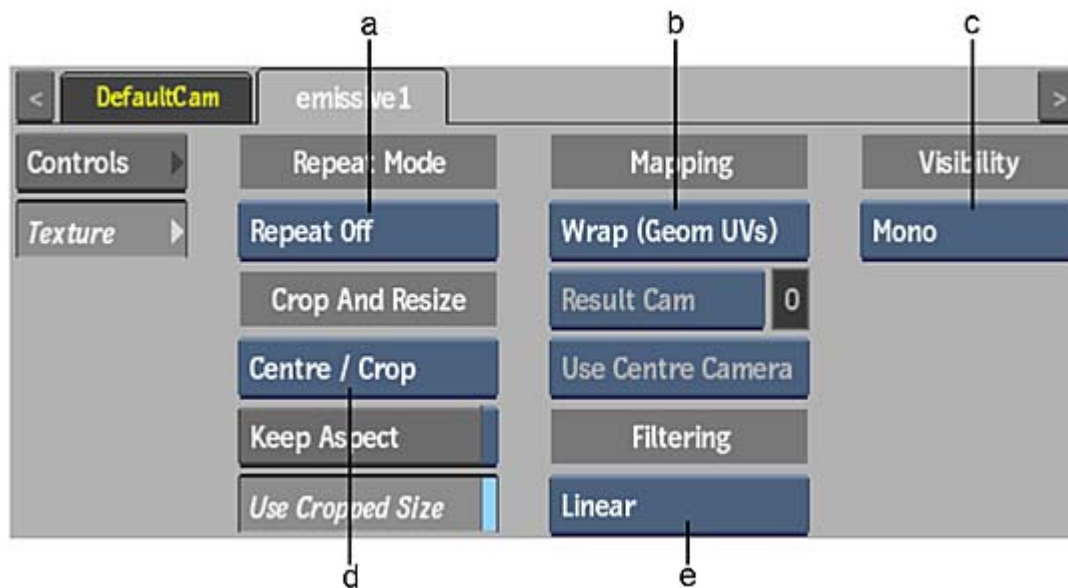

Effect field Displays the amount of emissive colour. Editable.

Softness X field Displays the amount of X-axis blur applied to the emissive map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the emissive map. Editable.

Regen button Enable to dynamically refresh the image as changes are made to the emissive settings.

Texture Tab

(a) Repeat Mode box (b) Mapping box (c) Camera Type box (d) Fit Method box (e) Filter box

Repeat Mode box Select how the emissive map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the emissive map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the emissive map with the cropped size of the emissive media. Disable to use the cropped emissive media as is.

Mapping box Select the type of texture mapping.

Wrap (Geom UVs) Wrap mapping completely envelops the 3D model with the texture map according to the object's texture coordinates. To use this option, you must import a model that has its own texture coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu. See [UV Map Settings](#) (page 553).

Plane Planar mapping applies the map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the texture values. Planar mapping positions the lower-left corner of the map on the 3D model's axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the "sides" of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the map based on the selected camera's field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number. Non-editable.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the emissive map.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.
EWA	A high-quality elliptical weighted average filter to produce enhanced rendering results (slower to process than other filters).
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

TIP You can set the default filtering type in the Action Setup menu Preferences tab.

Camera Type box Select the camera type visibility for the emissive map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

Diffuse Mapping

Use a diffuse map to define the diffuse reflection and main colour of a surface, 3D model, or 3D text. Since the diffuse map and its axis are parented by the surface or geometry node, animating the parent's axis also animates the diffuse map, which has the effect of keeping the map properly in place on the model. A diffuse map uses the specular highlight, diffuse colour, and shine set by its parent.

When adding a diffuse map to a shaded surface, the diffuse is used when generating the shadow. The diffuse is only used to apply the colour to the shadow, so effects such as surface displacement still reference the media associated with the surface. If a node has an applied diffuse map, it is the matte setting of the diffuse map that controls whether the object will be included in the various output mattes (scene matte, blend matte, for example).

To add a diffuse map:

- 1 In the schematic, select the surface, 3D model, or 3D text to which you want to apply the diffuse map.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the diffuse map texture (you can change this texture later).

A diffuse map uses the front and matte of the media. If you do not want to apply transparency to your diffuse map, turn its matte off.
- 4 Do one of the following:
 - Drag the Diffuse Map node from the node bin and place it in the schematic.
 - Drag the Diffuse Map node from the node bin and place it where you want it in Result view.
 - Double-click the Diffuse Map node. You do not need to be in Schematic view to add a node in this manner.

The diffuse object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the Diffuse node indicates the media used for the diffuse.

To specify different media as the diffuse source, select the media in the Media menu, then click Apply. If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can load an external texture directly from the Diffuse menu.

- 5 In the Rendering section of the Action Setup menu, enable or disable Shading depending on the method of diffuse mapping you are using. When Shading is enabled, normals are used. You must enable Shading when using Reflection mapping because it also uses normals.
- 6 Double-click the Diffuse node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
The Diffuse menu appears.

Diffuse Menu Settings

The Diffuse menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Effect field Displays the amount of diffuse colour. Editable.

Softness X field Displays the amount of X-axis blur applied to the diffuse map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the diffuse map. Editable.

Regen button Enable to dynamically refresh the image as changes are made to the settings.

Texture Tab

Repeat Mode box Select how the map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the diffuse map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the diffuse map with the cropped size of the diffuse media. Disable to use the cropped diffuse media as is.

Mapping box Select the type of texture mapping.

Wrap (Geom UVs) Wrap mapping completely envelops the 3D model with the diffuse map according to the object's diffuse coordinates. To use this option, you must import a model that has its own diffuse coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu. See [UV Map Settings](#) (page 553).

Plane Planar mapping applies the diffuse map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the diffuse values. Planar mapping positions the lower-left corner of the diffuse map on the 3D model's axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the "sides" of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the diffuse map based on the selected camera's field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number. Non-editable.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the diffuse map.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.

Select:	To apply:
EWA	A high-quality elliptical weighted average filter to produce enhanced rendering results (slower to process than other filters).
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

TIP You can set the default filtering type in the Action Setup menu Preferences tab.

Camera Type box Select the camera type visibility for the map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

Texture Name field Displays the name of an externally loaded diffuse map texture. Non-editable.

Load Texture button Click to open the Import Media browser to select an external single-frame image file to be used as the diffuse map texture. This file is not added to the Media list.

NOTE When a diffuse map is connected to a flat surface, you can enable Auto Expand in the Surface menu to automatically resize the surface when the diffuse map's Axis settings are changed.

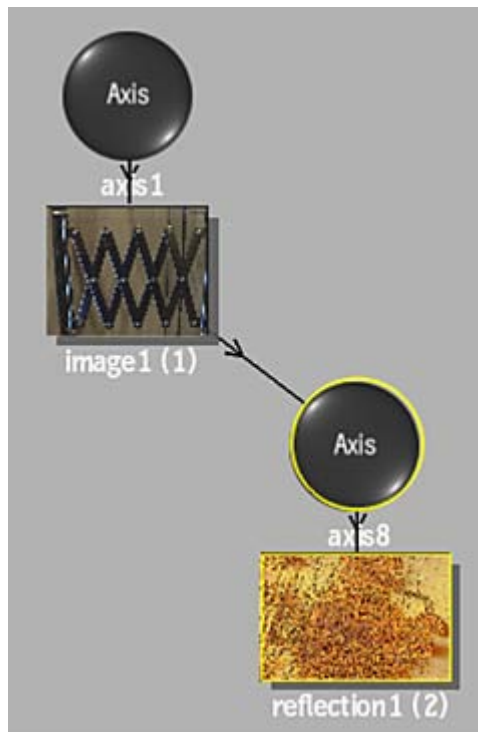

Reflection Mapping

Reflection mapping simulates a mirrored surface by using the specular reflection values in the map. You have the option of combining the result of a reflection map to a diffuse map.

To add a reflection map:

- 1 In the schematic, select the surface, 3D model, or 3D text to which you want to apply the diffuse map.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the diffuse map.
- 4 Do one of the following:
 - Drag the Reflection Map node from the node bin and place it in the schematic.
 - Drag the Reflection Map node from the node bin and place it where you want it in Result view.
 - Double-click the Reflection Map node. You do not need to be in Schematic view to add a node in this manner.

The reflection object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the Reflection node indicates the media used for the diffuse.

To specify different media as the reflection source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the Reflection node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
The Reflection menu appears.

Reflection Menu Settings

The Reflection menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

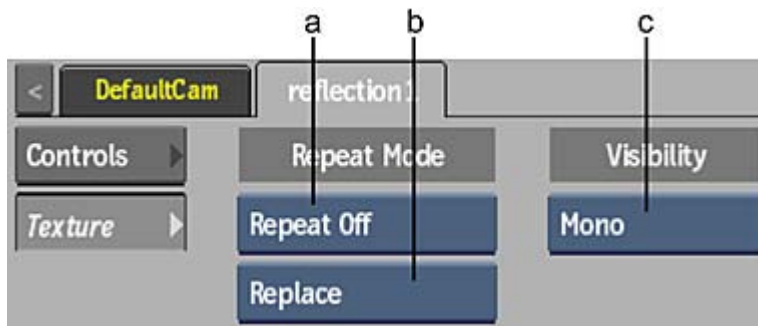

Effect field Displays the amount of diffuse colour. Editable.

Softness X field Displays the amount of X-axis blur applied to the diffuse map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the diffuse map. Editable.

Regen button Enable to dynamically refresh the image as changes are made to the settings.

Texture Tab

(a) Repeat Mode box (b) Add/Replace box (c) Camera Type box

Repeat Mode box Select how the map pattern is repeated on the surface.

Add/Replace box Select whether to add or replace the reflection map to the diffuse colour.

Camera Type box Select the camera type visibility for the map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

Position Mapping

A position map (sometimes called a world position pass), is an image where each pixel's R, G, B colour values represent the x, y, z coordinates of the corresponding vertex, in 3D world space. In Action, a position map works as a type of 3D displacement, that is, it displaces every pixel in that image to the actual location in space of the vertex it represents, allowing you to:

- Establish depth, position, and scaling in images, for compositing and creative purposes.

- Relight your scene.
- Create stereo objects.
- Creatively transfer the position of one object onto another object.

A typical workflow would be to import (from a 3D application) the beauty pass, the position pass (as a 16-bit floating point OpenEXR clip), the normal pass, and the FBX camera that rendered the scene. Then, apply the position and the normal map to the beauty pass image surface, and set the scale of the position map so that it aligns properly with the 3D camera frustum.

NOTE Make sure that your position pass rendering settings in the 3D application are sufficiently high so that the position map displays correctly in Flame Premium. For example, when rendering with Mental Ray in Maya, set the quality level to Production or higher.

When looked from the original camera POV, your scene looks just like the rendered image. But since pixels are accurately located in space relative to the original 3D scene with the attached position map, you can correctly position 2D layers in the same perspective as objects of the 3D scene.

Beauty Pass

Position Map

Action scene with camera orbited

You can use position maps generated by 3D applications or Action itself (Position is available as an output type in the [Output](#) (page 450) menu).

To add a position map:

- 1 In the schematic, select the surface to which you want to apply the position map.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the position map.
- 4 Do one of the following:
 - Drag the Position Map node from the node bin and place it in the schematic.
 - Drag the Position Map node from the node bin and place it where you want it in Result view.
 - Double-click the Position Map node. You do not need to be in Schematic view to add a node in this manner.

The position object is added to the schematic with its own parent axis. The new axis is the child of the selected surface. In Schematic view, the number in brackets next to the name of the Position node indicates the media used for the position map.

To specify different media as the position map source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

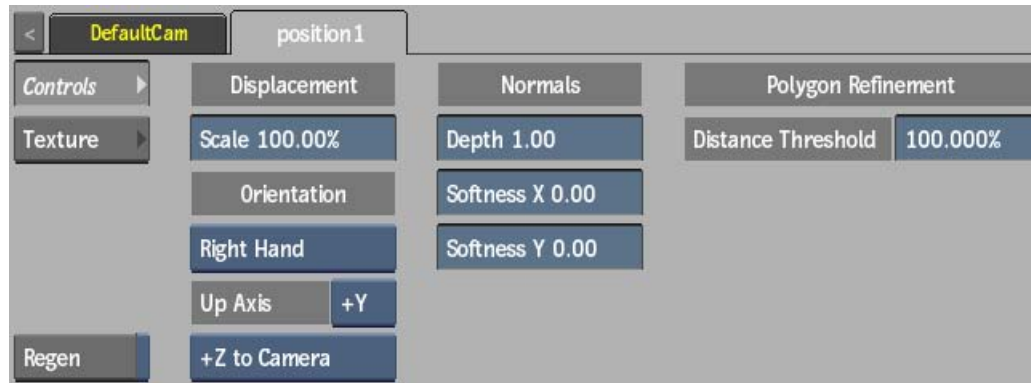

- 5 Double-click the Position node in the schematic, or follow the tab population rules for the Object menu.

The Position menu appears.

Position Menu Settings

Controls Tab

Use the Orientation settings to help Action with information on how the position map was rendered. The Normals settings affect the generated normals present in the position map.

Scale field Displays the scale of the position map in relation to Action space. Editable.

Orientation box Select whether the orientation of the coordinate system of the map is Left Hand or Right Hand.

Up Axis box Select which axis is the up axis of the map.

Camera box Select which axis of the map corresponds to the Z axis in Action. The selection in the Up Axis box determines the available selections in this box.

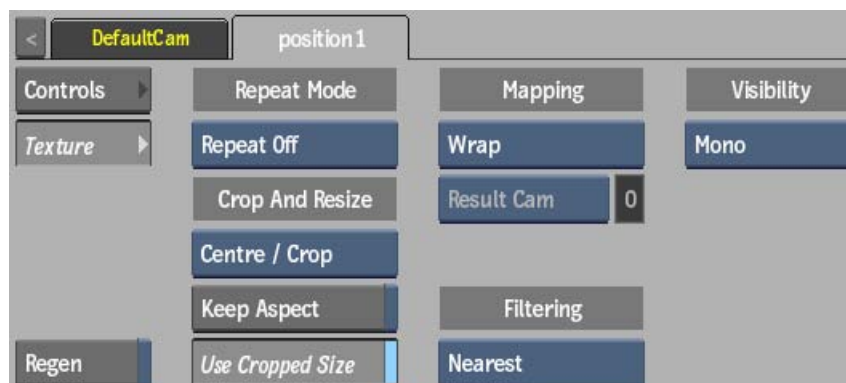

Depth field Displays the amount of Z scale applied to the generated normals. Higher values attenuate the effect toward the normals of the parent surface. Editable.

Softness X field Displays the amount of X-axis blur applied to the map. Editable.

Softness Y field Displays the amount of Y-axis blur applied to the map. Editable.

Distance Threshold field Displays the threshold at which the longest triangles producing disconnected meshes in the geometry are hidden. Editable.

Texture Tab

Repeat mode box Select how the map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the map with the cropped size of the media. Disable to use the cropped media as is.

Mapping box Select the type of texture mapping.

Wrap Wrap mapping completely envelops the 3D model with the texture map according to the object's texture coordinates. To use this option, you must import a model that has its own texture coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu.

Plane Planar mapping applies the map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the texture values. Planar mapping positions the lower-left corner of the map on the 3D model's axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the "sides" of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the map based on the selected camera's field of view (FOV). When you select Perspective as the mapping type, the Perspective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number.

Filter box Select the type of filtering to apply to the map.

Camera Type box Select the camera type visibility for the map.

UV Mapping

A UV map is a pass which records the way the pixels of an image should be displaced within the image plane, so that the warped texture looks like the textured geometry from the point of view of the CG camera. The UV map acts as a 2D distortion field, or a pixel look up table, recording where every pixel of an input image texture should be, had it been applied on a geometry filmed by the CG camera. It is a very effective way of faking 3D mappings, without having a single polygon. It is most effective when combined with a Normal map, which can be used to simulate the shading of the actual geometry even though everything is perfectly flat.

Applying a UV map to surface or geometry, warps its texture according to the defined UV. The U information is coded in the Red channel, while the V information is coded in the Green channel of the UV map image. For each pixel of the UV map, the red or green value corresponds to a given pixel on the unwrapped texture, and it is this pixel that gets displaced at the position of the same pixel in the attached surface or geometry.

Here are a few things to keep in mind when working with UV maps:

- To avoid pixelation in your imported UV passes, make sure that the UV pass is rendered as a 16-bit floating point image from your 3D application.

- It is a good idea to render UV passes without anti-aliasing to avoid warping on the edges of objects that the UV map is applied to. Since you can also output a UV Map from Flame Premium, make sure that anti-aliasing is not selected in the Render Options section of the Output menu.
- You can embed object IDs in the Blue channel when performing a UV render pass in Maya, allowing you to specify which objects are displaced within the UV map in Action. In Maya, when performing a UV Render Pass, enable *Embed Object ID in Blue Channel*. When disabled, blue channel information is ignored.
- For best results, in the Texture settings of the UV Map menu in Flame Premium, the Fit Method box should be set to Fill, and the Filter box to Nearest.
- If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

Flat texture

UV Map

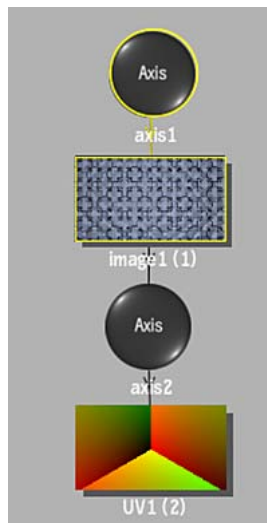

Texture with UV Map applied

Adding a UV Map

To add a UV map:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the UV map.
- 2 Click Media.
- 3 In the Media menu, select the media you want to use for the UV map.
- 4 Do one of the following:
 - Drag the UV Map node from the node bin and place it in the schematic.
 - Drag the UV Map node from the node bin and place it where you want it in Result view.
 - Double-click the UV Map node. You do not need to be in Schematic view to add a node in this manner.

The UV object is added to the schematic with its own parent axis. The new axis is the child of the selected surface or geometry. In Schematic view, the number in brackets next to the name of the UV node indicates the media used for the UV.

To specify different media as the UV source, select the media in the Media menu, then click Apply.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 5 Double-click the UV node in the Schematic view, or follow the tab population rules for the Object menu.

The UV menu appears.

UV Menu Settings

Regen button Enable to dynamically refresh the image as changes are made to the UV settings.

The UV menu is divided into two tabbed sections: Controls and Texture.

Controls Tab

Effect field Displays the amount of displacement applied to the UV map. Editable.

Softness X field Displays the amount of softness along the X axis of the UV map. Editable.

Softness Y field Displays the amount of softness along the Y axis of the UV map. Editable.

Apply Type box Select which attached maps are affected by the UV map.

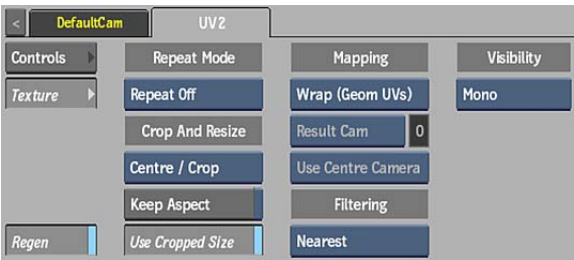

Use Object ID button Enable to use Object ID info embedded into the blue channel when using a UV map generated by Maya. When disabled, blue channel information is ignored.

The object ID allows you to control which objects within the UV map are displaced. In Maya, when performing a UV Render Pass, enable *Embed Object ID in Blue Channel*.

Object ID field Displays the specific blue value corresponding to an object ID. Editable.

Pick button Click to display the picker to select an object ID in the image through its blue value.

Texture Tab

Repeat mode box Select how the UV map pattern is repeated on the surface.

Fit Method box Select a fit method option to be applied to the UV map.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels (not available for the Fill fit method).

Use Cropped Size button Enable to replace the UV map with the cropped size of the UV media. Disable to use the cropped UV media as is.

Mapping box Select the type of texture mapping.

Wrap (Geom UVs) Wrap mapping completely envelops the 3D model with the diffuse map according to the object’s diffuse coordinates. To use this option, you must import a model that has its own diffuse coordinates. When using Wrap mode, you can also apply UV mapping settings from the Geometry menu. See [UV Map Settings](#) (page 553).

Plane Planar mapping applies the diffuse map without distorting the front plane of the 3D model, similar to a movie projector casting an image onto a screen. All 3D coordinates of the geometry are mapped to this plane to generate the diffuse values. Planar mapping positions the lower-left corner of the diffuse map on the 3D model’s axis. When you apply planar mapping, any surfaces on the 3D model perpendicular to the front plane cause the pixels at the edge of the texture to project along the “sides” of the object.

Perspective Perspective mapping is similar to planar mapping, except that it performs a perspective transformation of the diffuse map based on the selected camera’s field of view (FOV). When you select Perspective as the mapping type, the Per-

spective Camera box becomes active, allowing you to specify the active camera. The FOV of the camera has an impact on the resulting effect of any transform applied to the parent axis of the texture. On stereo cameras, the interaxial distance between left and right cameras also has an effect on the resulting perspective transform.

Projection The texture behaves as if it is projected by the selected camera. Projection mapping is useful as an alternative to projecting textures using the Projector node, especially when it is necessary to project while preserving a specific camera POV.

Camera box Specify which camera's FOV to take into account when using perspective or projection mapping.

Camera field Displays the active perspective or projection camera number. Non-editable.

Stereo Camera Projection box Select whether to use the centre, left, or right camera from a stereo camera rig when projection mapping.

Filter box Select the type of filtering to apply to the UV map.

Select:	To apply:
Nearest	No filtering — the pixel of the texture closest to the screen pixel is displayed.
Linear	Basic bilinear filtering.
Anisotropic	Non-proportional filtering between X and Y (faster to process than EWA, but with a lesser quality).
Aniso+Linear	A combination of Anisotropic and Linear filtering.
EWA	A high-quality elliptical weighted average filter to produce enhanced rendering results (slower to process than other filters).
EWA+Linear	A combination of EWA and Linear filtering (offers the most advanced filter processing).

Camera Type box Select the camera type visibility for the UV map. For example, you can use this setting to apply a Left Eye and Right Eye camera type for two maps that are children of the same surface or geometry in a stereo scene.

Projecting Textures

Like a slide projector, textures can be projected onto 3D models to create an effect where a texture is animated on an object in 3D space. The advantage of using a Projector node is that you can cast images on arbitrary surfaces. You can create a spotlight texture and project it onto a 3D model, so that you can see “into” it.

NOTE Some Action maps, such as Diffuse and Emissive maps, also allow you to use Projection mapping as a type of texture mapping. This method of projecting behaves as if it were projected by the selected camera.

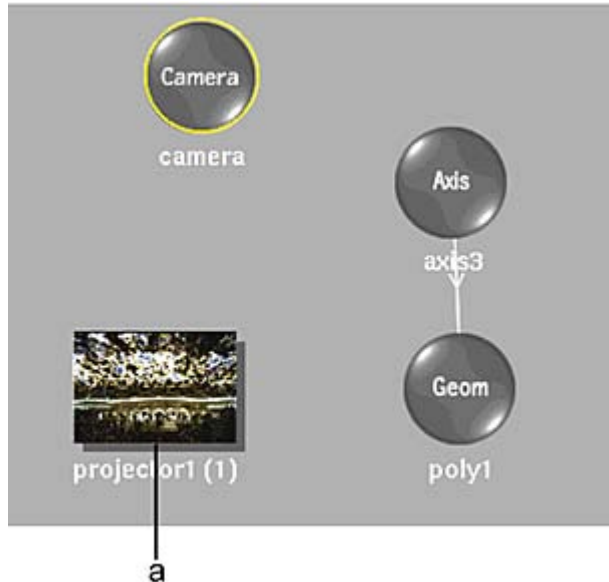

To project a texture:

- 1 Click Media to access the Media menu.
- 2 In the Media list, select the media that you want to project.

NOTE If you accessed Action as a Timeline FX, you are limited to one front/matte media, and therefore may not get the desired result. In this case, you can access Action from Batch or Batch FX, or from the Tools tab.

- 3 Do one of the following:
 - Drag the Projector node from the node bin and place it in the schematic.
 - Drag the Projector node from the node bin and place it where you want it in Result view.
 - Double-click the Projector node. You do not need to be in Schematic view to add a node in this manner.

The Projector node appears in the schematic and a projector icon appears in the scene.

(a) Projector node

- 4 Double-click the Projector node to display the Projector menu, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
The Projector is selected.
- 5 Switch to Camera view to manipulate the projector in the scene using the View box.
The following example illustrates projected media on a 3D model using Spotlight projection blend mode. See [Blending Projections](#) (page 645).

(a) Projector icon (b) Yellow outline shows the projector field of view

To add multiple projections:

- 1 Click Media to access the Media menu.
 - 2 In the Media list, select the media you want to use as projectors by **Ctrl**-clicking the media.
 - 3 Use the node bin to add a projector.
- Multiple Projector nodes appear in the schematic and projector icons appear in the scene.
- 4 Use the Order field in the Projector menu to set the order of projectors.

The front projector is projector1. A new projector is always added to the back. Changing the order number of a projector affects the order of other projectors.

Projecting Textures Settings

Projector Menu Settings

Motion Blur button Enable to use a motion blur effect for the selected projector (can only be used if the global Motion Blur is enabled in the Setup menu).

Active button Enable to activate the projected texture effect in the scene. When disabled, the Projector node remains in the schematic and the projector icon appears smaller in the image area.

X Position field Positions the projector in 3D space along the X axis.

Y Position field Positions the projector in 3D space along the Y axis.

Z Position field Positions the projector in 3D space along the Z axis.

TIP You can also set the texture projector position by dragging the projector in the scene.

Motion Path button Enable to use motion path animation for the projector.

X Rotation field Rotates the projector in 3D space along the X axis.

Y Rotation field Rotates the projector in 3D space along the Y axis.

Z Rotation field Rotates the projector in 3D space along the Z axis.

Blend Mode button Select a mode to modify how you want to blend the projected image in the scene. See [Blending Projections](#) (page 645).

Transparency field Displays the transparency level of the projected texture effect. Editable.

Field Of View field Displays the projector's field of view value. Editable.

Aspect Ratio field Displays the ratio of height to width for the projected image. Editable.

Order field Displays the order of projectors. Editable.

Red Colour field Defines the red value of the selected projector. Editable.

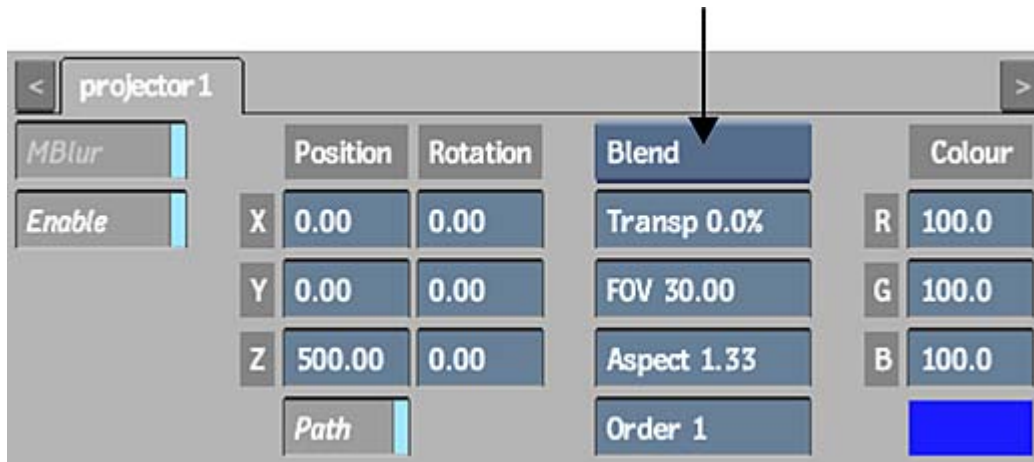

Green Colour field Defines the green value of the selected projector. Editable.

Blue Colour field Defines the blue value of the selected projector. Editable.

Projector colour pot Displays the colour of the projector. Editable.

Blending Projections

Use projection blend modes to modify how you want to blend the projected image in the scene. Select a mode from the Projection Blend Mode box.

Add Compensates for the soft or anti-aliased edge on an object in a front and matte clip media.

Blend Punches the matte through the front. This blends the edge of the front clip and adds additional softness to the media. This is the default setting. Use Blend mode when you do not want any shading cast on the geometries that are receiving the projection.

Max Compares the RGB channels of each pixel of the front clip and the back clip individually and returns the larger of the two values.

Min Compares the RGB channels of each pixel of the front clip and the back clip individually and returns the smaller of the two values.

Multiply Multiplies the RGB channel values of corresponding pixels of the front clip and the matte clip, and normalizes the result by dividing by 256 in 8-bit mode, or 4096 in 12-bit mode. The resulting RGB channel values are assigned to the corresponding pixels in the generated clip.

Hardware limitations may prevent transparency from working properly with Multiply.

Negate Creates a negative-like result. Try Negate with a soft white matte with a white front clip. This mode does not use the matte or transparency in its blend.

Screen Multiplies the inverse of the matte clip's colours with the colours of the front clip. The resulting colour is always lighter. Screen does not work with transparency.

When using a matte, set the diffuse r, g, b channels to 0, 0, 0 in the Channel Editor for the image surface you are blending.

Simple Add Punches the matte through the front using more softness than Blend mode. Simple Add mode is similar to Add but includes transparency.

Spotlight Creates a slide projector effect. This mode does not use the matte or transparency and decreases system performance.

Spotlight Blend Creates an effect where black areas of the front disappear. This mode does not use the matte or transparency; it works well with a clip on which an object is surrounded by black.

Subtract Subtracts the RGB channel values of the pixels in the matte clip from the RGB channel values of the pixels in the front clip and assigns the result to the RGB channel values of the pixel in the result.

If an RGB channel value from the matte clip is larger than the corresponding channel value in the front clip, yielding a negative result, that result is clamped at 0 (black).

Applying Selective Projections

You can use projections selectively; either inclusively or exclusively. Similarly to the Selective Lighting feature, you can connect a projection to an image, object, or its axis and make the projection affect only that connection (inclusive). Conversely, a projection that affects every object *except* the one it is connected to is exclusive.

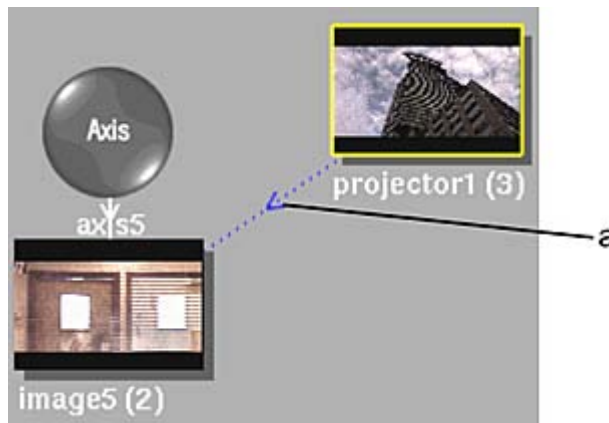

To use selective projections, you must have a scene with a minimum of two objects in order for the selective projection to affect one and not the other.

To create an inclusive selective projection:

- 1 Select the media to use as a texture for projection.
- 2 Add a projector using the Node bin.
The projection is added to the scene.
- 3 To make the projection selective, access the schematic by using the ~ key or by selecting Schematic from the View box.
In the schematic, the projector is displayed much like an image. By default, it projects an image across the entire scene.
- 4 Select Lighting from the Tools box to create lighting connections.

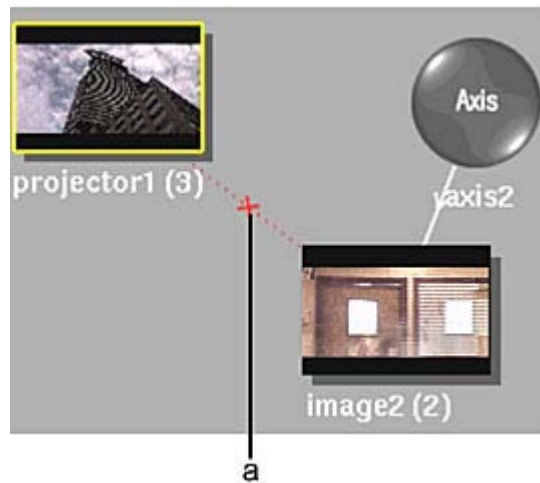

- 5 Do one of the following:
 - To project only a selected surface, drag a connection from the Projector node to one or several nodes in your scene. A selective projection connection is represented by a blue dotted line.Once a selective connection is created, the projector only affects the object to which it is connected.

(a) Inclusive projection connection

- To exclude a surface, hold the **Alt** key as you drag a connection from the Projector node to a surface node. The exclusive connection is represented by a red dotted line.
- Once an exclusive connection is created, the projector ignores the node(s) to which it is connected.

(a) Exclusive projection link

About Atomize

When you attach an Atomize node to a surface or geometry in Action, the object becomes a configurable point cloud. Pixels at each vertex of the surface or geometry become square or round points. The Atomize points always face the camera, and are displayed at the same size regardless of the distance from the camera. Atomize points inherit any properties of the parent object, as well as any attached maps (such as transparency, blend modes, and colours).

NOTE Atomize points are displayed in Action screen space, therefore they are affected by zooming in the image window.

Depending on the vertex resolution of the parent surface or geometry, the Atomize result can become quite detailed (more vertices equals more points), allowing you to creatively incorporate point clouds into your Action compositions.

Teapot Geometry with Diffuse Map

Teapot with Atomize applied

Adding an Atomize Node

To add an Atomize node:

- 1 In the schematic, select the surface or 3D geometry to which you want to apply the Atomize.
- 2 Do one of the following:
 - Drag the Atomize node from the node bin and place it in the schematic.
 - Drag the Atomize node from the node bin and place it where you want it in Result view.
 - Double-click the Position Map node. You do not need to be in Schematic view to add a node in this manner.

The Atomize object is added to the schematic as a child of the selected surface or geometry.

- 3 Double-click the Atomize node in the schematic, or follow the tab population rules for the Object menu.

The Atomize menu appears.

Atomize Menu Settings

Round Dot button Enable to display the points as circles; disable to display as squares.

Size field Displays the size of the points. Editable.

NOTE The size range is from 0 to 100, but the actual maximum value that will produce a change is determined by your graphics card. For example, you may notice that the size doesn't increase with a value higher than 64.

About 3D Paths

A 3D path is an animatable 3D spline that you attach to other Action objects, such as surfaces, geometries, 3D text, cameras, or lights. The attached objects then follow the spline based on the path normals, allowing you to create effects, such as a 3D roller coaster.

Adding a 3D Path Node

When you add a 3D Path node to your Action schematic, the node is added with an axis.

To add a 3D Path node to the scene:

- 1 Do one of the following:
 - Drag the 3D Path node from the node bin and place it in the schematic.
 - Drag the 3D Path node from the node bin and place it in Result view.
 - Double-click the 3D Path node. You do not need to be in Schematic view to add a node in this manner.

A Path object (called path1, by default), with its parent axis, appears in the schematic.

- 2 Create mode is automatically selected in the Tools box so you can create your spline. See [Creating Splines](#) (page 649).
- 3 Parent the 3D Path node to another object in your schematic, such as a Light node or a 3D Text node. The 3D path becomes part of the transformation hierarchy of the attached object.

3D Path node parented to a 3D Text node

- 4 To open the 3D Path menu, double-click the 3D Path node in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

Creating Splines

You can draw open or closed splines to use as your 3D path.

To create a spline:

- 1 Make sure that the Tools box is in Draw Shape mode (this is the default when you first add a 3D Path node).
- 2 In the image window, click to add vertices.
TIP Shift-drag to add freehand segments to the spline. Vertices are added where you drag, and appear when you release **Shift**. After closing or finishing the spline, you can use the Lasso Fit field to increase or decrease the number of vertices that define the freehand segments of the spline.
- 3 To complete your spline, do one of the following:
 - Click the first vertex to close the spline.
 - Click Finish in the 3D Path menu to leave the spline open. If you decide later that you want to close the spline, enable Closed in the 3D Text menu.
- 4 Make sure that the Tools box is in Select mode, so that you do not add more vertices by mistake. When the spline is closed or finished, its vertices and tangents can then be edited.

Editing Splines

Use the settings in the 3D Path tab to work with the spline you created. You edit splines in the same way as you edit garbage masks, working with their vertices and tangents. See [Manipulating Vertices and Tangents](#) (page 917).

Finish button Click to finish an open spline.

Closed button Enable to close a spline from the last to first point.

Motion Blur button Enable to use a motion blur effect for the selected path (can only be used if the global Motion Blur is enabled in the Action Setup menu).

Constant Shape button Enable to modify the spline's shape without setting keyframes. This forces all animatable parameters to be set for the whole clip rather than for only the current frame. It also removes any existing keyframes and applies the shape of the current frame to the rest of the clip.

Lasso Fit field Displays the number of points in the segments of the spline that are drawn freehand. Use a lower number to simplify the curve by removing vertices and tangents, resulting in a smoother curve. Editable.

X Vertex field Displays the position of the selected vertices on the X axis. Editable.

Y Vertex field Displays the position of the selected vertices on the Y axis. Editable.

Z Vertex field Displays the position of the selected vertices on the Z axis. Editable.

Auto Tangents button Enable to position a tangent for each vertex set, to create a smooth curve between the vertices. When enabled, it is possible to create a spline with both straight and curved segments.

When Auto Tangents is disabled, the tangents are positioned under the vertex, resulting in straight lines between vertices. When you draw freehand segments in a spline with Auto Tangents off, vertices are added with broken tangents, allowing the spline to follow your cursor movement.

Auto Adjust button Enable to automatically adjust the tangent handles of the two adjacent vertices when moving vertices, to create smooth curves between the vertices.

Changing Spline Display Properties

You can change spline display properties in the Display tab. For example, you can change the colour of tangents on the splines you draw. This is useful to better contrast the spline's tangents from the clip so that they are easier to work with.

Normals button Enable to display normals along the 3D path.

Normals colour pot Displays the normals colour. Editable.

Spacing field Displays the space between the displayed normals, in pixels. Also used to calculate the position of the object on the path. A lower value may result in better positioning and smoother movement of the object, but rendering may be slower. Editable.

Scale field Displays the scale of the displayed normals, in pixels. Editable.

Spline colour pot Displays the colour for the display of splines. Editable.

Tangents colour pot Displays the colour for the display of tangents. Editable.

Positioning Objects on the Path

Use the Position On Path settings in the 3D Path or Banking tabs to offset the position of attached objects along the path and beyond. For open paths, if you offset past the first or last points on the path, the position is extrapolated accordingly. For closed paths, if you offset past the first or last points on the path, the attached object continues on the path with a tangent interpolated from the first and last normals.

Offset field Displays the amount of offset to apply to the object on the 3D path. Use to animate the attached object along the path. Editable.

Offset box Select whether to offset the object from the path in a relative (expressed as a percentage of the path) or absolute mode (expressed in pixels).

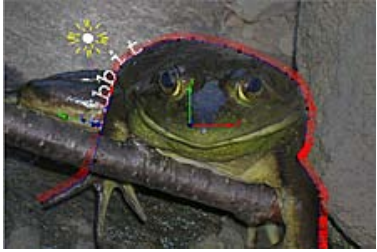

NOTE These settings are repeated in the 3D Path and Banking tabs to make it easier for you not to have to switch tabs to change the settings. The same settings are reflected in both tabs.

Aligning Objects on the Path

Use the Alignment to Path section of the 3D Path tab to set orientation behaviour.

Alignment option box Select how the object connected to the 3D Path node aligns to the path.

Select:	To:	Example:
Align Off	Not align the attached object to the path. In this case, the Orientation Axis box and banking controls are unavailable. This can be useful for vertical text effects.	
Align to Path	Align the attached object to the 3D path. You can then select which axis is aligned to the path in the Orientation Axis box, and use the banking controls.	
Look At	Point the attached object to a look-at object, such as a light. You can then select which axis is pointed to the look-at object in the Point Axis box, and use the banking controls. See Applying a Look-At Connection (page 653).	

Orientation Axis box Select which axis is aligned to the path. Available when Align to Path is selected in the Alignment option box.

Point Axis box Select which axis is pointed to the attached look-at object. Available when Look At is selected in the Alignment option box.

Applying a Look-At Connection

You can create interesting 3D path effects by attaching a look-at connection between the path and another object in your scene. The attached object on the path then rotates to face the look-at object, no matter where it is positioned. You attach a look-at connection in the schematic between the 3D Path node and any object with axis characteristics (Axis, Camera, Light, Projector, Particle Animator).

To apply a look-at connection:

- 1 Do one of the following:
 - Select Look At in the Alignment option box.
 - Select Lookat in the Tools box.
- 2 In the schematic, drag from the 3D Path node to an object with axis characteristics. The selected object is connected to the 3D Path node by an orange dotted line with an arrow.

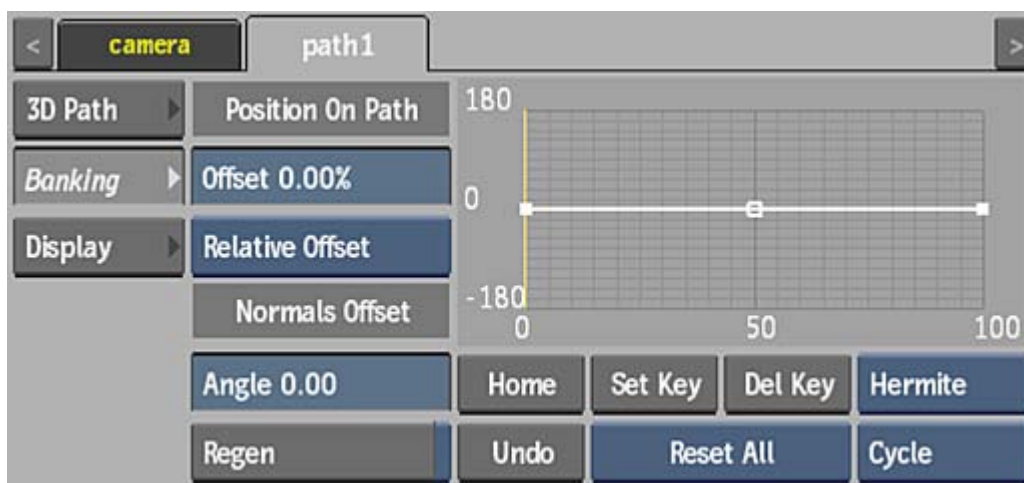

(a) Look-at connection

- 3 Select which axis looks at the attached object in the Point Axis box.
- 4 Optional: Use the banking curve to orient the attached objects.

Using the Banking Curve

When Align to Path or Look At is selected in the Alignment option box, the Banking tab becomes available. Banking uses the normals of the path to orient objects attached to it. Use the banking curve and settings to control the torsion effect of the object as it travels along the 3D path.

The Position on Path settings are the same as those in the 3D Path tab. See [Positioning Objects on the Path](#) (page 651).

Banking Curve Adds twists and torsion to the normals of the 3D path. Use the options in the Tools box to add, select, delete, or move keyframes on the Banking curve. The horizontal axis represents the length of the path, and the vertical axis displays the orientation, expressed in degrees.

Normals Offset Angle field Displays the angle of rotation of all normals, applied to the entire banking curve. Editable.

NOTE Changes made to the banking curve and Angle field are cumulative.

Regen button Enable to dynamically refresh the image as changes are made to the banking curve.

Home button Resets the Banking curve viewer to show the whole curve.

Undo button Undoes Banking curve operations.

Set Key button Sets the current values for the banking curve in the current frame (when Auto Key is disabled).

Del Key button Deletes the selected banking curve keyframes.

Reset Selection box Select whether to reset all of the banking settings (Reset All) or just the banking curve (Reset Key).

Interpolation box Select the default interpolation type for the Banking curve.

Extrapolation box Select the default extrapolation type for the Banking curve.

About the Camera

The scene is what you see through the camera lens. Typically, you work with the camera to frame and animate the view to achieve the effect you want. In Action, you have the choice of using the automatic camera or the manual camera, whose F-Stop, film size, and focal length you can set yourself. You can also animate specific camera properties.

Adding a Camera

By default, a camera exists in the Action scene (you may need to pan in the schematic to see the camera node). You can add multiple cameras in order to change point of view or depth of field from one camera to

another. Add and animate multiple cameras when creating compositions. You can also switch from one camera to another at any point.

To add a camera:

- 1 Do one of the following:
 - Drag the camera node from the node bin and place it in the schematic.
 - Drag the camera node from the node bin to Result view, so you can see its effect on the scene before placing it exactly where you want.
 - Double-click the camera node. The node appears next to the last added object. You do not need to be in Schematic view to add a node in this manner.

A new camera is added to the scene. An icon representing the camera is added to the schematic.

- 2 To display the Camera menu, double-click the selected camera in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

The result camera always appears as the first tab on the right side of the Object menu. To allow you to easily access the camera without losing your place in the scene, this special camera tab (appearing in orange) does not follow the tab population rules. If a camera node is selected in the schematic, the special Camera tab does not appear, and the normal tab population rules apply.

Camera Menu Settings

When accessing Action as a Timeline FX, you have access to a quick menu with some of these Camera settings. To see the full Camera menu, click the Editor button to enter Action.

X Eye field Displays the position of the camera eye on the X axis. Editable

Y Eye field Displays the position of the camera eye on the Y axis. Editable

Z Eye field Displays the position of the camera eye on the Z axis. Editable

Motion Path button Enable to animate the camera eye on a motion path. See [Moving the Camera Eye and Point of Interest](#) (page 659).

X Point of Interest field Displays the position of the point of interest on the X axis. Editable.

Y Point of Interest field Displays the position of the point of interest on the Y axis. Editable.

Z Point of Interest field Displays the position of the point of interest on the Z axis. Editable.

X Rotation field Displays the level of camera rotation along the X axis. Editable.

Y Rotation field Displays the level of camera rotation along the Y axis. Editable.

Z Rotation field Displays the level of camera rotation along the Z axis. Editable.

Camera Type box Select Free (to view the scene in the direction that you aim the camera), or Target (to aim the camera at a target object in the scene based on a point of interest).

Free cameras are easy to use because you do not have to manipulate the point of interest. You can simply animate the camera rotation or camera tilt as though it were on a tripod. Use the Distance field in conjunction with Free Camera.

Roll field Displays the amount of camera roll (available with Target Camera). Editable.

Use the Roll field in conjunction with Target Camera.

Field of View field Displays the camera field of view value, measured in degrees. Editable.

When PhysicalCam is disabled, use the field of view angle in the Y direction to adjust the width of the camera frustum. When PhysicalCam is enabled, use the focal length for the same purpose.

Distance field Displays the position of the camera's focus. This setting affects the depth of field (when enabled in the Action Setup menu). Editable.

Near field Displays the near view of the selected camera. Editable.

Far field Displays the far view of the selected camera. Editable.

See [Moving the Clipping Planes](#) (page 659).

Export Camera button Opens the Export Camera file browser to save a camera.

Exported data includes Eye X, Y, and Z; Poi X, Y, and Z; Fov; Roll, Target or Free Camera; motion path and explicit keyframe camera animation. See [Importing and Exporting Cameras](#) (page 660).

Import Camera button Opens the Import Camera file browser to import a camera. See [Importing and Exporting Cameras](#) (page 660).

Result Camera box Specify which camera is active. The active camera is the one that will be used when processing/rendering your scene.

Result Camera field Displays the active camera number. Non-editable.

Reset Camera button Resets the Camera menu to its default settings.

Camera box Not shown. When in Camera view, select which camera is used in the image window.

Parenting Offset box Select an offset option for viewing an image when parenting a camera node. When parenting a camera node, the image offset gets reset to the camera origin, which is not always the desired viewing option. Origin sets the image to the camera origin; Target sets the image to the default viewplane distance relative to the camera; and Live Target sets the image to the current viewplane distance based on the FOV. The offset value is computed from the default camera field of view and the default image size, and does not change even if other camera parameters are changed. This value is displayed in the Parenting Offset field.

Fog box Select a fog type to cause objects to fade as their distance from the camera increases. See [Applying Fog to the Scene](#) (page 671).

Fog colour pot Displays the fog colour. Editable.

Fog Start field Displays the distance at which the fog should start. Editable.

Fog End field Displays the distance at which the fog should end. Editable.

Fog Range field Displays the range or distance from the camera for exponential type fog. Editable.

Physical Camera button Enable to activate the physical camera, which simulates a manual camera. Use the physical camera fields to adjust the field of view for the camera.

f-stop box Select a depth of field value. F-stop is the ratio between the focal length of the lens and the diameter of the aperture. For example, the F-stop value for a 100mm lens with a 50mm full aperture is 2 (or $f/2$).

Large f-stop values correspond to smaller apertures. The depth of field for your physical camera increases as you increase the f-stop value.

Film Size box Select a standard film size. As the film size increases, the focal length also increases and the focal point moves further away from the camera eye. Changing the film size also increases the focal length.

Focal Length field Displays the field of view. Changes to the Focal Length automatically update the field of view (based on the film size) and vice versa. Editable.

As the focal length increases, the field of view decreases. As the focal length decreases, the field of view increases.

About the Frustum

The volume of space viewed by the camera eye is called the frustum. The frustum is in effect a viewing pyramid. The camera eye is located at the apex of the pyramid, and the far clipping plane forms the base. The pyramid may be truncated by the near clipping plane.

(a) Camera eye (b) Near clipping plane (c) Far clipping plane (d) Camera interest point or look-at point

If you place a surface within the frustum, it is visible in the final animation. If the surface is located outside the scope of the frustum, it is not visible at that frame in the animation.

Viewing the Camera and Frustum

To see the camera and frustum:

- 1 From the View box, select Side.
- 2 In the image window controls, click

to zoom out from the scene.

- 3 Select Pan in the Tools box and pan around the scene until you see the camera eye icon. Alternatively, use Orbit mode to pan around the scene in circular motion.
- 4 Go to the Camera menu and drag the Roll field until you see the four sides of the frustum.
- 5 To modify the frustum, do one of the following:
 - Change the position of the near clipping planes to alter the depth of the frustum. See [Moving the Clipping Planes](#) (page 659).
 - Change the position of either the camera eye or the camera's point of interest to alter the orientation of the frustum. See [Moving the Camera Eye and Point of Interest](#) (page 659).
 - If the Physical Camera button is disabled, enter a value in the FOV (field of view) field to adjust the width of the camera frustum.
 - If the Physical Cam button is enabled, enter a value in the Focal Length field to narrow or widen the frustum. You can also alter the depth of the frustum using only the near clipping plane.

Moving the Clipping Planes

The camera frustum is determined by six clipping planes: the left, right, top, bottom, near, and far clipping planes. The depth of the frustum is affected by the near and far clipping planes. The values for these channels are expressed in units relative to the position of the camera eye.

To move the clipping planes:

- 1 From the View box, select Side, Front or Top depending on how your camera is positioned. Ideally, you will want a view that profiles the camera so the near and far planes are visible.
- 2 In the Camera menu, enter a value in the Near field to edit the near clipping plane's position.
The value in the Near field corresponds to the position of the near clipping plane. The default value is 1. Any object between the camera eye and the near clipping plane is outside the camera frustum and does not get processed in the final result.
- 3 Enter a value in the Far field to edit the far clipping plane's position.
The value in the Far field corresponds to the position of the far clipping plane. The default value is 10000. Any object positioned behind the far clipping plane is outside the camera frustum and does not get processed in the final result.
- 4 Narrow or widen the frustum by modifying the camera's FOV (field of view). Increasing the FOV narrows the frustum and field of view. Decreasing the value widens the frustum and field of view.

Moving the Camera Eye and Point of Interest

Objects in the scene can be recorded from an arbitrary position as determined by the orientation of the camera eye in world space.

To change the position of the camera eye:

- 1 In the Camera menu, modify the Eye X, Y, and Z fields.

You can also animate the camera eye on a motion path. Enable the Motion Path button and drag the camera icon while viewing the scene in Top, Side, or Front view.

NOTE You can only animate the point of interest with a Target Camera.

The camera point of interest is the point in world space at which the camera eye is directed. The point of interest is always at the centre of the camera's frustum. Changing the position of the point of interest causes the orientation of the frustum to change. You can take advantage of the relationship between the point of interest and the frustum to make the camera follow a moving object. To do this, animate the point of interest while keeping the camera eye in a fixed position.

To change the point of interest:

- 1 In the Camera menu, do one of the following:
 - Modify the Interest X, Y, and Z fields.
 - Move the point of interest by dragging while viewing the scene in Top, Side, or Front view.

TIP You can animate the point of interest using a motion path by enabling the Motion Path button.

Adjusting the Depth of Field

Using depth of field, you can blur objects that are outside the camera's focal range. The further an object is from the focal range, the more it is blurred.

(a) Near sharpness plane (b) Focal range (c) Far sharpness plane (d) Motion path for point of interest (e) Camera point of interest (f) Motion path for camera eye (g) Camera eye

The Target camera uses depth of field and clearly indicates its focal range when in Top, Side, or Front view. With the Free camera, you can change the field of view by **Alt**-dragging the near sharpness plane. This changes the camera only; what you are viewing remains the same size.

To adjust the depth of field:

- 1 In the Action menu, click Setup.
- 2 In the Accumulation Settings section, enable Depth of Field. Objects are blurred on either side of the point of interest.
- 3 Change the amount of blur using the Depth of Field Softness field.

Importing and Exporting Cameras

You can either import a camera you created and edited in Action, or import one from another 3D application. Once a camera is imported, you can edit its parameters, change its animation, and then export it back to the application it came from.

FBX Cameras

Flame Premium supports the import and export of 3D data saved in the FBX 3D format. This format provides a means for exchanging 3D data for scene compositions—such as cameras—between tools and packages developed by different manufacturers.

To export a camera to FBX format:

- 1 Select the camera you want to export.
- 2 In the Camera menu, click Export.

The Export Camera file browser appears.

- 3 From the Export Type box, select FBX.

- 4 Select which elements of the FBX files you wish to export by clicking the corresponding filter button.

Enable:	To:
Rotate Axis	Rotate the exported camera by -90° on the X-axis so that it is compatible with the co-ordinate system of the 3D application.
Export Axes	Export the animated axes present in the Action scene.
Export Point Cloud	Export the 3D point cloud created by the 3D Tracker.

- 5 Navigate to the location where you want to export the camera animation.
- 6 Enter a name for your exported camera in the file field.
- 7 Click Save.

3ds Max Cameras

An alternative to animating a camera's position is to import a camera animation from 3ds Max. 3ds Max camera animation can be saved as a .3DS or .ase (ASCII Scene Export) file in your scene. While the .ase format contains only a camera's positional data, the .3DS format contains the camera's position, point of interest, roll and field of view values.

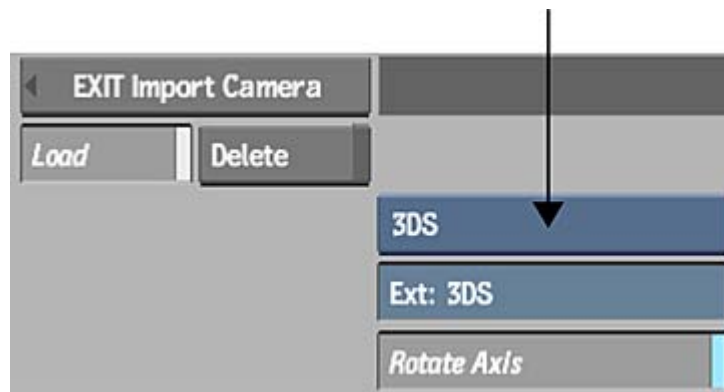

Once the camera is imported, you can edit any of the camera's values and, if necessary, export it back to 3ds Max in its native 3DS format using the Camera menu.

(a) Import Camera button (b) Export Camera button

To import a 3ds Max camera:

- 1 In the Camera menu, click Import.
The Import Camera file browser appears.
- 2 From the Import Type box, select either the .3DS or .ase format.

- 3 If needed, enable Rotate Axis to rotate the imported camera by 90° on the X-axis so that it is compatible with Action's coordinate system.
- 4 Navigate to the location where a 3ds Max camera setup was exported, and select the file.
You return to Action and the imported camera is applied to your scene.

To export a camera to 3ds Max format:

- 1 Select the camera you want to export.
- 2 In the Camera menu, click Export.

The Export Camera file browser appears.

- 3 From the Export Type box, select 3DS.

- 4 If needed, enable Rotate Axis to rotate the exported camera by -90° on the X-axis so that it is compatible with the coordinate system of the 3D application.
- 5 Navigate to the location where you want to export the camera animation.
- 6 Enter a name for your exported camera in the file field.
- 7 Click Save.

NOTE When exporting from Flame Premium, save the .3DS file in a directory that is readable by a 3ds Max system.

Camera, Working, and Orthographic Views

You can view the scene from various angles and display multiple views of these angles simultaneously. This is helpful in setting light sources, camera angles, stereo parameters, and animation keyframes more accurately.

You can view the scene from Camera view, the Working view, and three orthographic views. In Camera view, an object becomes smaller as it moves farther away from the camera. Working view is very similar to Camera view, except that no camera settings are affected. Working view is useful for trying out different settings and positions without actually making changes that can affect your cameras. In Orthographic view, an object remains the same size, regardless of its distance from the camera. Orthographic views are more helpful for aligning objects.

The following figures illustrate the different angles by which the scene can be viewed. The scene in this example contains a grey back clip and the 3D model of an apple.

Front view

Camera view

Side view

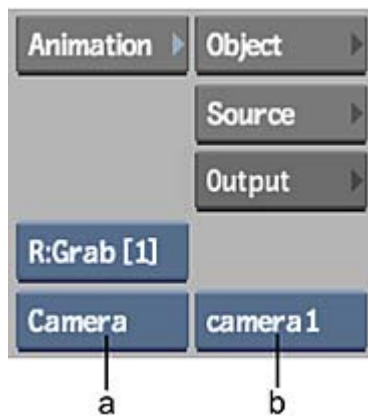

Top view

Setting Camera, Working, and Orthographic Views

To set camera, working, and orthographic views:

- 1 From the View box, select Camera, Working, or an orthographic view. When in Camera view, use the Camera box that appears to select which camera is used in the image window.

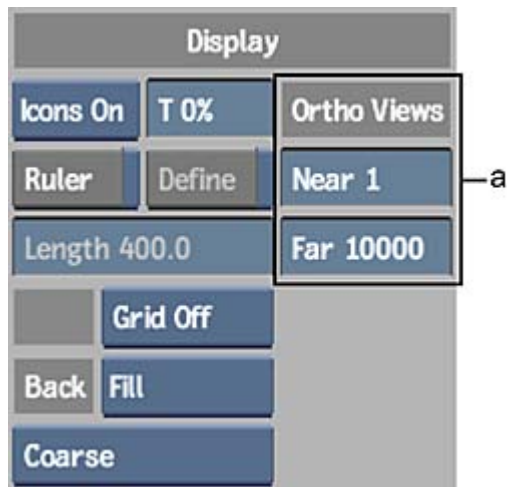

(a) View box (b) Camera box

Select:	To:
Camera	View the scene in Camera view. This is the scene as viewed by the camera eye. In other words, your field of vision in world space is equivalent to the viewing frustum of the camera. The size of objects depends on their distance from the camera eye.
Top	View the scene as if you are positioned on the positive Y-axis. This is an orthographic view; there is no perspective deformation.
Side	View the scene from the side, as if you are positioned on the positive X-axis. This is an orthographic view; there is no perspective deformation.
Front	View the scene as if your line of vision is directed into the camera eye. This is an orthographic view; there is no perspective deformation.
Working	View the scene just as in Camera view. Try out different positions and adjustments without affecting the camera settings.

- 2 If you have multiple cameras in the scene, use the Camera box to define which camera is used for the Camera view in the image window. The camera selected in this box is not necessarily the camera used to process the scene.
- 3 Use the Working view if you want to view the scene using different adjustments, without saving any of the settings to a camera setup. For this reason, no parameters are animatable.
- 4 Adjust the view with the Ortho Views controls, if needed.

When using an orthographic view, you may notice that parts of the object you are viewing are getting cut off. Adjust the near and far ortho views. You gain more space to view the object, but lose some viewing precision.

In the Display section of the Action Setup menu, adjust the Near and Far fields.

(a) Ortho Views in Setup menu

NOTE The Ortho Views parameters in the Action Setup menu are only for viewing objects, and cannot be animated or saved. The Near and Far fields in the Camera menu are used to set clipping planes. See [Moving the Near and Far Clipping Planes](#) (page 681).

In addition to Camera, Working, and the three orthographic views, you can also select Schematic view, which uses nodes to represent the objects in the scene and arrows to illustrate the relationships between objects.

Modifying the Camera

You can gesturally modify the camera directly in the scene using options in the Tools box. A mode remains in effect until you select a different mode.

To gesturally modify the camera:

- 1 Make a selection in the Tools box.

Select:	To:
FOV	Move the camera field of view.
Track Camera	Move the camera lens and look-at point.
Tilt	Tilt the camera up and down by moving the look-at point. Also changes the camera roll. This option only modifies Target cameras.
Roll	Rotate the camera on the Z-axis. This option only modifies Target cameras.
Orbit	Rotate the camera lens around the look-at point.
Dolly	Move the camera lens towards (zoom in) or away from (zoom out) the look-at point.

- 2 Drag the cursor in the image window.
The camera is modified. Related Camera menu controls are updated to reflect the changes.

Zooming In and Out

Use the Zoom option to move the camera eye toward or away from the point of interest. While viewing the scene in Camera view, zoom in or out from the point of interest to move the camera eye closer to or farther from the point of interest. In Top, Side, or Front view, you can enlarge or reduce the scene in the image window without affecting the camera. Zooming has no effect in Schematic view.

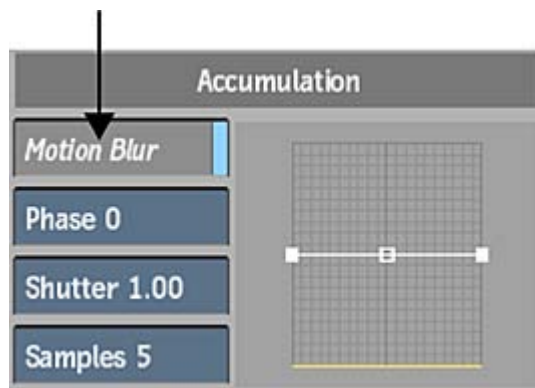

To zoom the camera:

- 1 From the Tools box, select Zoom.
- 2 Place the cursor in the image window.
The cursor changes to a magnifying glass.
- 3 To zoom in, drag the cursor to the left. To zoom out, drag the cursor to the right.

About Motion Blur

Use the Motion Blur tool to simulate the blur created by fast-moving objects. Motion Blur is used with both the normal and physical cameras. You can apply motion blur globally (to the entire scene) and then exclude objects in the scene from its effect.

To use motion blur, enable the Motion Blur button in the Action Setup menu and specify motion blur settings.

You can animate the Motion blur button, as well as the Phase, Shutter, and Samples fields. They can be found in the Channel Editor under the *motion_blur* folder.

See Accumulation Settings in [Rendering Tab](#) (page 439).

Blurring a Single Object

You can apply motion blur to an object rather than to the entire scene. To use the per object motion blur, you must apply Motion Blur globally, and then disable motion blur per object.

NOTE The motion blur curve in the Action Setup menu is global. It cannot be set per node. When motion blur is enabled, all surfaces have the same blur characteristics but not necessarily the same animation.

To blur a single object:

- 1 Enable Motion Blur in the Action Setup menu.
This activates a global motion blur applied to everything within the scene.
- 2 Disable motion blur per object (for example, in the surface, axis or light menu) to exclude objects from the global motion blur.

Creating Custom Motion Blurs

The motion blur curve controls the sample weight over the scope of the motion blur. The point on the left is the weight of the first sample and the point on the right is the weight of the last sample. By changing the curve, you can create custom motion blur effects such as a Gaussian blur.

As with the Channel Editor, you can add keyframes to the motion blur curve using Add mode, move keyframes with Move mode, and modify the curve's shape using tangent handles.

The original animation with Motion Blur disabled.

Motion Blur is enabled using a custom motion blur curve and phase set to 100.

Motion Blur is enabled using the same motion blur curve as above. Phase is set to -100.

TIP You can preview your motion blur effect by clicking Preview. This will display the rendered frame at the current frame in the timebar.

Simulating Motion Blur on a Still Object

You can add motion blur to an object that has no axis movement, by adding a second axis to simulate the motion.

To simulate motion blur on a still object:

- 1 From the View box, select Schematic.
- 2 From the Node bin, drag an Axis node to the schematic.

- 3 Press **Shift** and drag the original Axis node over the new Axis node.

Still object with Axis

New axis added

New axis as child of original axis

Image courtesy of Das Werk

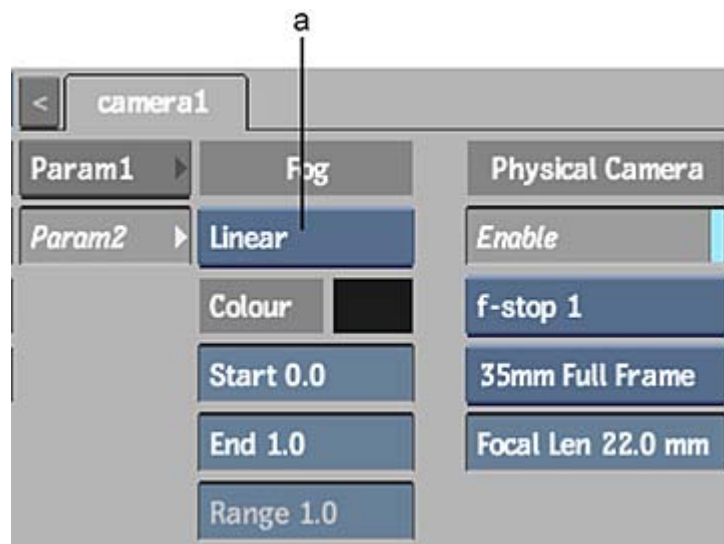

- 4 Enable Motion Blur and animate the new axis with the desired motion.

About Fog

Use fog in the scene to create visual effects such as mist, haze, and murky water. The fog effect causes objects to fade as their distance from the camera increases. The further an object is from the camera, the foggier the scene appears.

The fog effect is based on depth-cueing, which means the intensity of the fog varies along the Z-axis, and the specified colour gradually increases or decreases its intensity.

You control the density and colour of the fog using the fog controls in the Camera menu.

(a) Fog box

Try combining your fog effect with other effects such as transparency to create a more genuine look for non-solid substances such as water. You can also use expressions to improve the quality of fog in a scene so that it looks more natural. See [Working with Expressions in the Channel Editor](#) (page 1516).

Applying Fog to the Scene

To add fog to the scene:

- 1 In the Camera menu, select a fog type from the Fog box.

Type	Description
Linear	Specifies the distance at which fog should start and end.
Exponential	$\text{Fog} = e^{-(\text{density} * z)}$ where z represents the range or distance from the camera. The range should lie within the realm of the near and far clipping planes. The minimum value is 1.
Exponential2	$\text{Fog} = e^{-(\text{density} * z)^2}$. The exponential types provide more depth, more natural looking fog, and make the edges appear smoother.

- 2 For Linear fog, specify the distance at which the fog should start and end in the Start and End fields. For Exp or Exp2 fog, specify the range in the Range field.
- 3 To select the colour of the fog, click the colour pot to display the colour picker.
Typically, the fog colour should match the background colour of the image in the scene.

About the 3D Camera

The 3D camera is a full-featured animatable camera in Action that allows you to build 3D compositing scenes, mixing 3D objects and stereo objects.

Typically, you work with the 3D camera to frame and animate the view to achieve the effect that you want. You can also animate specific camera properties.

Use the 3D camera in Stereo mode to create three-dimensional renders with the illusion of a three-dimensional depth-of-field. When rendering a stereoscopic scene, Action takes into account all of the stereoscopic camera attributes. Action outputs two clips: one rendered for the left camera and one for the right camera. These clips can then be viewed in stereo mode, used in other stereo clips, output to VTR, or composited by another program.

Adding a 3D Camera

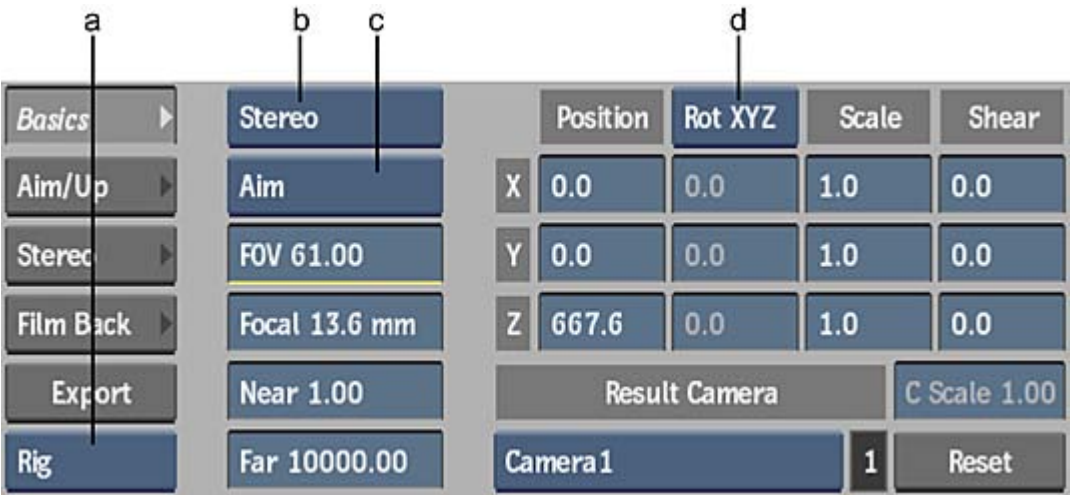

By default, a 3D camera exists in the Action scene when using stereo clips, or when Action has been set up to work in stereo (you may need to pan in the schematic to see the camera node). You can add multiple 3D cameras in order to change point-of-view or depth-of-field from one camera to another. You can add and animate multiple cameras when creating compositions. You can also switch from one camera to another at any point.

To add a stereo camera to a scene:

- 1 Do one of the following:
 - Drag the Camera 3D node from the node bin and place it in the schematic.
 - Drag the Camera 3D node from the node bin and place it where you want it in the Result view.
 - Double-click the Camera 3D node. You do not need to be in Schematic view to add a node in this manner.A new 3D camera is added to the scene. An icon representing the camera is added to the schematic.
- 2 Select the 3D Camera node to make it the active camera in the scene.
- 3 In the Object menu that appears, set the Result Camera to a numbered camera representing a 3D camera.
- 4 In the Output menu, set the Mode to Stereo and set the Camera to Result Cam.

3D Camera Parameters

Basics Tab

(a) Stereo Camera View Type box (b) 3D Camera Type box (c) Camera Type box (d) Rotation Order box

Export FBX Camera button Opens the Export Camera file browser to save an FBX camera.

Stereo Camera View Type box Available when Stereo is selected in the 3D Camera Type box. Select Left, Right, or Rig (for Stereo Rig).

3D Camera Type box Select whether the 3D camera is stereo or mono.

Camera Type box Select whether the camera is Free, Aim, or Aim and Up.

Select:	For:
Free	Static scenes and for simple animations (up, down, side-to-side, in and out), such as panning out of a scene. A Free camera views the scene in the direction that you aim the camera. You can simply animate the camera rotation or camera tilt as though it were on a tripod. Use the Rotation fields in conjunction with a Free camera.

Select:	For:
Aim	Slightly more complex animations (along a path, for example), such as a camera that follows the erratic path of a bird. The Aim camera ensures the camera is specifically aimed at a target object in the scene. Use the Roll and Aim fields in conjunction with the Aim camera.
Aim and Up	Complex animations, such as a camera that travels along a looping roller coaster. Use the Aim and Up camera to specify which end of the camera must face upward. Use the Roll, Aim, and Up fields in conjunction with the Aim and Up camera.

FOV field Displays the angular field of view value, measured in degrees. Use to adjust the width of the camera frustum. Editable.

Focal Length field Displays the focal length of the camera lens, measured in millimeters. Increasing zooms the camera in and increases the size of objects. Decreasing zooms the camera out and decreases the size of objects. Editable.

Near Clipping Plane field Displays the position of the near clipping plane, in pixels, which represents the distance from the camera to the closest point within which image details are processed. Editable.

Far Clipping Plane field Displays the position of the far clipping plane, in pixels, which represents the distance from the camera to the farthest point within which image details are processed. Editable.

See [Moving the Near and Far Clipping Planes](#) (page 681).

X Position field Displays the position of the camera, in pixels, on the horizontal (X) axis. Editable.

Y Position field Displays the position of the camera, in pixels, on the vertical (Y) axis. Editable.

Z Position field Displays the position of the camera, in pixels, on the perpendicular (Z) axis. Editable.

Rotation Order box Select the order in which the camera is rotated, on the horizontal, vertical, and perpendicular (X, Y, and Z) axes.

X Rotation field Displays the level of rotation of the camera on the horizontal (X) axis, in degrees. Active when Camera Type is set to Free. Editable.

Y Rotation field Displays the level of rotation of the camera on the vertical (Y) axis, in degrees. Active when Camera Type is set to Free. Editable.

Z Rotation field Displays the level of rotation of the camera on the perpendicular (Z) axis, in degrees. Active when Camera Type is set to Free. Editable.

X Scale field Displays the scale of the camera on the horizontal (X) axis, as a percentage. Editable.

Y Scale field Displays the scale of the camera on the vertical (Y) axis, as a percentage. Editable.

Z Scale field Displays the scale of the camera on the perpendicular (Z) axis, as a percentage. Editable.

X Shear field Displays the shearing of the camera (diagonal shift) on the horizontal (X) axis, as a percentage. Editable.

Y Shear field Displays the shearing of the camera (diagonal shift) on the vertical (Y) axis, as a percentage. Editable.

Z Shear field Displays the shearing of the camera (diagonal shift) on the perpendicular (Z) axis, as a percentage. Editable.

Result Camera box Specify which camera is active. The active camera is the one that will be used when processing/rendering your scene.

Camera Scale field Displays the size of the camera relative to the scene, independently for either Left or Right camera views. For example, if Camera Scale is set to 0.5, the camera's view covers an area half as large, but objects in the camera's view are twice as large. If Focal Length is set to 35, the effective focal length for the camera would be 70. Editable.

Reset button Resets the 3D Camera menu to its default settings.

FBX Unit Scaling field Not shown. This locked field displays the scale factor of the FBX camera used within the application. Use to help set the Pixels to FBX Units field when exporting an FBX camera. Non-editable.

Aim/Up Tab

When Camera Type is set to Aim or Aim and Up, the available options are enabled in the Aim/Up tab.

3D Camera Type box Select whether the 3D camera is stereo or mono.

Camera Type box Select whether the camera is Free, Aim, or Aim and Up.

Select:	For:
Free	Static scenes and for simple animations (up, down, side-to-side, in and out), such as panning out of a scene. A Free camera views the scene in the direction that you aim the camera. You can simply animate the camera rotation or camera tilt as though it were on a tripod. Use the Rotation fields in conjunction with a Free camera.
Aim	Slightly more complex animations (along a path, for example), such as a camera that follows the erratic path of a bird. The Aim camera ensures the camera is specifically aimed at a target object in the scene. Use the Roll and Aim fields in conjunction with the Aim camera.
Aim and Up	Complex animations, such as a camera that travels along a looping roller coaster. Use the Aim and Up camera to specify which end of the camera must face upward. Use the Roll, Aim, and Up fields in conjunction with the Aim and Up camera.

Parenting Offset box Select an offset option for viewing an image when parenting a camera node. Origin sets the image to the camera origin; Target sets the image to the default viewplane distance relative to the camera; and Live Target sets the image to the current viewplane distance based on the FOV.

Parenting Offset field Displays the offset value, as computed from the default camera field of view and the default image size. This value does not change even if other camera parameters are changed. Non-editable.

X Aim field Displays the position of the aiming target of the camera on the horizontal (X) axis, in pixels. Editable.

Y Aim field Displays the position of the aiming target of the camera on the vertical (Y) axis, in pixels. Editable.

Z Aim field Displays the position of the aiming target of the camera on the perpendicular (Z) axis, in pixels. Editable.

X Up field Displays the up direction on the horizontal (X) axis, in pixels. Editable.

Y Up field Displays the up direction on the vertical (Y) axis, in pixels. Editable.

Z Up field Displays the up direction on the perpendicular (Z) axis, in pixels. Editable.

Roll field Displays the amount of camera roll, in degrees. A positive value rolls the camera clockwise, where a negative value rolls it counter-clockwise. Available only with the Aim, and Aim and Up cameras. Editable.

Stereo Tab

Stereo Mode box Select the method for computing the zero parallax plane.

Select:	To:
Converged	Compute the zero parallax plane by toeing-in the cameras. You can compare this effect to our focusing on an object by rotating our pupils inwards. However, a dangerous side effect may occur where you get a keystone effect on the pairs of render images, causing visual confusion in other elements in the scene. In a rendered image, our focus tends to cascade over the entire image and we are not focusing on a single object, which is not true in real life. You should only use Converged when an object is at the center of the screen with no scene elements at the render borders on either the left or right camera frustum.
Off-axis	Compute the convergence plane by shifting the frustum using camera film back. This is the safer way to compute stereo image pairs and avoids keystone artifacts. Off-axis is the default setting.
Parallel	Create a parallel camera setup where there is effectively no convergence plane. This is useful for landscape settings where objects exist at infinite focus.

Interaxial Separation field Displays the distance between the left and right cameras, in pixels. Editable.

Zero Parallax field Displays the distance on the camera view axis, in pixels, where the zero parallax plane occurs (the point where objects appear off screen). Objects in front of the zero parallax plane have negative parallax. Objects behind the zero parallax plane have positive parallax. Editable.

NOTE In general, your object should be behind the zero parallax plane. In other words, the camera distance should be greater than the zero parallax plane value. The zero parallax value, the camera separation, and focal length are all used to determine the shift that must be applied to film back on the respective left and right cameras. The zero parallax distance is enabled only when Stereo Mode is set to Off-Axis or Toe-In.

Zero Parallax Plane button Enable to display the zero parallax plane.

Zero Parallax colour pot Displays the colour used for the zero parallax plane. Editable.

Zero Parallax Transparency field Displays the level of transparency for the zero parallax plane. Editable.

Safe Stereo Viewing Volume button Enable to display the safe viewing volume created by the intersection of the frustum of the left and right cameras.

Safe Stereo Volume colour pot Displays the colour used for the safe stereo viewing volume. Editable.

Safe Stereo Volume Transparency field Displays the level of transparency for the safe stereo viewing volume. Editable.

Toe In Adjust field Displays the offset, in degrees, applied to the computed toe-in effect when Stereo Mode is set to Converged. Editable.

Film Offset Left Cam field Displays the horizontal film offset for the left camera. Editable.

Film Offset Right Cam field Displays the horizontal film offset for the right camera. Editable.

Film Back Tab

Basics	User		Fit Res Gate	Horizontal	
Aim/Up	Aperture	X 0.84 Y 0.63	Film Fit Offset	0.0	
Stereo	Film Aspect	Ratio 1.33	Film Offset	X 0.00	Y 0.00
Film Back	Lens Squeeze	Ratio 1.000	Film Translate	X 0.00	Y 0.00
Export	Film Roll 0.000	Rot-Trans	Film Roll Pivot	X 0.00	Y 0.00
Rig	Pre Scale 1.000	Post Scale 1.000	Reset		

(a) Film Gate box (b) Film Roll Rotation Order box

Film Gate box Select a preset film frame format type. This action automatically sets the corresponding Camera Aperture, Film Aspect Ratio, and Lens Squeeze Ratio. To set these attributes individually, set Film Gate to User. The default setting is User.

Camera Aperture X field Displays the width of the camera Film Gate setting, measured in inches. This setting has a direct effect on the camera's angle of view and automatically updates Film Aspect Ratio. Editable.

Camera Aperture Y field Display the height of the camera Film Gate setting, measured in inches. This setting has a direct effect on the camera's angle of view and automatically updates Film Aspect Ratio. Editable.

Film Aspect Ratio field Displays the ratio of the camera aperture width versus height. Modifying this field automatically updates the Camera Aperture fields. Editable.

Lens Squeeze Ratio field Displays the amount horizontal compression that is applied to the image. Used with some cameras (for example, anamorphic cameras), which compress the image horizontally to record a wider aspect ratio image onto a square area on film. Editable.

Film Roll Value field Displays the amount of rotation applied to the film back. The rotation occurs around the specified pivot point. Used to compute a film roll matrix, which is a component of the post-projection matrix. Editable.

Film Roll Rotation Order box Select how the roll is applied with respect to the pivot value.

Enable:	To:
Rotate-Translate	First rotate the film back, then translate it by the pivot point value.
Translate-Rotate	First translate the film back, then rotate it by the film roll value.

Pre Scale field Displays the artificial 2D camera zoom that is applied before the film roll. Used in 2D effects. Editable.

Post Scale field Displays the artificial 2D camera zoom that is applied after the film roll. Used in 2D effects. Editable.

Film Fit Resolution Gate box Select the size of the resolution gate relative to the film gate (Film fit). If the resolution gate and the film gate have the same aspect ratio, then the Film Fit setting has no effect.

Select:	To:
Fill	Fit the resolution gate within the film gate.
Horizontal	Fit the resolution gate horizontally within the film gate.
Vertical	Fit the resolution gate vertically within the film gate.
Overscan	Fit the film gate within the resolution gate.

Film Fit Offset field Displays the offsets of the resolution gate relative to the film gate either vertically (if Film Fit Resolution Gate is Horizontal) or horizontally (if Film Fit Resolution Gate is Vertical). Film Fit Offset has no effect if Film Fit Resolution Gate is Fill or Overscan. Editable.

Film X Offset field Displays the horizontal offset, in pixels, of the resolution gate and the film gate relative to the scene. Changing the Film X Offset produces a two-dimensional track. Editable.

Film Y Offset field Displays the vertical offset, in pixels, of the resolution gate and the film gate relative to the scene. Changing the Film Y Offset produces a two-dimensional track. Editable.

Enter:	To:
1	Have the view guide fill the view. The edges of the view guide may be exactly aligned with the edges of the view, in which case the view guide is not visible.
> 1	Increase the space outside the view guide. The higher the value, the more space is outside the view guide.

Film X Translate field Displays the artificial 2D horizontal camera pan. Used in 2D effects. Editable.

Film Y Translate field Displays the artificial 2D vertical camera pan. Used in 2D effects. Editable.

Film Roll X Pivot field Displays the horizontal pivot point from the center of the film back, which is used during the rotating of the film back. Used to compute the film roll matrix, which is a component of the post projection matrix. Editable.

Film Roll Y Pivot field Displays the vertical pivot point from the center of the film back, which is used during the rotating of the film back. Used to compute the film roll matrix, which is a component of the post projection matrix. Editable.

Optimizing Attributes of the 3D Camera

Here are some general guidelines for tweaking the stereo attributes of the 3D camera:

- Many parameters are relative to each other, and can be scaled and changed upon import using the Auto Fit in Scene or FBX Unit to Pixels settings.
- Tweak the Interaxial Separation to move the cameras closer to or farther away from one another.

NOTE You should re-adjust your Interaxial Separation if you change your output device, since the settings for one display method may differ from another.

- Increase the Zero Parallax to move objects further away from the camera. The 3D effect becomes less pronounced in this case. Decrease your Zero Parallax to move objects closer to the camera. You can see more depth if you do this.

The stereoscopic effect is the most realistic when the Zero Parallax Plane is in between the two objects.

- You may need to re-adjust your camera attributes if you change the resolution of your output device.
- You can also increase the Far Clip Plane to increase the depth of the camera.
- In Anaglyph viewing mode, the red/cyan colors for objects are swapped depending on whether they are behind or in front of the parallax plane. For objects behind the zero parallax plane, they appear in cyan/red. For objects in front of the zero parallax plane, they appear in red/cyan.

Working with the Frustum

The volume of space viewed by the camera is called the frustum. The frustum is, in effect, a viewing pyramid. The camera is located at the apex of the pyramid, and the far clipping plane forms the base. The pyramid may be truncated by the near clipping plane. The point of interest, or aim, is the target at the center of the camera's view.

(a) Camera (b) Near clipping plane (c) Far clipping plane (d) Aiming target

If you place a surface within the frustum, it is visible in the final animation. If the surface is located outside the scope of the frustum, it is not visible at that frame in the animation.

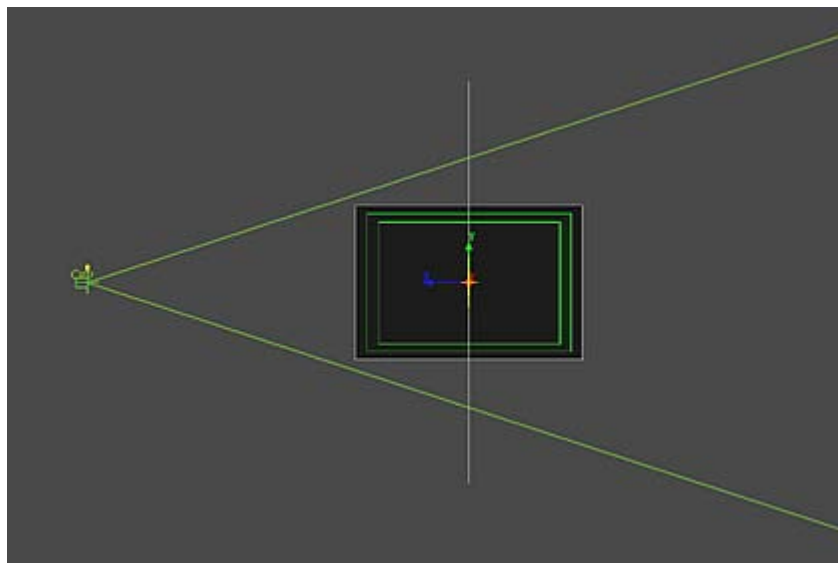

To see the camera and frustum:

- 1 From the View box, select Side.
- 2 In the image window controls, click

to zoom out from the scene.

- 3 Enable the Pan button, and pan around the scene until you see the camera icon.

- 4 From the Camera menu, click the Aim/Up tab.
- 5 Ensure that Camera Type is set to Aim, or Aim and Up.
- 6 Drag the Roll field until you see the four sides of the frustum.
- 7 On the Stereo tab, enable Zero Parallax Plane and Safe Stereo Viewing.

The safe viewable volume of the frustum, and the zero parallax plane area appear and are denoted with a transparent colour. The aiming target is centered at zero parallax.

- 8 Change the position of the near and far clipping planes to alter the depth of the frustum. See [Moving the Near and Far Clipping Planes](#) (page 681).
- 9 Change the position of the camera to alter the orientation of the frustum. See [Moving the 3D Camera](#) (page 681).

- 10 Change the position of the camera's aim to alter the orientation of the frustum. See [Adjusting the Aim of the 3D Camera](#) (page 681).
- 11 Adjust the angle of view to adjust the size of the objects as viewed by the camera. See [Adjusting the Field of View](#) (page 682).

Near and Far Clipping Planes

The camera frustum is determined by six clipping planes: the left, right, top, bottom, near, and far clipping planes. The depth of the frustum is affected by the near and far. The values for these channels are expressed in pixels relative to the position of the camera.

Set the Near and Far clipping planes to the lowest and highest respective values that produce the desired result. If the distance between the near and far clipping planes is much larger than is required to contain all the objects in the scene, the image quality of some objects may be poor.

TIP Objects that you want to render are usually within a certain range from the camera. Setting the near and far clipping planes just slightly beyond the limits of the objects in the scene can help improve image quality.

The ratio of far:near clipping planes determines the depth precision. Try to keep that ratio as small as possible for better results. Since most of the depth precision is concentrated around the near clip plane, try to avoid a lot of detail on distant objects.

Moving the Near and Far Clipping Planes

To move the near and far clipping planes:

- 1 From the View box, select Side or Top, depending on how your camera is positioned.
Either of these views profiles the camera so that the near and far clipping planes are clearly visible.
- 2 From the Camera menu, on the Basics tab, enter a value in the Near field to edit the position of the near clipping plane.
The value in the Near field corresponds to the position of the near clipping plane, in pixels, from the front of the camera. The farther away that the near clipping plane is placed, the higher the value. The default value is 1. Any object between the camera and the near clipping plane is outside the camera frustum and does not get processed in the final result.
- 3 Enter a value in the Far field to edit the position of the far clipping plane.
The value in the Far field corresponds to the position of the far clipping plane, in pixels, from the front of the camera. The lower the value, the closer the far clipping plane is placed. The default value is 10000. Any object positioned behind the far clipping plane is outside the camera frustum and does not get processed in the final result.

Moving the 3D Camera

Objects in the scene can be recorded from an arbitrary position as determined by the orientation of the camera in world space. The position of the camera can be moved left or right, up or down, or closer or farther from the central point of interest. The values for camera position are expressed in pixels relative to the aiming target.

To change the position of the 3D camera:

- 1 From the View box, select Front, Side, or Top, depending on how your camera is positioned, to provide a clear view of the camera motion.
- 2 From the Camera menu, on the Basics tab, modify the Position X, Y, and Z fields.

You can also animate the camera using keyframes and the Channel Editor.

Adjusting the Aim of the 3D Camera

The aiming target is the point in world space at which the camera is directed. The aiming target is always at the centre of the camera's frustum. Changing the position of the camera's aim causes the orientation of the frustum to change. You can take advantage of the relationship between the aim and the frustum to make the camera follow a moving object. To do this, animate the aim while keeping the camera in a fixed position. You can adjust the aim only with an Aim, or Aim and Up camera.

To adjust the aim of the 3D camera:

- 1 From the View box, select Front, Side, or Top, depending on how your camera is positioned, to provide a clear view of the camera motion.
- 2 Do one of the following:
 - From the Camera menu, on the Aim/Up tab, modify the Aim X, Y, and Z fields.
 - Move the aiming target by dragging.

You can also animate the aim using keyframes and the Channel Editor.

Adjusting the Field of View

For every shot, you can decide how big an object appears in the frame, for example, whether a shot includes an entire character or just its head and shoulders. This is directly controlled by adjusting the field of view.

The field of view is the amount of a scene (measurable in terms of area) that can be viewed by the camera. The field of view can be altered by changing the angle of view or the distance between the camera and the subject. See [Moving the 3D Camera](#) (page 681).

About the Angle of View

The angle of view, or more accurately, the angular field of view, is the amount of a scene (measurable in terms of an angle in degrees, originating at the camera position) that can be viewed by the camera. The angle of view is not affected by changes in the distance between camera and subject. It can be modified directly, in the FOV field, or indirectly, via the Focal Length field.

The angle of view and the focal length are inversely proportional. As you extend the camera's focal length, the field of view gets narrower. As you shorten the focal length, the field of view gets larger.

Playing with the relationship between distance and angle of view affects the focus and perspective of objects in the scene that can be used to creative advantage.

For example, a pair of objects that are placed a distance apart from each other, but in line with the camera, can appear differently when changing these two parameters.

If these objects are viewed by a camera at long range, but using a lens with a high focal length (narrow angle of view), they will appear large in the frame and in equal focus, and will seem to be located on the same plane.

These same objects, when viewed at close range, but using a lens with a low focal length (wide angle of view), will appear to also fill the frame, but the size difference between them will be exaggerated (the foreground object will appear much bigger than the background object) and there will be a very noticeable focus difference.

Focal Length

The focal length of a lens is the distance from the center of the lens to the film plane. The shorter the focal length, the closer the focal plane is to the back of the lens. Focal length is usually expressed in millimeters.

The object's size in the frame is directly proportional to the focal length. If you double the focal length (keeping the distance from the camera to the object constant), the subject appears twice as large in the frame. The size of the object in the frame is inversely proportional to the object's distance from the camera. If you double the distance, you reduce the size of the object by half in the frame.

Adjusting the Angle of View

To adjust the angle of view:

- 1 From the Camera menu, ensure that the Basics tab is active.
- 2 If you are using degrees for angle of view, enter the value directly in the FOV field.
Increasing the FOV value widens the frustum and decreases the Focal Length. Decreasing the FOV value narrows the frustum and increases the Focal Length.
- 3 If you are using different lens sizes, enter a value in the Focal Length field.
Increasing the Focal Length narrows the frustum and decreases the angle of view. Decreasing the Focal Length widens the frustum and increases the angle of view.

Importing and Exporting 3D Cameras

Flame Premium supports the import of Alembic 3D data, and the import and export of 3D data saved in the FBX 3D format. These formats provide a means for exchanging 3D data for scene compositions—such as cameras—between tools and packages developed by different manufacturers.

You can either import a camera you created and edited in Action, or import one from another 3D application. Once a camera is imported, you can edit its parameters, change its animation, and then export it back to the application it came from.

NOTE Some parameters in Maya are not supported in FBX, such as Shear, FilmPostScale, and CamScale. Also, many parameters that are animatable in Maya and Flame Premium are not supported as animation curves in FBX. The 3D Camera does not support depth of field.

Export a 3D camera from Action to FBX format, which can be used later by any other FBX-compatible application.

To export a 3D camera from Action to FBX format:

- 1 Select the camera that you want to export.
- 2 In the 3D Camera menu, click Export.

The Export Camera file browser appears.

- 3 Set the FBX Scale and Export Options, as needed.
- 4 Navigate to the location where you want to export the camera animation.
- 5 Enter a name for your exported camera in the file field.
- 6 Click Save.

Export FBX Cameras Settings

Pixels to FBX Units field Displays the scaling factor to apply to the exported FBX file to be used in the 3D application. Use the Units box to select the unit of measurement. Editable.

Units box Select a unit of measurement to apply to the exported FBX file.

Rotate Axis button Enable to rotate the 3D model by 90 degrees on the X-axis so that it is compatible with the target's coordinate system.

Export Axes button Enable to export the animated axes present in the Action scene.

Export Point Locators button Enable to export the 3D point locators created by the Analyzer.

Bake Animation button Enable to add a keyframe at every frame of the exported FBX camera file.

Camera, Working, and Orthographic Views

You can view the scene from various angles and display multiple views of these angles simultaneously. This is helpful in setting light sources, camera angles, stereo parameters, and animation keyframes more accurately.

You can view the scene from Camera view, the Working view, and three orthographic views. In Camera view, an object becomes smaller as it moves farther away from the camera. Working view is very similar to Camera view, except that no camera settings are affected. Working view is useful for trying out different settings and positions without actually making changes that can affect your cameras. In Orthographic view, an object remains the same size, regardless of its distance from the camera. Orthographic views are more helpful for aligning objects.

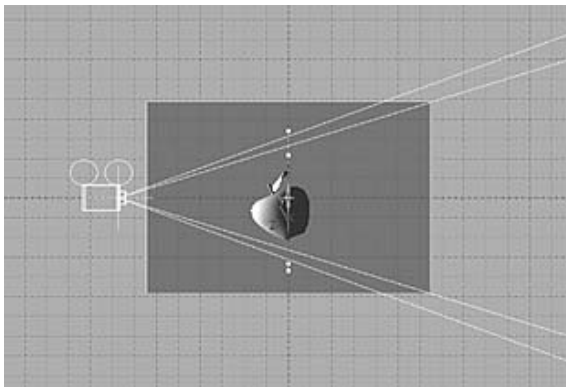

The following figures illustrate the different angles by which the scene can be viewed. The scene in this example contains a grey back clip and the 3D model of an apple.

Front view

Camera view

Side view

Top view

Setting Camera, Working, and Orthographic Views

To set camera, working, and orthographic views:

- 1 From the View box, select Camera, Working, or an orthographic view. When in Camera view, use the Camera box that appears to select which camera is used in the image window.

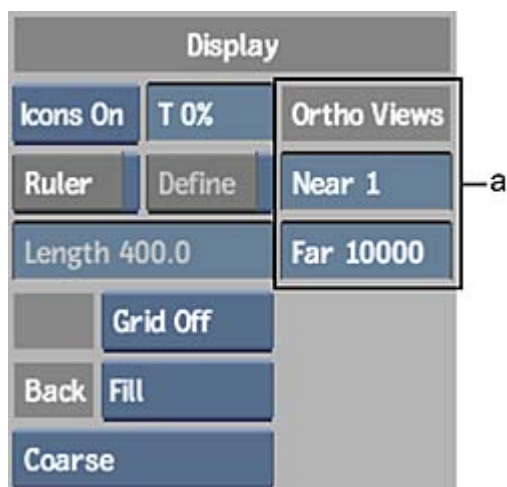

(a) View box (b) Camera box

Select:	To:
Camera	View the scene in Camera view. This is the scene as viewed by the camera eye. In other words, your field of vision in world space is equivalent to the viewing frustum of the camera. The size of objects depends on their distance from the camera eye.
Top	View the scene as if you are positioned on the positive Y-axis. This is an orthographic view; there is no perspective deformation.
Side	View the scene from the side, as if you are positioned on the positive X-axis. This is an orthographic view; there is no perspective deformation.
Front	View the scene as if your line of vision is directed into the camera eye. This is an orthographic view; there is no perspective deformation.
Working	View the scene just as in Camera view. Try out different positions and adjustments without affecting the camera settings.

- 2 If you have multiple cameras in the scene, use the Camera box to define which camera is used for the Camera view in the image window. The camera selected in this box is not necessarily the camera used to process the scene.
- 3 Use the Working view if you want to view the scene using different adjustments, without saving any of the settings to a camera setup. For this reason, no parameters are animatable.
- 4 Adjust the view with the Ortho Views controls, if needed.

When using an orthographic view, you may notice that parts of the object you are viewing are getting cut off. Adjust the near and far ortho views. You gain more space to view the object, but lose some viewing precision.

In the Display section of the Action Setup menu, adjust the Near and Far fields.

(a) Ortho Views in Setup menu

NOTE The Ortho Views parameters in the Action Setup menu are only for viewing objects, and cannot be animated or saved. The Near and Far fields in the Camera menu are used to set clipping planes. See [Moving the Near and Far Clipping Planes](#) (page 681).

In addition to Camera, Working, and the three orthographic views, you can also select Schematic view, which uses nodes to represent the objects in the scene and arrows to illustrate the relationships between objects.

Modifying the Camera

You can gesturally modify the camera directly in the scene using options in the Tools box. A mode remains in effect until you select a different mode.

To gesturally modify the camera:

- 1 Make a selection in the Tools box.

Select:	To:
FOV	Move the camera field of view.
Track Camera	Move the camera lens and look-at point.
Tilt	Tilt the camera up and down by moving the look-at point. Also changes the camera roll. This option only modifies Target cameras.
Roll	Rotate the camera on the Z-axis. This option only modifies Target cameras.
Orbit	Rotate the camera lens around the look-at point.
Dolly	Move the camera lens towards (zoom in) or away from (zoom out) the look-at point.

- 2 Drag the cursor in the image window.

The camera is modified. Related Camera menu controls are updated to reflect the changes.

Zooming In and Out

Use the Zoom option to move the camera eye toward or away from the point of interest. While viewing the scene in Camera view, zoom in or out from the point of interest to move the camera eye closer to or farther from the point of interest. In Top, Side, or Front view, you can enlarge or reduce the scene in the image window without affecting the camera. Zooming has no effect in Schematic view.

To zoom the camera:

- 1 From the Tools box, select Zoom.
- 2 Place the cursor in the image window.
The cursor changes to a magnifying glass.
- 3 To zoom in, drag the cursor to the left. To zoom out, drag the cursor to the right.

About the Analyzer

Use Action's Analyzer to compute the path of live-action camera and object motion in 3D space. Using the calculated position and motion of the virtual camera, you can match image sequences perfectly, placing any element in the scene. The perspective of the element you place in the scene changes with the perspective of the background as the camera moves. The virtual camera motion is intended to be identical to the motion of the actual camera that shot the scene.

Use the following workflow as a quick start guide to the Analyzer. Follow the links for more detailed information.

Step 1

Select back or front/matte media (mono or stereo) to analyze and add an Analyzer node.

Optional steps:

- Perform a lens correction.
- Adjust the four corners of the perspective grid to set the focal length.
- Add manual trackers to obtain a more predictable and consistent result.

NOTE Adding manual trackers can be initiated post-process.

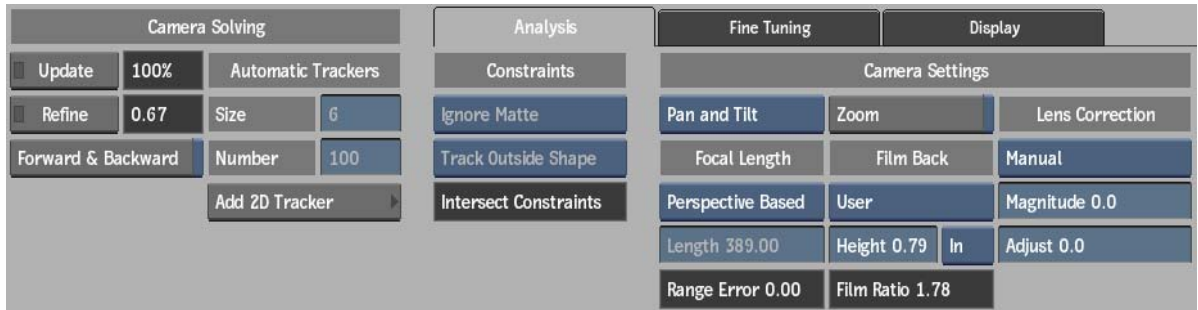

[Tracking using the Analyzer Node](#) (page 691)

Step 2

Perform Camera Tracking in the Analyzer menu.

Optional steps:

- Add mask constraints to moving areas or areas not wanted in the analysis.
- Add properties of the camera that shot the footage to be analyzed.

[Camera Tracking](#) (page 693)

Step 3

Fine-Tune and recalibrate or refine the camera tracking analysis. This step is optional depending on the results of your initial analysis.

[Fine Tuning the Analysis](#) (page 702)

Step 4

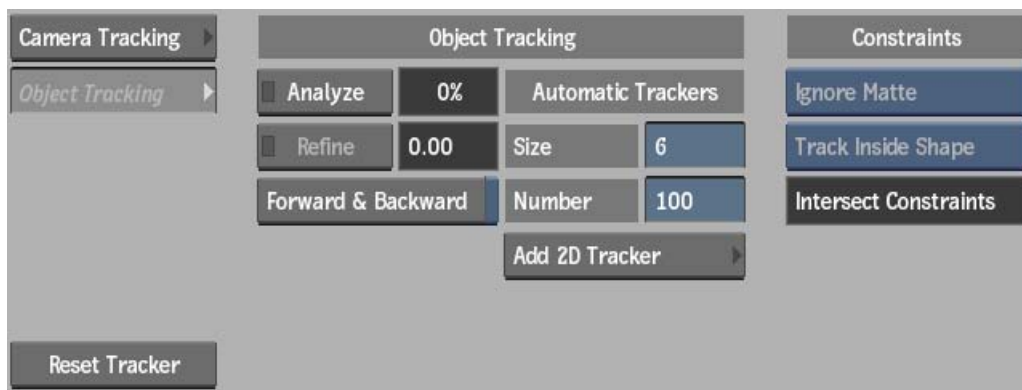

Create a Point Cloud of selected points after the analysis.

[Converting the Camera Analyzer Results](#) (page 705)

Step 5

Perform Object Tracking. If needed, after camera tracking, you can track moving objects in the scene — such as inside the masks that were not tracked in the camera tracking analysis.

[Object Tracking](#) (page 706)

Preparing to Analyze

A good analysis result is often footage dependant, therefore you may need to perform object tracking after the initial camera tracking.

Here are some things to keep in mind that can improve your analysis:

- The Analyzer works best when tracking an image sequence that has a moving camera or environment. Action GMasks or mattes should be used to isolate the background and the objects in the scene that have different motions. Masking objects cause them to be ignored in the tracking process. You should also mask any logos or watermarks in your image sequence.
- The analysis is based on point-like and corner-like image features. Balls, spheres, lines, and smooth surfaces are not considered.
- Crop out any black areas around your image (such as letterbox areas). When cropping, it is very important to keep the optical centre of the image in the centre, that is, the crop should be symmetrical in both dimensions.
- 3D tracking analyses each frame extensively and with high resolution clips, the process can be lengthy. Unlike 2D tracking, however, you are not required to analyse full-resolution clips. In many cases, analyzing proxies will produce acceptable 3D tracking results quicker than the time that would be required for the full-resolution clips.
- If you have information about the camera that shot the scene you want to track, such as the focal length of the lens and the film back size, it is recommended you specify these details to improve the results of the tracking analysis.

Obtain better tracking results by adding manual trackers

Add manual trackers to produce a more consistent track result. Each tracker consists of an inner reference box, which establishes the reference point for the tracking, and an outer tracker box, which follows the movement of the reference point. You can explicitly choose specific trackable features in the image (see [How the Stabilizer Works](#)) (page 870).

While trackers can be added both pre- or post-processing, it is recommended to do so pre-process if there is going to be a difficult sequence to track. Add trackers post-process to improve the results of the automatic processing. If added post-process, click the Update button.

When tracking, the more track points you have in each frame, the smoother and more accurate the tracking results. As you place the trackers on the image, consider the following guidelines:

- Scatter the trackers by placing them on markings, corners, and shadows in the widest area possible. For example, avoid placing all trackers on the floor; place them on walls and other objects in the scene, as well as on the floor.
- Create a sense of depth by positioning trackers on points that lie in different planes, as well as on points located in the foreground and the background of the sequence.
- Avoid tracking points such as highlights or a point where the foreground and a background object meet, as they do not represent physical 3D points.
- Balance the number of trackers within each frame of the sequence so that as you move through the clip, some points leave the frame and other points appear in the frame. However, maintain a balance so that too many points do not leave or enter the frame at the same time.
- Avoid positioning the trackers in uniform areas or on linear edges where the track points may slide along the edge.

To add manual trackers:

- 1 In the Analyzer menu, click the Add 2D Tracker button.
The Stabilizer tool opens and automatically displays the Analyzer media
- 2 Click Add Tracker.
A tracker will appear on the middle of the view.
- 3 Place the tracker over a trackable feature.
Add as many as you need to improve the tracking.
Manually added trackers will be assigned a number, incrementing from the first tracker. Manual trackers can then be selected by either:
 - Selecting them directly on the screen or,
 - Selecting the corresponding Tracker button.
- 4 Click Analyze.
- 5 Click Return when done to return to the Analyzer menu.
The trackers will now be visible in the Analyzer view in a different color from the automatically generated trackers.

NOTE Manually added trackers have persistence. They cannot be filtered, and they will not be deleted in a reset. However a tracker can be manually deleted by first selecting it, and in the Fine Tuning section, clicking Delete.

Adding an Analyzer Node

When you add a Stereo or Mono Analyzer in Action, a number of nodes are added to the schematic.

To add an analyzer to a scene:

- 1 From the Media list, select the back or front/matte media that you want to analyze. If you want to analyze a stereo clip, select the left clip, then press **Ctrl** and select the right clip (you cannot select Back media for a Stereo Analyzer).
- 2 Do one of the following:
 - Drag the Analyzer Mono or Analyzer Stereo node from the node bin and place it in the schematic.
 - Double-click the Analyzer Mono or Analyzer Stereo node. You do not need to be in Schematic view to add a node in this manner.

NOTE If you accessed Action as a Timeline FX, Analyzer Stereo is not available.

The image window automatically switches to an analyzer view to help you view the interactive result of your analysis.

In the schematic view, you can see that an Analyzer node is added to the scene. The number in brackets next to the name of the Analyzer node indicates the media used for the analyzer (a zero (0) indicates Back media). The Analyzer node is parented to a 3D Camera node, which is synced to the analysis of the Analyzer node, as well as an Image (or Stereo Object) node with an axis.

To specify different media as the analyzer source, with the Analyzer node selected in the schematic, select the new media in the Media list, then click Apply.

- 3 To display the Analyzer menu, double-click the Analyzer node in the schematic, or click the Analyzer button.

In the Analyzer menu, you can access Camera and Object tracking settings.

Viewing Analyzers

When you add a mono or stereo analyzer node to your scene, the image window automatically switches to an analyzer view to help you view the interactive result of your analysis. There are other views available from the View box for working with analyzers.

View box Select an option from the Action Analyzers section to set the view in the image window.

Select:	To Display:
Analyzer 2D	2D tracks after analysis. By default, these are displayed as blue squares in the image.
Analyzer 3D	3D points after a mono analysis. By default, these are displayed as green crosses in the image. The F7 keyboard shortcut is a toggle keyboard shortcut; each time you press it, the view changes from Analyzer 2D to Analyzer 3D.

Select:	To Display:
Analyzer 3D Left or Analyzer 3D Right	3D points from the left or right eye perspective after a stereo analysis. The F7 keyboard shortcut is a toggle keyboard shortcut; each time you press it, the view changes from Analyzer 2D to Analyzer 3D Left to Analyzer 3D Right.
Analyzer Working	The Analyzer Working view. This view provides you with the ability to view your analyzed scene using a working camera, which you can modify to view the scene without modifying the tracked virtual camera. This can be helpful to orbit the scene in order to view the depth of 3D points, for example.

Analyzer View box Select which analyzer to display in the image window.

If your scene has multiple analyzers, use the Analyzer View box to select which analyzer to display in the image window. This setting appears under the Analyzer button, and is available when the image window is in Analyzer 2D or Analyzer 3D view.

Reset button Click to reset any camera movements in the Analyzer Working view.

This setting appears under the Analyzer button, and is available when the image window is in Analyzer Working view.

Camera Tracking

You can perform automatic 3D tracking based on the camera properties of the device used to acquire the image sequence you want to track. You can specify these properties, or let the analyzer automatically detect the best solutions for the analysis. Even if you want to perform object tracking on specific moving areas of the scene, you also start with an analysis using camera tracking to create a properly tracked camera.

TIP To improve the results of the track, consider adding [2D manual trackers](#) (page 690) either pre- or post-process.

To create a 3D camera track:

- 1 Add an Analyzer Mono or Analyzer Stereo node, as explained in [Adding an Analyzer Node](#) (page 691).
- 2 In the Camera Tracking menu, set Analysis options. For example, decide if you need to use a matte or GMask in the analysis. In an image sequence of a busy street, you can create a matte or mask of moving elements (such as cars and people) to isolate this area from the analysis. See [Analysis Settings](#) (page 699) for details of each Lens Correction, Constraints, and Camera setting.

- 3 Enable Forward & Backward to track the image sequence backward after the forward tracking has completed. This option takes longer, but you may get better results.

- 4 If needed, adjust the size and number of trackers.

Smaller trackers can speed up the calculation, while larger trackers make the analysis more robust with regard to image noise and variations. A general rule is to increase the size of the trackers when tracking high-resolution footage (2K or larger) that contains more noise.

- 5 Click Analyze.

You can see a progress indicator beside the Analyze button. You can interrupt the analysis and resume it by clicking Analyze again.

Most of the time, tracking occurs in the background, allowing you to continue working while tracking. In Batch or Batch FX, you can use connected input and matte clips as the media to be tracked. In this case, tracking becomes a foreground process.

After tracking has completed and you press Confirm, the Analyze button changes to Update, and you can see the 2D tracks (the blue squares in the following example) and 3D points (green crosses) in your image, provided that you are in Analyzer 3D view.

Image courtesy of Behavior Communications Inc.

The 3D camera connected to the analyzer node synchronizes to the results of your 3D tracking, and any further changes you make to the 3D track are reflected in this camera.

- 6 If you are satisfied with the results of the tracking analysis, proceed to [Converting the Camera Analyzer Results](#) (page 705). If you want to tweak your track results, see [Fine Tuning the Analysis](#) (page 702).

NOTE As a general rule, a Refine field value between 1 and 1.5 is considered a good quality track.

Set the focal length by adjusting the perspective grid

The tracking analysis algorithm can make a best estimate of the focal length for the camera without any user input (see [Analysis Settings](#) (page 699)). In order to refine the algorithm's analysis you can use a perspective-based grid to define the focal length. The focal length determined through the perspective grid is then used as part of the analysis. If you do not use this perspective grid or manually enter a value for the focal length, the algorithm guesses at an estimate of the focal length.

To set the focal length:

- 1 With the Analyzer object selected in the schematic, select the Analyzer 3D view from the View box.
- 2 From the Analysis tab in the Analyzer, select Perspective Based from the Focal Length box.

A perspective grid appears in the view with the selected media.

- 3 While in Analyzer 3D view, drag each of the four corners of the rectangle to the desired location to form a rectangular grid. The rectangle automatically aligns to the new perspective. The Range Error, which displays the error estimate for the focal length, should be small relative to the focal length (should be less than 10% of the focal length).

NOTE When dragging one of the corner points of the rectangle, if your desired location cannot be computed (for example, if a point goes past another point on the plane), the location is remembered with a dotted line and red circle. Once you move other corners, your original location may now become viable, and the rectangle and grid align properly.

(See [Perspective Grid](#) (page 508) for specific details on placing the corner points.)

- 4 If you want to add manual trackers pre-process, do so now.
- 5 Click the Analyze button to start the tracking.
- 6 When the tracking analysis is complete, click Confirm.

Camera Tracking Settings

Camera Tracking Settings

Use the settings in the Camera Solving section to perform an automatic 3D track.

Camera Tracking button (Not shown) Displays the Camera Tracking menu, where you can track based on the settings of the camera.

Analyze button Click to analyze the image (when complete, Analyze button changes to Update).

Update button (Not shown) Click to delete all previous 3D points, and start tracking based on new information.

Analyze Progress field Displays the progress of analyzing or updating. Non-editable.

Refine button Click to use the current results of the track analysis as a starting point, and refine from this point. Click Refine again to stop the process.

Pixel Error Value field Displays a representation of the distance of 2D tracks from repositioned 3D points. Non-editable.

Forward & Backward button Enable to track the image sequence backward after the forward tracking has completed.

Size field Displays the size of the trackers. Editable.

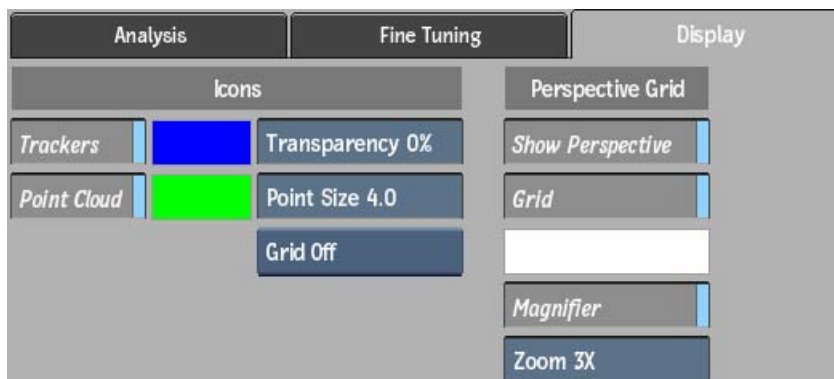

Number field Displays the number of 2D tracks created by the analysis. Editable.

Add 2D Tracker button Click to enter the Stabilizer to add manual trackers.

Reset Tracker button (Not shown) Resets all tracker data in the Analyzer menu.

Tracker Display Settings

The settings help you view your trackers in the image window.

Tracker Display button Enable to display 2D tracks in the image.

Tracker Display colour pot Displays the colour of the trackers. Editable.

Point Cloud Display button Enable to display 3D tracker points in your image.

Points Display colour pot Displays the colour of the points. Editable.

Transparency field Displays the transparency level of the trackers and points in the image. Editable.

Point Size field Displays the size of the 3D points in the image. Editable.

Grid box Select the type of grid to display in the scene. Use to position objects in the scene more accurately.

Select:	To:
Grid Off	Disable the grid.
Grid XY	Use a grid constructed on the X and Y planes.
Grid XZ	Use a grid constructed on the X and Z planes. The XZ grid is visible only when the camera is moved from its default position.
Grid YZ	Use a grid constructed on the Y and Z planes. The YZ grid is visible only when the camera is moved from its default position.

NOTE The Action grid is independent from the global grid in the Grids and Guides menu.

You can change the display of the perspective grid with the following settings (available when Perspective Based is selected in the Focal Length box in the Analysis tab):

Show Perspective button Enable to display the grid corners in the Analyzer view.

Grid button Enable to display the perspective grid in the Analyzer view.

Grid Colour pot Displays the colour of the grid lines. Click to change the colour.

Magnifier button Enable to display the magnifier while dragging a corner of the perspective grid rectangle.

Zoom field Displays the zoom factor of the magnifier. Editable up to 5x.

Analysis Settings

Use the Analysis settings before clicking Analyze.

Constraints Settings

Use the constraint settings pass information to the analyzer about any mattes or masks in the scene.

Matte Media box Select whether the Action matte is used for tracking. Not available if Back media is being analyzed.

Select:	To:
Ignore Matte	Not use a matte.

Select:	To:
Track Inside Matte	Use a matte to delimit the tracking results. White areas of the matte are considered for calculating the solution, and black areas are ignored.
Track Outside Matte	Use an inverted matte to delimit the tracking results. Black areas of the matte are considered for calculating the solution, and white areas are ignored.

GMask Option box Select whether to track inside or outside of an attached GMask shape.

While in an Analyzer view, you can add a GMask node and instantly draw the constraining mask. If added while in Analyzer view, the GMask and Axis nodes are automatically connected to the image as part of the Analyzer tree. If you want to use an existing GMask node, make sure that you parent the Surface (mono analyzer) or Stereo Object (stereo analyzer) to the Axis of the GMask in the schematic.

If the area to be constrained is moving, you can perform shape tracking from within the GMask menu. See [Tracking a Mask](#) (page 725).

Intersect Constraints field Displays that the intersection of the two constraints above are used as the tracking region. Non-editable.

Camera Settings

Before analysing the 3D motion, define your camera properties. The camera represents the device used to acquire the sequence of images you are tracking. For each camera parameter, you can choose to let the auto 3D tracker calculate the value automatically, you can specify the value yourself, or you can set a [perspective grid](#) (page 695) to estimate the focal length. This information can help the automatic 3D camera tracker calculate better results.

Camera Settings			
Free 3D Motion	Zoom		Lens Correction
Focal Length	Film Back		Manual
Perspective Based	User		Magnitude 0.0
Length 40.85	Height 0.79	In	Adjust 0.0
Range Error 3.93	Film Ratio 1.78		

NOTE You can set the camera properties before initial tracking, or after initial tracking when calibrating or refining the track.

Camera Type box Select the type of camera motion in the tracking shot.

Select:	To:
Free 3D Motion	Track a clip shot with a free-moving camera.
Pan and Tilt	Track a rotating clip shot with a camera on a tripod.
Auto Detect Motion	Automatically detect the camera type and track accordingly (default value).

Focal Length box Select Auto to let the 3D tracker calculate the camera values automatically. Select Manual to specify the values yourself. Select Perspective Based to use the perspective rectangle in the image to automatically determine the focal length of the camera.

Length field Displays the focal length of the camera, in millimeters. Editable.

Range Error field Displays the error of the estimate for the focal length. This should be a small number relative to the focal length. Non-editable.

Zoom button Enable to calculate the zoom value of the reconstructed camera for each frame.

Film Back box Select the film back size of the camera that shot the scene.

Height field Displays the height of the film back. Editable.

Film Back Units box Select the unit of measurement (inches or millimeters) for the film back height.

Film Ratio field Displays the film aspect ratio of the camera. Non-editable.

Lens Correction Settings

You can apply lens correction before or after your initial analysis. If you make any changes after analysis, you'll need to update or refine the track. While not necessarily required, performing a lens correction may give better tracking results.

Lens Correction Mode box Select Manual and set the Magnitude and Adjust fields if you want to apply lens correction during analysis.

Magnitude field Displays the magnitude of lens correction. Editable.

Adjust field Displays the level of secondary adjustment of lens correction. Editable.

Stereo Analysis Settings

The Stereo Analysis settings display information about the 3D camera after a stereo analysis is performed. These are locked fields, and are meant as informational only.

Stereo Mode field Displays the stereo mode of the 3D camera after a stereo analysis. Non-editable.

Interaxial Separation field Displays the interaxial distance between the left and right cameras of the 3D camera after a stereo analysis. Non-editable.

Zero Parallax field Displays the distance on the camera view axis (where the zero parallax place occurs) of the 3D camera after a stereo analysis. Non-editable.

Fine Tuning the Analysis

If the initial camera track analysis does not give desired results, you can use some or all of the Fine Tuning options to update and refine your track analysis. These procedures are not necessarily required, but depending on your image and the initial tracking, may give better tracking results.

Defining Real World Measurements

You can use the Real World Measures settings to select two points in your analyzed scene, and enter a measurement that represents the distance between the two points. Establishing real world units is helpful when exporting the point cloud through the 3D camera for use in a 3D application.

To define real world units in your analyzed scene:

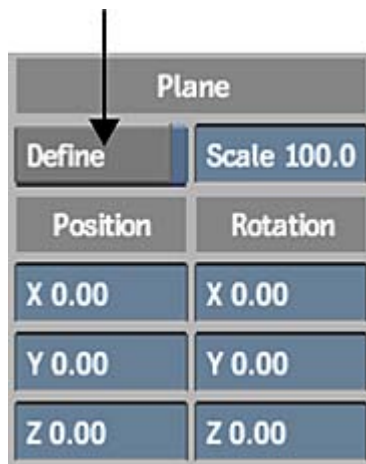

- 1 In the Real World Measures section of the Fine Tuning tab, enable Define.
- 2 Select a point in the image, then press **Alt** and select a second point.
A red line is drawn between the two points.
- 3 Disable Define.
- 4 In the Length field, enter a measurement of the length between the two points, in the unit of your choice (centimeters, inches, etc.). The Action scene scales to the distance you enter.
If you export the point cloud through the 3D camera, you'll be able to specify the unit of measurement in the [Export Camera menu](#) (page 683).

Setting the Orientation

Although it is not mandatory to define a ground plane in your image, it helps orient the reconstruction of the cameras.

To define the camera track ground plane:

- 1 In the Plane section, enable Define.

NOTE If you selected Pan and Tilt as the camera type (or if the Auto Detect switched to Pan and Tilt) the Plane Define button is not available. The rest of the settings in this group are still available, but only for orientation purposes.

- 2 Select a minimum of three points in the image that represent the plane of the X/Z axes, such as the ground, a table, or any flat surface.

The selected points appear as red squares with white crosses.

TIP You may want to disable the tracker temporarily and point display options (or raise the transparency level) to help you find and select the plane points.

- 3 Use the Position and Rotation controls to define the orientation of the ground plane.
- 4 Use the Scale field to specify the scale of the scene.
- 5 Disable Define.

Filtering Trackers to Fine Tune the Track Analysis

Use the Filter settings to delete lower quality trackers.

To fine-tune the track analysis:

- 1 Use the Quality slider to adjust the number of good trackers kept. The higher the quality setting, more low quality trackers are selected, such as trackers that drift off their initial reference point. Click Delete to delete the selected trackers.

Trackers of lower quality may hinder the accuracy of the camera tracking.

NOTE After you have made a change that requires the 3D tracking analysis to be refined or updated, notice that the LED next to the Refine and Update buttons turns yellow. This signifies that a Refine or Update is required, but you do not have to perform it until you have completed your tracker selections.

- 2 Adjust the Short slider to select short duration trackers, that is, trackers that only track a feature for a few frames. Click Delete to delete the selected trackers, leaving the longer duration trackers intact.
- 3 You can manually select and delete trackers from the image that you feel are not tracking properly. Do one of the following:
 - To select an individual tracker, click the tracker, and then click Delete.
 - To select multiple trackers in the same area, **Ctrl**-drag a selection box over a series of trackers, and then click Delete.
 - With Delete mode selected in the Tools box, select trackers in the image.

Refining or Updating the Track

Once you are satisfied with your fine tuning changes, you can refine or update your Analyzer.

To refine or update the 3D track:

- 1 Depending on the changes you have made, you can choose to refine or update the 3D track. Do one or both of the following:

- Click Update.

NOTE The update operation deletes all previous 3D points and starts over based on the new information. Depending on your footage, and how many trackers you added, deleted, or linked, multiple updates may yield different results.

- Click Refine.

The track analysis uses the current results as a starting point, and refines from this point.

Click Refine again to stop the process once an acceptable pixel error value is reached. The pixel error value is a representation of the distance of the 2D tracks from the computed 3D points.

TIP The refine process is footage-dependant, so your acceptable pixel error value may change depending on what is tracking. Since the refine process continues until you stop it, as a general rule, if the pixel error value does not change for a length of time (for example, 30 seconds), you can stop the refine process. The lower the pixel error value, the more accurate the reconstructed track is.

Fine Tuning Settings

Real World Measures Settings

Define button Enable to define a target length between two points in the image. Select one point, then press Shift and select the second point. When defining is complete, disable Define. Establishing real world units is helpful when exporting the point cloud through the 3D camera for use in a 3D application.

Length field Displays the measurement of the length between the two points, in the unit of your choice (centimeters, inches, etc.). Editable.

Plane Settings

Plane Define button Enable to define the ground plane in the image (when defining is complete, disable Define).

Plane Scale field Displays the scale of the ground plane. Editable.

X Position field Displays the position of the ground plane on the X axis. Editable.

Y Position field Displays the position of the ground plane on the Y axis. Editable.

Z Position field Displays the position of the ground plane on the Z axis. Editable.

X Rotation field Displays the rotation of the ground plane on the X axis. Editable.

Y Rotation field Displays the rotation of the ground plane on the Y axis. Editable.

Z Rotation field Displays the rotation of the ground plane on the Z axis. Editable.

Filter Settings

Quality field Displays the number of good trackers that are kept, as a percentage. Editable.

Short field Displays the percentage of short duration trackers (trackers that only track a feature for a few frames). Editable.

Delete button Deletes the selected trackers.

Converting the Camera Analyzer Results

When you are satisfied with the results of the 3D camera tracking analysis, you can convert the selected reconstructed points to a point locators object or actual axes in your scene. The point locators object is useful because you can easily snap objects to it.

To create a point locators object or axes from the 3D camera tracking results:

- 1 In the Analyzer view, select the points in the image that you want converted. Selected points are displayed as green squares with red crosses.

TIP Press `ctrl` and draw a rectangle over multiple points to select them. If any points are already selected, they become unselected.
- 2 Enable Fixed Camera if you want to generate a fixed camera and a moving 3D point cloud.
Typically, 3D tracking results in a moving camera and fixed points, but you also can set the camera to be fixed and the points to move.
- 3 Do one of the following:
 - Click Create Point Locators.
Selected point are converted to a point locators object with a parent axis. Double-click the newly created point locators object to access its menu, where you can change display settings and enable snapping. See [Using the Point Locators Object](#) (page 710).
 - Click Create Axis.
Selected points are converted to axes with a parent axis. The axes synchronize to the results of your 3D camera tracking, and any further changes you make to the 3D track are reflected in these axes.

NOTE If you want to apply settings manually to a synchronized axis, change its name so that it does not update automatically when Analyzer settings are changed. If you reset the Analyzer settings, the synchronized axes become regular Action axes.

- 4 Use the created point locators or axes to view the reconstructed scene geometry or camera motion. You can attach objects such as surfaces, 3D text, and 3D models to the new point locators or axes to help position them in 3D space.

Output Settings

Fixed Camera button Enable to generate a fixed camera and a moving 3D point cloud.

Create Axis button Click to convert selected points to axes.

Create Point Locators button Click to convert selected points to a point locators object. Double-click the new point locators node in the schematic to open the Point Locators menu.

Object Tracking

If the image sequence you are tracking has multiple moving objects, you can perform object tracking to track these objects relative to the same camera. Since you perform camera tracking first, you can use the camera data generated from the camera tracking analysis. For example, you can perform a camera tracking analysis on the complete scene, then use masks or mattes to perform multiple object tracking passes focusing on various moving objects in the scene. Each result can be converted to separate point clouds or axes, but all results conform to the 3D camera synced to the original camera tracking.

NOTE To improve the results of the track, consider [adding 2D manual trackers](#) (page 690) either pre- or post-process.

To create an 3D track analysis based on object properties:

- 1 Create a camera track analysis, as explained in [Camera Tracking](#) (page 693).
- 2 Click Object Tracking to switch to the Object Tracking menu.

- 3 From the Object Motion box, make a selection about the object you are tracking in relation to the camera.

Select:	To:
Free 3D Motion	Track an object moving independently from the camera.
Orbit Around Cam	Track an object rotating around the camera, or far away from the camera.
Auto Detect Motion	Automatically detect the motion type of the object and track accordingly. For small objects, Auto Detect may not be able to establish the proper motion. In this case, select Free 3D Motion or Orbit Around Cam.

- 4 Set any needed constraints:

- Use the Matte Media box to select whether to use the Action matte for object tracking. If you select to track inside the matte, white areas of the matte are considered for calculating the solution, and black areas are ignored (vice-versa for tracking outside the matte).
- Use the GMask Option box to select whether to track inside or outside of an attached GMask node. This option is only available if a GMask node is attached to Analyzer tree. If you used a GMask constraint while camera tracking, the opposite option is automatically selected for object tracking.

The tracking analysis uses an intersection of the constraints, so you may choose to hide or disconnect gmask if you want to perform a separate object track for each one.

- 5 In the Object Tracking section, enable Forward and Backward to track the image sequence backward after the forward tracking has completed. This option takes longer, but you may get better results.

- 6 Set the size of the automatic trackers in the size field.

- 7 Click Analyze.

Most of the time, tracking occurs in the background, allowing you to continue working while tracking. In Batch or Batch FX, you can use connected input and matte clips as the media to be tracked. If this case, tracking becomes a foreground process.

You can see a progress indicator beside the Track button. You can interrupt the analysis and resume it by clicking Track again. After tracking has completed and you press Confirm, the Track button changes to Update, and you can see the 2D tracks and 3D points in your image.

Filtering Trackers to Fine Tune the Track Analysis

Use the Filter settings to delete lower quality trackers.

To fine-tune the track analysis:

- 1 Use the Quality slider to adjust the number of good trackers kept. The higher the quality setting, more low quality trackers are selected, such as trackers that drift off their initial reference point. Click Delete to delete the selected trackers.

Trackers of lower quality may hinder the accuracy of the camera tracking.

NOTE After you have made a change that requires the 3D tracking analysis to be refined or updated, notice that the LED next to the Refine and Update buttons turns yellow. This signifies that a Refine or Update is required, but you do not have to perform it until you have completed your tracker selections.

- 2 Adjust the Short slider to select short duration trackers, that is, trackers that only track a feature for a few frames. Click Delete to delete the selected trackers, leaving the longer duration trackers intact.
- 3 You can manually select and delete trackers from the image that you feel are not tracking properly. Do one of the following:
 - To select an individual tracker, click the tracker, and then click Delete.
 - To select multiple trackers in the same area, **Ctrl**-drag a selection box over a series of trackers, and then click Delete.
 - With Delete mode selected in the Tools box, select trackers in the image.

Setting the Scale

After tracking has occurred, you can set the scale of the tracked object. Since you are tracking a specific object as part of an image, setting the relative scale of the object in relation to the image helps you to position objects in the reconstructed scene when you convert the 3D points into a point cloud or axes.

Refining or Updating the Track

Once you are satisfied with your fine tuning changes, you can refine or update your Analyzer.

To refine or update the 3D track:

- 1 Depending on the changes you have made, you can choose to refine or update the 3D track. Do one or both of the following:

- Click Update.

NOTE The update operation deletes all previous 3D points and starts over based on the new information. Depending on your footage, and how many trackers you added, deleted, or linked, multiple updates may yield different results.

- Click Refine.

The track analysis uses the current results as a starting point, and refines from this point.

Click Refine again to stop the process once an acceptable pixel error value is reached. The pixel error value is a representation of the distance of the 2D tracks from the computed 3D points.

TIP The refine process is footage-dependant, so your acceptable pixel error value may change depending on what is tracking. Since the refine process continues until you stop it, as a general rule, if the pixel error value does not change for a length of time (for example, 30 seconds), you can stop the refine process. The lower the pixel error value, the more accurate the reconstructed track is.

Converting Object Tracking Results

When you are satisfied with the results of the 3D object tracking analysis, you can convert the selected reconstructed points to a point locators object or actual axes in your scene. The point locators object is useful because you can easily snap objects to the locators. An image that does not deform is the best candidate for the point locators.

To create a point locators object or axes from the 3D object tracking results:

- 1 In the Analyzer view, select the points in the image that you want converted. Selected points are displayed as green squares with red crosses.

TIP Press `ctrl` and draw a rectangle over multiple points to select them. If any points are already selected, they become unselected.

- 2 Do one of the following:

- Click Create Point Locators.

Selected point are converted to a point locators object with a parent axis. Double-click the newly created point locators object to access its menu, where you can change display settings and enable snapping. See [Using the Point Locators Object](#) (page 710).

- Click Create Axis.

Selected points are converted to axes with a parent axis. The axes synchronize to the results of your 3D camera tracking, and any further changes you make to the 3D track are reflected in these axes.

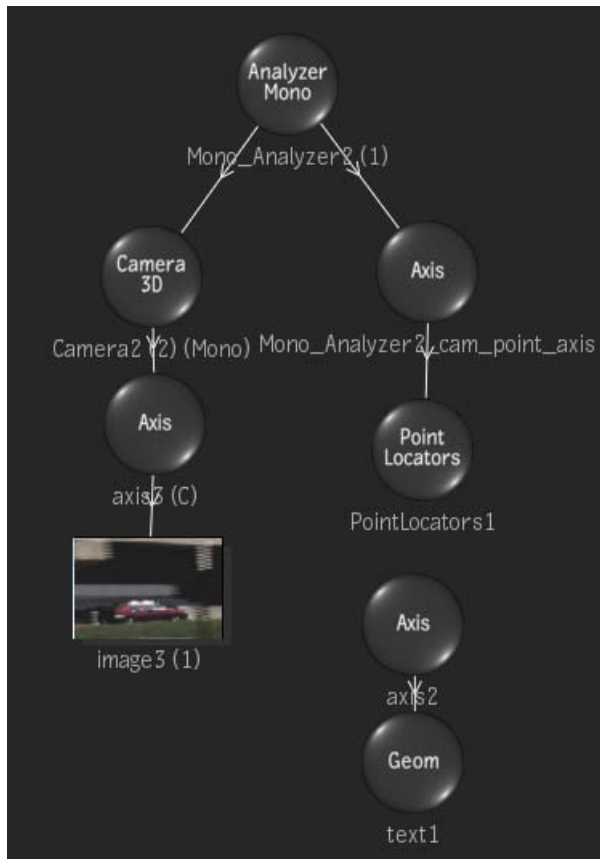

NOTE If you want to apply settings manually to a synchronized axis, change its name so that it does not update automatically when Analyzer settings are changed. If you reset the Analyzer settings, the synchronized axes become regular Action axes.

- 3 Use the created point locators or axes to view the reconstructed scene geometry or camera motion.
You can attach objects such as surfaces, 3D text, and 3D models to the new point locators or axes to help position them in 3D space.

Using the Point Locators Object

Once you have created one or more point locators objects from your camera or object tracking analysis, you can use the Point Locators menu to help you snap objects to the points in 3D space and have them perfectly follow the movement in the scene.

In the schematic, you can see that the axis of a point locators object is automatically attached to the Analyzer node. You can then add objects (such as a 3D text geometry), and use the Point Locators menu settings to help you position the object into your scene.

NOTE If the point locators object is moving (that is, you performed object tracking), you'll need to parent the point locators object to the object you want to position, so that it can properly follow the movement of the point locators.

To access the Point Locators menu, double-click the point locators object in the schematic.

Point Locators Menu Settings

Point Locators Display box Select how the point locators are displayed in the image. You can choose between spheres, boxes, and crosses.

Point Locators Colour pot Displays the colour of the point locators. Editable.

Point Size field Displays the size of the point locators. Editable.

Transparency field Displays the transparency level of the point locators. Editable.

Delete Selected button Click to delete selected points.

Snap To Point button Enable to snap an object automatically to a point in the point locators object. Use Shift and drag the object towards the point locator.

Snap Tolerance field Displays the minimum distance between the object and the point locator for snapping to occur. Editable.

Transform box Select how an attached object behaves based on the movement of the point locators.

Select:	To:
No Transform	Apply no transformation on the attached object.
Plane Transform	Align an object based on the average plane of the maximum number of points.
Centroid Transform	Align an object to the centre of the point locators.

About Source Nodes

Use source nodes in Action to create more advanced techniques such as transforming or replacing a front or matte clip or applying motion blur. Source nodes can be used to separate front and matte clips in media and then apply separate transformations to each clip. For example, if you apply media to a surface and you want to create an effect where the matte moves into the scene, add a source that isolates the matte clip. A matte source lets you animate the matte's position separately from the front. You can also use source nodes to apply several matte clips to a single front clip.

NOTE When applying colour corrector, blur, and crop effects with source nodes, the effects are applied to the result of the source of the media. In contrast, keyer effects are applied only to the input clip of the media.

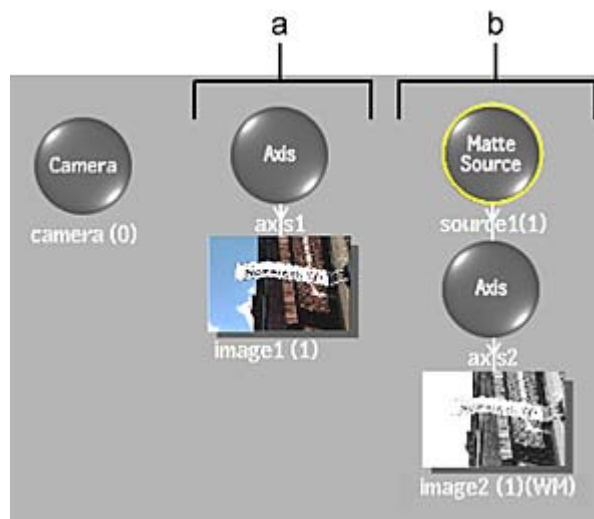

Creating a Matte or Front Source

When you create a matte or front source, a new branch appears in the schematic showing the matte or front clip is separated from its media, ultimately replacing the matte or front with itself. This method of using source nodes lets you animate the media's matte or front separately.

To create a matte or front source:

- 1 In Action, click Media.
- 2 In the Media list, select the matte or front media that you want to replace.
- 3 Do one of the following:
 - Drag the Source Matte or Source Front node from the node bin and place it in the schematic.
 - Double-click the Source Matte or Source Front node. You do not need to be in Schematic view to add a node in this manner.
 - Drag the Source Matte or Source Front node from the node bin directly to the image window. The view switches to Source view automatically.

A source node is created in Schematic view that parents an axis and a surface.

(a) Normal branch (b) Source branch

To view the contents of the source node in the image window, see [Viewing a Source Node](#) (page 715).

NOTE You can change a source from a front to a matte source, or vice versa, from the Source Type box in the Source menu.

- 4 Select the axis or surface parented by the source and create the animation.

The changes applied to the axis or surface connected to a source are applied to the media's matte or front.

For example, on a matte source, if you change the axis's scale to 80%, the media's matte is scaled 80% when used with the media's front. In addition, if you replace the surface by a bilinear or bicubic, you can create complex animations where the matte behaves like a page turn leading into the scene.

Accessing the Source Menu

Once you added source nodes to your scene, you can access the Source menu to apply various settings.

To access the Source menu:

- 1 Do one of the following:
 - Select a Source Matte or Source Front node in the schematic, and then click the Source menu button.

NOTE If no source node is selected when first accessing the Source menu, or if there are no source nodes present in the scene, all of the options in the menu are disabled.

 - Double-click a Matte or Front Source node in the schematic.

Parenting and Redrawing Source Nodes

A source cannot be parented by other objects in the schematic. If you attempt to parent a source, the connection is refused. You can, however, parent objects inside a source node and they appear in your scene based on the Source Type settings in the Object Image menu.

NOTE Be careful when you unparent or delete a source. Surfaces or other objects that were parented by the source are added to the scene.

See [Connecting Action Nodes](#) (page 436).

Replacing the Front or Matte Clip

When working with source nodes, you can replace the media's front and matte clips with the front, matte, or a combination of the front and matte clips from other media. These changes can be made in the Source menu, or from the Sources tab in the Object Image menu of the image attached to the source node.

To replace the media's front or matte:

- 1 Double-click the source node in the schematic.
- 2 In the Source menu, change the source node from Matte to Front or vice versa.

- 3 Enable Override.

- 4 Select the type of source from the Source Type box.

You can also change the source type in the Object Image menu for an image parented by a source node. The source type set in the Object Image menu is independent of the source type set in the Source menu for the parent source node or nodes.

- 5 If you selected Custom, select the clip to use as the front and matte from the image parented by the source. You can select Front, Matte, or White for each.

For example, if you select F: Matte and M: Matte, only the matte of the source's child image is rendered and used. A summary of your choice can be seen under the image node in the schematic. In this case you will see (MM).

NOTE You can combine multiple parent sources each with their own override setting.

Source Settings

Source box Select a Front or Matte source.

Override button Enable to override a source node selection on the parent source.

Source Type box Select a source type. When selecting Custom, you can also designate a Front and Matte type in the boxes below.

Select:	To:
Front only	Set the source to use only the front of the selected surface; the matte will be replaced with white (displayed as FW under the selected surface in the schematic).
Matte only	Set the source to use only the matte of the selected surface; the front will be replaced with white (displayed as WM under the selected surface in the schematic).
Custom	Set the source to have all the options of replacing the front and the matte of the selected surface by White, original Front or original Matte.

Front Type box Select the clip to use as the front from the image parented by the source.

Matte Type box Select the clip to use as the matte from the image parented by the source.

Source View box Select which source to view in the image window. See [Viewing a Source Node](#) (page 715).

Viewing a Source Node

There are different ways to view a source node while working in Action. For example, a 2-up view with Schematic and Source views allows you to view the complete scene and the interactive result of your source node.

The Src Working view provides you with the ability to view your source scene using a working camera, through which you can experiment without saving anything while preserving your camera setups. Each source node has its own working camera apart from the regular camera.

You can also select Source Result, Source Front, and Source Matte views from the View box.

To view a source node:

- 1 From the View box, select a Source view.

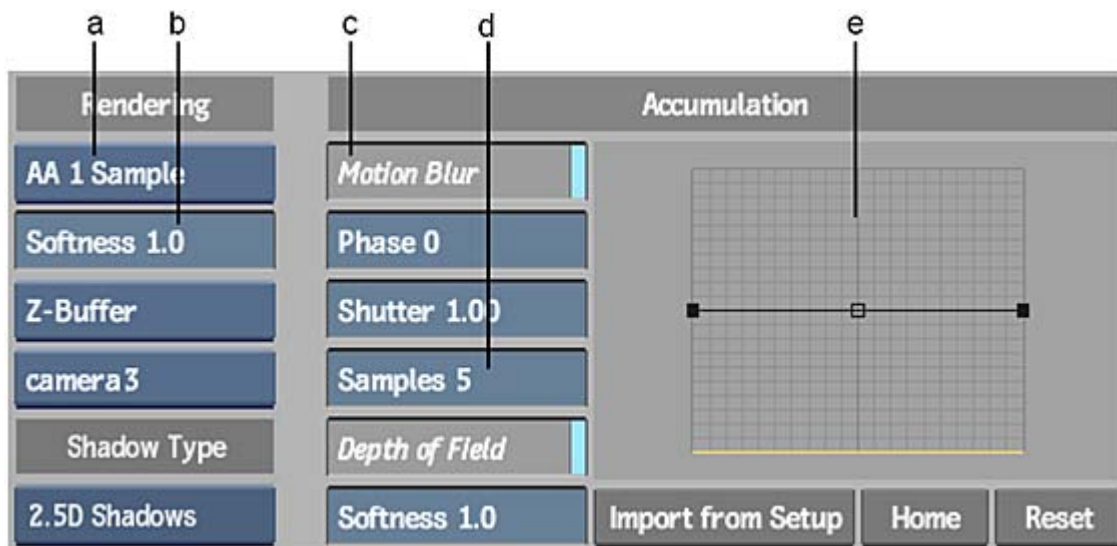

(a) View box (b) Source View box

- 2 Press **F6** again to cycle through the Source Result, Source Front, and Source Matte views.
- 3 From the Source View box, select which source node you want to view.

Blurring with Source Nodes

Motion blur and anti-aliasing can be set for either the front or matte clip of the media. Motion blur simulates the blur created by fast-moving objects by blurring the motion of the front or matte media.

Similar settings for anti-aliasing and motion blur can be found in the Action Setup menu. You have the option of using the same settings from the Setup menu for source nodes, or you can create specific source node settings.

(a) Anti-Aliasing box (b) Anti-Aliasing Softness field (c) Motion Blur button (d) Samples field (e) Motion Blur Curve

Rendering Settings

Anti-Aliasing Sample box Select an anti-aliasing sampling level.

Softness field Displays the softness of the anti-aliasing sample. Editable.

Z-Buffer Mode box Select an option to determine whether the distance from the camera eye is considered.

Select:	To:
Z-Buffer	Arrange sources according to their distance from the camera eye.
Z-Buffer Off	Not consider the distance from the camera eye when arranging sources.
Shadow Mix	To render each shadow in the correct Z order with its corresponding source.

Camera Selector box Select the child camera under a parent source node.

Shadow Type Settings

Source Shadow Type box Select the type of shadow cast for the source node. This setting is available in the Shadow Cast menu only if the shadow cast node is a child of a source node, and is repeated in the Source menu.

Accumulation Settings

Motion Blur button Enable to use a motion blur effect for the selected source node (can only be used if the global Motion Blur is enabled in the Action Setup menu).

Phase field Displays the frame that motion blur is based on (before or after the current frame). Editable.

Shutter field Displays the duration of motion blur at each frame. Editable.

Samples field Displays the quality level of motion blur and the depth of field produced by the number of samples taken at each frame. Editable.

Increasing the number of samples causes the processing time to increase linearly. The number of motion blur samples is multiplied by the number of anti-aliasing samples. To reduce the total number of passes made for each frame, reduce the level of anti-aliasing when Motion Blur is enabled.

TIP You can animate the Motion Blur button, as well as the Phase, Shutter, and Samples fields in the Channel Editor under the *source > motion_blur* folder.

Depth of Field button Enable to use the camera's depth of field.

Softness field Displays the softness of the depth of field. A low value yields a sharp falloff between focused and unfocused regions. Editable

Motion Blur Curve Displays the sample weight over the scope of the motion blur.

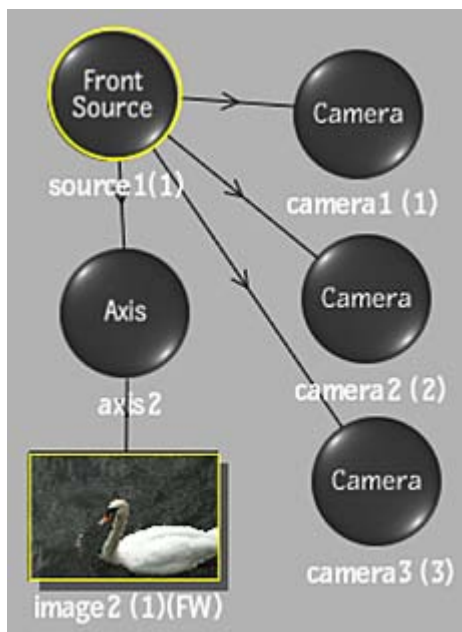

Import from Setup button Click to use the anti-aliasing and motion blur values from the Setup menu.

Home button Resets the curve viewer to show the whole curve.

Reset button Resets the anti-aliasing and motion blur settings to their default values.

Adding Cameras

You can add multiple cameras under a parent source node to change the point of view (by orbiting to a different orientation, for example). Camera 0 is always the default camera in a scene (you may need to pan in the schematic to see this camera).

If you have multiple child cameras under a selected parent source node, you can switch from one camera to another from the Camera Selector box.

About Action GMask

In Action, a GMask object is an animatable spline-based object that you draw directly in an Action scene that allows you to apply transparency effects to the scene. A mask can be applied to all media by default, or limited to selected media. Depending on what you want to accomplish, you can create a transparency that reveals the background image, or hide a portion of the matte source or a front source. You can move the mask in the 3D environment using the Axis object.

When creating a mask for a stereo object, you can apply it to both eyes simultaneously. You can change the camera visibility options to apply a mask to only the Left Eye or Right Eye. Use the Visibility box to set the camera visibility options. To set up stereo objects in Action, see [Starting a Stereoscopic Session](#) (page 501).

Adding a GMask Node

When you add a GMask node to the schematic, it is added with an Axis node.

To add a GMask node:

- 1 Do one of the following:
 - Drag the GMask node from the node bin and place it in the Schematic view.
 - Drag the GMask node from the node bin and place it in Result view.
 - Double-click the GMask node.

A GMask object (called gmask1, by default), with its parent axis, appears in the schematic. Once you have added the object, you can create the mask. See [Creating a Mask](#) (page 719).

TIP You can also create a mask using a preset shape. In this case, instead of the GMask node, select a GMask Plane, GMask Ellipse, or GMask Rectangle node.

Adding a GMask node to the schematic will apply the mask to the entire scene. You can link the GMask object to specific media to apply a mask selectively. You can also apply a link to exclude a mask.

To apply selective masks:

- 1 Add a GMask object to the scene. All media is affected.
- 2 Select GMask Link from the Tools box.
- 3 Do one of the following:
 - To apply a mask to an image, click the GMask node, and drag it to an image you want masked.

The selected image is connected to the mask by a blue line with an arrow, and only the selected surfaces are masked.

- To exclude a mask from an image, hold the **Alt** key while clicking and dragging from the GMask node to the image you do not want masked.

Excluded images are connected to the mask by an aqua dotted line with an "X", and they are not masked.

Creating a Mask

After you have added a GMask object to the scene, you can now create the mask itself.

To create a mask:

- 1 In the Tools box, select Draw Shape (this is set by default when you first add the GMask node).
- 2 Do any of the following to draw the mask:
 - Click to add vertices.
 - Shift-click to hide vertices and tangents as you add them.
 - Shift-drag to draw the mask freehand. Vertices and tangents are hidden as you add them. After closing the mask, you can use the Lasso Fit field (in the Vertices tab of the GMask menu) to increase or decrease the number of vertices that define the freehand segments of the mask.
 - Click and drag out the tangents to adjust the curvature of the spline at the current vertex.
- 3 Complete the mask by closing the mask shape or leaving it as an open spline.

Editing the Mask

You can edit the mask in three ways: by gestural action, by using the Edit Box, or by modifying the settings in the GMask tabs. Editing operations, such as adding and removing vertices, can be effected whether or not the mask is completed. You can also edit mask properties, move vertices and tangents, add and edit the gradient, track the mask, change display properties before mask completion, and make shape transformations by enabling the Edit Box button.

To add points to a mask:

- 1 In the Tools box, select Add Points.
- 2 Do one of the following:
 - Click on a spline between two existing vertices to add a new vertex.
 - Click on the first or last point of an open mask and click where you want to add a new point to continue drawing the mask.

To delete points from the mask:

- 1 In the Tools box, select Delete.
- 2 Click on a vertex to delete it.

If the vertex is in a mask that is a closed shape, the splines that connected it to adjacent vertices will be replaced by a single spline.

Closing the Mask

A mask can be closed gesturally or in the Mask tab.

- 1 Create the mask.
- 2 Do one of the following:
 - Create a spline to connect the last point in the mask to the first point.
The mask is completed once it is a closed shape. The Closed button is enabled.
 - In the Mask tab, enable the Closed button.
A spline connects the last point in the mask to the first point.

NOTE It is still possible to change the size of the mask by enabling the Edit Box.

Finishing the Mask

You can finish a mask without closing it to make a shape.

To finish a mask:

- 1 Create the mask. Do not close the shape.
- 2 Click the Finish button.

The mask is complete. The Finish button changes to the Edit Box button. The Edit mode changes from Draw Shape to Select.

A mask can still be adjusted after it is finished.

To adjust the mask:

- 1 Enable the Edit Box button.
- 2 Click and drag any of the points along the border of the Edit Box to adjust the mask.

You can also adjust the mask using the following keyboard shortcuts:

- Press **Alt** to drag the Edit Box proportionately.
- Use **Shift** to drag the opposite sides of the Edit Box proportionately.
- Use **Shift + Alt** to drag the Edit Box proportionately from the centre.

Changing Basic Mask Properties

You can customize a mask's properties by changing settings in the node's Mask tab.

Transparency field Displays the percentage of transparency of the mask. Editable.

Intensity field Displays the blend between the outgoing and incoming image inside the mask. Editable.

Smoothing field Displays the percentage of gradient blur softness. Editable.

Camera box Specify which camera to take into account when working with a GMask. Select Auto Frame when the GMask is co-planar with the image. When the GMask is under a Perspective Grid node, or is not under the image, select a specific camera to view the scene from the same perspective in Result (F4) or Object (F8) view.

Camera field Displays the active camera number. Non-editable.

Closed button Enable to connect a spline from the last point in the mask to the first control point (enabled automatically if you close the mask gesturally).

Invert button Enable to apply settings to the area outside of the mask.

Lock button Enable to lock the relative position of vertices.

Animation box Select Shape Animation to group all keyframes into a single channel called shape; select Vertex Animation to locate all keyframes on their respective channels.

Blend Mode box Displays the blending mode of the mask when it overlaps with another mask. Locked when a master blend option is selected in the Output menu.

Correlation box Select how overlapping gradients are blending. This box is displayed when an Autodesk Maya Composite blending mode is selected in the Blend Mode box.

Post Processing box Select whether to use the mask as a mask or occluder when encountering post processing effects. If you attach a Gmask to a specific post-processing node, for example a blooming effect, and choose Use as Occluder, only the effect will be blocked by the occluder.

Motion Blur button Enable to apply a blur effect to the selected mask. (Motion blur must be enabled in the Setup menu.)

Visibility box Select to apply the mask to the Right, Left, or Mono camera in a stereo scene.

Mask Display Properties

You can change the display properties of your mask in the Display tab.

Spline colour pot Displays the colour of mask splines. Editable.

Vertices colour pot When the mask is active, displays the colour of the unselected vertices. Editable.

Gradient colour pot When the gradient is active, displays the colour of the gradient spline. Editable.

Tangents Display option box Select to show all, selected, or no tangents on any mask that is selected.

Manipulating Vertices and Tangents

You can manipulate vertices and tangents during and after mask creation. Edit vertices and tangents gesturally when the Tools box mode is set to Select or Break Tangents. Alternatively, edit them using the Vertices tab.

Vertices selected as a group can be transformed around a localized pivot. The angle and length of tangent handles can also be manipulated as a group.

Selecting Vertices and Tangents

You can select vertices and tangent handles using the Select option of the Tools box:

- To select an individual vertex or tangent handle, click the vertex or tangent handle.
- To select multiple vertices, **Ctrl**-drag a selection box over a series of vertices.
- To select multiple vertices using the pen, press the pen button and drag a selection box over a series of vertices.
- To add more vertices to an existing selection, press **Shift+Ctrl** and drag a selection box over the additional vertices.
- To deselect all vertices, click anywhere outside the mask.

Moving Vertices and Tangents

You can move vertices and tangents using the Select option of the Tools box:

- To move a vertex or tangent in any direction, click the vertex or tangent and drag.
- To move selected vertices in any direction, click one of the selected vertices and drag.
- To ensure better continuity on a garbage mask, automatically adjust tangents as you move vertices or scale the mask. Enable Auto Adjust and drag a vertex. To toggle temporarily enable or disable Auto Adjust, press and hold **G** and then drag a vertex. Auto Tangents must be enabled to use the Auto Adjust feature.
- To keep tangent handles an equal length, **Ctrl+Alt**-drag one vertex handle to automatically change the length of the other tangent handle at the same time.

You can use the Vertices tab to move vertex and tangent positions.

The Selection fields display the current position of the vertex. If multiple vertices are selected, the position displayed is of the vertex that is closest to the initial vertex created in the mask.

Depending on the Transformation and Pivot Type options, you can move sets of selected vertices by editing the Translate, Scale, Shear and Rotation fields. You can also move tangent handles independently.

Transforming a Selection of Vertices

You can select multiple vertices in a mask and transform them as a group using the parameters. With the exception of translating vertices, transformation results are dependent on the position of the pivot point, displayed as a green or red circle in the image window. All transformations can be animated.

To transform a localized selection of vertices:

- 1 Select the node of the mask you want to edit.
- 2 **Ctrl**-drag over the vertices that you want to transform as a group.
- 3 Click the Vertices button.
- 4 Select an option from the Transformation box.
Fields associated with the transformation type will be enabled.
- 5 Select an option from the Pivot Type box. (If Translate is selected as the transformation type, the box is disabled.)

NOTE If the pivot point is selected, the position can also be moved by editing the X and Y Selection fields.
- 6 Do either of the following:
 - The active fields can be used to transform the selection.
 - Move the selection gesturally in the image window.

Vertices and Tangents Settings

Vertices Settings

Transformation box Select the type of modification that is permitted on the selected vertices. In the image window, the pivot icon indicates the transformation type.

Pivot Type box Select to place the pivot in the center of the mask (Centroid) or vertex selection set (Selection), or set the pivot gesturally (Manual).

X Selection field Displays the position on the X axis of the selected vertex. Editable.

Y Selection field Displays the position on the Y axis of the selected vertex. Editable.

X Translate field Displays the position on the X axis of the selected vertex. Editable.

Y Translate field Displays the position on the Y axis of the selected vertex. Editable.

X Scale field Displays the scale value on the X axis of the selected vertices. Editable.

Y Scale field Displays the scale value on the Y axis of the selected vertices. Editable.

Proportional button Enable to change the scale fields proportionally.

X Shear field Displays the shear value on the X axis of the selected vertices. Editable.

Y Shear field Displays the shear value on the Y axis of the selected vertices. Editable.

Proportional button Enable to change the shear fields proportionally.

Z Rotation field Displays the rotation value on the Z axis of the selected vertices. Editable.

Tangents Settings

In Angle field Displays the angle of the incoming tangent handle. Editable.

In Distance field Displays the length of the incoming tangent handle. Editable.

Out Angle field Displays the angle of the outgoing tangent handle. Editable.

Out Distance field Displays the length of the outgoing tangent handle. Editable.

Auto Tangent button Enable to create tangents automatically. When enabled, the Tracker will affect tangents.

Auto Adjust button Enable to modify tangents on either side of the selected vertex automatically. Press G to temporarily enable or disable during a gestural operation.

Equal Length button Enable to set tangents on either side of vertices to be the same length (based on the proximity to the next vertex).

Lasso Fit button Set the tolerance for the number of points in the segments of the mask if it was drawn freehand.

Breaking, Removing, and Adding Tangents

You can separate two tangent handles (break the tangent) and move them separately option from the Tools box:

- To break and move a tangent handle, select Break Tangent and click the tangent handle. The tangent is displayed as a dashed line, indicating it is "broken."
- To reconnect two broken tangent handles, click the vertex or select Auto Tangent and click either of the two tangent handles. The tangent is displayed as a solid line.
- To change the position of an individual tangent handle after releasing the cursor, use the Select option in the Tools box.

In the Vertices tab, use the fields in the Tangents section to change the length and angle for the incoming and outgoing tangent handles. If the tangents do not combine to form a straight line, the tangents will be broken and displayed as a broken line.

You can also use the Break option to remove tangents from vertices by clicking the vertex while in Break mode. When you remove a tangent, the interpolation of the spline between the two vertices is modified.

The shape of the border line differs depending on whether adjacent vertices are broken:

- If adjacent vertices are unbroken, the border line curves as it approaches the vertices.
- If adjacent vertices are broken, the border line is straight as it approaches the vertices.

You can create a garbage mask composed entirely of straight edges by removing the tangents from all the vertices:

- To remove the tangent of a vertex, select Break Tangent and click the vertex.
- To add a tangent back to a vertex, select Auto Tangent and click the vertex. Alternatively, using the Break Tangent option, click the vertex and drag the tangent out again.

Adding a Gradient to a Mask

The gradient allows you to create a region of softness around the mask edge. It applies a gradient according to the distance of the borders from the mask spline. You can create a uniform gradient or customize it at different parts of the mask. The gradient can have two softness borders, one inside and one outside the mask edge.

To add a gradient to a mask:

- 1 From the Tools box, change the mode to Add Points.
- 2 Hold down **Shift** and drag away from the spline.
- 3 Click on the mask spline.
- 4 (Optional) Do one of the following:
 - **Shift**-click on the spline again and drag in the same direction as the existing gradient to add a point in the gradient at a different position and distance from the mask.
 - **Shift**-click on the spline and drag away from it in the other direction to create a second gradient.

The position and distance of a gradient point from the mask spline can be controlled gesturally in Select mode, or in the Gradient tab.

Gradient Settings

Position field Displays the relative position of the gradient control point in relation to the vertices. For example, if the control point is between the third and fourth vertices, its value is 3.5. Editable.

Offset field Displays the distance from the gradient spline to the mask spline. Editable.

Gradient Curve Displays the transparency distribution of the gradient. The y axis represents the percentage of transparency and the x axis represents the percentage of distance from the vertex to the spline. This curve can be animated. You can edit, add and delete points from the curve.

Set Key button Sets the current values for the gradient curve in the current frame(when Autokey is disabled).

Delete Key button Deletes the selected gradient curve keyframes.

Reset Selection box Select whether to reset all of the gradient settings (Reset All) or just the gradient curve (Reset Key).

Home button Resets the gradient curve viewer to show the whole curve.

Undo button Undoes the gradient curve operations.

Tracking a Mask

You can track a mask in your scene from the GMask object's Tracking tab. You can track the mask vertices using the [Tracker](#) (page 883), or track shapes using the GMask object's own shape tracker.

To apply shape tracking to a mask:

- 1 Select the mask you want to track.
- 2 In the GMask menu, click the Tracking tab.
- 3 Under Shape Tracking, set the Use Media field to assign the back or front/matte media (select 0 if you want to track the Back media).
- 4 Select an option from the Track Direction box to determine if the frames before or after the current frame will be used for analysis.

TIP When tracking a shape that cuts off during analysis (for example, a person walking into or out of the frame), begin shape tracking when the whole shape is apparent, and track in the direction of the frames at which the shape begins to disappear.

- 5 Adjust any other [Tracking Settings](#) (page 725), as needed.
- 6 Click the Shape Track button to perform the shape tracking analysis.
- 7 To perform additional analysis in a different direction from the first frame of the analysis, toggle the Forward and Backward box and click Shape Track again.

Tracking Settings

Vertices Tracking Settings

Tracker menu button Opens the Tracker menu where you apply tracking data to selected vertices.

Tracking View box When the current node is attached to a Source node, select to track the media in the Source Front, Source Matte or Source Result view.

Camera box Specify which camera to take into account when working with a GMask. Select Auto Frame when the GMask is co-planar with the image. When the GMask is under a Perspective Grid node, or is not under the image, select a specific camera to view the scene from the same perspective in Result (F4) or Object (F8) view.

Camera field Displays the active camera number. Non-editable.

Shape Tracking Settings

Shape Track button Click to generate tracking data. Tracking information is stored in the Axis node to which the mask is attached.

Shape Track Progress field Displays the progress of the tracking operation. Non-editable.

Use Media field Displays the back or front/matte media number (as defined in the Media list) of the media that will be tracked (select 0 if you want to track the Back media). Editable.

Track Axis Hierarchy button Enable to overwrite and store tracking information in the topmost Axis node in the schematic hierarchy.

Transform Type box Select the type of shape tracking to perform.

Track Direction box Select to track the image sequence forward or backward from the current frame.

Trackers Settings

Size field Displays the area in pixels of each tracker. Editable.

Maximum Number field Displays the number of trackers to use in the analysis. Editable.

Motion Tolerance field Set a value to determine the tolerance level of acceptable changes in the pixel environment. If an external object passes in front of the tracked object, a low tolerance value ensures that the motion of an external object does not get tracked through the analysis. Editable.

Filtering field Displays the level of smoothing to apply to the shape tracking animation curve. Editable.

Rendering the Mask

In the Output menu, you can set up preferences to render the mask. See [Processing Multiple Outputs](#) (page 450).

To make the mask visible in the output, enable Use GMask in the Render Options panel.

The mask output in the render is dependent on the settings of the Type box In the Output Options panel. Do any of the following:

- Set the Type box to Comp to reveal the background in the masked area in the render.
- Set the Type box to Matte or Media Matte to render a matte output of the scene or the selected object in the scene that reveals the colour, intensity and smoothing in the masked area.

About Action's Particle System

Use Action's 3D particle system to create a variety of effects such as snow, rain, fog, and tornadoes, as well as fireworks, sparks, and explosions.

Particles are 3D objects that originate from a surface, light, or 3D object. Particles can be spheres, cones, squares, points, lines, or any image, 3D text, or 3D object. Particles are generated in the direction of the normals of a surface, light, or 3D object—a normal is a line perpendicular to the surface of an object.

In Action, the main components for generating particles are generators, manipulators, and bouncers. You can also use the particle system to explode a 3D object or an image.

NOTE Rendering particles is faster if Z-Buffer On is selected in the Rendering section of the Action Setup menu.

Generators

To create a particle stream, start by adding a particle generator that creates a stream of particles when attached to a light source, 3D object, or surface. You can use three different generators: light source, surface, and 3D object.

Particle generators have two settings:

- The Generate setting creates a stream of particles using the shape of a surface, a 3D object, or the spread of a light source. See [Generating Particles](#) (page 760).

- The Explode setting breaks up a surface or 3D object. See [Exploding Objects and Surfaces](#) (page 773).

Manipulators

Particle manipulators are used to influence either the position or the speed of particles. Manipulators can simulate the effects of a vortex, gravitational pull, or the pull toward a point, line, or plane. Manipulators are parented by the particle stream that they influence.

Action offers eight manipulators. Instructions on how to use each manipulator are provided in [Manipulating Particles](#) (page 776).

Bouncers

Particle bouncers are used to influence the behaviour of particles when they come into contact with a surface. You can parent an axis or light source to a particle bouncer. See [Bouncing Particles](#) (page 794).

NOTE Action setups created in a pre-9.0 version of Flame Premium that use a Variation value for Number, LifeTime, Speed, and TrailSize can be restored in the current version, but will render slightly differently.

Particles Workflow

The following table shows a possible workflow when working with particles in Action.

Step:	Refer to:
1. Add a particle generator.	Generating Particles (page 760).
2. Add a particle manipulator.	Manipulating Particles (page 776).
3. Set the particle path.	Forming a Particle Path (page 785).
4. Add bouncers.	Bouncing Particles (page 794).
5. Modify the particle stream.	Setting Stream Properties (page 763).
6. Apply texture to particles.	Applying Textures to Particles (page 772).
7. Add gravity.	Simulating Gravity (page 780).
8. Render particles.	Setting Particle Rendering Properties (page 766).

Using Particle Presets

A number of particle presets are included in Action, such as a fog effect to add to your scene. These presets can also help you learn how the particle system works. The presets are divided into a number of categories and are easily added to your scene from the Action node bin.

To add a particle preset:

- 1 Do one of the following:
 - Drag the Presets node from the node bin and place it in the schematic.
 - Double-click the Presets node. You do not need to be in Schematic view to add a node in this manner.
The file browser opens.

- 2 From the Preset Type box, select Particles.

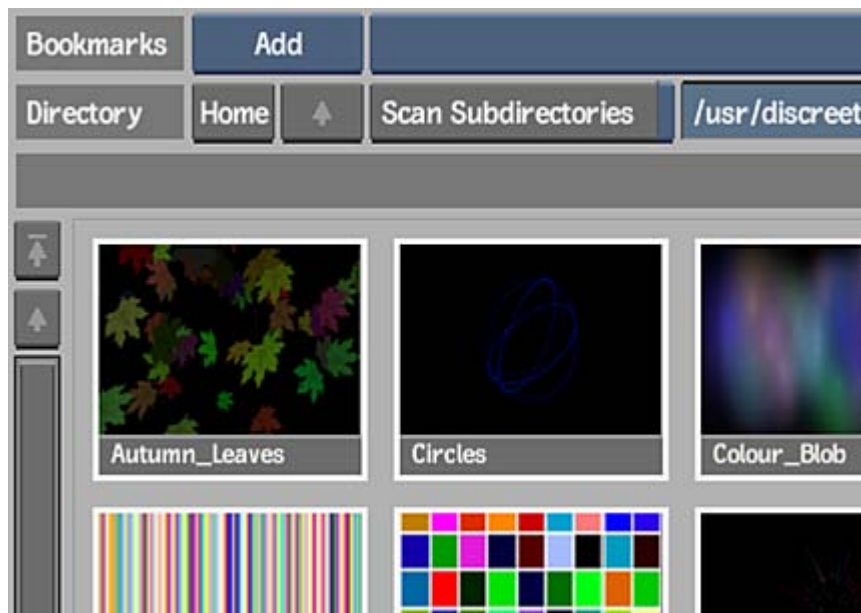

The Particle Preset file browser appears, pointing to the default location of the presets: *usr/discreet/<product home>/particle_presets*.

- 3 Optional: Enable Scale to Action Resolution to load the preset in the current Action resolution.
- 4 Optional: Select which rendering settings to enable or disable in the preset (Z-Buffer, Shading, Polygon Resolution, and Colour Clamping).

NOTE These settings are enabled by default, and by disabling any of them, you may not see the intended results in the preset.

- 5 Navigate through the subfolders to select the particle preset you want to load. Hold **Ctrl** and click to select multiple presets.

TIP Switch to Proxies view to see a visual representation of the presets.

- 6 Click Load.
The particle preset is then appended to your Action scene.

Some presets have *.psd* textures associated with them, and are added to the Media list (and in the Batch/BFX Sources or Desktop Reels folder) when the preset is loaded into Action. You should save these textures into an appropriate library. For this reason, Particle Presets are not available when accessing Action as a Timeline FX.

Presets Browser Settings

Preset Type box Select the category of presets to display in the browser.

Scale to Action Resolution button Enable to load the preset in the current Action resolution.

Z-Buffer button Enable to load the Z-buffer rendering settings of the preset.

Shading button Enable to load the shading rendering settings of the preset.

Polygon Resolution button Enable to load the rendering resolution settings of the preset.

Colour Clamping button Enable to load the resolution colour clamping settings of the preset.

Particle Preset Reference

A number of particle presets are included in Action, such as pyrotechnic or liquid effects to add to your scene. These presets can also help you learn how the particle system works. The presets are divided into a number of categories and are easily added to your scene from the Action node bar.

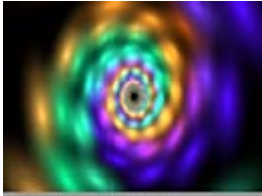

Use the following tables to get a quick overview of the particle presets, along with best use comments, if applicable. For more information on particles in general, see [About Action's Particle System](#) (page 726).

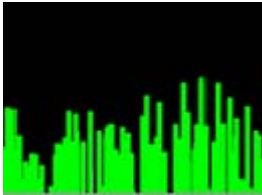

Abstract/Backdrops

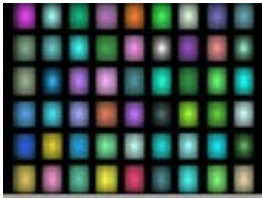

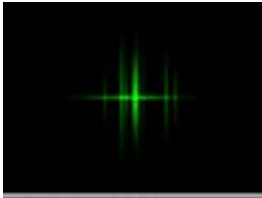

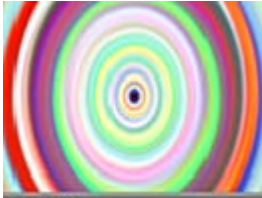

Use these presets as backdrops or to create abstract art particle effects in your scene.

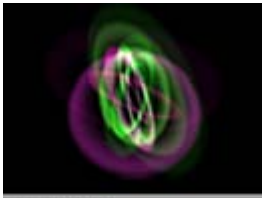

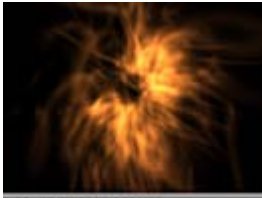

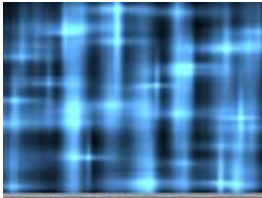

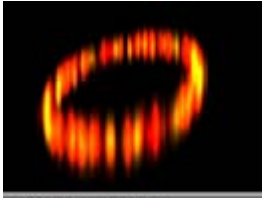

Proxy	Name/Description/Comments
	Animated_Coloured_Background Use Number and Lifetime to slow down or speed up the animation. Try with Z Rotation and Spin settings.
	Art_Coloured_Lines Speed sets the amount of stripes. Try with Colour variance in motif_generator menu.

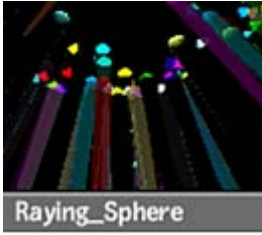

Proxy	Name/Description/Comments
 Autumn_Leaves	Autumn_Leaves Use Number, Size, and Speed settings. Try with the Rotation and Spin settings.
 Burning_Text	Burning_Text Particle Generator and cascade effect to burn the text and make it disappear.
 Circles	Circles Use Number, Lifetime, and Size settings. Try with the Spin setting.
 Colour_Blob	Colour_Blob Animated coloured gradients. Use Number, Lifetime, and Size settings. Try with Blending modes and Lighting.
 Colour_Cloud	Colour_Cloud Animated. Use Number and Size settings. Try with Z Rotation and Lighting.

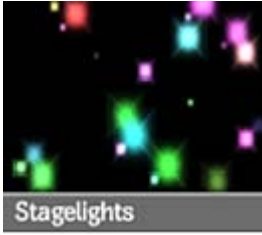

Proxy	Name/Description/Comments
 Colour_Vortex	Colour_Vortex Animated. Play with circ_gradient_ax (especially Y Scaling). Try with Z Spin setting. For a nice spiral effect, try Timesteps = 2 and Trail values up to 50.
 Coloured_Arcs	Coloured_Arcs Arcs rotating towards the camera. Try text_ax (posX=140, RotZ=200, ScaleX=30).
 Concentric_Circles	Concentric_Circles Animated. Use circles_emitter Number and Lifetime fields to set the amount of circles.
 Concentric_Circles_2	Concentric_Circles_2 Use Number and Size. Speed up or slow down animation with Lifetime.
 Crazy_Serpentine	Crazy_Serpentine Random circular patterns. Try with the size manipulator (Magnitude). Modify the Power animation in vortex manipulator.

Proxy	Name/Description/Comments
 <p data-bbox="315 422 558 453">Crazy_Stars</p>	<p>Crazy_Stars Pulsing coloured stars. Use Number and Size settings.</p>
 <p data-bbox="315 716 558 747">Digital_Animation</p>	<p>Digital_Animation Animated rectangles. Use Number, Lifetime, Size, and Speed settings. Change colour using light_colour.</p>
 <p data-bbox="315 1010 558 1041">Dots_Spiral</p>	<p>Dots_Spiral Animate Size setting. Try with Magnitude in size manipulator. Change colour using the Geometry settings of dots_generator.</p>
 <p data-bbox="315 1304 558 1335">Dots_Vortex</p>	<p>Dots_Vortex Use the Size setting. Try with Magnitude in the size manipulator and with Power in the vortex manipulator (try Power = 5). Move the camera and see the effect of gravity.</p>
 <p data-bbox="315 1598 558 1629">Fairy_Text</p>	<p>Fairy_Text 3D text made of coloured stars. Try star_text_ax (Scale=22) and generator (Number=95, Number_V=25, Lifetime=75, Size=12, Size_V=20, Speed_V=0,1).</p>

Proxy	Name/Description/Comments
 <p>Flashing_Squares</p>	<p>Flashing_Squares Influence the colour using the light's colour settings.</p>
 <p>Glow_Scanline</p>	<p>Glow_Scanline Vertical and horizontal moving glows. Use Number, Lifetime, and Size to characterize horizontal & vertical glows. Use Magnitude in the V_size and H_size manipulators to set the scaling's amplitude. Use Magnitude in the V_horizontal_osc manipulator to set the horizontal motion's amplitude. Change colour with the light.</p>
 <p>Glowing_Streaks</p>	<p>Glowing_Streaks Coloured streaks coming from behind the camera to the centre of the frame. Try Number=110, Number_V=35, Lifetime=1, and Speed_V=70. Orbit the camera.</p>
 <p>Glowline</p>	<p>Glowline Moving horizontal glows. Use Number, Lifetime, and Size settings to characterize the glow. Try with Magnitude in the size manipulator to scale the glows.</p>
 <p>Hypno</p>	<p>Hypno Influence the colour using the light's colour settings.</p>

Proxy	Name/Description/Comments
 <p data-bbox="315 420 558 457">Hypnotic</p>	<p>Hypnotic Try with Rotation and Spin settings. Orbit the camera.</p>
 <p data-bbox="315 714 558 751">Kaleidoscope</p>	<p>Kaleidoscope Change the colour using the light's colour settings.</p>
 <p data-bbox="315 1008 558 1045">Light_Canvas</p>	<p>Light_Canvas Grid of animated glows. Influence the colour using the light's colour settings. Characterize the vertical and horizontal glows using the circgrad_V_ax and circgrad_H_ax axes.</p>
 <p data-bbox="315 1302 558 1339">Light_Dots</p>	<p>Light_Dots Speed up or slow down the effect using the Power setting in the size Animator.</p>
 <p data-bbox="315 1596 558 1633">Moving_Glows</p>	<p>Moving_Glows Circular illuminated glow. Change colour by colour correcting the white media. Use Number and Size to characterize the ring. Use the pos_scale axis to set the position and rotation of the ring in the scene.</p>

Proxy	Name/Description/Comments
	Path_Light Animated glow on a path.
	Pop_Art Try with a close-up shot of a face as REPLACE_ME media. Zoom in to have fewer coloured squares in the frame, or zoom out to have more.
	Psychedelic_Texture Animated. Use Magnitude in the size manipulator to set pattern size. Try with the Trailsize field in the Generator menu.
	Random_Texture Animated. Use Number, Lifetime, Size, and Speed settings to characterize the texture. Try with the Spin settings to set the animation.
	Raying_Sphere Black sphere emitting coloured streaks. Use Number and Speed settings. Try with the Tailsize field.

Proxy	Name/Description/Comments
 <p data-bbox="315 422 358 449">Sky</p>	<p>Sky Moving cloudy sky. Use Number and Colour_V settings to characterize the sky. Use Position settings in the sky_motion manipulator to set how the clouds are moving.</p>
 <p data-bbox="315 716 448 743">Space_Blob</p>	<p>Space_Blob Coloured glows with a burning effect. Try the PD_ax settings, and influence colour using the Light's colour settings.</p>
 <p data-bbox="315 1010 505 1037">Spectrum_Lights</p>	<p>Spectrum_Lights Animated vertical glows. Use Number, Lifetime, and Size to characterize the lights. Try with Magnitude in the size manipulator to control the scaling amplitude of the lights.</p>
 <p data-bbox="315 1304 440 1331">Stagelights</p>	<p>Stagelights Use Number, Lifetime, and Size. Try with Magnitude in the size manipulator to control the scaling amplitude of the stagelights.</p>
 <p data-bbox="315 1598 451 1625">Star_Spiral</p>	<p>Star_Spiral Use Number, Lifetime, and Size. Try with Magnitude in the size manipulator to control the scaling amplitude of the stars.</p>

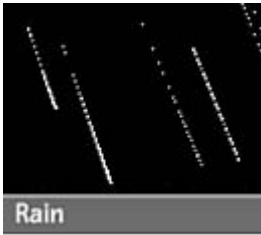

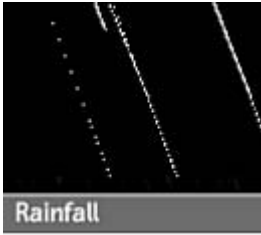

Proxy	Name/Description/Comments
	Text_Atom Animated 3D Text birth.
	Text_Distort Use Number, Lifetime, and Size. Try with Rotation_V, Spin, and Spin_V settings. Try also to change the light's colour and the glow_generator's Material settings.
	Text_Dots Use Number, Lifetime, and Size. Try with Rotation_V, Spin, and Spin_V settings. Try also to change the light's colour and the glow_generator's Material settings.
	Text_Glow Use the Size setting. Try with Magnitude in the size manipulator.
	Text_Particules Animated cascade effect with the 3D Text Geom node.

Proxy	Name/Description/Comments
 Texture	Texture Use the Size setting. Try with the Rotation_V setting. Play with the texture_ax settings.

Atmospheric

Use these presets to create weather-like effects, such as clouds, rain, or snow.

Proxy	Name/Description/Comments
 Cloud_Generator	Cloud_Generator A one-frame cloud. Use Number and Size settings. Try with the texture's Axis settings and the geometry's Magnitude and Scaling settings.
 Fog	Fog Use Number, Lifetime, Size, and Speed to characterize the fog.
 Heavy_Fog	Heavy_Fog Use Number, Lifetime, Size, and Speed to characterize the fog.

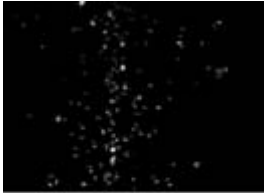

Proxy	Name/Description/Comments
	<p>Rain Use Number and Speed to trigger the amount of rain. Colour correct the white media's Front, and set rain_generator Transparency to improve blending.</p>
	<p>Rainfall Use Number and Speed to trigger the amount of rain. Colour correct the white media's Front, and set rain_generator Transparency to improve blending. Use gravity's Rotation_Y to make it windier.</p>
	<p>Snow Use Number, Size, and Speed for characterizing the snow.</p>
	<p>Snow_Graphical Use Number, Size, and Speed for characterizing the snow. Play with lighting.</p>
	<p>Snow_Windy Use Number, Size, and Speed for characterizing the snow. Try with wind's Magnitude and axis animation to mimic the wind.</p>

Proxy	Name/Description/Comments
	Surfing_Clouds Flying into the clouds. Use gravity's Rotation_X expression to stay above clouds, or dive into them.
	Tornado Use Magnitude in the size manipulator to scale the tornado. Use Magnitude and Power in the twist manipulator to alter the shape of the tornado.
	Tornado_ZatZero Same as Tornado, but with emitter Z=0.

Liquids

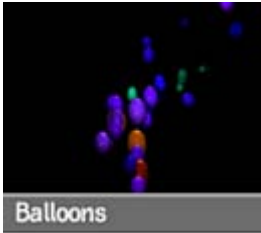

Use these presets to create fluid effects, such as bubbles.

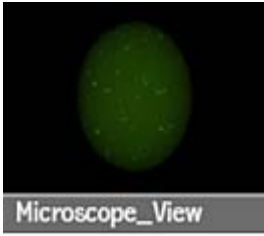

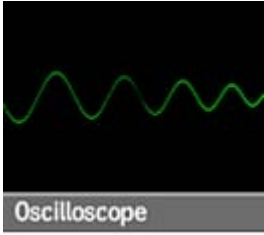

Proxy	Name/Description/Comments
	Bubbles_Graphical Use Number, Size, and Speed settings to characterize the bubbles. Process with Motion Blur enabled for better rendering.

Proxy	Name/Description/Comments
 <p data-bbox="315 422 560 453">Bubbles_rising</p>	<p>Bubbles_Rising Bubbles coming toward camera. Use Number, Size, and Speed settings to characterize the bubbles. Use Mass_V to randomize the bubble motion.</p>
 <p data-bbox="315 716 560 747">Inside_Water_Ray...</p>	<p>Inside_Water_Rays Sun rays under water. Use water_generator for the water and rays_generator for the rays coming from the sun above the surface.</p>
 <p data-bbox="315 1010 560 1041">Sea</p>	<p>Sea Water surface. Try the Spin_V settings to animate the sea. Customize by adding more lights to the scene.</p>
 <p data-bbox="315 1304 560 1335">Water_Bubbles</p>	<p>Water_Bubbles Use Number, Size, and Speed to characterize the bubbles. Try the Spin & Spin_V settings to control the flow.</p>
 <p data-bbox="315 1598 560 1629">Waterfall</p>	<p>Waterfall Use Number, Size, and Speed to characterize the water. Try with size and gravity manipulators.</p>

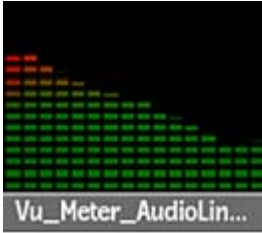

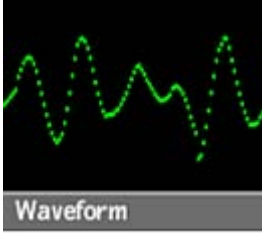

Miscellaneous

Use the miscellaneous presets to add dirt or scratches to your scene, as well as many other effects.

Proxy	Name/Description/Comments
 A cluster of colorful balloons (purple, blue, green, orange) floating against a black background. The word "Balloons" is written in a small white font at the bottom left of the image.	Balloons Animated. Use Number, Size, and Speed settings to characterize the balloons. Try the Spin & Spin_V settings to control the flow.
 A glowing blue arc of light against a black background. The word "Blue_Thing" is written in a small white font at the bottom left of the image.	Blue_Thing Moving glow following a path. Use Number, Lifetime, and Size settings to characterize the glow. Try with Rotation and Spin for motion. Change the path.
 A cluster of green, translucent, irregular shapes resembling broken glass shards against a black background. The word "Broken_Window" is written in a small white font at the bottom left of the image.	Broken_Window Pieces from a broken window flying towards the camera.
 A few small, white, irregular shapes resembling dirt particles against a black background. The word "Dirt" is written in a small white font at the bottom left of the image.	Dirt Use Number and Size settings. Try with variance.
 A dark, textured background with a few small, white, irregular shapes resembling dust particles. The word "Dust" is written in a small white font at the bottom left of the image.	Dust Modify dust size using PD_ax Scale and generator Number settings.

Proxy	Name/Description/Comments
	<p>Dust_Ray Dust revealed by rays of light.</p>
	<p>Hair Use Number and Size settings. Try with variance. hair_generator4 is linked to hair_generator1, and hair_generator3 is linked to hair_generator2.</p>
	<p>Microscope_View Modify lights. Try neuronal_tex_ax settings.</p>
	<p>Oscilloscope Change the colour by using beam_generator's Diffuse setting. Use axis to control the beam's amplitude, frequency, and phase.</p>
	<p>Paint_Effect Use Number, Lifetime, and Size settings to customize the paint effect. Try changing the texture media (white square, soft cloud, etc.).</p>

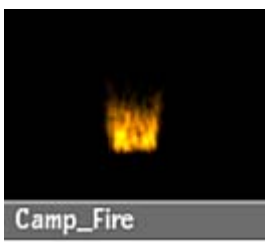

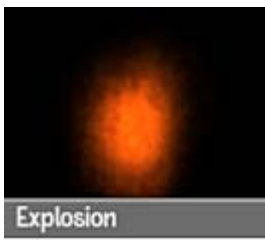

Proxy	Name/Description/Comments
 <p>Scratch</p>	<p>Scratch Use axis to control the scratch's position, the amplitude of the horizontal motion of the scratch, and the frequency of the scratch. Hide some generators for fewer scratches, or duplicate generators if you want more scratches.</p>
 <p>Shotgun</p>	<p>Shotgun Slow-motion shotgun effect.</p>
 <p>Simple_Sun</p>	<p>Simple_Sun Processes quicker than Sun.</p>
 <p>Sun</p>	<p>Sun Astronomical view of the sun. Slower to process than Simple_Sun.</p>
 <p>Vu_Meter</p>	<p>Vu_Meter Animated. Use beamgen Speed, PD_axis Scale_Z, and beam_emitter positioning to modify the number and width of stripes.</p>

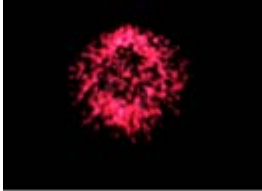

Proxy	Name/Description/Comments
	Vu_Meter_AudioLink Similar to Vu_Meter, but you can link an audio clip to produce the animation.
	Waveform Animated audio signal monitor effect. Use axis to control the beam.

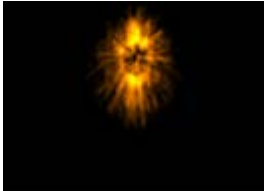

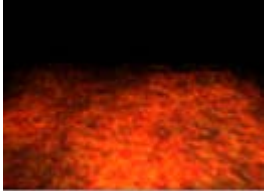

Pyrotechnic

Use the pyrotechnic presets to create fire and flame effects.

Proxy	Name/Description/Comments
	Birthday_Sparkles Customize the sparkles with Number, Lifetime, and Speed.
	Bouncing_Sparkles Sparkles bouncing on a plane. Use white_ax settings to place the bouncer plane in the scene.

Proxy	Name/Description/Comments
	Camp_Fire Adapt the source of fire with emitter_ax. Characterize the flame with Number, Lifetime, and Size.
	Camp_Fire_Smoke Adapt the source of fire with emitter_ax. Characterize the flame with Number, Lifetime, and Size. Adjust the manipulators.
	Candle_Flame Characterize the flame with Number, Lifetime, and Size.
	Explo_Zero_Gravity Explosion in a zero gravity environment.
	Explosion Exploding towards the camera.

Proxy	Name/Description/Comments
 Fire_ring	Fire_Ring Characterize the fire with Number, Lifetime, and Size. Adjust the camera.
 Fire_Turbulence	Fire_Turbulence Fire agitated by the wind.
 Fireworks	Fireworks Animated.
 Fireworks_BigBlue	Fireworks_BigBlue Animated.
 Fireworks_BigRed	Fireworks_BigRed Animated.

Proxy	Name/Description/Comments
 Fireworks_Cartoon	Fireworks_Cartoon Animated.Process with Motion Blur enabled.
 Fireworks_on_Path	Fireworks_on_Path Adjust the path.
 Gas_Flame	Gas_Flame Characterize the flame with Number, Lifetime, and Size.
 Lava	Lava Lava flowing from the top of a volcano. Change the flow using the path manipulator.
 Lava_Surface	Lava_Surface Speed up or slow down the lava using the transform manipulator position settings.

Proxy	Name/Description/Comments
	Match_Flame Characterize the flame with Number, Lifetime, and Size.
	Meteor Meteor burning in space. Adjust the camera.
	Moving_Sparkles Animate sparkles on a path. Change the path.
	Rocket_Propulsion Rocket engine output.
	Text_Plasma Customize with Number, Lifetime, and Speed.

Smoke

These presets allow you to create various smoke effects.

Proxy	Name/Description/Comments
	Carbo_Snow Snow coming toward camera. Use Size to characterize the snow. Use the Magnitude setting of the gravity manipulator to set the snow's motion.
	Dark_Smoke Use on a light background. Use Number, Lifetime, Size, and Speed to characterize the smoke. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.
	Fire_Smoke Characterize the smoke with Number, Lifetime, Size, and Speed settings. Use the Magnitude setting of the gravity manipulator to set the smoke's motion. Modify the fire colour using the fire_light_1 and fire_light_2 colour settings.
	Fire_Smoke_ZatZero Similar to Fire_Smoke, but with emitter Z=0.
	Gun_Smoke_MB Smoke produced by a shotgun. Process with Motion Blur enabled.

Proxy	Name/Description/Comments
 <p>Heavy_Smoke</p>	<p>Heavy_Smoke Use Number, Lifetime, Size, and Speed settings to characterize the smoke. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.</p>
 <p>Heavy_Smoke_ZatZ...</p>	<p>Heavy_Smoke_ZatZero Similar to Heavy_Smoke, but with emitter Z=0.</p>
 <p>Jet_Engine_Smoke</p>	<p>Jet_Engine_Smoke Use Number, Lifetime, Size, and Speed settings to characterize the smoke. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.</p>
 <p>Nozzle</p>	<p>Nozzle Characterize the smoke with Number, Lifetime, Size, and Speed settings. Use vortex settings to set the smoke's motion. Change the bouncer. Not scalable.</p>
 <p>Pyroclastic_Cloud</p>	<p>Pyroclastic_Cloud Change the path. Characterize the smoke with Number, Lifetime, Size, and Speed settings. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.</p>

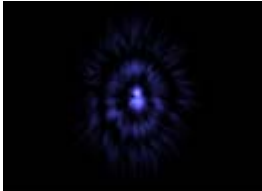

Proxy	Name/Description/Comments
 <p>Smoke</p>	<p>Smoke Use Number, Lifetime, Size, and Speed settings to characterize the smoke. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.</p>
 <p>Smoke_Light</p>	<p>Smoke_Light Characterize the smoke with Number, Lifetime, Size, and Speed settings.</p>
 <p>Smoke_Lookat</p>	<p>Smoke_Lookat Smoke pointing to a target. Use Number, Lifetime, Size, and Speed settings to characterize the smoke. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.</p>
 <p>Smoke_Track</p>	<p>Smoke_Track Use Number, Lifetime, Size, and Speed settings to characterize the smoke. Use the Magnitude setting of the gravity manipulator to set the smoke's motion.</p>
 <p>Smoke_ZatZero</p>	<p>Smoke_ZatZero Similar to Smoke, but with emitter Z=0.</p>

Proxy	Name/Description/Comments
	<p>Train_Smoke Smoke produced by a steam engine in motion. Use Number, Lifetime, Size, and Speed settings to characterize the smoke. Use the Magnitude setting of the train_speed manipulator to control the train's speed and its effect on the smoke.</p>
	<p>Train_Smoke_ZatZero Similar to Train_Smoke, but with emitter Z=0.</p>
	<p>Vapour Vapour rising from the ground. Use Number, Lifetime, Size, and Speed settings to characterize the vapour. Try the Rotation_V and Spin_V settings to control the vapour animation</p>
	<p>Wheel_Burning_MB Animated. Process with Motion Blur enabled.</p>

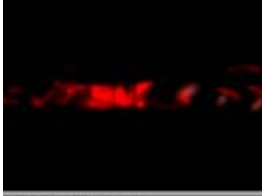

Space

Use these presets to create astronomy effects.

Proxy	Name/Description/Comments
 Aurora	Aurora Aurora borealis effect. Use Number and Size to characterize the aurora. Use Lifetime to speed up or slow down the animation. Change colours by modifying the left_light & right_light settings.
 Blue_Star	Blue_Star Slow moving star. Use Number, Lifetime, Size, and TrailSize settings.
 Blue_Star_2	Blue_Star_2 Slow moving star. Similar to Blue_Star, but with a bigger hotspot in the middle. Use Number, Lifetime, Size, and TrailSize settings.
 Blurry_Sparks	Blurry_Sparks Use Number, Lifetime, Size, and Speed settings to set how the sparks are emitted. Use the transparency, gravity, and size manipulators to specify the behaviour of the falling sparks.
 Cosmic_Light	Cosmic_Light Try with the PD_ax settings.

Proxy	Name/Description/Comments
 <p>Cosmic_Marguerite...</p>	Cosmic_Marguerite_Blue Pulsating blue light. Try with galaxy_tex_ax settings (posX=0, posY=0, scaleX=14, scaleY=125).
 <p>Cosmic_Marguerite...</p>	Cosmic_Marguerite_Green Pulsating and rotating green light. Orbit the camera.
 <p>Eye_Strike</p>	Eye_Strike Moving glows. Try with the circ_gradient1_ax and circ_gradient2_ax settings.
 <p>Glowing_Star</p>	Glowing_Star Try with the circgrad_tex_ax settings. Orbit the camera.
 <p>Light_Mvt_1</p>	Light_Mvt_1 Try with the PD_ax settings. Process with Motion Blur enabled.

Proxy	Name/Description/Comments
 	Light_Mvt_2 Orbit the camera.
 	Light_Mvt_3 Orbit the camera (Orbit 90°).
 	Light_Mvt_4 Change the Rotation and Spin settings.
 	Light_Speed Use Number, Speed, and TrailSize settings. Use the speed manipulator's power to set the Z acceleration.
 	Moving_Star_Field Flying into space. Use Number and Speed settings.

Proxy	Name/Description/Comments
 <p>Pulsar</p>	<p>Pulsar Pulsating glow. Use Number, Lifetime, Size, Speed, and TrailSize settings.</p>
 <p>Red_Pulse</p>	<p>Red_Pulse Pulsating red star. Customize the star with Number and Speed settings. Set the star's intensity with transparency magnitude.</p>
 <p>Red_Thing</p>	<p>Red_Thing Glowing red light. Change the colour with the Light Colour settings.</p>
 <p>Space_Dust</p>	<p>Space_Dust Reset vortex (Rot_Z) and try with vortex (Rot_Y). Try vortex (Rot_Y=-90). Change the camera settings.</p>
 <p>Space_Odyssey</p>	<p>Space_Odyssey Change the space_tex_ax settings (animated) and emitter_ax1 Rot_X setting.</p>

Proxy	Name/Description/Comments
 <p data-bbox="315 422 558 457">Star</p>	<p>Star Glowing animated star. Use Number, Size, and Speed settings to characterize the star. Change colour using the light's Colour settings.</p>
 <p data-bbox="315 716 558 751">Star_Field</p>	<p>Star_Field Flickering stars in the sky. Modify Number at frame 0 to control the amount of stars in the sky.</p>
 <p data-bbox="315 1010 558 1045">Star_Glow</p>	<p>Star_Glow Glowing aggregate of stars. Customize the generator with the Rotation and Spin settings.</p>
 <p data-bbox="315 1304 558 1339">Stellar</p>	<p>Stellar Orbit the camera and change the stellar_tex_ax settings.</p>
 <p data-bbox="315 1598 558 1633">Stellar_Fusion</p>	<p>Stellar_Fusion Rotating celestial bodies. Orbit the camera.</p>

Generating Particles

You can create a particle stream that behaves in different ways depending on the type of generator you use. When creating a particle stream, you can use three different generators: light source, surface, and 3D object.

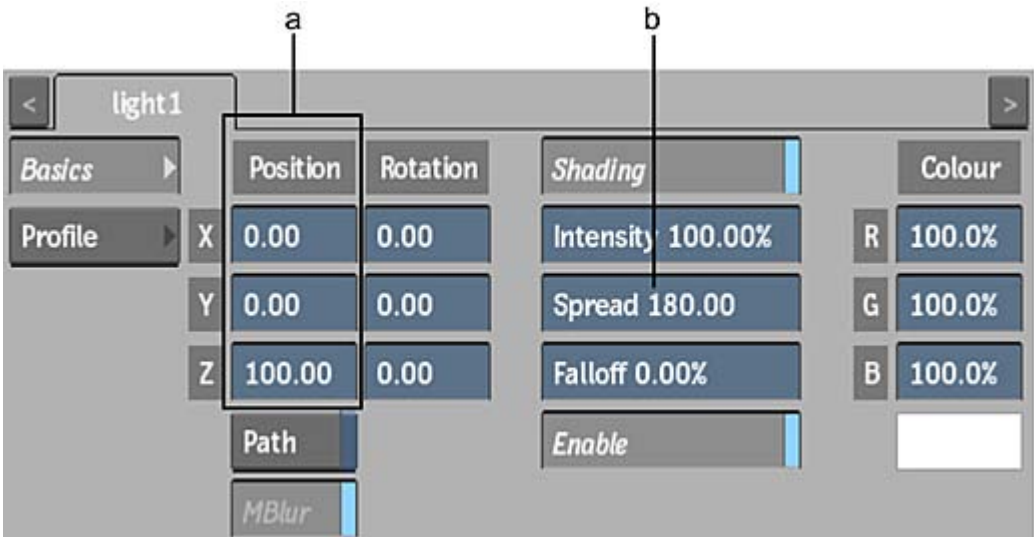

Use as a Generator:	To:
light source	Create a stream of particles starting from a single point.
surface	Generate particles based on the area, shape, and colour of a surface.
3D object	Generate particles from the centre of each polygon.

Using a Light Source

When a particle generator is attached to a light source, it uses the position and rotation of the light source to move and rotate the particle generator.

To add a particle stream using a light source:

- 1 Add a Light node to your scene.
- 2 Double-click the new light in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).
- 3 Adjust the spread and position of the light source in the Light menu. Use the Spread field to set the spread of the particle stream. The Intensity, Falloff, and Colour fields are not used by the particle generator.

(a) Position fields (b) Spread field

- 4 With the light node selected in the schematic, do one of the following:
 - Drag the particle generator node from the node bin and place it in the schematic.
 - Double-click the particle generator node. You do not need to be in Schematic view to add a node in this manner.

A particle generator object is added and automatically connected to the selected light source.

- 5 Set the particle generator's properties. See [Customizing the Particle Stream](#) (page 763).
- 6 If you do not want the light source to illuminate the scene, deactivate the light by clicking the Enable button in the Light menu. When Enable is deactivated, the light source is used as a particle generator only.

With a light source, you can animate the position of the particle stream by moving the light, changing the spread, and rotating the light. Because the generator is a light source, you can animate the position of the particle generator using a motion path.

Using a Surface

Use a surface as a particle generator to generate particles based on the area, shape, and colour of a surface. You can use a surface's matte to restrict where particles are generated. When the matte is off, the particle stream is generated from the entire surface. When the matte is on, particles are only generated where the matte is white or grey.

You can animate the shape of the surface using its tangent handles. The starting area of the particle stream matches the surface's shape animation. See [Changing the Shape of a Surface](#) (page 483).

To add a particle stream using a surface:

- 1 Select or add a surface that you want to use as a particle generator.
- 2 Adjust the surface's shape, position, and other attributes. See [Modifying Surfaces](#) (page 474).
- 3 With the surface node selected in the schematic, do one of the following:
 - Drag the particle generator node from the node bin and place it in the schematic.
 - Double-click the particle generator node. You do not need to be in Schematic view to add a node in this manner.

A particle generator object is added and automatically connected to the selected surface.

- 4 Set the particle generator's properties. See [Customizing the Particle Stream](#) (page 763).
- 5 If you do not want the surface to appear in the scene, you can hide the surface in Schematic view. A particle stream is generated from the hidden surface.
- 6 To make the generated particles change as the surface's clip changes, enable Indirect in the Particle Generator menu.

Using a 3D Object

You can use a 3D object as a particle generator. Particles are generated from the centre of each polygon.

To add a particle stream using a 3D object:

- 1 Select or add the 3D object that you want to use as a particle generator.
- 2 With the 3D object node selected in the schematic, do one of the following:
 - Drag the particle generator node from the node bin and place it in the schematic.
 - Double-click the particle generator node. You do not need to be in Schematic view to add a node in this manner.

A particle generator object is added and automatically connected to the selected 3D object.

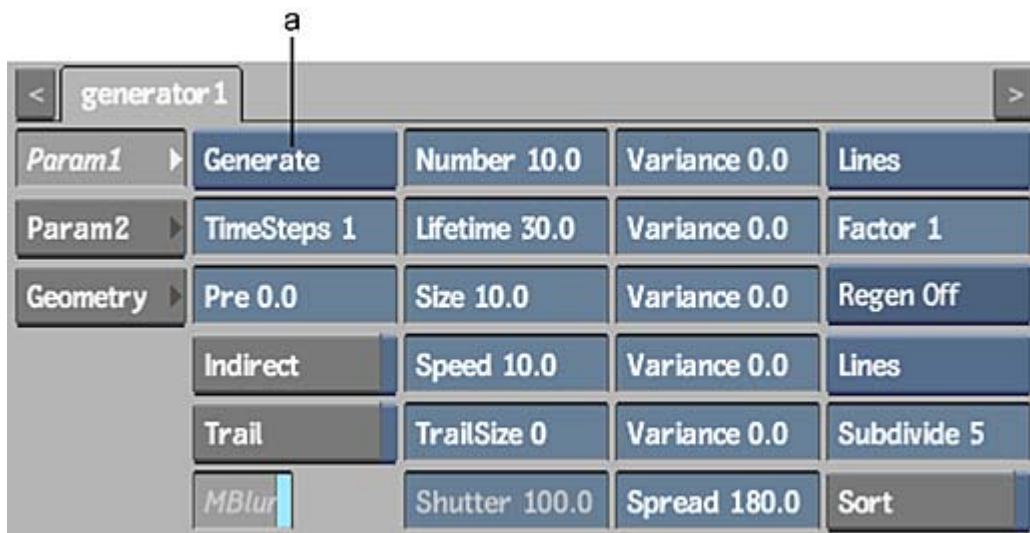

- 3 Set the particle generator's properties. See [Customizing the Particle Stream](#) (page 763).
- 4 If you do not want the 3D object to appear in the scene, hide the model in Schematic view. A particle stream is generated from the hidden model.

Customizing the Particle Stream

Whether you use a light source, 3D object, or surface, the particle stream uses the same properties, allowing you to create custom particles and apply textures to particles. To access these properties, double-click the particle generator in the schematic, or follow the tab population rules for the Object menu. See [Populating Menu Tabs of Selected Objects](#) (page 431).

Setting Stream Properties

The following properties in the Particle Generator Param1 menu affect the particle stream.

(a) Stream Type box

Stream Type box Select whether the particle stream will Generate or Explode.

TimeSteps field Displays the time simulation of the Generator per frame. By default, Timestep is set to 1, which means that time simulation is once per frame. Editable.

When Timestep is set to 2, the position of each particle is calculated once between frames. Any change in speed or position caused by manipulators or bouncers is applied between frames. When Timestep is set to 3, the position of each particle is calculated twice between frames. The greater the timestep value, the longer it takes to process.

Typically, you use Timestep with a particle manipulator or bouncer on a particle stream. In the following example, the same particle settings and manipulator (AccPoint) are used. Only the timestep values are different. The particle stream on the left uses a timestep of 1 while the stream on the right uses a timestep of 6.

In the following figure, notice the particle stream on the right is more accurate.

Pre field Displays the start point of the particle stream. With a value of 0.0, the particle stream starts creating particles at frame 1. With a value of 100, the clip begins as if the particle stream has been generating for 99 frames. Editable.

Indirect button Enable to allow the part of the surface used by the particle to change with each frame. For example, if the media applied to the surface changes from red to blue over 10 frames, each particle changes from red to blue as the surface changes. Disable to lock the part of the surface used by the particle to the frame where the particle was generated. For example, if the media applied to the surface changes from red

to blue over 10 frames and a particle is generated at the first frame, when the surface was red, the particle stays red.

Trail button Enable to draw each particle with a trail. Set the length of the trail in the TrailSize field.

Motion Blur button Enable to use a motion blur effect for particles emitted from the selected Generator (can only be used if the global Motion Blur is enabled in the Action Setup menu).

Shutter field Displays the length of the tail for lines, cones, and quads. Shutter is expressed as a percentage. At 100%, the tail's length is the same as the head (Size field). At 400%, the tail's length is four times the size of the head. Editable.

Shutter at 100%

Shutter at 400%

Spread field Displays the spread for the second particle generator when two particle generators are parented. When the first particle stream dies, the second particle stream begins. Editable.

See [Combining Particle Streams](#) (page 797). This also sets the spread of a particle stream that bounces off surfaces. See [Bouncing Particles](#) (page 794).

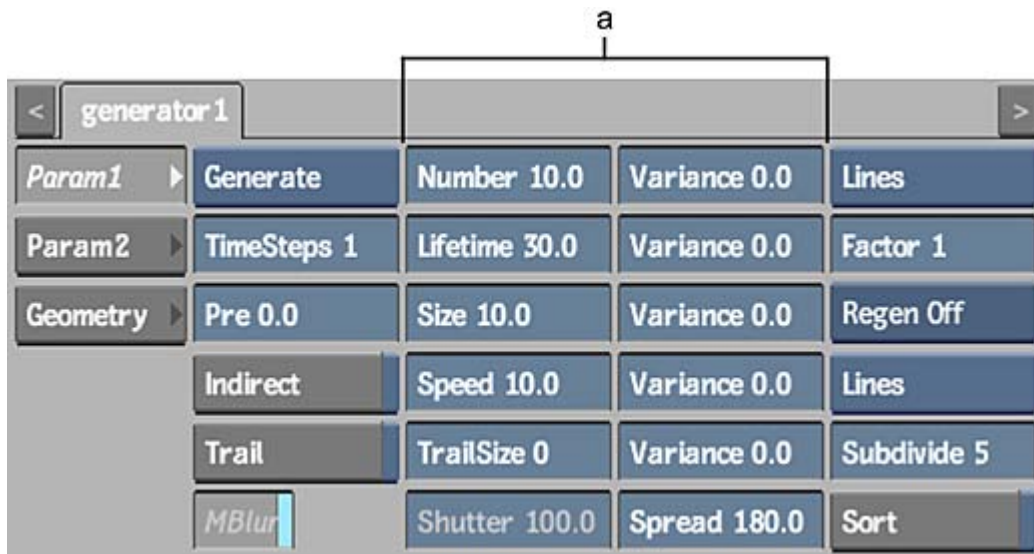

Setting Particle Properties

In the middle of the Generator Param1 menu, a table lists the different particle generation properties.

Each parameter has a variance value used to specify how much the parameter varies each time particles are generated. Exactly what gets varied depends on the parameter.

For example, if you set the Number parameter to 10 and its Variance parameter to 5, the number of particles generated at each frame is randomly selected between 5 and 15.

The unit of measurement used by each Variance field matches the parameter it is varying. For example, if the Number parameter is expressed in particles per frame, so is its Variance field. The Speed parameter is in pixels per frame and so is its Variance field.

(a) Particle generation properties

Number field Displays the number of particles generated per frame. Editable.

If you specify a number less than 1 (from 0.1 to 0.9), particles are generated randomly. For example, if you set the number to 0.1, a particle is generated every 10 frames. The exact frame within those 10 frames when the particle is generated is randomly selected. If you set the number of particles to 0.3, a particle is randomly generated approximately every three frames.

Number Variance field Displays how much the number varies each time particles are generated. Editable.

Lifetime field Displays the number of frames each particle lasts. For example, if Lifetime is 20 frames, a particle generated at frame 15 disappears at frame 35. Editable.

Lifetime Variance field Displays how much the lifetime varies each time particles are generated. Editable.

Size field Displays the size of each particle, in pixels. This parameter only affects cones, spheres, quads, squares, and objects. Editable.

Size Variance field Displays how much the size varies each time particles are generated. Editable.

Speed field Displays the speed of each particle, in pixels per frame. Editable.

Speed Variance field Displays how much the speed varies each time particles are generated. Editable.

TrailSize field Displays the length of each particle's trail, in particles. A particle trail only appears when the Trail button is enabled. Editable.

TrailSize Variance field Displays how much the trail size varies each time particles are generated. Editable.

Setting Particle Rendering Properties

The following Generator properties affect the rendering and previewing of the particle stream.

NOTE Rendering particles is faster if Z-Buffer On is selected in the Rendering Section of the Action Setup menu.

(a) Interactive Type box (b) Render Type box

Interactive Type box Select the type of particle to display in the scene. For example, as you move between frames, the particle stream is redrawn. If you are using a custom 3D object for each particle, redrawing the scene may take a while. By changing the interactive type to a point or line, your interaction with Action is much quicker.

Factor field Displays the number of particles shown in the scene while working in Action (use to speed up work - does not affect the rendered result). Editable.

For example, if you generate 1000 particles with manipulators and bouncers, interacting with Action may become slow because calculations have to be made for each particle. If you specify a factor of 10, the number of particles is reduced to 10%, or 100 particles. Using Action is then faster, yet when you click Preview or Process, 1000 particles are created.

Regenerate box Select how you want to update the scene when you change particle generator parameters. Regen All updates the particle and the object generating the particle, but may cause performance slowdowns. Regen Anim only updates the particle in the scene.

Select:	To:
Regen All	Automatically update the particle and the object generating the particle (such as a surface) when you change any particle generator parameter. This option allows you to see the particle with all settings, such as position and colour correction, but may cause performance slowdowns, since the generating object and particle stream are recalculated each time a parameter is changed.
Regen Anim	Automatically update the particle in the scene when you change any particle generator parameter. The object generating the particle is not automatically updated in this case, so you may not see your exact desired results. If Regen All is causing slowdowns, you can try this option to get a faster update.
Regen Off	Not update the scene automatically, unless the frame is changed.

Render Type box Select the type of particle used when rendering the scene.

Select:	To:
Node	Use your own 3D object, text, or a surface for each particle. See Using Custom Particles (page 770).
Cones	Use a cone for each particle. You can adjust the size of the cone's tail.
Spheres	Use a 3D object of a sphere for each particle.
Polygons	Explode 3D objects and surfaces. See Exploding Objects and Surfaces (page 773).
Quads	Use a square with a tail for each particle. You can adjust the size of the square's tail.
Squares	Use a square for each particle.
Lines	Use a line for each particle.
Points	Use a single pixel for each particle. Points are not affected by size or trail.

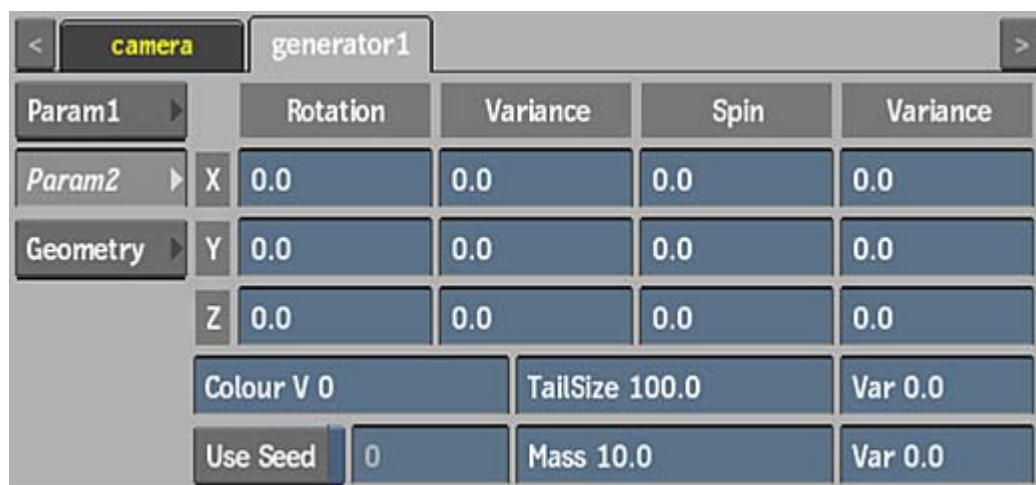

Subdivide field Displays the number of polygons used to render cones and spheres. The larger the number of subdivisions, the smoother the cones or spheres are drawn, but rendering time is increased. Editable.

If you are using an imported 3D object or text for a particle, use the Subdivide field and button in the Geometry menu to set the number of polygons. The Geometry menu's Subdivide field works differently than the Subdivide field in the Generator menu. See [Subdividing a Model](#) (page 556).

Sort button Enable to determine how the particles are drawn, according to the Z-order. If a Particle Generator node is selected, the state of the Sort button is the same in the Param1 and Geometry menus.

Setting Additional Generator Properties

Additional particle generator controls can be found in the Param2 tab.

X Rotation field Displays the X orientation for particles that have just been born (spawned). Editable.

Y Rotation field Displays the Y orientation for particles that have just been born (spawned). Editable.

Z Rotation field Displays the Z orientation for particles that have just been born (spawned). Editable.

X Rotation Variance field Displays the variation of the X rotation of a particle once spawned from the particle generator. Editable.

Y Rotation Variance field Displays the variation of the Y rotation of a particle once spawned from the particle generator. Editable.

Z Rotation Variance field Displays the variation of the Z rotation of a particle once spawned from the particle generator. Editable.

X Spin field Displays a value to act as a speed setting to an X rotation animated over time. Editable.

Y Spin field Displays a value to act as a speed setting to a Y rotation animated over time. Editable.

Z Spin field Displays a value to act as a speed setting to a Z rotation animated over time. Editable.

X Spin Variance field Displays a variation to the X Spin channel once particles are spawned from the particle generator. Editable.

Y Spin Variance field Displays a variation to the Y Spin channel once particles are spawned from the particle generator. Editable.

Z Spin Variance field Displays a variation to the Z Spin channel once particles are spawned from the particle generator. Editable.

Colour Var field Displays the variation of the colour of each particle based on the colour set in the Diffuse colour bar (Particle Geometry menu). Editable.

Use Seed button Enable to override the particle's seed (useful if you want to change the position of each particle in the particle stream).

Seed field Displays the random seed value for the particle stream properties. Editable.

TailSize field Displays the width of a particle's tail, expressed as a percentage. Works only with quad and cone particle types. Editable.

TailSize Variance field Displays the variation of the TailSize value, as a percentage. Editable.

Mass field Displays the mass of each particle (used with Damping when manipulating particles). Editable. See [Setting Manipulator Properties](#) (page 776).

Mass Variance field Displays the variation of the mass, as a percentage. Editable.

Setting Geometry Properties

You can use the Particle Geometry menu controls to add colour, specular highlight, shine, and transparency to all particles. To access this menu, click the Geometry tab in the Generator menu.

Use the available particle geometry controls to affect the particle stream, whether it is a surface or a geometry. The controls behave in the same manner as when using with the Geometry menu for a 3D model. See [3D Geometry Menu Settings](#) (page 552).

Setting Channel Editor Properties

The Channel Editor includes the particle properties included in the Particle menus for which you can set values and create particle animation effects. You set these properties in conjunction with those located in the Particle Generator, Particle Manipulator, and Particle Bouncer menus.

You must first add a particle generator, a particle manipulator, or a particle bouncer to the scene to view and set values for their corresponding properties in the channel hierarchy of the Channel Editor.

Using Custom Particles

You can create particle streams using your own 3D objects or text. You can also use the shape of any surface for each particle. For example, create custom particles using a light source, 3D object, or surface as a particle generator. See [Generating Particles](#) (page 760).

To use a 3D object or text as a custom particle:

- 1 From the node bin, add a particle generator to your scene.
- 2 In the schematic, double-click the Particle Generator node to access the Generator menu.

(a) Interactive Type box (b) Render Type box

- 3 From the Render Type box, select Node as the particle type and change the Interactive Type box to Node to view the 3D object or text as you make changes to your particle stream.
- 4 Import the 3D object or create the text. See [Importing 3D Models](#) (page 544) or [About 3D Text](#) (page 563).

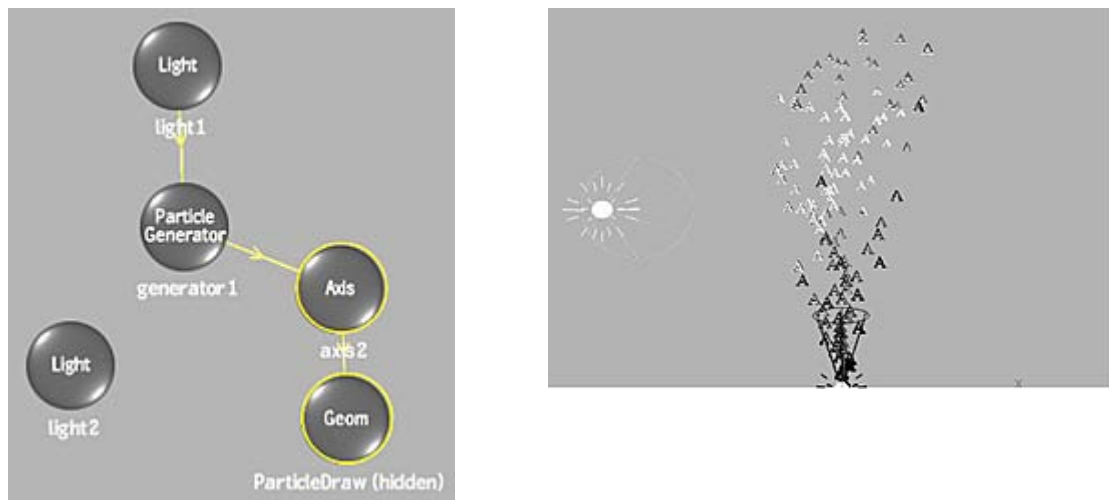

TIP The 3D object or text used for the custom particle can also include a deformation mesh. See [Deforming Models and Surfaces](#) (page 557).

- 5 In Schematic view, rename your 3D object or text "ParticleDraw". This name is case sensitive so make sure it is typed exactly as shown.
- 6 Parent the particle generator to the 3D object or text.

If you want to add transformations, such as rotating all the particles, parent the particle generator to the axis of the 3D object or text as shown in the next step.

7 Hide the 3D object or text.

The particle generator uses the 3D object or text named ParticleDraw. The following figure shows the schematic and the result of using the letter A as a custom particle and a light source as the particle generator.

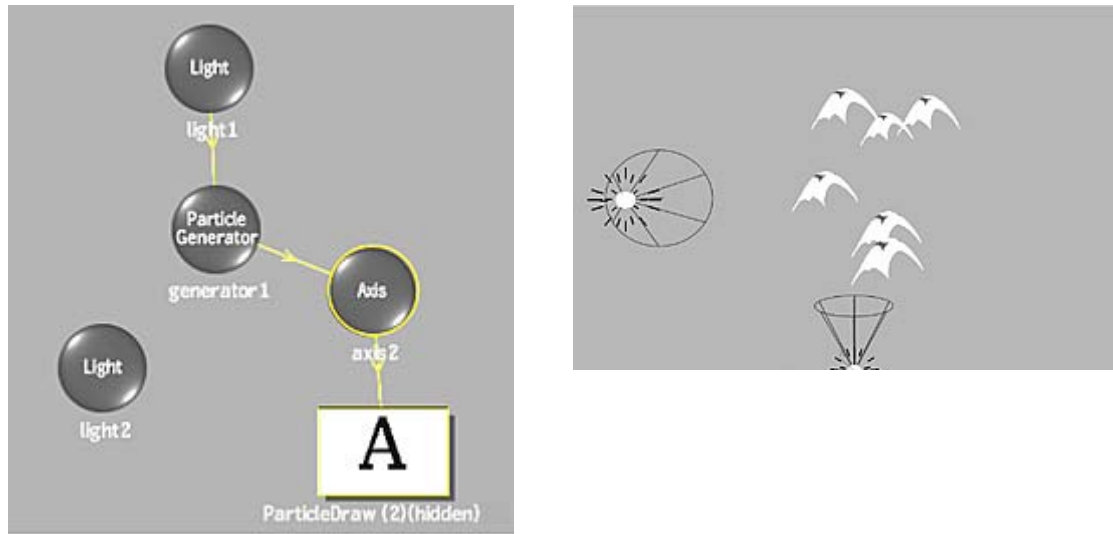

To use a surface as a custom particle:

- 1 Add a particle generator.
You can use a light source, 3D object, or surface as a particle generator. See [Generating Particles](#) (page 760).
- 2 Select Node as the particle type in the Render Type box. To view the surface as you make changes to your particle stream, change the Interactive Type box to Node as well. See [Setting Particle Rendering Properties](#) (page 766).
- 3 Add a surface to the scene. It can be a flat image, a bilinear, a perspective, or an extended bicubic surface. See [Adding Surfaces](#) (page 473).

NOTE You do not have to apply media to the surface because the particle generator only uses the surface's shape and not its media. To have an image appear on each particle, you have to apply a texture to the particle generator. See [Applying Textures to Particles](#) (page 772).

- 4 Rename your surface "ParticleDraw". This name is case sensitive so make sure it is typed exactly as shown.
- 5 Parent the particle generator to the surface.
If you want to add transformations, such as rotating all the particles, parent the particle generator to the axis of the surface as shown in the next step.
- 6 Hide the surface.

The following figure shows the schematic and the result of using an extended bicubic surface as a custom particle and a light source as the particle generator. The shape of the surface is animated and its axis is used to rotate the particles.

NOTE You can animate the shape of a bilinear, perspective, or extended bicubic surface, and have the particles reflect the animation.

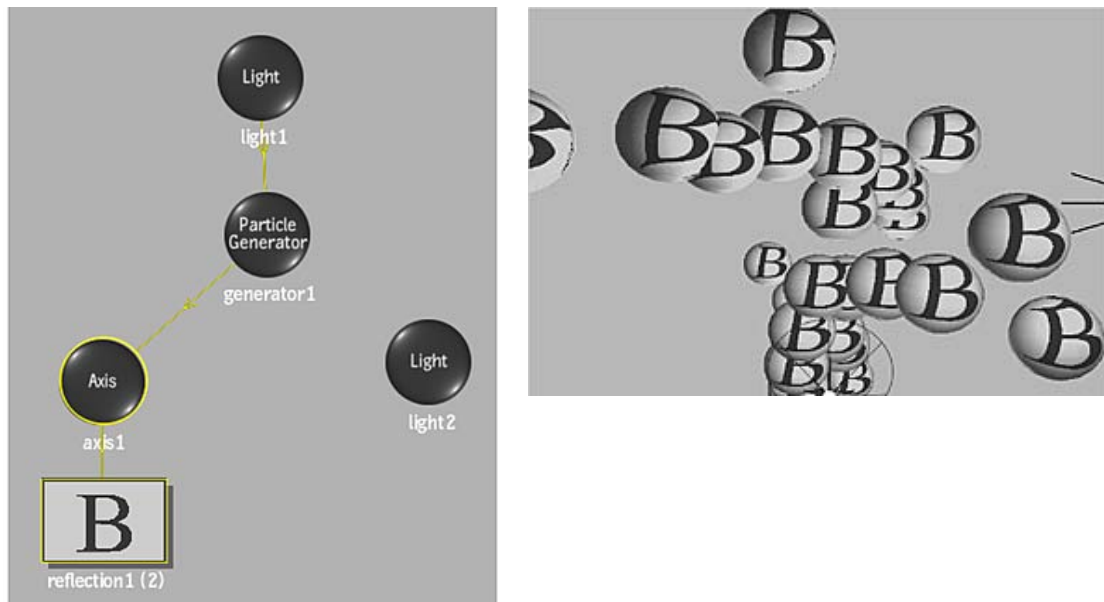

Applying Textures to Particles

You can apply textures to particles using the same method as applying textures to 3D objects and text. You can also set its texture mapping using the Texture menu.

To apply a texture to a particle stream of spheres:

- 1 Create a particle generator.
- 2 From the Render Type box, select Spheres as the particle type. To view the 3D object or text as you make changes to your particle stream, change the Interactive Type box to Spheres as well. See [Setting Particle Rendering Properties](#) (page 766).
- 3 In the schematic, select the Particle Generator.
- 4 From the Node bin, double-click the a texture map node.
A texture is added using the currently selected media and is parented by the particle generator.
- 5 Apply the appropriate media to the texture object and set texture menu settings.

For example, the following shows the schematic and the result of a particle stream using spheres and a reflection map, making each particle resemble a glass ball.

Exploding Objects and Surfaces

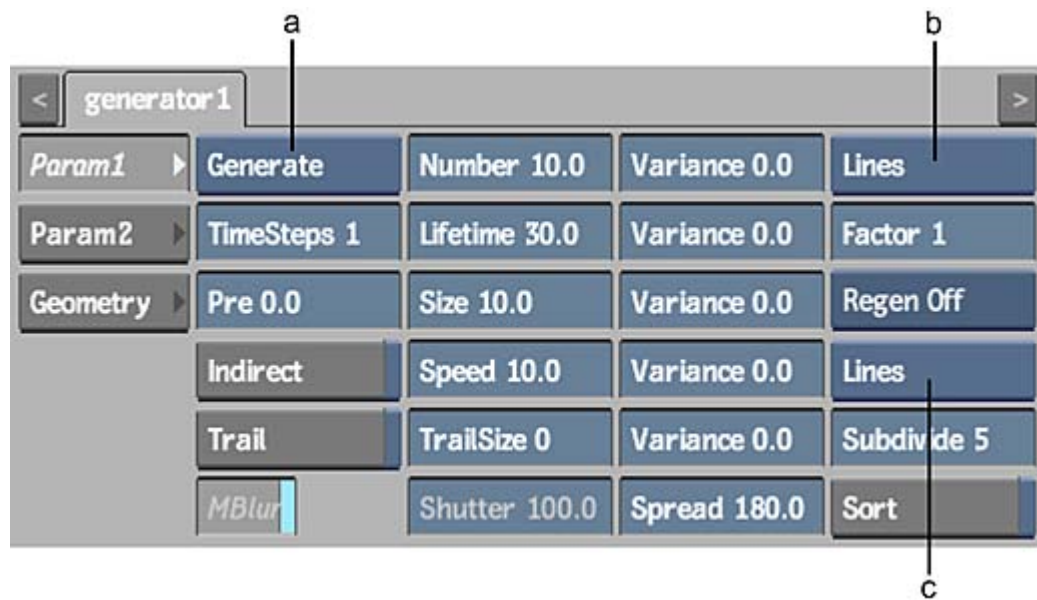

Whether you use a 3D object or a surface, exploding works much the same way. The shape of the 3D object or the surface is recreated by the particle generator, then the shape is exploded into polygons. For this to work correctly, the original 3D object or surface must be hidden.

Exploding Objects

The properties used to explode an object cannot be animated. When something explodes, it happens at a single point in time. This means that all the settings in the Particle Generator menu are used at once, at the beginning of the explosion.

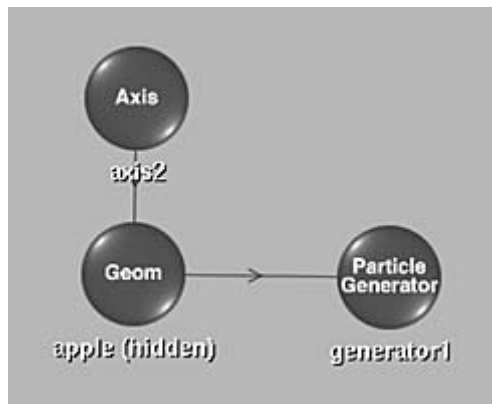

To explode a 3D object:

- 1 Import a 3D object or create 3D text.
- 2 In the schematic, select the 3D object.
- 3 Add a particle generator. See [Generating Particles](#) (page 760).
- 4 From the Particle Generator menu, select Explode from the Stream Type box.

(a) Stream Type box (b) Interactive Type box (c) Render Type box

- 5 From the Render Type box, select Polygon as the particle type.
To view the explosion as you make changes to your particle stream, change the Interactive Type box to Polygon as well. See [Setting Particle Rendering Properties](#) (page 766).
- 6 In the Number field, set the number of polygons to be removed from the 3D object with each pass. For example, if you specify 10 as the number of polygons per frame, then at each frame, 10 polygons are removed from the 3D object.
- 7 Set the other properties in the PartGen menu. See [Customizing the Particle Stream](#) (page 763).
- 8 Hide the 3D object or 3D text.
The following figure shows the schematic and the result of exploding a 3D object of an apple. The number of polygons is set to 200. The result shows frame 20.

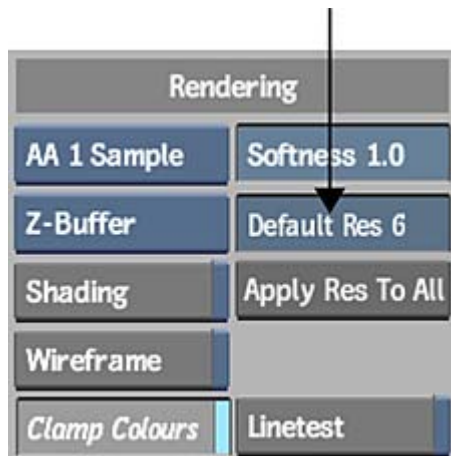

Exploding Surfaces

To make the media applied to the surface appear during the explosion, you must also apply a texture to the particle generator.

To explode a surface:

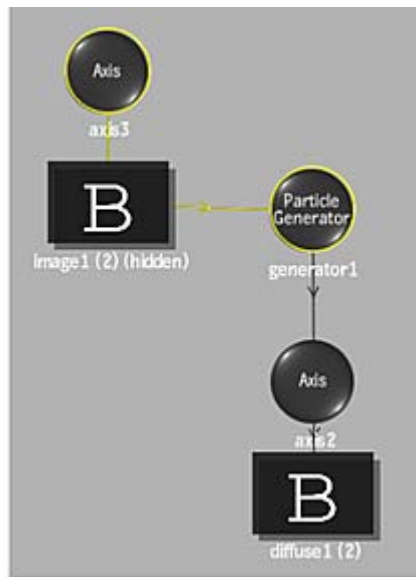

- 1 Select or add a surface and adjust its shape, position, rotation, and other attributes. See [Adding Surfaces](#) (page 473).
- 2 Select the surface in Schematic view and add a particle generator. See [Generating Particles](#) (page 760).
A particle generator is automatically connected to the surface.
- 3 From the Particle Generator menu, select Explode as the Stream Type.
- 4 Select Polygon as the particle type from the Render Type box. To view the explosion as you make changes to your particle stream, change the Interactive Type box to Polygon as well. See [Setting Particle Rendering Properties](#) (page 766).
- 5 Set the other properties in the Particle Generator menu. See [Customizing the Particle Stream](#) (page 763).
- 6 In the Rendering section of the Action Setup menu, adjust the default resolution.

Resolution is used to set the size of the polygons exploded from the surface. The higher the resolution, the larger the polygon.

- 7 Hide the surface.
- 8 Select the particle generator in Schematic view.
- 9 From the Node bin, double-click the Diffuse Map node.
A diffuse object appears in the schematic and is parented by the particle generator. See [Diffuse Mapping](#) (page 628).
- 10 Double-click the diffuse object and, in the Diffuse menu, select Wrap from the Mapping box.
- 11 Apply the appropriate media to the Diffuse element and set any other Diffuse menu settings.

The following figure shows the schematic and the result of exploding a surface with diffuse mapping set to Wrap.

Manipulating Particles

You use manipulators to direct the particle stream and create a number of different effects, such as a swirling vortex, a swarm of objects orbiting a point, or a waterfall. A particle stream can have an unlimited number of manipulators. Manipulators only influence the particle stream that parents them.

When manipulating particles, you use the Particle Manipulator menu to set a manipulator's type, magnitude, power, and damping properties, as well as position, rotation, and scale.

Particle manipulators can be animated using motion paths. You can use the same operations on a particle manipulator that you use on an axis.

Creating a Particle Manipulator

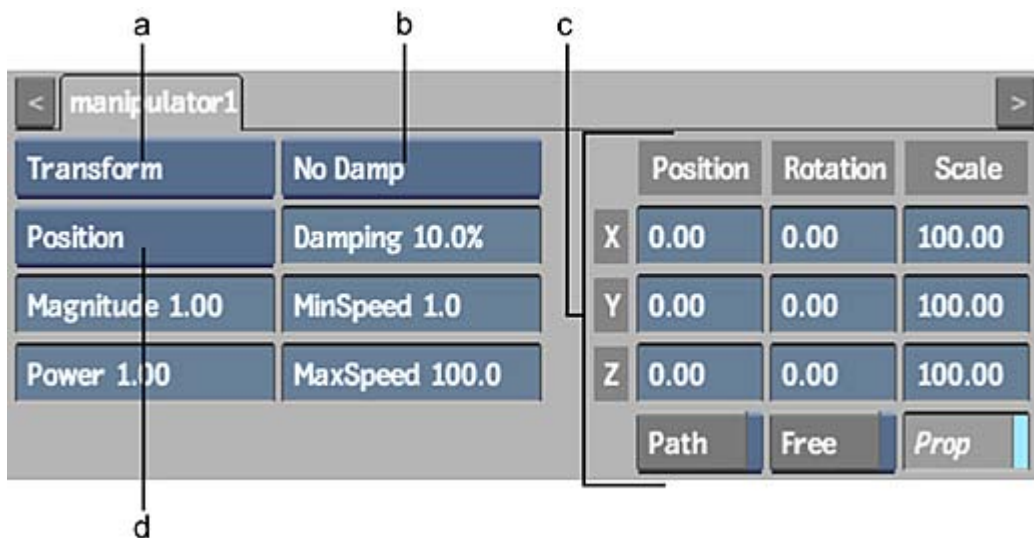

To create a particle manipulator:

- 1 In the schematic, select the particle generator that you want the manipulator to influence.
- 2 From the Node bin, double-click the Particle Animator node.

A particle animator element is added to the scene and parented by the selected Particle Generator element.

Setting Manipulator Properties

You use the Particle Manipulator menu to select the type of manipulator, its speed and position, and the power of its falloff. To access the Particle Manipulator menu, double-click the particle animator node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).

(a) Manipulator Type box (b) Damping box (c) Axis controls (d) Influence box

The particle manipulator controls are described as follows.

Manipulator Type box Select the type of manipulator.

Select:	To:
Gravity	Simulate the effect of gravity. See Simulating Gravity (page 780).
Transform	Apply transformations from the Axis menu to the position or speed of each particle. See Applying Transformations (page 779).
Vortex	Mimic the effect of a vortex. See Creating a Vortex Effect (page 781).
Acceleration Point	Pull particles toward a point. See Using an Acceleration Point Manipulator (page 782).
Acceleration Line	Pull particles toward a line. See Using an Acceleration Line Manipulator (page 783).
Acceleration Plane	Pull particles toward a plane. See Using an Acceleration Plane Manipulator (page 784).
Path	Make the particles follow a path. See Forming a Particle Path (page 785).
Function	Enter a mathematical expression to use as a particle manipulator. See Using a Function as a Manipulator (page 786).

Influence box Select whether the manipulator influences each particle's position or speed.

Set the initial speed of each particle using the Speed field in the Surface Particle Generator menu.

By selecting Speed in the Influence box located on the Particle Manipulator menu, each particle's speed is changed with each pass by the selected manipulator.

When you influence by position, the position is applied only once. For example, the following figure uses a gravity manipulator to illustrate the difference between position and speed. The gravity manipulator on

the left uses the default gravity manipulator with a magnitude of 4 and with position as the influence. The gravity manipulator on the right uses exactly the same settings except the influence is set to speed.

Magnitude field Displays the unit of measurement specific to each manipulator. Editable.

Magnitude is used by each manipulator for everything from extra scale when using Transform, to a pixel per frame acceleration factor when using AccPoint, AccLine, or AccPlane.

Power field Displays the amount of falloff from the centre of a manipulator. Editable.

If you specify 0 as the power, there is no falloff; the manipulator's influence is universal. This means that a particle is affected no matter where it is located in the scene. A negative value makes particles that are farther away affected by the manipulator.

Damping box Select the type of friction to apply (damping affects the speed of particles by applying friction based on each particle's mass, size, or both).

Select:	To:
No Damp	Turn off damping. Particles have no friction.
Damp Mass	Activate damping based on mass. The greater a particle's mass, the slower its speed in relation to the manipulator. You set the mass using the Mass channel in the Channel Editor.
Damp Size	Activate damping based on particle size. The larger the particle, the slower it moves in relation to the manipulator. This corresponds with the Size field in the Surface Particle Generator menu.
Damp Both	Activate damping based on mass and particle size.

Damping Percentage field Displays the percent value of how much Damping affects the position or speed of the particles. Editable.

Minimum Speed field Displays the minimum speed range for particles affected by Damping. Editable.

Maximum Speed field Displays the maximum speed range for particles affected by Damping. Editable.

NOTE You can use the Min and Max Speed fields to force a minimum and maximum speed on particles without damping. To do this, select Damp Mass, Damp Size, or Damp Both. Change the Damping Percentage to 0% and change the Min and Max Speed fields accordingly. Use this feature to stop particles from being over accelerated. For example, when you use a vortex manipulator, the closer particles pass to the centre of the vortex, the more they are accelerated. Occasionally, a particle may be over accelerated and shot too far, too fast. By forcing a maximum speed, particles are not accelerated past a certain value.

Load button Not Shown; available when Function is selected as the Manipulator type. Loads a mathematical expressions to be used as a particle manipulator.

Save button Not Shown; available when Function is selected as the Manipulator type. Saves a mathematical expressions to be used as a particle manipulator.

Expression field Not Shown; available when Function is selected as the Manipulator type. Displays a mathematical expression to be used as a particle manipulator. Editable.

See [Using a Function as a Manipulator](#) (page 786).

Axis controls Use these controls to animate the position, rotation, and scale of the manipulator.

Control	Description
Position	Use the Position X, Y, and Z fields to displace each particle along the X, Y, and Z axes.
Rotation	Use the Rotation X, Y, and Z fields to rotate each particle. Each particle is not the centre of its rotation. Particles rotate around the manipulator's axis.
Scale	Use the Scale X, Y, and Z fields to increase or decrease the speed or position of each particle along the X, Y, and Z axes. For example, if speed is the selected influence, a Scale X of 100% has no effect while a Scale X of 105% increases the speed along the X axis by 5% with each pass. Enable Prop to proportionally scale the axes.

Enable the Path button to animates the position of the axis using a spline drawn in the scene. Disable Path to animate the position of the axis using explicit animation.

Free button Enable to ignore transformations from parent axes.

Applying Transformations

Use a transform manipulator to apply the accumulated transformations from the Axis controls to the position or speed of each particle. Unlike other manipulators, the transform manipulator is not used to position the manipulator in the scene. Transform manipulators are always placed at the centre of the particle stream they influence.

The following figure provides an example of creating a particle stream influenced by a transform manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

<

manipulator1

>

Transform	No Damp		Position	Rotation	Scale
Speed	Damping 10.0%	X	0.00	6.00	100.00
Magnitude 1.00	MinSpeed 1.0	Y	0.00	4.00	100.00
Power 1.00	MaxSpeed 100.0	Z	0.00	0.00	100.00
		<div>Path</div> <div>Free</div> <div>Prop</div>			

In the Particle Manipulator menu, use Magnitude as an extra scaling factor whose sensitivity depends on the transformations in the Axis menu. For example, the following is a copy of the above particle stream with Magnitude set to 0.99 instead of 1.0; the particle generator and transform settings are the same.

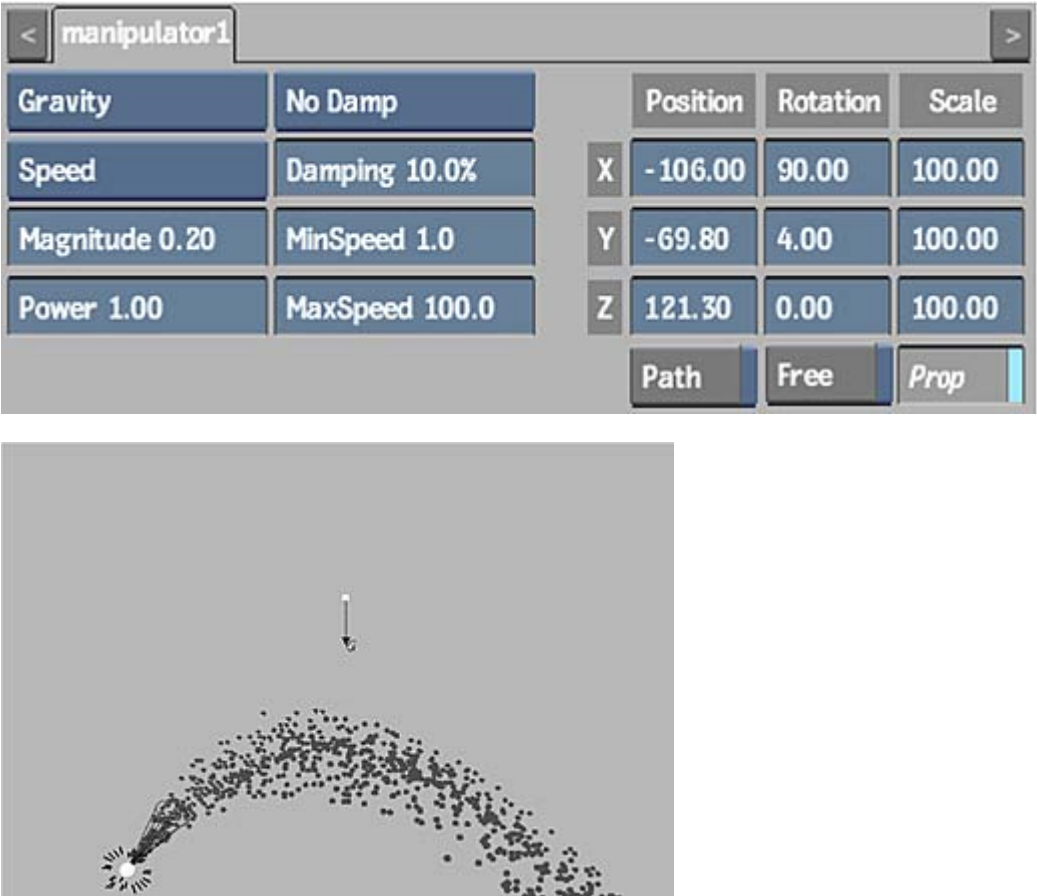

Simulating Gravity

Use a gravity manipulator to simulate the effects of gravity. This manipulator works on speed or position. The Power field has no effect.

Magnitude specifies the gravitational pull in pixels per frame. A higher magnitude produces a higher gravity, which exerts a greater influence on each particle.

The icon for a gravity manipulator uses an arrow to indicate the direction of the influence. You can change the position and rotation of the arrow using the Axis menu. You can also change the scale of the gravity manipulator as another way of increasing its influence.

The following figure provides an example of creating a simple particle stream influenced by the gravity manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

Creating a Vortex Effect

Use a vortex manipulator to influence the motion and rotation of particles. This manipulator works on speed or position. Power is the falloff from the centre of the vortex and magnitude is used for the scale of the vortex's rotation.

You can also use the Axis controls to apply additional transformations to the vortex. Scale changes the size of the vortex, and rotation affects the spin of the vortex.

The following figure provides an example of creating a simple particle stream influenced by the vortex manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

<

manipulator1

>

Vortex	No Damp		Position	Rotation	Scale
Speed	Damping 10.0%	X	-9.35	39.00	100.00
Magnitude 2.00	MinSpeed 1.0	Y	11.72	24.00	100.00
Power 1.00	MaxSpeed 100.0	Z	295.33	0.00	100.00
		<div>Path</div> <div>Free</div> <div>Prop</div>			

NOTE The icon used to show a vortex does not indicate the limit of the vortex. The icon is only used to represent the vortex in the scene and is not meant as an accurate depiction of the size, strength, or limit of the vortex's influence.

Using an Acceleration Point Manipulator

The Acceleration Point manipulator mimics the gravitational pull between bodies. Unlike the gravity manipulator, which pushes particles in a specific direction, Acceleration Point continually pulls particles toward itself on all three axes (X, Y, Z).

Magnitude is the gravitational pull in pixels per frame. A higher magnitude produces a higher gravity, which results in a greater influence. Power is the distance from the centre, or the radius, of the pull.

The following figure provides an example of creating a simple particle stream influenced by the Acceleration Point manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

Prop

NOTE The Axis controls are used only to position the Acceleration Point in the scene. Scale and rotation have no effect.

Using an Acceleration Line Manipulator

Like Acceleration Point, the Acceleration Line manipulator continually pulls particles toward itself. Acceleration Line, however, manipulates particles on two axes instead of all three.

You can set the two axes by rotating the manipulator using the Rotation fields. The Axis controls are also used to position the Acceleration Line manipulator in the scene. Scale may change the appearance of the Acceleration Line icon, but has no effect on particles.

Magnitude is the gravitational pull in pixels per frame. A higher magnitude produces a higher gravity, which results in a greater influence. Power is the falloff from the manipulator, or the radius of the pull.

The following figure provides an example of creating a simple particle stream influenced by the Acceleration Line manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

Using an Acceleration Plane Manipulator

Like Acceleration Point and Acceleration Line, the Acceleration Plane manipulator continually pulls particles toward itself. With Acceleration Plane, however, particles are manipulated on only one axis set by rotating the plane using the Rotation fields.

Use the Axis controls to position the Acceleration Plane manipulator in the scene. The Scale and fields are not used.

Magnitude is the gravitational pull in pixels per frame. A higher magnitude produces a higher gravity, which results in a greater influence. Power is the falloff from the manipulator, or the radius, of the pull.

The following figure provides an example of creating a simple particle stream influenced by the Acceleration Plane manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

<

manipulator1

>

Acceleration Plane	No Damp		Position	Rotation	Scale
Position	Damping 10.0%	X	0.00	90.00	100.00
Magnitude 1.00	MinSpeed 1.0	Y	-64.00	-53.20	100.00
Power 1.00	MaxSpeed 100.0	Z	0.00	2.00	100.00
		<div>Path</div> <div>Free</div> <div>Prop</div>			

NOTE Because Acceleration Plane influences particles on only one axis, the effect may not be noticeable until you change views or orbit the camera.

Forming a Particle Path

Use the path manipulator to make particles follow the motion of a path.

The motion of a path is applied to the speed or position of each particle. Note that particles do not directly follow the path. You can make the particles seem to follow the path by lowering the particle speed and magnitude, which is used as a scaling factor. Power is not used.

Use the Axis controls to animate the path. You can also use the Rotation and Scale fields to add extra transformations.

The following figure provides an example of creating a simple particle stream influenced by the path manipulator. The settings in the Particle Manipulator menu and the resulting effect are shown.

<

manipulator1

>

Path	No Damp		Position	Rotation	Scale
Position	Damping 10.0%	X	103.00	90.00	100.00
Magnitude 0.60	MinSpeed 1.0	Y	136.25	-53.20	100.00
Power 1.00	MaxSpeed 100.0	Z	0.00	2.00	100.00

Path

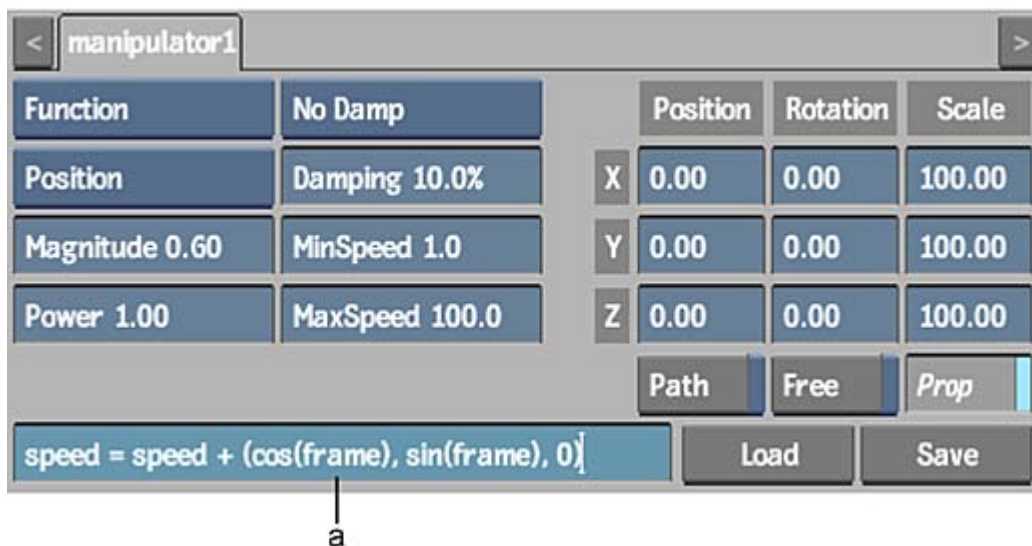

Free

Prop

Using a Function as a Manipulator

Select Function to specify your own mathematical expressions to be used as a particle manipulator. You can use the channels from the Particle Manipulator and Particle Generator menus in your expressions, as well as arithmetic operations, mathematical conventions, functions, and constants.

(a) Expression field

The arithmetic operators, conventions, constants, and functions that you can use in your expressions are listed in the following sections. Before writing your own expressions, you should understand the following:

- A vector is a 3D coordinate written using the convention (x, y, z) where x, y, and z are separate values.
For example, pos represents the position of each particle. If you want to increase the Y position of each particle with each pass, use the expression `pos = pos + (0,1,0)`.
- Make sure assigned values and vector values are within an acceptable range. For example, transparency (opacity of each particle) is a value between 0 and 1. The expression `transparency = size` does not work unless size (particle size from the PartGen menu) falls between 0.0 and 1.0.
To make transparency dependent on size, size must be divided by an appropriate value. For example, if size is between 1 and 10, use the expression `transparency = size / 10`.
- Some functions return scalars and other functions return vectors. Make sure that when you use a function, it returns the right value and that this value is within an acceptable range.
For example, rgb is a vector of values between 0.0 and 1.0. The expression `rgb = (0, 0, noise3(pos))` gives an error because noise3 returns a vector. The expression `rgb = (0, 0, frame)` does not give an error, but frame is the frame number and it is never less than 1. This means the blue channel is always set to full blue (1).
- You can specify more than one function by separating each with a semicolon.
For example, to place the two expressions in the Expression field, you would type:
`speed = speed + pos; pos = pos + (0,size,0)`

Expression field operators are listed in the following table.

Operator	Description
=	Equals
+	Addition
-	Subtraction

Operator	Description
*	Multiplication
/	Division
%	Percentage
(x,y,z)	Vector where x, y, z may also be the results of functions
==	Equivalence
!=	Not equal to
<	Less than
<=	Less than or equal to
>	Greater than
>=	Greater than or equal to

Particle and manipulator variables that you can use in the Expression field are listed in the following table.

Particle Symbol	Description
pos	Position, a vector (x,y,z).
speed	Speed, a vector (x,y,z).
rgba	Red, green, blue, and alpha colour channels for each particle, expressed as a 4D vector (r,g,b,a). Each component is a value between 0 and 1.
rgb	Red, green, and blue colour channel, expressed as a vector (r,g,b). Each component is a value between 0 and 1.
red	Red channel, a value between 0 and 1.
green	Green channel, a value between 0 and 1.
blue	Blue channel, a value between 0 and 1.
transparency	Transparency of each particle (surface or geometry), a value between 0 and 1.
lifetime	Lifetime of each particle, in frames.
lifetimel	A value between 1.0 and 0.0 where 1.0 is when a particle is first generated and 0.0 is when it ends.

Particle Symbol	Description
mass	Mass of each particle.
size	Size of each particle, in pixels.
tailSize	Width of the particle's tail, a value between 0 and 1.

The following variables are read only. You cannot change them in the Expression field, but you can use them in your calculations.

Manipulator Symbol	Description
frame	Current frame
magnitude	Value from the Magnitude field
power	Value from the Power field
damping	Value from the Damping field
minSpeed	Value from the MinSpeed field
maxSpeed	Value from the MaxSpeed field

Single argument arithmetic functions are listed in the following table.

One Argument	Description
$\sin(a)$	Sine of a
$\cos(a)$	Cosine of a
$\tan(a)$	Tangent of a
$\text{asin}(a)$	Arcsine of a
$\text{acos}(a)$	Arccosine of a
$\text{atan}(a)$	Arctangent of a
$\exp(x)$	Exponential function of x
$\text{expm1}(x)$	Equivalent to $\exp(x)-1$
$\log(x)$	Natural logarithm of x
$\log_{10}(x)$	Base 10 logarithm of x

One Argument	Description
<code>log1p(x)</code>	Equivalent to $\log(1 + x)$
<code>sqrt(x)</code>	Square root of x
<code>abs(x)</code>	Absolute value of x
<code>trunc(x)</code>	Integer value of x
<code>floor(x)</code>	Smallest integer greater than or equal to x
<code>ceil(x)</code>	Largest integer greater than or equal to x
<code>round(x)</code>	x rounded to the nearest integer
<code>radians(a)</code>	a converted to radians
<code>degrees(r)</code>	r converted to degrees
<code>sign(x)</code>	Returns +1 or -1 depending on the sign of x
<code>length(p)</code>	Euclidean length of point p
<code>noise(v)</code>	Noise of vector v , returns a float
<code>fnoise(v)</code>	Fractal noise vector v , returns a float
<code>noise3(v)</code>	Noise of vector v , returns a vector

Making Particles Transparent

The following example illustrates how to make particles become transparent as they reach the end of their lifetime using the expression `transparency = lifetimeI`. The settings in the Particle Manipulator menu, Particle Generator menu, and the resulting effect are shown.

1 generator1				
Param1	Generate	Number 20.0	Variance 0.0	Lines
Param2	TimeSteps 1	Lifetime 63.0	Variance 0.0	Factor 1

Making Particles Spin

The following example illustrates how to spin particles using the expression:

speed = speed + (cos(frame),sin(frame),0)

The settings in the Particle Manipulator menu, Particle Generator menu, and the resulting effect are shown. Notice that the particle Timestep value is increased to improve the accuracy of the particle stream.

Arithmetic functions that have two or more arguments are listed in the following table.

Symbol	Description
$\text{atan}(x,y)$	Arctangent of y over x
$\text{pow}(x,y)$	x to the power of y
$\text{mod}(x,y)$	Returns the remainder of dividing x by y
$\text{min}(x,y)$	Minimum value of x and y
$\text{max}(x,y)$	Maximum value of x and y
$\text{step}(x,y)$	Returns 0 if $x < y$, 1 if $x \geq y$
$\text{dot}(v1, v2)$	Dot product of two vectors; returns a scalar
$\text{cross}(v1, v2)$	Cross product of two vectors; returns a vector
$\text{turbulence}(v, o)$	Turbulence of vector v and octave o ; returns a float
$\text{turbulence3}(v, o)$	Turbulence of vector v and octave o ; returns a vector
$\text{smoothstep}(min, max, x)$	Returns 0 if $x < min$, 1 if $x \geq max$; if neither are true, returns a hermite interpolation between 0 and 1
$\text{clamp}(x, min, max)$	x clamped to the range $[min, max]$

The following example illustrates how to create animated turbulence using the expression:

$\text{pos} = \text{pos} + \text{turbulence3}(\text{pos}, 1) * \text{power}$

Bouncing Particles

You can bounce a particle stream off either an image or a bouncer. When particles bounce off an image, they bounce off the surface wherever its matte is white or grey. Particles only pass through the areas of the image where its matte is pure black. If a surface's matte is turned off, particles bounce off the entire surface.

When you use a bouncer, it must be the parent of an axis or a light source. A bouncer shows up as a sphere in the Action scene when you use it with a light source. Otherwise, all other types of surfaces create flat bouncers.

Whether you use a bouncer or an image, bouncing particles are controlled using the Particle Bouncer menu.

(a) Bounce Type box

Bounce Type box Select a bounce behaviour.

Select:	To:
Bounce	Bounce particles off images or bouncers. All bounce properties work with this type of bounce behaviour.
Extinct	Make particles disappear when they reach a surface. Only the Max Dist parameter works with this type of bounce.

Select:	To:
Generator	Create an additional particle stream when particles bounce. When using this bouncing behaviour, you must add another particle generator. See Combining Particle Streams (page 797).
Generator+ Extinct	Make particles disappear and create an additional particle stream when particles reach a parented surface. Only the Max Dist parameter works with this type of bounce unless the particles end in another particle stream. See Combining Particle Streams (page 797).

Friction field Displays a percentage to influence the angle of bouncing particles. Editable.

The greater the percentage, the more particles bounce straight. For example, in the left figure, Friction is set to 100%, which bounces particles almost perfectly straight. In the figure on the right, Friction is set to 20%, which causes the particles to deviate once they make contact (bounce).

Resilience field Displays the amount of energy lost with each bounce. Editable.

For example, at a Resilience of 100%, the figure on the left shows there is no energy lost between bounces. Each bounce is at the same height as the last bounce. When Resilience is set to 80%, 20% of energy is lost between each bounce. At 50%, the figure on the right shows the height of each bounce is reduced by 50%. Note that Friction is set to 0 for both examples.

Maximum Distance field Displays the distance a particle must travel past an image for it to still bounce or become extinct. Editable.

Because an image is only a pixel in width, it is unlikely that fast moving particles will hit the image directly. Max Dist acts like a buffer zone after the surface. If particles fall through the surface, set the Max Dist to -100. Particles that miss the surface by 100 pixels will still bounce.

If particles still fall through the surface, increase the timestep to increase the accuracy of the particle stream.

Bouncing Particles Off an Image

You can bounce particles off an image surface only. Particles will bounce off bilinear and bicubic surfaces, but only on the original flat surface and not on any changes in shape.

To create the bouncing particle effect, you start with a particle generator. When you determine the image off which you want to bounce particles, you must parent the particle generator to the image; otherwise, the particles will ignore the image. The following figure shows the schematic and the result of bouncing particles off an image using a light source as a generator.

To bounce particles off an image:

- 1 Add an image off which you want to bounce particles.
- 2 Create a particle generator using a light source, 3D object, or surface as a particle generator. See [Generating Particles](#) (page 760).
- 3 Parent the particle generator to the image's axis.
- 4 Select the image's axis and, in the Axis menu, enable Free.
The parent-to-child relationship between the particle generator and the image is severed, allowing you to place the image in the scene more easily. Any transformations and animations from the particle generator are not passed to the image.
- 5 Move the image in the scene until the particle stream passes through it. To do this, you may have to switch views or orbit the camera.
- 6 In the schematic, select the image.
- 7 From the Node bin, double-click the Particle Bouncer node.
A particle bouncer is added and parented by the image.
- 8 To access the Particle Bouncer menu, double-click the particle bouncer node in the schematic, or follow the tab population rules for the Object menu (see [Populating Menu Tabs of Selected Objects](#) (page 431)).

Bouncing Particles Off a Bouncer

A particle bouncer element is added and automatically parented to a light source. The particle bouncer may not be parented by the right light source or axis. The bouncer must be parented by the light or axis added in the last step.

NOTE The shape of the bouncer depends on the particle generator type.

The following figure shows the schematic and the result of bouncing particles off a bouncer.

To bounce particles off a bouncer:

- 1 Create a particle generator using a light source, 3D object, or surface as a particle generator. See [Generating Particles](#) (page 760).
- 2 Add an axis or a light source to the scene.
- 3 From the Node bin, double-click the Particle Bouncer node.
- 4 If you are using an axis to set the position of the particle bouncer, select the axis and go to step 5. Otherwise, go to step 7.
- 5 In the Axis menu, enable Free to sever the parent-to-child relationship between the particle generator and the axis.
Any transformations and animations from the particle generator are not passed to the axis. This makes it easier to place the particle bouncer in the scene.
- 6 Parent the particle generator to the particle bouncer's axis or light source.
You must parent the particle generator to the axis or light source; otherwise, the particles will ignore the particle bouncer.
- 7 In the Particle Bouncer menu, select Bounce from the Bounce Type box and set the appropriate bounce properties.

NOTE If the particle bouncer is not parented correctly, unparent the particle bouncer and make the axis or light source added in the last step its parent.

Combining Particle Streams

You can combine two or more particle streams by parenting them together. This has two possible results depending on whether the first particle stream ends or bounces off an object.

NOTE Multiple particles can be parented, but only in a straight line, that is, a particle can only be the particle of one other particle. For example Particle 1 can parent Particle 2, and Particle 2 can parent Particle 3 in the same scene.

Particles Generating Another Particle Stream

When each particle in the particle stream ends, the second particle stream begins. This can be used, for example, to create fireworks.

To make particles generate other particles:

- 1 Create a particle generator. You can use a light source, 3D object, or surface as a particle generator. See [Generating Particles](#) (page 760).
- 2 In the schematic, select the Particle Generator.
- 3 Add another particle generator by double-clicking the Particle Generator node in the Node bin.
- 4 In the Particle Generator menu, set the second particle generator's Spread and other properties as appropriate. See [Setting Particle Properties](#) (page 765).

NOTE In the Channel Editor's folder for the second particle generator, you can set the Spread_V channel to add variance to the value in the Spread field.

The following figure shows the schematic and the result of a particle stream that generates a second particle stream. The first particle stream generates spheres and the second particle stream generates quads.

Particles Bouncing into Another Particle Stream

When bouncing particle off a bouncer, you can generate a second stream of particles. For example, use this technique to give the effect of water or sparks bouncing off an image.

There are two different effects that you can create depending on your bouncer's settings. The following example illustrates the Generator bounce type.

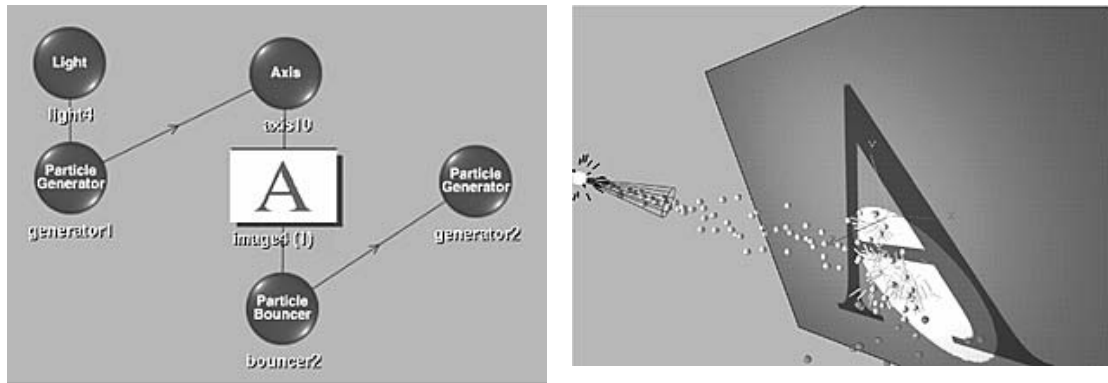

To make bouncing particles generate another particle stream:

- 1 Create a schematic that bounces particles off an image or a bouncer. See [Bouncing Particles](#) (page 794).

- 2 In the schematic, select the Bouncer object.
- 3 In the Particle Bouncer menu, select Generator from the Bounce Type box.
- 4 Add another particle generator by double-clicking the Particle Generator node in the Node bin.
- 5 In the Particle Generator menu, set the particle generator's other properties as appropriate. See [Generating Particles](#) (page 760).
- 6 In the Channel Editor, open the second particle generator folder to reveal the properties folder.
- 7 Set the Spread and Spread_V channels to control the spread of the second generator.

If you set the Spread to less than 180, you can also control the rotation of the second particle stream using the Friction field in the Particle Bouncer menu.

The following figure shows the schematic and the result of bouncing particles into another particle stream where the first particle stream continues after bouncing off an image surface. The first particle stream generates spheres and the second particle stream generates quads.

Sample Particle Setups

Ten particle setups are provided in the directory `/usr/discreet/<product_home>/examples`. To load one of the setup files, open Action using a black frame as the front, back, and matte clips.

A brief description of each example particle setup is provided in the following table.

Setup File Name	Description
Bounce Example	Uses a gravity manipulator and a bouncer attached to an axis. The bouncer appears as a sphere in Camera view. The particles fall down and bounce off the bouncer.
Bounce Example 2	Uses a gravity manipulator and two image surface bouncers.
Bounce Example 3	Uses an Accpoint manipulator and a bouncer linked to an axis. The bouncer follows the Accpoint manipulator.
Explode Example	An example of exploding 3D text. The Geom node is hidden in Schematic view. The setup uses an Explode generator and Polygon particles. To add 3D text (Geom node), go to the Text menu, click the Text field and type the text string, then click Create.

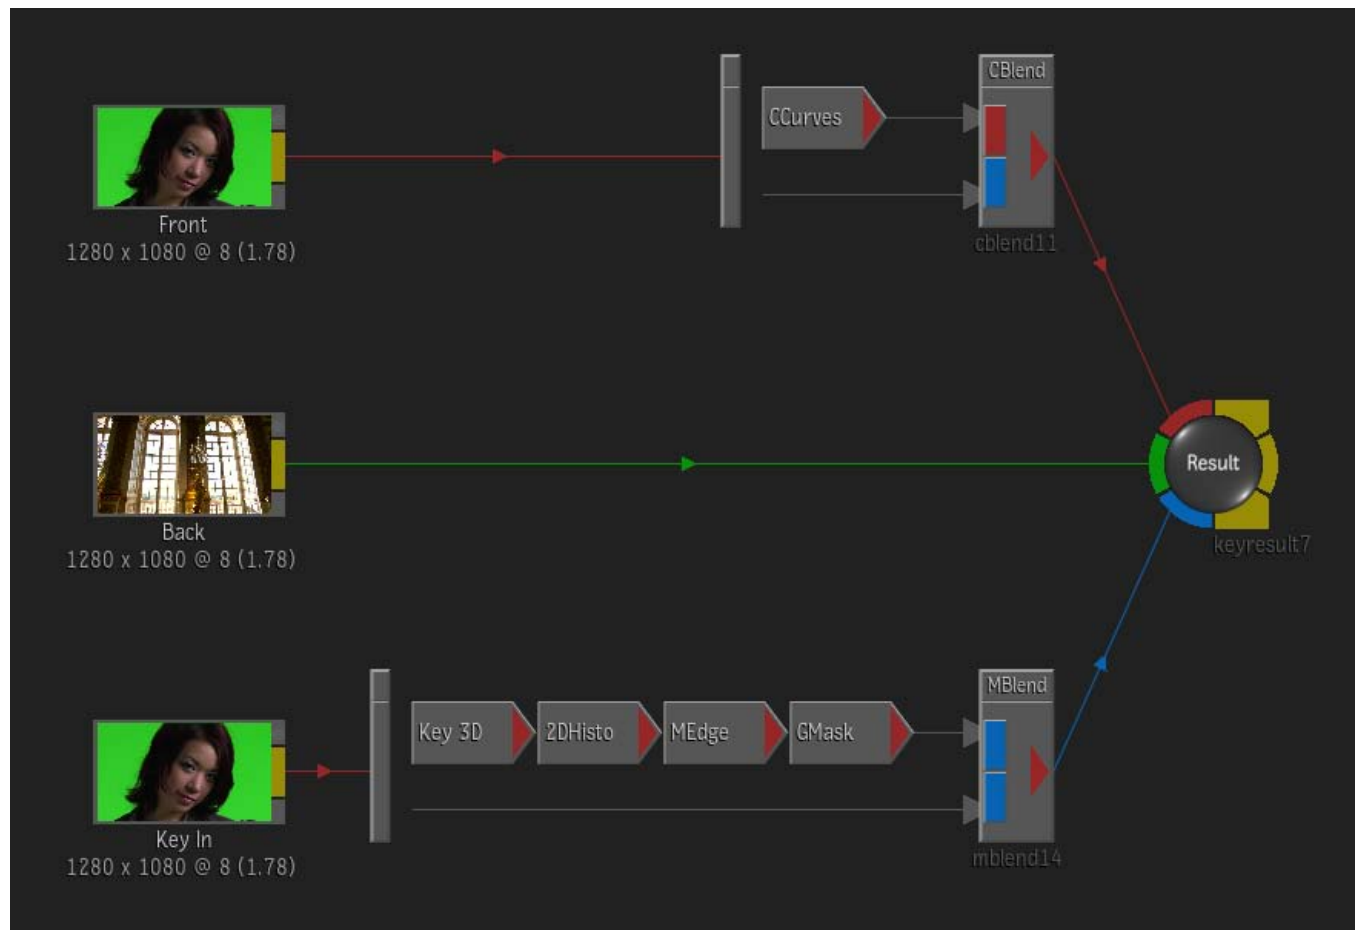

Setup File Name	Description
Explode Example 2	An example of exploding an image surface. The image surface is hidden. Media1 is applied to the generator as a texture and uses Wrap mapping mode. Replace Media 1 with an image of your choice.
FireWorks Example	Uses two linked generators. The first generator generates few particles at each frame. When these reach the end of their lifetime, the second generator is activated.
Function Example	Uses a function manipulator that increases the particles' transparency as they reach the end of their lifetime.
Function Example 2	Uses a function manipulator with sine and cosine functions to modify the speed of the particles.
Node Example	Uses 3D text for the particles. The Geom node (the 3D text) must be named "ParticleDraw". The generator is parented to the axis of the Geom node, and the selected particle type is Node.
Transform Example	Uses a transform manipulator.

Chroma Keying and Working with Green Screens

17

The Modular Keyer is a schematic environment, like Batch FX, that is designed specifically for keying. Within the Modular Keyer, you can choose different Start Modes or presets, which generate node schematics adapted to the different keys you want to pull, such as 3D keys, chroma keys, etc.

When you start the Modular Keyer for the first time, Flame builds a default schematic that includes the 3D Keyer node, in addition to a number of other nodes, that all work well together to create and refine a basic key. This is the 3D Keyer Start Mode.

NOTE If you want to reload a keyer setup or BFX from Flame Premium 2013 or prior, consider the following:

- If you enabled the Flame Reactor rendering engine when you created your project, make sure the media in the Setup/BFX is 8 bit or 16 bit floating point, as the Flame Reactor engine only supports 8 bit and 16 bit floating point media.
 - If you enabled the Legacy Rendering engine when you created your project, the media in the Setup/BFX can be 8, 10 or 12 bit but not 16 bit floating point as the legacy keyer does not support 16 bit floating point media.
-

Within the Modular Keyer, the keyers are represented as processing pipelines, which are collections of interconnected nodes. As you perform keying tasks in the Modular Keyer, you navigate from node to node to accomplish the final key, displayed in the Result node.

As a general example, you could proceed as follows:

- Key out the selected colour in the Keyer node;
- Adjust your blacks and your whites in the 2D Histogram node;
- Refine your matte in the Matte Edge node;
- Mask out troublesome areas of your matte in the GMask node;
- Perform colour correction of the front clip in the Colour Curves node;
- View the result in the Result node.

Because it is node-based, you have a lot of flexibility with the Modular Keyer. You can:

- Choose a different Start Mode to start with a different default keying pipeline. Options are:
 - Channel Keyer.
 - Default MK (3D Keyer)
 - HLS Keyer.
 - Luminance Keyer.
 - Master Keyer.
 - GMask. See [Masking and Rotoscoping](#) (page 905)
 - RGB Keyer.
 - RGBCMYL Keyer.
 - YUV Keyer.

IMPORTANT When you select another Start Mode, any work in progress will be lost and the selected keyer is loaded with the default settings.

- Add other effects nodes from the node bin to further refine your key.

NOTE All of the legacy keyers had a colour section available in the settings. This colour section of the legacy keyers is only carried over to the Modular Keyer if the legacy keyer setup used the Master Keyer. If any other legacy keyer was used (RGB, Luminance, etc.), the colour section is discarded when the setup is loaded. To retain the colour section of these legacy keyer setups, enable Classic Engine in the Projects and Users dialog box. Also, motion blur data, from the GMask section of the legacy keyers is not carried over to the Modular Keyer.

Setting Up the Nodes and Media to Pull a Key

To pull a key, you must first set up your composite in the Modular Keyer.

There are two ways to set up the composite in the Modular Keyer:

- Through Batch FX.
- Through the Action Timeline FX.

There are three ways to set up the composite in the Modular Keyer:

- From the Timeline, through the Action Timeline FX.
- From the Timeline through Batch FX.
- From the Tools menu.

To set up the composite in the Modular Keyer from the Timeline through the Action Timeline FX:

- 1 Select the track you want to key, and add an Action Timeline FX.
The track below the selected track is taken as the Background.
- 2 Double-click the Action entry in the FX ribbon, or click the Editor button to enter Action.
- 3 In Action, click the Media button to display the Media menu.
- 4 Double-click the K field in the front/matte row to enter the Modular Keyer.
The 3D Keyer processing pipeline appears. The 3D Keyer is the default keyer.

NOTE Once inside the Modular Keyer, the Modular Keyer node bin is displayed at the bottom of the screen. Though very similar to the Batch FX Node bin, the Modular Keyer node bin contains only nodes that are relevant for keying. To return to Batch FX view, click Return.

- 5 Use the desired Start Mode, and create your key.

To set up the composite in the Modular Keyer from the Timeline through Batch FX :

- 1 From the timeline, select the segment you want to use as your front.
- 2 Click FX and select Create Batch FX
You are taken to the Batch FX view. The schematic is displayed and your front clip is connected to the output node.
- 3 From the Batch FX node bin, drag the Modular Keyer node between the front clip and the output node and release it when the connection goes from red to yellow.
The front clip is connected to the front (red) input of the Modular Keyer node, which is connected to the output node.
- 4 Double-click the back (green) input of the Modular Keyer node.
You are taken to the Viewing panel and the cursor becomes green and prompts you to select a back clip.
- 5 In the Viewing panel or the Media panel, click on the clip you want as your back.
The cursor becomes blue and prompts you to select a matte clip.
- 6 In the Viewing panel or the Media panel, click on the clip you want as your matte.
You are taken back to the Batch FX schematic and your front, back and matte clips are connected to the front, back and matte inputs of the Modular Keyer node. You are ready to start creating your key.
- 7 Double-click the Modular Keyer node.
- 8 Click the Edit button that appears at the bottom of the screen.
The 3D Keyer processing pipeline appears with your front, back and matte clips connected to the front, back and matte inputs of the 3D Keyer. The 3D Keyer is the default keyer.

NOTE Once inside the Modular Keyer, the Modular Keyer node bin is displayed at the bottom of the screen. Though very similar to the Batch FX Node bin, the Modular Keyer node bin contains only nodes that are relevant for keying. To return to Batch FX view, click Return.

- 9 Double-click the 3D Keyer node to display the 3D Keyer menu at the bottom of the screen.
- 10 Select the desired Start Mode, and create your key.

To set up the composite in the Modular Keyer from the Tools menu:

- 1 Select the Tools tab, on the bottom of the window.
The Tools menu is displayed.
- 2 Under the Composite tab, click Modular Keyer.
The cursor becomes red and prompts you to select a front clip.
- 3 From the Media panel or the Viewing panel, click the clip you want as your front.
The cursor becomes green and prompts you to select a back clip.
- 4 From the Media panel or the Viewing panel, click the clip you want as your back.
The cursor becomes blue and prompts you to select a matte clip.
- 5 From the Media panel or the Viewing panel, click the clip you want as your back.
The cursor becomes white and prompts you to select a render location in your workspace for your resulting key.
- 6 Click on a grey area of the Viewing panel or in a folder in the Media panel to select the render location.
You are taken inside the Modular Keyer and the 3D Keyer processing pipeline is displayed, with your front, back and matte clips connected to the front, back and matte inputs of the 3D Keyer. The 3D Keyer is the default keyer.

NOTE Once inside the Modular Keyer, the Modular Keyer node bin is displayed at the bottom of the screen. Though very similar to the Batch FX Node bin, the Modular Keyer node bin contains only nodes that are relevant for keying. To return to Batch FX view, click Return.
- 7 Double-click the 3D Keyer node to display the 3D Keyer menu at the bottom of the screen.
- 8 Select the desired Start Mode, and create your key.

NOTE You can also access the Modular Keyer, as well as all the other Keyers in the application through Batch, where each Keyer is represented as an effects node. See [Using Batch and ConnectFX](#) (page 361).

After you have set up the nodes and media, [set up the viewports for keying](#) (page 804).

Setting Up Viewports for Keying

After you have [set up your processing pipeline and your media](#) (page 802), you want to set up the viewports for keying.

When keying, you want to set the viewport to 2-up view, to display the schematic and the result views simultaneously, enabling you to view the result as you work.

To set up the viewports for keying:

- 1 From the Layout box, select 2-up.
The view area is split in two. The schematic view is displayed on the left, by default.
- 2 Click in the right-side viewer to select it.
A white frame appears around the viewer to show that it is selected.
- 3 From the View box, select Result.
The result of your key, in its current state, is displayed in the right-side viewer.

About the 3D Keyer

Like traditional keying, the 3D Keyer in the Modular Keyer and Batch is used to select a range of colours to key out, such as the blue or green background in a clip. In the 3D Keyer, however, this range of colours is represented visually in an RGB viewer. You can use the RGB viewer to analyse the colour areas in a clip, and then refine the key with increased accuracy.

The 3D Keyer can be used for many purposes other than pulling a key from the key-in clip. For example, in the Modular Keyer, you could use the Keyer-3D node in the Matte pipe of the CBlend node to isolate a region of the front clip to which you want to apply a particular colour correction.

NOTE It is recommended that you be familiar with the use and terminology associated with the Modular Keyer before you use the 3D Keyer.

3D Keying Workflow

The following table shows the recommended workflow for the 3D Keyer.

Step:	Refer to:
1. Open the Modular Keyer, select the clips, and then open the 3D Keyer.	Setting Up the Nodes and Media to Pull a Key (page 802).
2. Sample for tolerance.	Setting the Tolerance (page 806).
3. Sample for softness.	Setting the Softness (page 809).
4. Minimize the noise in softened areas.	Removing Noise from Softened Areas (page 811).
5. Remove grey areas from the key using negative sampling and patches, garbage masks, or RGB colour and softness adjustment.	Removing Grey Areas in the Key (page 814), About Garbage Masks (page 905), Techniques for Adjusting Softness (page 835).
6. Adjust the luminance of the key.	Adjusting the Luminance of the Key (page 852).
7. Adjust the edges of the key.	Modifying the Edges of the Key (page 858).
8. Remove colour spill.	Adjusting Spill Controls with the Colour Curves Node (page 861).
9. Adjust front and matte curves.	Adjusting the Front and Matte Luminance Curves (page 863).
10. Render the clip.	Rendering Your Key (page 866).

Creating a Precise Key in the 3D Keyer

This section describes the tools you use to create a precise key with the 3D Keyer. You can learn other techniques for perfecting your key in [More Keying Techniques](#) (page 835).

Using the RGB Viewer

The RGB viewer is a 3D colour model for the key-in clip. Its X, Y, and Z axes represent the red, green, and blue components of the key-in clip's colour space. The cubes of colour show the distribution of all the colours of the key-in clip in RGB colour space. This 3D colour map is referred to as the 3D histogram.

(a) The colours in the key-in clip are represented by the colour cubes of the 3D histogram **(b)** More prevalent colours are represented by larger cubes **(c)** Black canvas background **(d)** Red, green and blue axes

When you scroll through a clip, the 3D histogram cubes update to display the colour distribution of each frame.

Use the 3D histogram to analyse the colour mapping of the key-in clip and to locate the colours to be keyed out. When you sample for tolerance and softness, the sampled areas are represented as ellipsoids in the RGB viewer. You can manipulate sampled objects in the viewer to fine-tune the key. When you plot a colour to key in the image, its location is plotted in the RGB viewer.

You can turn the display of the histogram and the black canvas background on and off and set options to control their appearance. Change the display any time as you create the key to help you best visualize the contents of your image and work with the RGB viewer. To learn more about controlling the display of the RGB viewer, see [Setting the 3D Histogram Display](#) (page 820).

Setting the Tolerance

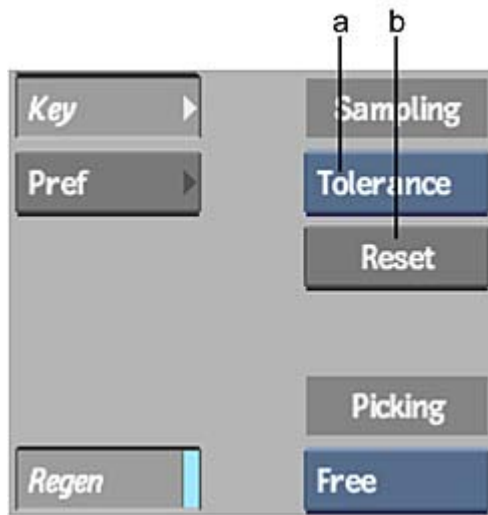

The first step in pulling a key with the 3D Keyer is to set a range of colours to be keyed out from the front clip. This is called the tolerance range. All pixels in the key-in clip in the tolerance range are black in the matte.

To specify the tolerance range, sample the area that you want to key out in the image window. Take one or more samples until you are satisfied with the result. The tolerance range must not be too large or the edge of the composite will be too hard and the subject in the front clip will appear to be pasted into the back clip.

To set the tolerance range:

- 1 Click Key.

The 3D Key menu appears.

(a) Sampling box (b) Sampling Reset button

- 2 Make sure you are at frame 1. If you move to a different frame while sampling, you will set a second tolerance keyframe (at the new frame) and animate the tolerance.

NOTE To avoid setting keyframes, disable Auto Key.

- 3 In the Sampling box, set the sample type to Tolerance.
- 4 Press **Ctrl** and drag the cursor in the area to be keyed out.

A red rectangle appears. The pixel values in the rectangle are used to define the tolerance range. Notice that the rectangle has a maximum size. This ensures that the result is computed quickly.

NOTE You can also take a sample by clicking the image and dragging the colour picker in the area to be keyed out. All pixel values that the colour picker samples are used to set the tolerance range.

- 5 If needed, add to the tolerance range by sampling several more rectangles. The ellipsoid gets bigger as you add to the tolerance.

NOTE If you are not satisfied with the result of the last sample, click Undo. The last sample you performed is cancelled. To reset the entire tolerance sample, click the Sampling Reset button. To remove the entire sample range at the current frame and start over with a new sample, press **Ctrl+Alt** and drag the cursor in the area to be keyed out.

Viewing the Tolerance Sample

The tolerance sample in the RGB viewer is represented as an ellipsoid by default. The ellipsoid shows you the location, in RGB colour space, of the range of colours included in the sample. All colours in the tolerance ellipsoid are black on the matte.

(a) Tolerance ellipsoid

When the histogram is displayed, you can see the location of the sample in relation to the other colours in the image. When it is hidden, you can see the sample more clearly. As you work, show or hide the histogram using the following techniques:

- To display or hide the histogram, press **H**. See [Setting the 3D Histogram Display](#) (page 820).
- To view the sample more closely, rotate the RGB viewer by pressing **Ctrl** and dragging it. To zoom in on the RGB viewer, press **Shift** and drag inside it from left to right. To move the RGB viewer, press **Alt** and drag it.

Viewing the Convex Hull

The tolerance ellipsoid surrounds the exact colours sampled, which are connected in RGB space to form a 3D convex hull. You can see the convex hull in the ellipsoid by changing the tolerance display.

To view the convex hull:

- 1 Press **H** to remove the histogram.
- 2 In the Tolerance Display box, set the tolerance display to Cloud, which is semi-transparent.

(a) Tolerance Convex Hull box (b) Tolerance Display box (c) Softness Display box

NOTE To learn more about controlling the display of the tolerance sample, see [Changing the Display of Key Elements](#) (page 822).

- 3 In the Softness Display box, set the softness display to None.

NOTE When you set the tolerance range, the 3D Keyer automatically creates a minimum softness range that is equivalent to the tolerance range. This creates a softness ellipsoid of equal size to the tolerance ellipsoid in the RGB viewer. Sometimes the softness ellipsoid is visible at this point, depending on the way the ellipsoids are displayed.

- 4 Set the Tolerance Convex Hull box to Vert&Surf.

You can now see the convex hull, with vertices indicating the exact colour areas sampled.

(a) Convex hull (b) Convex hull vertices

The convex hull contains the exact colour values of the tolerance sample, while the ellipsoid represents the actual area in which corresponding pixels will be black in the matte. The 3D Keyer uses the ellipsoid rather than the convex hull to determine the keyed out area because it is much faster to calculate.

You can change the shape of the convex hull directly in the RGB viewer to adjust the tolerance. The ellipsoid re-oriens itself according to the new shape. See [Reshaping the Convex Hull](#) (page 834).

- 5 For the next step, return the softness display to Cloud.

Setting the Softness

The next step is to set a range of colours in the key-in clip to be partially transparent so as to soften the transition between the front and back clips in the composite. This is called the softness range. To specify the softness range, sample the areas to be softened in the image window. The pixels in the key-in clip in the softness range are grey in the matte. The key should have the greatest possible softness value.

As shown in the following steps, the softness range can be set using the RGB or YUV colour models. RGB Softness is the default setting.

To sample for softness:

- 1 Make sure you are at frame 1. If you move to a different frame while sampling, you will set a second softness keyframe (at the new frame) and animate the softness.

NOTE To avoid setting keyframes, disable Auto Key.

- 2 From the Sampling box, select Softness.

- 3 From the View box, select Front to view the input image for the 3D Keyer.
- 4 Identify an area where softness is needed. For example, if the clip consists of a talent in front of a blue or green screen, softness is needed at the edge of the talent to soften the transition between the front and back clips. If the clip contains transparency, softness is needed in the semi-transparent area.
- 5 From the View box, select the current result view (displayed as <Currently Selected Node> Result, in the View box) to monitor the result as softness is applied to the matte while you sample.

TIP You can switch views as you sample the image. The current result view (displayed as <Currently Selected Node> Result, in the View box), shows the result of the processing pipeline up to the selected node. To see the Front Source, select Front from the View box.

- 6 Zoom in to see the image more closely.
- 7 Click in the area you identified.
The cursor changes to a colour picker.
- 8 Drag the colour picker over the area in the image to be softened. Avoid sampling any area that should not be softened, such as the key itself; however, there is no need to avoid areas that have been keyed out. For transparencies, drag the colour picker in the area that you want to be semi-transparent.

A softness ellipsoid appears in the RGB viewer. Notice the tolerance ellipsoid in the softness ellipsoid.

(a) Softness ellipsoid (b) Tolerance ellipsoid

All colours in the softness ellipsoid (except those inside the tolerance ellipsoid) will be grey on the matte. In the softness ellipsoid, the closer a point is to the tolerance ellipsoid, the darker the grey will be. For example, the mid-point between the edge of the tolerance ellipsoid and the edge of the softness ellipsoid is always the same mid-grey.

Notice how the softness ellipsoid increases in size as you sample the edges.

NOTE The softness is rendered interactively on the matte - you see the results immediately. For information on rendering the softness only after releasing the cursor, see [Regen](#) (page 838).

- 9 Like the tolerance ellipsoid, the softness ellipsoid has a convex hull. To see it clearly, set the Tolerance Display and Tolerance ConvexHull display to None, and set the Softness ConvexHull display to Vert&Surf.

(a) Softness convex hull

- 10 If needed, take another sample elsewhere on the edges or transparency. Each time you sample, the pixels touched by the colour picker contribute to the previously calculated softness range.
NOTE If you are not satisfied with the result of a sample, click Undo. To reset the entire softness sample, click the R button. To remove the entire sample range and start over with a new sample, press **Ctrl+Alt** and drag the cursor in the area to be softened.
- 11 From the View box, select MK Schematic and, in the schematic, click the Result node.
- 12 From the View box, select the current result view (displayed as <Currently Selected Node> Result, in the View box) to view the result.
The edges are softened but may be grainy.

Removing Noise from Softened Areas

Once you sample for softness, use the Minimize Noise option to remove grain from the softened areas. Graininess, also known as noise, can occur at the edges of the key, or in the semi-transparent areas such as water or glass.

First, sample an area containing noise. The 3D Keyer analyses the sampled area. Using Minimize Noise, you can then scale the softness in such a way as to minimize the noise in the softened areas.

Minimize Noise is especially useful for semi-transparent areas and edges requiring a lot of softness, such as smoke, reflection, and shadows.

TIP If the entire clip is grainy, or if you are not satisfied with the results after scaling the softness, consider using another approach. For example, degrain the clip with Degrain before keying with the 3D Keyer. You can add a Degrain node to the beginning of the Matte branch anytime. Additionally, use Minimize Noise on a degrained clip if needed.

To remove noise:

- 1 Sample for softness. See [Setting the Softness](#) (page 809).
- 2 Zoom in and choose the area you want to analyse. Look for graininess in the softened areas. For transparencies, look for graininess in the semi-transparent areas.
- 3 Press N (Noise) and drag a rectangle in the selected area.
The 3D Keyer analyses the pixels in the rectangle.
- 4 Select Min Noise from the Softness Scaling box.

(a) Softness Scaling box (b) Scaling field

An arrow appears in the softness ellipsoid, showing the direction in which the softness needs to be increased to reduce graininess in the sampled area.

- 5 Increase the softness using one of the following methods:
 - Drag the cursor over the Scaling field to the right. The softness is increased based on the results of the analysis from the grainy region. Observe that the softness ellipsoid is scaled in the direction of the arrow.

NOTE Each time you change the Scaling value, it is returned to 1.00.

- Use a colour value plotted in the image window as the basis for virtual point scaling of softness. To do this, use the **O** keyboard shortcut to plot a point in the image window, then press **Ctrl+V**, and click and drag in the Player.
- 6 If some edges or areas are still not softened, analyse again in that area and repeat the procedure.
 - 7 Return the Softness Scaling to Prop (proportional scaling).

Alternatively, press **Alt + N** to scale softness based on the Minimize Noise analysis. This keyboard shortcut is the equivalent of selecting Minimize Noise in the Softness Scaling box, then scaling the softness using the Scaling field.

NOTE When Minimize Noise scaling is selected, it controls the arrow in the RGB viewer. To manually control the arrow, you must return to proportional scaling.

To scale softness using **Alt+N**:

- 1 Perform a noise analysis.

NOTE **Alt + N** only works if an analysis for the noise has been done.

- 2 Press **Alt + N** and click and hold the cursor anywhere in the image window. Drag the cursor to the left to decrease the noise or to the right to increase it.

The softness is scaled according to the noise analysis. Notice that Minimize Noise appears in the Softness Scaling box as you use the keyboard shortcut. When you release the cursor, the Softness Scaling option returns to Prop.

TIP For transparencies, use the **V** keyboard shortcut to remove unwanted grey areas in the matte, then use **Alt+N** to reduce noise in areas you chose to soften (the transparency). Perform the two procedures alternately until you achieve the best result.

Using YUV Softness

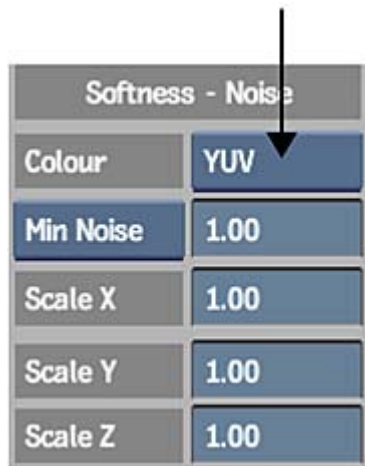

If you are not satisfied with the softness result—for example, if graininess still remains in the softened areas, try using YUV Softness. This option calculates the softness according to the YUV colour space.

YUV Softness often creates softened areas that are smoother and is typically useful for shadows and transparencies. However, since it removes more noise, the resulting softness range is less precise.

NOTE You can switch between RGB and YUV Softness and retain their settings.

To use YUV Softness:

- 1 Select YUV from the Softness box.

- 2 Sample for softness as described in [Setting the Softness](#) (page 809).
- 3 Minimize the noise as described in [Removing Noise from Softened Areas](#) (page 811).

Compare YUV with RGB Softness

Select RGB Softness from the Softness box. The previous RGB Softness range is still in effect. Compare the results with the YUV Softness. Generally, the softness ellipsoid is larger with YUV Softness, as shown in the following example.

With RGB Softness, the softness ellipsoid is bound by the convex hull

With YUV Softness, the softness ellipsoid is scaled according to the Y component of YUV colour space

If you are satisfied with the result, use YUV Softness. If not, return to RGB softness.

Removing Grey Areas in the Key

Once you have added softness, check to see if there are any grey areas in the key resulting from the setting. If so, there are several techniques to remove the grey areas:

- Perform negative sampling on the areas.
- Use patches.

- Use garbage masks.
- Manipulate the softness element in the RGB viewer.
- Use the Softness fields.

In this section, two methods are shown: using Negative Sampling to refine the softness range, and using the Patch tool to create “selective keys” in the white areas of the matte. To learn other ways to remove unwanted grey areas, see [Techniques for Adjusting Softness](#) (page 835).

Negative Sampling

This is probably the simplest method of removing greys from the matte. You sample in the unwanted grey area to subtract those colour values from the softness range.

Try this method first to see if it solves the problem. However, if the colour values in the foreground subject are too similar to those at the edges, you may remove too much of the softness.

To perform negative sampling:

- 1 From the View box, select the current result view (displayed as <Currently Selected Node> Result, in the View box). Identify the unwanted grey areas in the matte.
 - 2 Select Sample Softness from the Sampling box.
 - 3 Press **Alt** and click a grey area. Gently drag the cursor over the area.
- If the negative sampling removed too much of the desired softness or brought back graininess, click Undo and try another method.

Adding a Patch

Patches are another type of sample you can take in the image window. Unlike tolerance and softness, you can specify the colour that a patch sample renders on the matte. Patch samples can be rendered as white, black, or any shade of grey on the matte. You can also set the opacity of a patch.

One use for patches is to remove unwanted grey areas from the matte. Use a patch to isolate a range of colours from those that have been included in the softness range, then set the colour you want the pixels to have on the matte. Sampling a patch to remove grey areas in the key is similar to creating a garbage mask by keying instead of drawing.

You can use up to three different patches in a key.

To sample a patch:

- 1 From the View box, select the current result view (displayed as <Currently Selected Node> Result, in the View box).
- 2 Identify the unwanted grey areas in the matte.
- 3 In the Sampling box, set the sample type to Patch1.

- 4 In the Patches box, select Patch 1.

(a) Patches box (b) Active button (c) Patches Softness field

- 5 Enable Active.
- 6 Specify the colour in which you want to render the patch. In this example, make the patch white by setting the P1(Patch 1) Colour to 100 (this is the default value). To render the sampled values as black, enter a value of 0. Use a value between 0 and 100 for any shade of grey.
- 7 Sample the unwanted grey area by dragging the cursor over it.
The grey areas of the matte corresponding to the colour values sampled are changed to white.
All the colour values sampled are included in the patch. Notice the patch in the RGB viewer, represented by a white wireframe box. All colour values in the box will be rendered white on the matte.

- 8 If necessary, sample again to add to the patch. Watch the edges to make sure they are not affected by the sample.

TIP To remove colour values from the sample, press **Alt** as you sample. To undo a sample, click **Undo**.

- 9 If needed, soften the edges of the patch by dragging the cursor to the right or left in the Patches Softness field.

A negative softness value softens the edges of the patch inwards from the edge. A positive value softens the edges outwards beyond the edge, adding softened pixel values to the patch.

TIP You can view softness as a red wireframe box when the patch is displayed in Box mode. See [Changing the Patches Display](#) (page 823).

- 10 If needed, adjust the opacity of the patch using the P1 Opacity field. A value of 100% renders the patch as fully opaque. A value of 0% renders the patch as fully transparent.

The RGB viewer now contains three key elements:

- The tolerance sample (as an ellipsoid)
- The softness sample (as an ellipsoid)
- The patch (as a white wireframe box)

For instructions on completing the key using the basic keying technique, see the sections referred to in [3D Keying Workflow](#) (page 805).

Animating Key Elements

In a live-action clip, you can animate the tolerance, softness, and patch ranges as the subject in the clip moves. You can also animate the colour, opacity, and softness of patches.

Animating the Range of Key Elements

You animate the tolerance, softness, and patch ranges by changing the range at different frames. In the Channel Editor, range changes appear in the Shape channel. You can set a Shape keyframe by:

- Adding or subtracting pixel values from the range by sampling again in the image.
- Adjusting the key elements in the RGB viewer. All transformations made to a key element are applied to its Shape keyframe, including translation, rotation, scaling, and noise analysis.
- Changing the values in the Softness Scaling X, Y, and Z fields.

If you display the convex hull while animating a key element, the convex hull fills the ellipsoid in between keyframes. The sample is recreated to fill the ellipsoid on interpolated frames. This ensures the smoothest possible transition between keyframes.

To display the Channel Editor, click the Animation button.

NOTE To animate key elements, enable Auto Key.

Shape Keyframes

The shape of ellipsoids and patches is defined by their translation, rotation, and scaling values, so the Shape keyframe is actually composed of multiple parameters. The Y value in the Channel Editor does not have the same significance as it does for a single parameter (for example, opacity). Instead, the Y value is composed of sequential numbers that represent keyframes that have been set. Each consecutive keyframe is assigned a sequential Y value: the first keyframe has a Y value of 1, the second has a Y value of 2, and so on. Although the Y value does not represent a single value, you can still adjust the curve to tweak the shape.

To animate the range of a key element:

- 1 Perfect the key at frame 1.
- 2 Enable Auto Key.
- 3 Scroll to other frames and, where necessary, adjust the range using any of the techniques provided in this chapter.

Keyframes are added at each frame where you change the tolerance, softness, or patch range.

NOTE When you set a tolerance keyframe, a softness keyframe is also set. This is because the softness range is always at least as large as the tolerance range. When you set the tolerance range, the 3D Keyer automatically creates a minimum softness range that is equivalent to the tolerance range. When you adjust the tolerance, the softness range is also adjusted to accommodate the change.

- 4 Optionally, tweak the animation by adjusting the shape curve in the Channel Editor. The image updates as you make changes.

Changing the Interpolation

Parameter values in between keyframes are interpolated. Change the type of interpolation using the Channel Editor.

The default interpolation for the shape curve is Bézier, which creates a smooth transition between keyframes. If your clip has a very sudden change in the colour values (for example, if a light was switched on at a particular frame), use Constant interpolation between the two keyframes where the change occurs. See [Setting Interpolation](#) (page 2222).

Animating the Patch Parameters

Animate the colour, softness, and opacity of patches by changing the values in the Patches menu. Channels for each of these parameters are located in the Patch folders of the Channel Editor.

To animate the patch parameters:

- 1 Go to the appropriate frame.
- 2 Enable Auto Key.
- 3 Change the values in the Colour, Opacity or Softness fields as needed.

Resetting a Channel

There are two ways to reset a channel:

- Using the Reset button under the Sampling box.
- Using the Rst Chn button in the Animation controls.

Mastering the RGB Viewer

The RGB viewer gives you a graphic representation of what you are doing in the key. In this section, learn how to:

- Move, rotate, and zoom in on the RGB viewer.
- Change the display of the 3D histogram and canvas.
- Change the appearance of elements in the RGB viewer.
- Select key elements in the RGB viewer.
- Plot pixels in the image and in the RGB viewer.
- Translate, rotate, and scale key elements in the RGB viewer.
- Reshape the convex hull by manipulating its vertices.

Moving, Rotating, and Zooming in on the RGB Viewer

The RGB viewer represents the 3D colour space of a key-in clip. As you work on the precision of a key, you will want to change the position, orientation, and size of the RGB viewer. Use **Alt**, **Shift**, and **Ctrl** to move, rotate, and zoom in on the RGB viewer.

To:	Do this:
Move the viewer	Alt -click the viewer and drag it.
Zoom in on the viewer	Shift -click the viewer and move the cursor to the left or right.
Rotate the viewer	Ctrl -click the viewer and move the cursor in any direction. By default this rotates the viewer around its centre. Using Rotation Axis options in the Preferences menu, you can also rotate the viewer around a plotted point, or around the centre of the tolerance or softness ellipsoid. This makes it easier to zoom in on specific elements in the viewer.

Resetting the RGB Viewer

To reset the viewer's position, orientation, and size, click Home in the lower-left corner of the Key, Patches, or Preferences menu.

NOTE Other settings, such as resolution or canvas light, are not reset.

Setting the Display of the RGB Viewer

As you work with sampled elements in the RGB viewer, set the display of the 3D histogram, canvas background, and border lines to suit the operation you are performing. For example, when modifying the softness range, consider hiding the 3D histogram to see the softness ellipsoid more clearly.

Setting the 3D Histogram Display

The 3D histogram provides a visual representation of the colours in the key-in clip. It shows how the colours in your clip are distributed in RGB colour space, with exposure and contrast settings taken into account.

The most prevalent colours are represented by larger cubes; colours that are less prevalent are represented by smaller cubes.

NOTE The size of the cubes approximates the colour usage in the image, but it is not intended as an exact representation. You can increase the resolution of the cubes using the histogram grid.

When a floating-point image is used as a key-in clip, the RGB Viewer will support this input and also activate options to change the display of colour space in the 3D histogram. These options are available in the Histogram panel of the Key menu. When the range in the histogram exceeds 1, a cube outline indicating the colourspace from 0 to 1 is displayed in the RGB viewer.

Frame option box Select an option to display the entire histogram, or a selected range of values.

Select:	To display:
All Objects (Shift+A)	All objects in the 3D histogram. This is the default setting.
(0,1) (Shift+0)	Objects with colour values between 0 and 1.
Free (Shift+F)	Objects within a user-defined range. Use the Range field to navigate between views including the full range view and a percentage of the range.
Plot (Shift+O)	Objects with colour values between a range that comprises all values between 0 and 1, and the plot value.

Range field Displays the percentage of the full range that is displayed in the histogram. Editable when the Frame option box is set to Free.

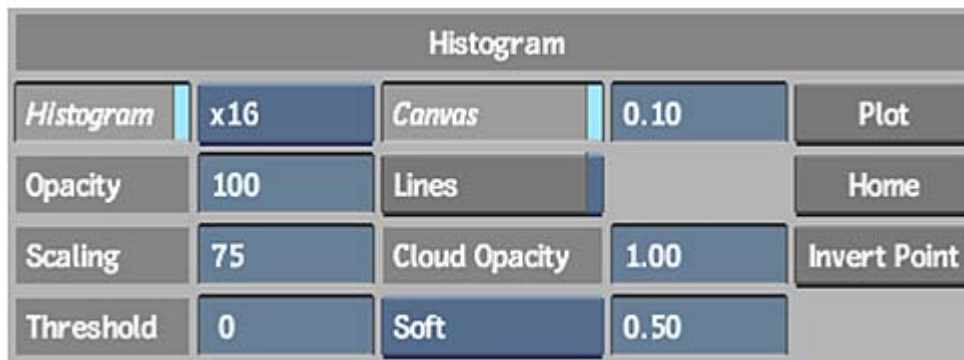

Store button Click to store the current value in the Range field in memory for later use. Active when the Frame option box is set to Free.

Recall button Click to retrieve the last Range value that was stored in the buffer.

Change other display elements of the histogram using the Preferences menu. To access the Preferences menu, click Pref.

Histogram Enable to show or hide the histogram. Alternatively, use the H keyboard shortcut.

Histogram grid Enable to displays the resolution for the cubes:

- x16 (the default)
- x8 displays fewer and larger cubes
- x32 displays smaller cubes

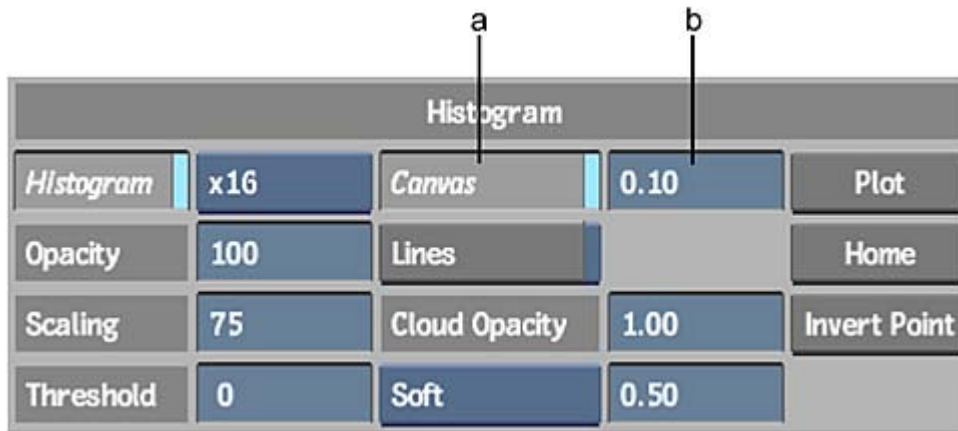

Opacity field Displays the opacity of the cubes. As you adjust the opacity, smaller cubes become transparent at a faster rate than larger ones. The default setting is 100% opacity.

Scaling field Resizes the cubes. Cubes representing less prevalent colours (the smaller cubes) are scaled down more than those representing more prevalent colours. The cube of the most prevalent colour remains the same size (as set in the Histogram Grid box). By increasing the size difference between the colours of greater and lesser prevalence, you can see the main components of the colour space more clearly.

Threshold field Removes the display of colours that are less prevalent in the image. As you increase the threshold, less prevalent colours are increasingly removed from the histogram.

Setting the Canvas Display

The canvas is the black background of the RGB viewer. Control the display of the canvas using the Preferences menu.

(a) Canvas button (b) Canvas Light field

Canvas button Enable to show or hide the canvas. Alternatively, use the C keyboard shortcut.

Canvas Light field Displays the amount of lighting in the RGB viewer. The light source emanates from behind the viewer.

Setting the Line Display

You can show or hide a white outline of the borders of the RGB viewer, as well as green wireframe boxes around selected ellipsoids. Show the boxes to quickly identify the selected element, or hide them to reduce “clutter” in the viewer.

To show or hide lines in the RGB viewer:

- 1 Enable or disable the Lines button in the Setup menu.

Changing the Display of Key Elements

You can change the display of the tolerance ellipsoid, softness ellipsoid, and patches as you work on the key to suit the operation you are performing. For example, to adjust the tolerance range after setting the softness, you could set the softness display to wireframe, or remove its display altogether, for a better view of the tolerance. See [Setting the Tolerance](#) (page 806) and [Setting the Softness](#) (page 809).

Setting the Tolerance and Softness Ellipsoids

As you sample the tolerance and softness in a key, corresponding key elements appear in the RGB viewer. Set the appearance of the tolerance and softness ellipsoids to make it easier to work with them while refining the precision of the key.

Use the Key menu to set the display of the tolerance and softness in the RGB viewer.

(a) Tolerance Convex Hull box (b) Tolerance Display box (c) Softness Convex Hull box (d) Softness Display box

Tolerance and Softness Display boxes Select an option to set the appearance of the tolerance and softness ellipsoids.

Select:	To display:
Ellipsoid	An opaque ellipsoid of the exact colours sampled.
Cloud	A semi-transparent grey ellipsoid. You can set the transparency of the ellipsoid using the Cloud Opacity field in the Preferences menu. See Setting the Cloud Opacity (page 824).
Wireframe	The ellipsoid as a wireframe outline
None	No ellipsoid. Note that when an ellipsoid is not displayed, it still has an effect on the image

Tolerance and Softness Convex Hull boxes Select an option to set the appearance of the tolerance and softness convex hulls.

Select:	To display:
Vertices	Only the vertices of the convex hull.
Surface	Only the surface of the convex hull.
Vert&Surf	Both the surface and vertices of the convex hull.
None	No convex hull.

NOTE Vertices do not appear on keyed elements when Tolerance Display or Softness Display is set to Ellipsoid (because an ellipsoid is opaque).

Changing the Patches Display

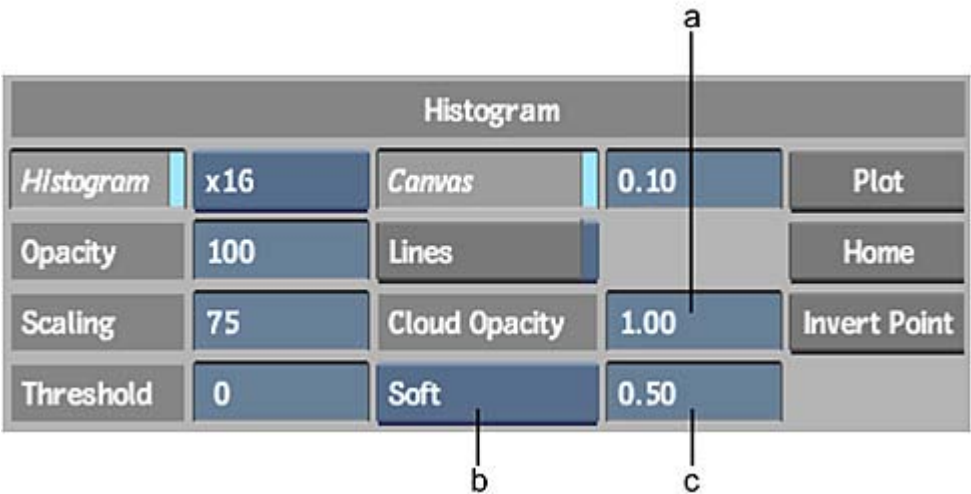

You set the display of each of the three patches individually. In the Patches menu, use the Display boxes to set the display of patches 1, 2 and 3.

Display box Select an option to set the appearance of the current patch.

Select:	To display:
Box	The patch as a wireframe box.
Surface	The convex hull of the patch.
Box&Surf	Both the wireframe box and convex hull of the patch.
Cloud	The patch as a semi-transparent grey box. You can set the transparency of the box using the Cloud Opacity field in the Preferences menu. See Setting the Cloud Opacity (page 824).
None	No patch. When a patch is not displayed, it still has an effect on the image.

Setting the Cloud Opacity

You can control the opacity of the Cloud setting of ellipsoids and patches as they appear in the RGB viewer using the Cloud Opacity fields in the Preferences menu.

(a) Overall Opacity field (b) Key Element box (c) Individual Opacity field

You can adjust the opacity for all key elements or for individual key elements:

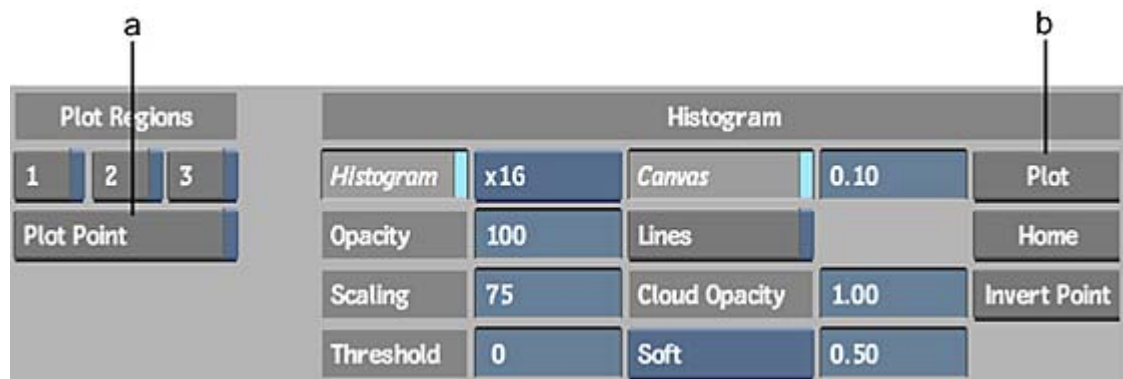

- To set the cloud opacity for all ellipses and patches, use the Overall Opacity field.
- To set the cloud opacity for an individual key element, select the element from the Key Element box, then set the opacity in the Individual Opacity field.

Displaying Plotted Points and Regions

When you plot colour values and ranges of colour values in the key image, you can display or hide the plotted points and regions in the RGB viewer.

To show or hide plotted points:

- 1 Enable or disable the Plot Point button in the Preferences menu.

(a) Plot Point button (b) Plot button

NOTE When you plot a colour value, the Plot Point button is automatically enabled to display the colour value in the viewer.

To show or hide Plot Regions 1, 2, or 3:

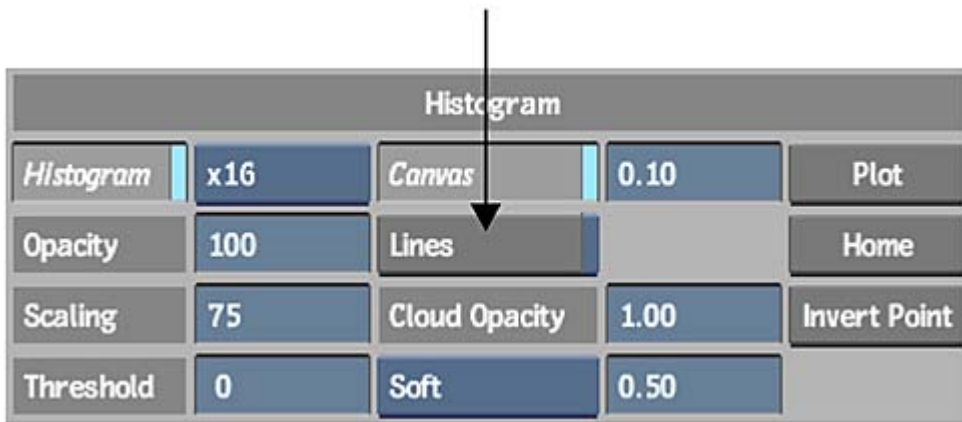

- 1 Enable or disable the corresponding buttons in the Preferences menu.

Selecting Key Elements in the RGB Viewer

As you translate, scale, and rotate key elements in the RGB viewer, you must select them individually. The 3D Keyer provides two methods for selecting key elements—clicking on them in the viewer or using the Picking box. The Picking box enables precise selection especially when tolerance, softness, and patch elements overlap each other in the RGB viewer.

The Preferences menu contains the Lines button. Use this button to display lines around key elements when they are selected in the viewer. This can make it easier to identify the selected key element.

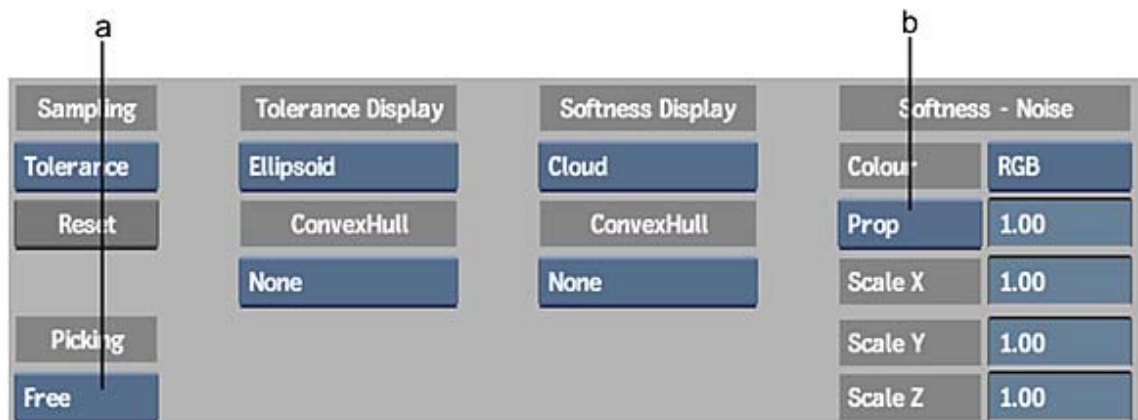

Clicking Key Elements

When you click key elements in the RGB viewer, a directional arrow appears through the selected element. The arrow points in a particular direction according to where you click on the element. See [Controlling Elements with the Directional Arrow](#) (page 828).

The Picking box must be set to Free to select an element by clicking it. Also, the Softness Scaling must be set to Prop not Minimize Noise (Minimize Noise selects softness and controls the arrow direction).

To select key elements by clicking:

- 1 In the Key menu, select Free from the Picking box and make sure that Prop is selected in the Softness Scaling box.

(a) Softness Scaling box (b) Picking box

- 2 Select a key element in the RGB viewer by clicking it.

A directional arrow appears through the selected key element and, if the Lines button is enabled, a green wireframe box appears around the selected key element.

- 3 At this point, you are ready to proceed with modifying the selected key element. See [Translating, Scaling, and Rotating Key Elements](#) (page 832) and [Reshaping the Convex Hull](#) (page 834).

If you are unable to select the element, the element may be behind or inside another element. You can hide the element that is in the way by setting its display to None. See [Changing the Display of Key Elements](#) (page 822). Alternatively, use the Picking box to select the element, as described in the next procedure.

Using the Picking Box

When an element is selected with the Picking box, you cannot select other elements in the viewer by clicking on them. This helps prevent other key elements from being selected by accident while you work with a particular key element.

The Picking box is also useful because it allows you to select a key element without changing its current arrow position. For example, if you accidentally click elsewhere in the viewer and lose the selection, and you want to re-select the element without changing the arrow position, use the Picking box.

NOTE When you use the Picking box to select a key element that has not been previously selected, the arrow is not displayed. You must actually click the element to set the arrow direction.

To select key elements using the Picking box:

- 1 In the Key menu, verify that the Softness Scaling is set to Prop (Minimize Noise forces the softness to be selected).
- 2 Select the key element from the Picking box.

If lines are displayed in the viewer, a selected ellipsoid has a green wireframe box around it and patch boxes change from white to green. If the element's arrow direction has been set, the arrow is displayed.

- 3 To display the element's arrow and set its direction, click the element.
At this point, you are ready to proceed with adjusting the range of the selected key element.

Controlling Elements with the Directional Arrow

Each key element (tolerance, softness, and patches) has a directional arrow that passes through its centre point. Use this arrow to indicate the direction in which you want to perform a particular action, such as scaling or translating the element.

- To display an element's arrow, select the element by clicking on it.
- To set the arrow direction manually, click inside the key element anywhere between its centre and the area towards which you want the arrow to point.

(a) Click in the element to set the arrow direction.

NOTE You can only click on a part of the element's surface that is visible. If necessary, rotate the RGB viewer so that the correct area of the surface is visible.

- To point the arrow towards a plotted point, simply select the element (either by clicking on it or using the Picking box) before plotting. The arrow will automatically point towards the plotted point.
- To reverse the direction of the arrow, click the Reverse Point button in the Key menu.

NOTE When Minimize Noise is enabled, this tool controls the arrow direction. See [Removing Noise from Softened Areas](#) (page 811).

Plotting Colour Values

You can plot pixels in the key image and view the location of the pixel colour value in the RGB viewer. You can plot a single colour value or a range of colour values. These plotted areas do not affect the key at all—they simply identify colour values in the viewer.

You can plot a colour value to view its location in relation to key elements in the viewer. Additionally, you can employ a number of techniques to modify a key element in relation to a plotted colour value or range of values. For example, you could plot a colour value corresponding to an unwanted grey area in the foreground subject, and then translate or scale the softness ellipsoid such that the colour value is outside the ellipsoid.

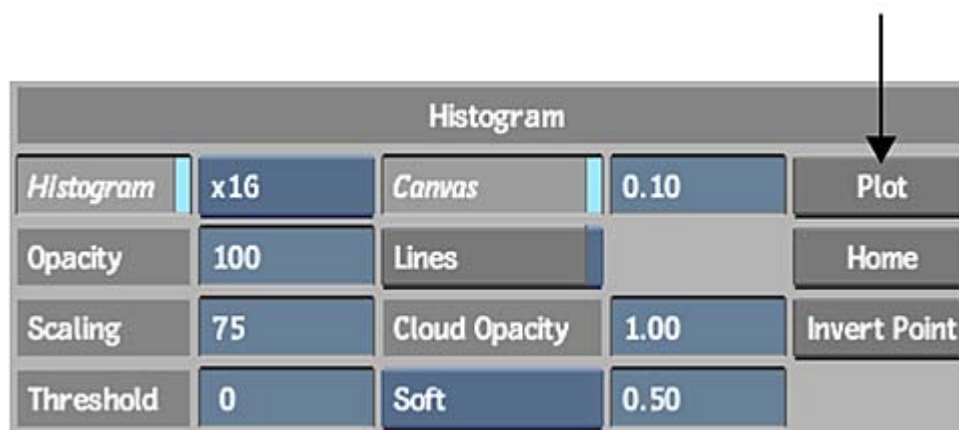

Plotting Single Colour Values

Plotting a pixel in the key image sets the exact location of the colour value in the RGB viewer. The colour value is identified by a small, white wireframe cube in the viewer. As an alternative, you can use the Plot tool to select a colour value directly in the viewer by clicking on a 3D histogram cube.

If a key element in the viewer is selected before you plot the colour value, the element's directional arrow moves to point towards that colour. Plotting pixels in this way allows you to quickly refine the matte by translating or scaling a key element with respect to the plotted colour.

To plot a pixel on the key image:

- 1 In the RGB viewer, select the key element that you want to modify in relation to a plotted colour value. For example, click a patch key element.
If you have problems selecting the element, see [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 If needed, zoom in on the key image so that you can select a pixel more easily.
- 3 Click Plot.

Plot is enabled.

- 4 Click a pixel in the key image. You can also drag the cursor in the image, then release the cursor when the colour picker is over the desired pixel.
In the RGB viewer, the colour value of the selected pixel is plotted and the arrow of the selected key element moves to point towards the plotted colour value.

If needed, rotate the viewer by pressing **Ctrl** and dragging it to get a better view of the key element with respect to the plotted value.

- 5 Proceed with modifying the selected key element. Using the keyboard shortcuts, you can move the selected key element to refine the key.

Press:	To:
V-click	Sample pixels where you click in the image. The arrow is repositioned in the RGB viewer. Drag left or right to scale along this axis.
6 and drag key element	Move the selected key element in the direction of the arrow.
7 and drag key element	Rotate the selected key element in any direction around its centre point.
8 and drag key element	Scale the selected key element proportionally from its centre. Drag left to scale down and right to scale up.
9 and drag key element	Scale the selected key element in the direction of the arrow (non-proportionally) from its centre. Drag left to scale down and right to scale up.
0 and drag key element	Scale the selected key element in the direction of the arrow (non-proportionally), starting from the point on the key element's surface where the back of the arrow remains anchored in place.

As you move the key element away from the plotted pixel, you can see the effect on the key image or the matte.

To select a colour value in the RGB viewer:

- 1 In the RGB viewer, select the key element that you want to modify in relation to a plotted colour value. For example, click a patch key element.
If you have problems selecting the element, see [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 Press **H** to display the 3D histogram.
- 3 If needed, zoom in on the viewer or rotate it so that you can select a histogram cube more easily.
- 4 Click Plot.

Plot mode is activated and the cursor changes to a colour picker.

- 5 Select a cube in the histogram of the RGB viewer. If needed, drag the colour picker around the viewer until it is pointing to the correct colour value.
The selected cube is surrounded by a white wireframe box and the direction of the key element arrow moves toward the selected cube.

Plotting a Range of Colour Values

When you plot a range of colour values in the image, the resulting plotted region in the RGB viewer appears as a 3D convex hull. You can plot up to three colour ranges in the image. The plotted regions do not in themselves affect the key image in any way.

A plotted region allows you to compare the intersection of a key element with a particular colour range in the image, providing you with yet another alternative for adding precision to your key.

For example, use this tool to plot a colour range that you do not want to be softened. Using the plotting region as the reference, you translate and scale the softness ellipsoid away from the plotted region to ensure the softness precision of the key. Plotted regions also help you to determine whether or not to use a garbage mask. If a colour that you want to soften is the exact colour that you want key out, then you should apply a garbage mask.

To plot a region:

- 1 In the Preferences menu, enable the Plot Regions 1 button.
The display of Plot region 1 is enabled.
- 2 In the Sampling box, select Plot1.

- 3 In the key image, sample one or more pixels using the same methods that you use for sampling tolerance or softness by dragging in the image.
A 3D convex hull appears in the RGB viewer.

(a) Each vertex contributes to the convex hull that represents the plotted region.

- 4 Continue sampling pixels in the key image until you are finished plotting the region.

Plotting Several Regions You can plot a second and third region, and compare the positions of the convex hulls. To plot a second region, use the procedure described above, selecting Plot 2 from the Sampling box and enabling the Plot Regions 2 button.

For example, sample one plot region in an area of the matte containing unwanted grey areas, and another plot region where the grey area is intentional. You can then observe where the colours of the two regions are the same (where the plotted regions intersect), and adjust the softness accordingly.

To:	Do this:
Remove the grey areas from the foreground subject.	Move the softness key element away from the plotted region intersection.
Prevent the matte from becoming over softened or transparent.	Use a patch.
Keep part of the key that has the exact colour as the area being softened.	Use a garbage mask.

Translating, Scaling, and Rotating Key Elements

You can fine-tune the key by translating, scaling, or rotating the tolerance ellipsoid, softness ellipsoid, and patches in the RGB viewer. For example, scale the softness ellipsoid in a particular direction to increase the softness. You use the same methods for all three key element types.

To translate or scale an element in a particular direction, you use its arrow to specify the direction. When scaling an element along the axis of the arrow, you have the option of scaling it equally in both directions from its centre, or scaling it only in the forward direction of the arrow. You can also scale an element proportionally in all directions (X, Y and Z directions).

Before performing the following operations, set up the RGB viewer to best display the elements you are working with. Zoom in on the element, decide if you want to show the histogram, and hide elements that are in the way. See [Changing the Display of Key Elements](#) (page 822).

TIP Display the 3D histogram as you make modifications to see the areas of colour that you are working in. Try reducing the size and opacity of histogram cubes to see more clearly. See [Setting the 3D Histogram Display](#) (page 820).

To modify the tolerance or softness using these techniques, the ellipsoid must be displayed. The Tolerance Display or Softness Display must be set to Ellipsoid, Wireframe, or Cloud. Likewise, when reshaping patches, the patch box must be displayed. The box is displayed when the Display is set to Cloud, Box, or Box&Surf.

See [More Keying Techniques](#) (page 835) to learn ways to apply these techniques in specific situations.

To translate a key element:

- 1 Select the element. See [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 Identify the direction in which you want to translate the element and set the arrow in this direction. You can do this manually. See [Controlling Elements with the Directional Arrow](#) (page 828).
- 3 Alternatively, you can also plot a pixel on the image or a histogram cube (see [Plotting Single Colour Values](#) (page 829)). When you plot a pixel on the image or a histogram cube, the arrow of the selected key element automatically points towards the plotted pixel.
- 4 Press 6 and drag the cursor in the RGB viewer. Drag to the right to translate the element forward along the arrow axis, or to the left to translate it backward.

To rotate a key element:

- 1 Select the element. See [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 Press 7 and drag the cursor in the key element.
The key element rotates in any direction around its centre point.

To scale a key element proportionally:

- 1 Select the element. See [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 Press 8 on the keyboard and drag in the RGB viewer. Drag to the right to increase its size, or to the left to make it smaller.

To scale a key element from its centre:

- 1 Select the element. See [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 Set the arrow in the desired direction. You can do this manually. See [Controlling Elements with the Directional Arrow](#) (page 828).
You can also set the arrow by plotting a point on either the image or a histogram cube. When you plot a point on the image or a histogram cube, the arrow of the selected key element automatically points towards the plotted pixel. See [More Keying Techniques](#) (page 835).
- 3 Press 9 and drag the cursor in the RGB viewer. Drag to the right to scale it larger along the axis of the arrow, and to the left to scale it smaller.
The element is scaled equally in the forward and backward directions of the arrow.

To scale a key element in one arrow direction:

- 1 Select the element. See [Selecting Key Elements in the RGB Viewer](#) (page 825).
- 2 Set the arrow in the desired direction. You can do this manually. See [Controlling Elements with the Directional Arrow](#) (page 828).
- 3 You can also set the arrow by plotting a point on either the image or a histogram cube. When you plot a point on the image or a histogram cube, the arrow of the selected key element automatically points towards the plotted pixel. See [More Keying Techniques](#) (page 835).

- 4 Press **0** and drag the cursor in the RGB viewer. Drag to the right to scale it larger in the forward direction of the arrow, or to the left to scale it smaller towards the centre of the element.
The element is scaled in the forward direction of the arrow only.

Reshaping the Convex Hull

You can exclude or add specific ranges of colour to a sample by modifying the shape of the convex hull of the softness ellipsoid, tolerance ellipsoid, and patches. You do this by manipulating the vertices on the hull. The ellipsoid or patch box changes shape according to the new shape of the convex hull.

This can be an accurate way of modifying the sampled ranges since you can see the area of RGB colour space in which you are working and because you can plot specific parts of the image and add them to the hull. Also, scaling the ellipsoid using one vertex of the convex hull provides a more precise (localized) result than scaling using the arrow alone (using **0**).

To change the shape of the convex hull, you can add and move vertices, or delete vertices from the convex hull entirely.

Before performing the following operations, set up the RGB viewer to best display the elements you are working with. Zoom in on the element, decide if you want to show the histogram, and hide elements that are in the way.

To reshape the convex hull of the tolerance or softness, the ellipsoid must be displayed. It must be set to Ellipsoid, Wireframe, or Cloud. Likewise, when reshaping patches, the patch box must be displayed. The box is displayed when the Display is set to Cloud, Box, or Box&Surf.

It is best to show the convex hull. Although it is not necessary to perform the operation—unless you are deleting vertices, you can see what you are doing more clearly. See previous sections in this chapter, such as [Changing the Display of Key Elements](#) (page 822).

To add vertices to the hull and move them:

- 1 Select the key element by clicking it.
- 2 Position the arrow of the selected element in the direction in which you want the ellipsoid or patch to grow or shrink. For example, point the arrow towards colours you want to include in your sample. Alternatively, plot a point to position the arrow. See [Controlling Elements with the Directional Arrow](#) (page 828).
- 3 Press and hold **v** on the keyboard and click anywhere in the RGB viewer.
A vertex is added to the hull at the intersection of the arrow and the edge of the ellipsoid or patch.

(a) Vertex is added to the hull

NOTE When using ∇ in the RGB viewer, you can scale any convex hull (tolerance, softness or patches). If you use ∇ in the image window, it will apply to softness only.

- 4 To add colours to the sample, drag the cursor to the right. This moves the vertex in the forward direction of the arrow.

To remove colours from the sample, drag the cursor to the left. This moves the vertex backward towards the centre of the element.

When you are satisfied with the result in the image window, release the cursor.

The hull is reshaped as you move the vertex. If you did not display the convex hull, it is temporarily displayed while you are moving the vertex. The direction of the arrow may change slightly as you move the vertex, but the direction it moves in is always the direction in which the arrow was initially pointing.

NOTE You can release the ∇ key and the cursor, then press them again to scale the same vertex. You retain control over the new vertex until you change the position of the arrow.

To remove a vertex from the convex hull:

- 1 Display the convex hull of the key element, including the vertices. See [Changing the Display of Key Elements](#) (page 822).

NOTE You do not have to select a key element to delete a vertex from its convex hull.

- 2 If necessary, zoom in on the element to distinguish the vertices more clearly.
- 3 Press and hold the - sign on the keypad (not the one on the keyboard) and click on the vertex that you want to remove.

See [Techniques for Adjusting Softness](#) (page 835).

More Keying Techniques

In this section, learn how to adjust the key using various methods to manipulate the key elements (tolerance, softness, and patches) in the RGB viewer, as well as the Softness Scaling controls in the Key menu.

It is recommended to read [Creating a Precise Key in the 3D Keyer](#) (page 805) and [Mastering the RGB Viewer](#) (page 819) before proceeding.

Techniques for Adjusting Softness

This section includes three additional methods for adjusting the softness of the key.

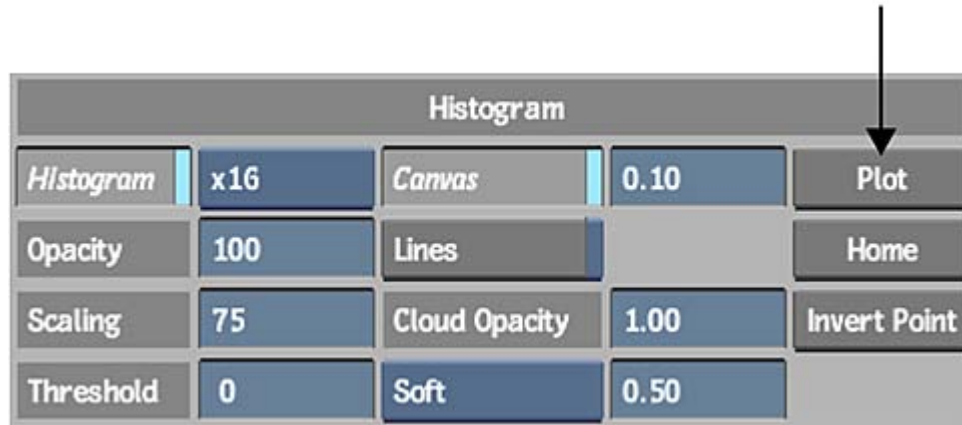

Scaling the Softness Ellipsoid to Remove Grey Areas

Increasing the softness may create unwanted grey areas in the foreground subject. There are several ways to remove these grey areas. One method is to plot a pixel in a grey area, then translate, scale, or rotate the softness ellipsoid such that the plotted region is no longer in the ellipsoid. In effect, you will no longer be softening the plotted region.

If you translate, rotate, or proportionally scale the softness ellipsoid, all areas of the ellipsoid are affected to a degree. By contrast, when you use vertex scaling, you can affect a more localized area of the ellipsoid, leaving the rest of the ellipsoid unchanged. Vertex scaling is therefore often the most accurate method to use.

To scale the softness ellipsoid:

- 1 Show the canvas (press C) and hide the histogram (press H).
- 2 Use the Soft Display box to change the display of the softness ellipsoid to Cloud.
- 3 Select the softness ellipsoid in the RGB viewer by clicking on it or selecting Softness from the Picking box.
- 4 From the View box, select Keyer 3D Result to see the matte.
- 5 Zoom in to see the grey pixels up close.
- 6 Click Pref.
- 7 In the Preferences menu, click Plot.

- 8 Plot a grey pixel in the foreground subject by clicking it.
The colour value of the pixel you clicked is plotted in the RGB viewer. The softness ellipsoid arrow passes through the plotted point.
- 9 To view the exact location of the plotted colour value in relation to the softness ellipsoid, rotate and scale the viewer.
The plotted point inside the softened region is represented by the softness ellipsoid.
- 10 Press V, click in the viewer and drag the cursor to the left to scale the ellipsoid down along the axis of the arrow. Watch the image update interactively. As soon as the grey area in the subject disappears, release the cursor to stop scaling the ellipsoid.
NOTE If you are not satisfied with the result, click Undo to return the ellipsoid to its previous shape, then scale again.
- 11 If some grey areas remain, plot those areas and repeat the procedure.

Scaling the Softness Ellipsoid to Add to Softness

You can also use the technique described in the previous section to increase the softness at the edges of the key. Start by identifying the region where you want to introduce more softness, and then plot a pixel in that area. You see the colour value in the viewer. Press the V keyboard shortcut, then either enlarge or decrease the size of the softness ellipsoid minimally by dragging the cursor to the right or left. Include the colours you want and exclude the rest.

TIP Display the 3D histogram to help you figure out the direction in which you want to scale the tolerance or softness.

Using the Softness X, Y, and Z Fields

You can also adjust the softness in the key by changing the values in the Softness Scaling X, Y and Z fields. Drag the cursor over the fields, watching the result in the image window. You can often get a good result just by experimenting.

Softness - Noise	
Colour	RGB
Prop	1.00
Scale X	1.00
Scale Y	1.00
Scale Z	1.00

NOTE The Sampling box does not have to be set to Softness to use these fields.

Adjusting Transparencies with Patches

When keying transparencies, the transparency is sometimes either not visible enough or too prominent in the final composite. You can use patches to lighten or darken transparencies.

To adjust a transparency using a patch:

- 1 Use the basic keying technique to get the transparency as soft as possible.
- 2 Sample a patch in the transparency. See [Adding a Patch](#) (page 815).
- 3 View the final composite by displaying the CurResult view.
- 4 Do one of the following:
 - To lighten the transparency, set the Colour of the patch to 0 and the Opacity to 100, then lower the Opacity.
 - To darken the transparency, set the Colour of the patch to 100 and the Opacity to 0, then raise the Opacity.

Setting 3D Keyer Preferences

The following section explains the available preferences for working in the 3D Keyer.

Auto Key

Enable this button to set keyframes to animate the key. See [Animating Key Elements](#) (page 817) for details.

Regen

When you sample (softness, tolerance, and so on) using the colour picker or the numeric fields, you have the option of having the image update interactively as you move the cursor, or having the image update only when you release the cursor.

It is useful to update the image only after sampling if interaction during sampling is slow. This can happen if you are working with high resolution images, or if you are sampling while viewing a context from further along the pipeline. This can also occur in the current result view (displayed as <Currently Selected Node> Result, in the View box), where a large amount of processing is required to display the result.

To update the image interactively:

- 1 Enable Regen.

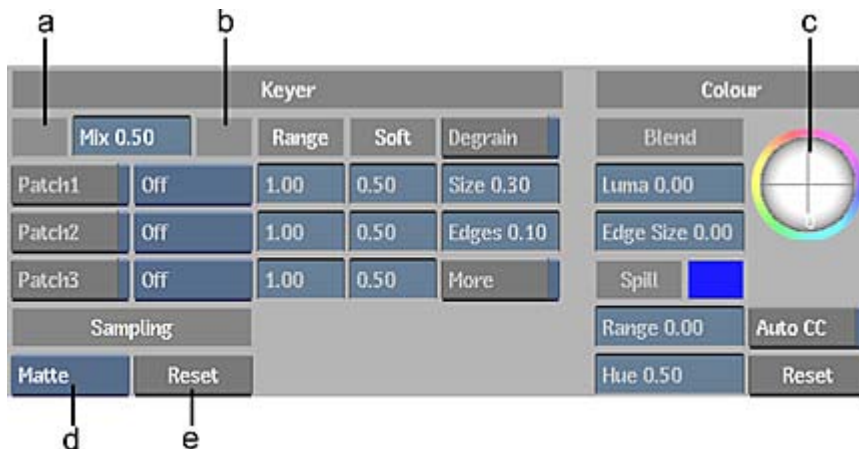

To update the image after completing the sample:

- 1 Disable Regen.

Creating and Refining a Key in the Master Keyer

Use the Master Keyer method to create a complete key—extract colours to generate a matte and then refine the result—using only the Master Keyer menu. The Master Keyer uses an algorithm that quickly isolates a colour and is very good for chroma keying.

With the Master Keyer, you can refine the key by gesturally modifying the matte, removing colour spill, blending edges, applying patches, and removing grain.

(a) Primary Sample colour pot (b) Secondary Sample colour pot (c) Edge Balance trackball (d) Sampling box (e) Reset button

The following procedure is a recommended workflow for keying a clip with the Master Keyer. You may not need to complete all the procedures. You may also revisit procedures as you develop the key.

To create a complete key:

- 1 Generate and refine a matte using the Matte controls.
- 2 Remove any colour spill.
- 3 Improve the blend between the front and back clips.
- 4 If the image is grainy, apply the Degrain algorithm.

- 5 Create any necessary patches to remove unwanted grey areas from the matte.

Generating Mattes

Use the Matte controls in the Master Keyer to generate and refine a matte for your chroma key.

To generate and refine a matte:

- 1 In the Master Keyer menu, select Matte from the Sampling box.

- 2 Set the view to Result or Matte view.
- 3 Click the Primary Sample colour pot and then sample the image. Click the image to sample a single pixel.
The Auto CC button is enabled and the initial pure colour value for the key is set.
- 4 Click the Secondary Sample colour pot and then sample the image. Sample an area where you do not want any softness in the matte.
- 5 Drag in the Mix field to adjust the mix between the primary and secondary sample. Drag right to include more of the secondary sample or left to include less.

TIP You can adjust the mix at any time as you develop the key.

- 6 Gesturally refine the matte. In the image window, click an area of the matte that you want to refine—only those parameters that pertain to the area you click appear. Parameters are displayed in order of importance, from top to bottom (those that are brightest and at the top have the greatest effect on the image). You can then modify a parameter by dragging its highlighted slider.

- To add softness, drag a slider to the right.
- To remove softness, drag a slider to the left.

The red indicator shows the original value and the yellow indicator shows the current value.

- 7 To modify more than one parameter, move the mouse between the parameters to highlight a parameter, or drag the pen vertically. When you highlight the parameter you want to adjust, drag the slider.

TIP If you do not like the result, you can click Undo to reset parameters directly after you complete the operation. There is only one level of undo in the Keyer menu.

- 8 When you are finished modifying the displayed parameters, click another area of the image without highlighting a parameter to hide them. Alternatively, you can press any key, such as spacebar or Esc. The parameters are no longer displayed.
- 9 Repeat steps 6 to 8 in other parts of the matte to further refine it. Only the parameters that apply to the problem area will appear.

- 10 To scroll through the image and display the pertinent parameters, Alt-drag the image without clicking it. The parameters update as you drag. You can then modify the displayed parameters by clicking the image and dragging the highlighted slider.

NOTE To reset matte parameters, click the Reset button, next to the sampling box. All matte parameters are reset, except the Mix field and the key colour.

After you have generated your matte, [perform basic colour spill removal](#) (page 840).

Basic Colour Spill Removal

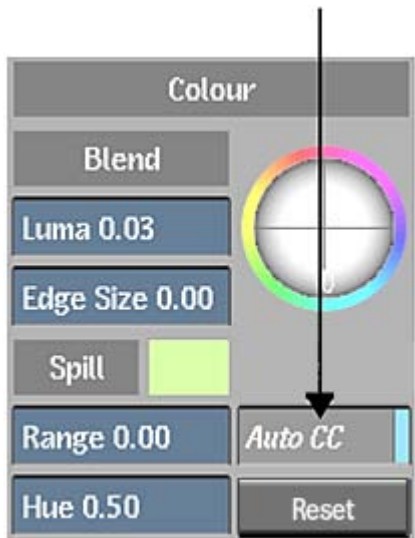

After you [create and refine your matte](#) (page 839) for the key, you can perform basic colour spill removal by gesturally modifying the Spill parameters.

To gesturally remove colour spill:

- 1 In the Master Keyer menu, select Spill from the Sampling box.

- 2 Set the view to Result view.
3 Enable Auto CC to apply the Spill settings to the front clip.

- 4 Remove any colour spill. Click anywhere in the image window, and then modify the parameters that appear by dragging the sliders—you do not need to click a specific area.

Drag:	To:
Range	Set the range for the removal of colour spill along the edges of the key. Drag right to soften the edge and remove colour spill further into the key. Drag left to harden, or create a thinner, edge.

Drag:	To:
Hue	Modify and suppress colours that are adjacent to the primary sample.

The red indicator shows the original value and the yellow indicator shows the current value. The values also appear in the Spill fields. The original values should be good, so make small adjustments only.

- 5 To modify both parameters, move the mouse between them to highlight a parameter, or drag the pen vertically. When you highlight the parameter you want to adjust, drag the slider.

If you do not like the result, you can click Undo to reset parameters directly after you complete an operation. There is only one level of undo in the Modular Keyer.

- 6 When you are finished modifying the displayed parameters, click another area of the image without highlighting a parameter to hide them. Alternatively, you can press any key, such as spacebar or Esc. The parameters are no longer displayed.

NOTE To reset Spill parameters, click the Reset button, next to the sampling box.

If you are satisfied with your colour spill removal, move on to [blending your front and back clips](#) (page 842).

If you want to perform additional colour spill suppressions, see [Advanced Colour Spill Removal](#) (page 841).

Advanced Colour Spill Removal

If you want to suppress colour spill beyond what was shown in [Basic Colour Spill Removal](#) (page 840), you can use the Spill controls in the Colour menu to eliminate and disguise the colour spill in the Master Keyer. You can sample the colour you want to remove, and then adjust the Range and Hue fields to suppress the selected colour and shift its adjacent colours.

(a) Spill Colour pot **(b)** Auto CC button in Range menu **(c)** Spill fields

When you sample an image to generate a key from a Range menu, the sampled colour in the Spill colour pot is also updated. However, the inverse is not true—if you sample a colour using the Spill colour pot, sampled colours used to generate keys are not updated. You can therefore sample colour spill without affecting the original sample.

NOTE To apply these settings to the key, the Auto CC button must be enabled.

To remove colour spill from a key:

- 1 Click the Result node so that you can see the changes in the right side viewer. If you do not see the result, see [Setting Up Viewports for Keying](#) (page 804).
- 2 Enable Auto CC in the Colour menu to apply the Spill settings to the front clip.
- 3 The Spill colour pot displays the colour that will be suppressed in the clip. By default, the original colour extracted from the key-in clip is displayed. In many cases, you can use this colour because the colour spill is the same colour as the original colour. However, if the colour spill is not the same, change the colour sample. Click the colour pot, use the colour picker to sample the colour spill in the image window, and then click the colour pot again.

NOTE When you select the colour you want to key from the Master Keyer menu, the colour that appears in the Spill colour pot is automatically updated to match the key colour. However, the inverse is not true—when you sample a colour from the Spill colour pot, the sampled colour used to generate a key is not updated.

- 4 Drag in the Spill fields to remove the colour spill.

Drag:	To:
Range	Suppress the primary sample colour where there is colour spill (along the edges of the key).
Hue	Modify colours that are adjacent to the primary sample and further remove colour spill.

NOTE You can reset the Spill parameters, Blend parameters, and the Edge Balance trackball by clicking Reset, located to the right of the Hue field.

When you are satisfied with your colour spill removal, move on to [blending your front and back clips](#) (page 842).

Blending Front and Back Clips

After you [remove colour spill](#) (page 840), you can use the Blend parameters in the Master Keyer to gesturally modify the luminance at the edge of the key so that it blends with the luminance in the background clip. For example, when the front clip is darker than the back clip, you can use the Master Keyer's Blend parameters to lighten the edge of the key.

When you blend front and back clips, you can add a cast to the edge of the key and further merge the clips.

To blend the front and back clips:

- 1 In the Master Keyer menu, select Blend from the Sampling box.

- 2 Set the view to Result view.

- 3 Enable Auto CC to apply the Spill settings to the front clip.

- 4 Blend the front and back clip. Click anywhere in the image window, and then modify the parameters that appear by dragging the sliders—you do not need to click a specific area.

Drag:	To:
Luma	Darken or lighten the edge of the key. Luma only affects the luma of the edge.
Edge Size	Set the range for the blend. Drag right to soften the edge and blend further into the key. Drag left to harden, or create a thinner, edge. Edge Size affects both the Luma field and the Edge Balance trackball.

TIP To drag faster, apply more pressure with the pen, or hold Alt+Spacebar while you drag.

The red indicator shows the original value and the yellow indicator shows the current value. The values also appear in the Blend fields.

- 5 To modify both parameters, move the mouse between them to highlight a parameter, or drag the pen vertically. When you highlight the parameter you want to adjust, drag the slider.

TIP If you do not like the result, you can click Undo to reset parameters.

- When you are finished modifying the displayed parameters, click another area of the image without highlighting a parameter to hide them. Alternatively, you can press any key, such as `spacebar` or `Esc`. The parameters are no longer displayed.
- To add a cast to the edge of the key and improve the overall look by matching the edge with a colour cast in the back clip, drag the Edge Balance trackball toward the colour you want to add. The trackball only affects the chroma of the edge.

NOTE To reset Blend parameters, click the Reset button, next to the sampling box. All blend parameters are reset, except the Edge Balance trackball. Ctrl-click the Edge Balance trackball to reset it.

After you have set your blend parameters for the front and back clip, [remove grain from your clips](#) (page 844).

Removing Grain

After you have [set your blend parameters for the front and back clips](#) (page 842), you may want to remove grain from your clips. Graininess can make it difficult to pull a clean and effective key. Use the Degrain tools in the Master Keyer to remove grain from clips.

NOTE Degrain parameters are animatable. Degrain samples are also animatable and appear in the Channel Editor as the Degrain_Matrix channel, located in the Key_Degrain folder. See [Animating Keyframes](#) (page 1491).

To remove grain:

- In the Master Keyer menu, select Degrain from the Sampling box.

- Set the view to Result view.

- 3 Sample a grainy area of the image. To sample a single pixel, click the image. To sample an area of the image, Ctrl-drag a selection box.
The Degrain button is enabled and the algorithm is applied to the image—grain is removed from the image.
- NOTE** The Degrain button is either enabled or disabled for the entire clip—you cannot turn it on and off for different frames in the clip.
- 4 Drag in the Degrain fields to modify the grain size and restore edge sharpness.

(a) Size field (b) Edges field

Drag:	To:
Size	Estimate the size of the grain in the image.
Edges	De-sharpen the edge of the image. By default, Degrain sharpens the edges. Use the Edges field to restore the natural look of the edges in the image.

- 5 If you are not satisfied with the result, you can start over with a new sample, and then adjust the Degrain fields. To resample an area of the image, Ctrl+Alt-drag the image.
The sample is outlined in green, indicating that you are resampling the image.
- NOTE** You can also reset Degrain parameters. To reset Degrain parameters, click the Reset button, next to the sampling box.
- 6 If resampling the image and adjusting the Degrain fields does not sufficiently remove grain, enable More to increase the overall effect of Degrain.
- NOTE** The More button is either enabled or disabled for the entire clip—you cannot turn it on and off for different frames in the clip. When you enable More, processing speed slows down.

After you have removed grain from your clips, you may still have to [remove unwanted greys](#) (page 845).

Removing Unwanted Greys

If you have unwanted grey areas in the matte, you can use up to three patches in the Master Keyer to isolate a range of colours to be included in, or excluded from, the key.

NOTE Patch parameters are animatable. Patch samples are also animatable and appear in the Channel Editor as a Matrix channel, located in the Patch folder.

There are three types of patches in the Master Keyer, that are applied to different areas of the image.

Selected patch:	Is applied to:
Black	Areas of the image to be included in the black part of the matte.
White	Areas of the image to be included in the white part of the matte.
Edge Analysis	Areas of the image that are along the edge of the key. Edge Analysis is useful when there is a specific edge you want to erode but cannot do so with the Matte parameters. You can then increase or decrease the softness of this patch using the Soft field.

To remove unwanted greys:

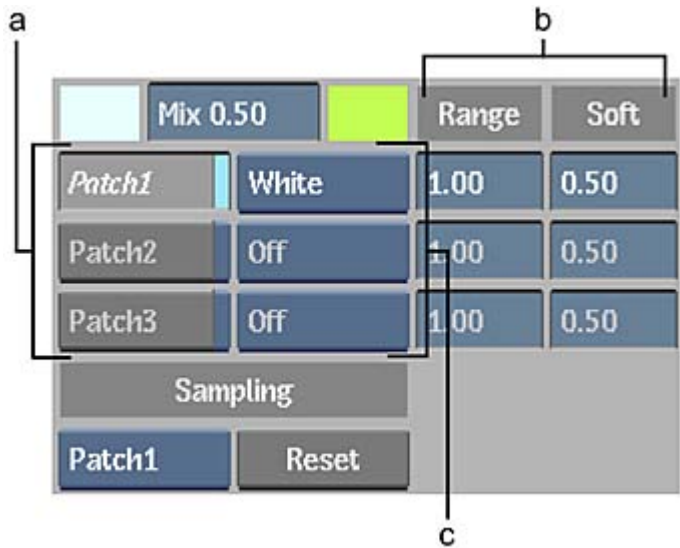

- 1 In the Master Keyer menu, select Patch1, Patch2, or Patch3 from the Sampling box.

- 2 Set the view to Matte view or Result view.
- 3 Sample the image where you want to apply the patch. To sample a single pixel, click the image. To sample an area of the image, Ctrl-drag a selection box.

When you Ctrl-drag to sample, the sample is outlined in red. In the Master Keyer menu, the Patch button is enabled and the appropriate patch appears in the Patch box and is applied to the image.

NOTE A Patch button is either enabled or disabled for the entire clip—you cannot turn it on and off for different frames in the clip.

(a) Patch buttons (b) Patch controls (c) Patch boxes

- 4 To add more colour to the patch, resample the image.
- 5 To use the same patch but start with a new sample, Ctrl+Alt-drag the image.
The sample is outlined in green, indicating that you are resampling the current patch.
- 6 To manually select a patch type, select it from the Patch box.

NOTE If you want to reset the patch so that you can automatically select the patch type, you must disable the patch and set the patch type to Off. You can then resample an area in the image and generate a patch type.

- 7 To improve the patch, use the Patch controls.

Drag:	To:
Range	Increase or decrease the colour range that is included in the patch.
Soft	Soften the edge.

NOTE To reset Patch parameters, click the Reset button, next to the sampling box.

Creating a Key by Extracting a Single Colour with the Channel Keyer

You can extract one of the three primary colours (red, green, or blue), or a custom colour from the key-in clip. This method is useful for clips containing transparencies such as glass or smoke.

Extracting a Primary Colour

Extract one of the three primary colours from the key-in clip when you have a front clip shot in front of a blue, red, or green screen.

To create a key by extracting a primary colour:

- 1 From the Start Mode dropdown list, select Reset to Channel and click Confirm.
The Channel keyer processing pipeline is displayed in the schematic view.
- 2 Double-click the Channel Keyer node.
The Channel controls appear.

(a) Channel Mode box (b) Softness field

- 3 Select one of the primary colour options (Red, Green, Blue) from the Channel Mode box.
- 4 Enable More to enhance the keying effect.
The More option extends the range of the colour to be extracted from the key-in clip.
- 5 Increase or decrease the softness for the key using the Softness field.

The softness value determines how much of the key-in clip is partially transparent in the matte. Softness creates a smoother transition between the front and back clips in the composite clip.

- 6 Click Result to see the result of your key.

Extracting a Custom Colour

Use the Custom colour channel option in the Channel Keyer to select the colour to be extracted from the key-in clip. This option can give good results when keying transparencies, particularly by experimenting with the Softness and Colour Spread values.

To create a key by extracting a custom colour:

- 1 From the Start Mode dropdown list, select Reset to Channel and click Confirm.
The Channel keyer processing pipeline is displayed in the schematic view.
- 2 Double-click the Channel Keyer node.
The Channel controls appear.

(a) Channel Mode box (b) Average Colour pot (c) Softness field (d) Colour Spread field

- 3 Select Custom from the Channel Mode box.
- 4 Click the Average Colour pot.
The cursor changes to a colour picker.
- 5 Click the image to select a single colour, or drag the colour picker across a region to obtain the average of the colours encountered by the colour picker. Try selecting different colours in the background area to get the best result.

TIP To keep shadows, click just outside them. To remove shadows, click inside them.

- 6 Adjust the softness for the key using the Softness field.
Increasing softness raises the level of grey in the matte. Lowering it makes the matte sharper.
- 7 Adjust the colour spread for the key using the Spread field.
Increasing the colour spread value extends the range of colours extracted from the key-in clip.
- 8 Click the Result node so that you can see the changes in the right side viewer. If you do not see the result, see [Setting Up Viewports for Keying](#) (page 804).

NOTE To improve the key at this point, try adjusting it with the histogram in the 2D Histogram node. See [Adjusting the Luminance of the Key](#) (page 852).

Creating a Key by Extracting a Range of Colours with the HLS, YUV, RGB and RGBCMYL Keyers

Another technique for creating a key is to extract a range of colours from the key-in clip. Use this technique for clips where the colour you are extracting contains impurities.

When you build a key by defining a colour range, you can use one of four colour models: RGB, YUV, HLS, or RGBCMYL. Each model interprets the key-in clip differently and gives a slightly different result.

After you choose a colour model, you set a range of colours to become partially transparent in the key-in clip to soften the transition between the front and back clips. This is called the *softness range*. All pixels in the front clip within the softness range become grey in the matte. The key should have the greatest possible softness value.

After setting the softness range, you set a range of colours to be keyed out in the key-in clip. This is called the *tolerance range*. All pixels in the front clip within the tolerance range become black in the matte. The tolerance range must not be too large or the edge of the composite will be too hard and the subject in the front clip will appear to be pasted into the back clip.

About the Different Colour Models

There are four colour models you can use.

HLS

In the HLS Keyer menu, you set the softness and tolerance ranges using the hue, luminance, and saturation channels.

YUV

In the YUV Keyer menu, you set the softness and tolerance ranges using the luma and chroma signals of YUV component video.

RGB

In the RGB Keyer menu, you set the softness and tolerance ranges using the red, green, and blue channels.

RGBCMYL

In the RGBCMYL Keyer menu, you set the softness and tolerance ranges using the red, green, blue, cyan, magenta, yellow, and luminance channels. This colour model provides subpixel resolution.

Selecting a Colour Model Based Component Keyer

To determine which component keyer will give you the best key, try creating a sample matte for each keyer.

To create a sample matte for each keyer:

- 1 From the Start Mode dropdown list, select one of the following: Reset to RGB, Reset to YUV, Reset to HLS, Reset to RGBCMYL.
- 2 Select Key In in the View box to view the key-in clip.
- 3 Double-click the Keyer node in the schematic.

The softness for each model is set automatically to 50, which helps you to quickly gauge the model that will create the best key for your clip.

- 4 At frame 1, click the Average Colour pot.
- 5 Drag the colour picker around the area you want to key out.
The average colour sampled by the colour picker appears in the Average Colour pot. In each channel of the colour model, the channel value of the average colour appears as a white line. All pixels in the key-in clip with the selected colour value are keyed out.
The yellow lines in the colour model channels indicate the limits of the softness range. The pixels in the front clip with colour values at the centre of the range are black (transparent) in the matte. As you move away from the centre, the pixels become more opaque.
- 6 From the View box, select Matte.
- 7 Repeat this procedure to plot the average colour using the other colour models, and then view each resulting matte to determine which model gives the best result. After you decide on a colour model, use the tools described in the next sections to refine your matte.

After you have selected a colour model and set the average colour, [set the softness range](#) (page 850).

Setting the Softness Range

After you [choose a colour model based component keyer and set the average colour](#) (page 849), adjust the softness range. The softness at the edges of the matte increases as you increase the softness range. To set the softness, you can use the colour picker, the numeric fields, or the Master Softness field.

To set the softness using the colour picker:

- 1 Zoom in to see the edges of the matte more clearly.
- 2 Click Softness in the selected colour model menu.
The cursor changes to a colour picker.
- 3 Position the colour picker at the edge of the matte. To increase the softness, click and slowly drag the colour picker toward the centre of the matte. The values within the area you selected are used to adjust the maximum and minimum values for the softness range. The positions of the yellow lines change as you drag the cursor on the image.

(a) Master Softness field (b) Minimum Softness field (c) Maximum Softness field

- 4 To increase or decrease the softness range, click the + or - button beside the Softness button and then click an area of the image.

To set the softness range using the numeric fields:

- 1 Set the minimum value for the softness range using the Minimum Softness field on the left side of the colour bar.
- 2 Set the maximum value for the softness range using the Maximum Softness field on the right side of the colour bar.

NOTE You can also set the softness range by entering a numeric value in the Master Softness field.

TIP As a reference, when setting softness and tolerance ranges, you can display the colour value for any pixel in the key-in clip using the Plot tool. You can then adjust the tolerance or softness range so the pixel falls within one of the ranges. For example, plot pixels at the edges of the matte to check for softness, or plot pixels in the background to check for tolerance.

To plot a pixel's colour values:

- 1 Click Plot.
The cursor changes to a colour picker.
- 2 Select a pixel in the image area.
A red bar appears in each colour gradient showing the colour value of the pixel.

After you have adjusted the softness range, [set the tolerance range](#) (page 851).

Setting the Tolerance Range

After you define the softness range in a colour model based component keyer, you can set the tolerance range to remove the greys outside the key shape. The maximum and minimum tolerance values define the range of colours to be keyed out in the key-in clip.

To set the tolerance range using the colour picker:

- 1 Click Tolerance.
The cursor changes to a colour picker.
- 2 Drag the colour picker around the area of the image that you want to key out.
The colour values that the colour picker samples are used to set the maximum and minimum values for the tolerance range. The white lines define the limits of the tolerance range. All colour values between the white lines are extracted from the key-in clip.

(a) Master Tolerance field (b) Minimum Tolerance field (c) Maximum Tolerance field

- 3 To increase or decrease the tolerance range, click the + or - button beside the Tolerance button.

NOTE An alternative method of setting the tolerance range is to press Ctrl and draw a rectangle in the area of the image you want to key out.

To set the tolerance range using the numeric fields:

- 1 Set the minimum value for the tolerance range using the Minimum Tolerance field on the left side of the colour bar.
- 2 Set the maximum value for the tolerance range using the Maximum Tolerance field on the right side of the colour bar.

NOTE You can also set the tolerance range by entering a numeric value in the Master Tolerance field.

TIP As a reference, when setting softness and tolerance ranges, you can display the colour value for any pixel in the key-in clip using the Plot tool. You can then adjust the tolerance or softness range so the pixel falls within one of the ranges. For example, plot pixels at the edges of the matte to check for softness, or plot pixels in the background to check for tolerance.

To plot a pixel's colour values:

- 1 Click Plot.
The cursor changes to a colour picker.
 - 2 Select a pixel in the image area.
A red bar appears in each colour gradient showing the colour value of the pixel.
-

Creating a Key by Setting the Luminance

You can create a key using only the Luminance channel. The softness and tolerance values are expressed as percentages.

This technique is useful for clips with high contrast or filmed against a black background. You can also use the Luminance channel to adjust a matte that has already been rendered. Load the matte as the key-in clip, and then adjust it in the Luminance menu.

NOTE When you load a matte as the key-in clip and open the Luminance menu with default menu values, the resulting Keyer matte is identical to the original matte.

To create a key by setting the luminance:

- 1 From the Start Mode dropdown list, select Reset to Luminance and click Confirm.
The Luminance Keyer processing pipeline is displayed in the schematic view.
- 2 Double-click the Luminance Keyer node.
The Luminance controls appear.

(a) Master Tolerance field (b) Master Softness field

- 3 Set the softness in the Master Softness field.
- 4 Set the tolerance in the Master Tolerance field.
A value of 100 for the tolerance creates an entirely opaque matte.

Refining Your Key

Adjusting the Luminance of the Key

After creating a key, you can adjust luminance values to fine-tune the result. The 2D Histogram node in the schematic displays the distribution of luminance values within the matte. The horizontal axis of the histogram

represents the range of luminance values in the matte and spans from 0 (black) to 255 (white). The vertical axis shows the number of pixels at each luminance value.

Setting the Range of the Luminance Values

Use the List and Gain fields with the Input Level controls, in the 2D Histogram node in the schematic, to set the range of luminance values in the matte. You can darken black areas of the matte or remove grey from white areas of the matte.

(a) Minimum Input level (b) Maximum Input level

Removing Grey from the Black Areas of the Matte

The Minimum Input level sets the start of the range of luminance values. Pixels with luminance values below the Minimum Input level are mapped to black (0).

You can set the Minimum Input level by dragging the black triangle, or by setting a value in the Minimum Input Level field.

The matte before adjusting the Input levels

The matte after lowering the Minimum Input level

Removing Grey from the White Areas of the Matte

The Maximum Input level sets the end of the range of luminance values. Pixels with luminance values greater than the Maximum Input level are mapped to white (255).

You can set the Maximum Input level by dragging the white triangle, or by setting a value in the Maximum Input Level field.

The matte before adjusting the Input levels

The matte after lowering the Maximum Input level

Remapping Black and White

Use the Output levels in the 2D Histogram node in the schematic to remap the luminance values for black (0) and white (255). You can brighten the dark areas of the matte or darken the white areas.

(a) Minimum Output level (b) Maximum Output level

Brightening the Matte

The Minimum Output level sets the luminance value of all black (0) pixels in the matte. Black pixels in the matte are mapped to the luminance value set by the Minimum Output level.

You can set the Minimum Output level by dragging the black triangle, or by setting the value in the Minimum Output Level field.

The matte before adjusting the Output levels

The matte after lowering the Minimum Output level

Darkening the Matte

The Maximum Output level sets the luminance value of all white (255) pixels in the matte. White pixels in the matte are mapped to the luminance value set by the Maximum Output level.

You can set the Maximum Output level by dragging the white triangle or by setting the value in the Maximum Output Level field.

The matte before adjusting the Output levels

The matte after lowering the Maximum Output level

Boosting the Luminance of the Key Using Gain and Lift

You can remove grey from the key by increasing the gain and lowering the lift values in the 2D Histogram node in the schematic. Increase the gain to eliminate the light greys that may be in the white area of the matte, and decrease the lift to eliminate dark greys in the black area of the matte.

NOTE Adjusting these values increases the contrast and may harden the edges of the matte.

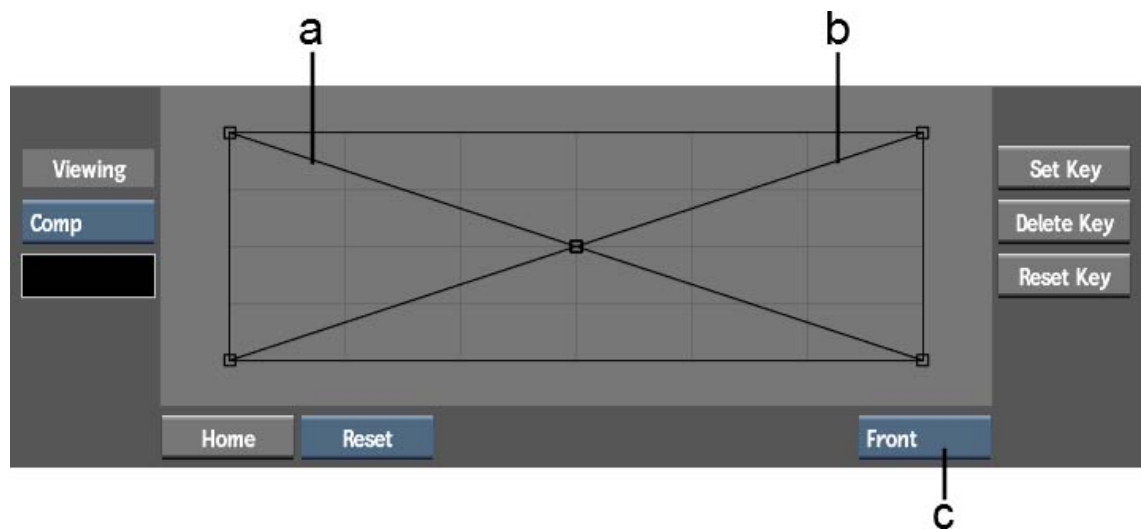

Using the Luminance Curves

When you create a matte for the front clip, the Keyer automatically creates a matte for the back clip to specify which part of the back clip is used for the composite. By default, the back matte is the inverse of the front matte.

You can adjust the luminance of the front matte and back matte separately in the Blending menu in the Result node in the schematic. For example, increase the luminance of the back matte so that more of the back clip shows through at the edges of the key. This creates a better blend at the edges of the key.

To adjust the luminance curve:

- 1 Double-click the Result node in the schematic.
The Luminance curve appears.

(a) Front matte curve (b) Back matte curve (c) Front/Back box

- 2 Use the Viewing box to select the image you want to view as you adjust the curves.

Select:	To view:
Result	The composite clip.
Matte	The front matte. You cannot see changes made to the back matte when this view is selected.
Bmatte	The back matte. You cannot see changes made to the front matte when this view is selected.
Comp	The composite with a coloured background. The default colour is black. To select a different colour, click the colour pot to the right of the Comp button. The colour picker appears.
Key In	The image that was used to pull the key.
Back	The background image that is revealed when the front is keyed.
Front	The image to which you applied the key.

- 3 To adjust the luminance curve for the front matte, select Front from the Front/Back box. To adjust the back matte curve, select Back. Alternatively, click a curve to select it. The selected curve changes to white.

(a) 255 (White) (b) Output (remapping of luminance values) (c) 0 (Black) (d) 0 (Black) (e) Input (current luminance values) (f) 255 (White)

- 4 Click a point to display its tangent handle and drag the handle to adjust the curve. Use other modes in the Tools box to further adjust the curve, adding or deleting points or breaking tangent handles, as needed.

Modifying the Edges of the Key

Use the Shrink, Erode, and Blur controls in the Matte Edge node in the schematic, to enhance the edge of the keyed image.

Use:	To:
Edges	Detect the edges of your matte and fine-tune the edges with tolerance controls. This is useful for cleaning up difficult mattes.
Shrink	Remove pixels from the edge of the matte. This control should not be used when the object in the front clip has soft edges, such as hair.
Erode	Blend the light and dark edges of the matte.
Blur	Apply a softening filter to the edge of the matte. You can select either a Gaussian filter or Box filter.

To access the Edge Matte controls:

- 1 Double-click the Matte Edge node in the schematic.
The Edge Matte controls appear.

To detect the edges of your matte:

- 1 In the Matte Edge menu, enable Edges.
The edges of your matte are detected and displayed in the viewer.
- 2 Fine-tune the edges by modifying the Min and Max fields (tolerance) and the Width field, which determines the width, in number of pixels, of the detected edges.

To shrink the edge of the matte:

- 1 In the Matte Edge menu, enable Shrink.
- 2 Set a value in the Shrink Width field.

This value specifies the width of the border, in number of pixels, that is removed from the edge of the matte.

The matte before enabling the Shrink filter

The matte after setting the shrink width value to 1.00

To erode the edge of the matte:

- 1 In the Edge Matte menu, enable Erode.
- 2 Set a value in the Erode Width field.

This value specifies the width of the matte border, in number of pixels, that will be softened.

The matte before enabling the Erode filter

The matte after setting the erode width value to 1.00

To blur the edge of the matte:

- 1 In the Edge Matte menu, enable Blur.
- 2 Set values in the Blur Width and Height fields.

These values specify the width and height of the Blur filter applied to the edge of the matte.

The matte before enabling the Blur filter

The matte after setting the blur width and height values to 1.00

Adjusting Spill Controls with the Colour Curves Node

After you create a key and key out any trouble areas, some of the background colour may have spilled over at the edge of the key. Colour spill suppression in the component keyers is done through the Colour Curves node. The Colour Curves menu lets you sample the colour you want to suppress and then suppress that colour where necessary, using the suppression curve.

- Adjust the Suppression curve in the Colour Curves node to suppress a selected colour.
- Adjust the Hue Shift curve in the Colour Curves node to perform a hue shift on a selected colour.

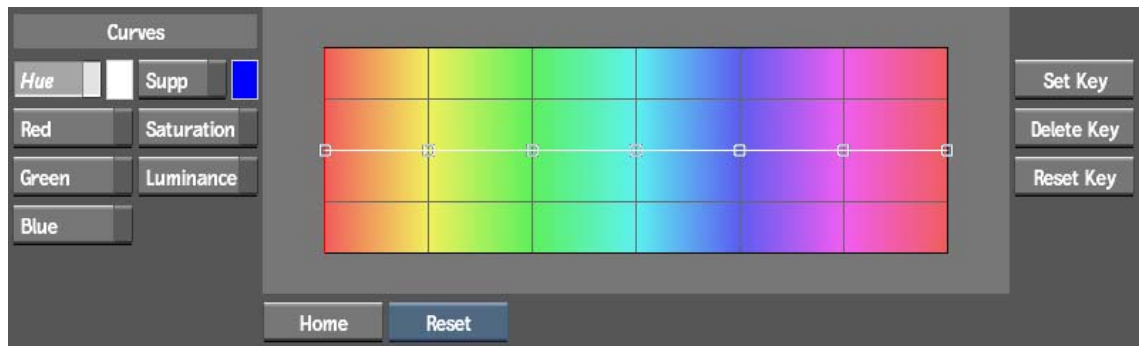

NOTE To remove colour spill in the Master Keyer, see [Basic Colour Spill Removal](#) (page 840) and [Advanced Colour Spill Removal](#) (page 841). Alternatively, you can connect a Colour Curves node between the front clip and the front input of the Master Keyer and follow the procedures below.

Adjusting the Suppression Curve

To suppress colour spill using the suppression curve:

- 1 Set the view to Result, so that you can see the changes as you make them.
- 2 Double-click the Colour Curves node in the schematic.

The Colour menu appears.

The Colour menu displays colour curves over a hue spectrum. When you modify the shape of a curve over a region of the spectrum, only those colours are affected.

- 3 Click Supp to modify the Suppression curve.
- 4 The colour pot next to the Suppress button displays the colour that will be suppressed in the clip when you modify the curve. By default, the blue colour is displayed. To change the colour sample, click the colour pot, use the colour picker to sample the colour spill in the image window, and then click the colour pot again.
- 5 Click the colour pot next to the Supp button.
The cursor turns into a colour picker.
- 6 Select a pixel within the spill.
A red vertical bar appears in the hue spectrum identifying the colour to be suppressed.
- 7 Use the cursor to move the points along the Suppression curve.
- 8 On the Suppression curve, drag the point closest to the plotted colour down to a value of 25, intersecting the plotted colour.
The colour spill is suppressed.
- 9 Continue modifying the shape of the curve until you are satisfied with the result.
- 10 Click Saturation to adjust the saturation of the spill.

NOTE Once you remove the saturation from a spill, you may want to increase the values for the other curves (for example, red and green if you removed a blue spill) to reconstruct some of the natural colours at the edge of the keyed image.
- 11 Click Red, Green, or Blue to edit individual colour curves.
- 12 Click Luminance to adjust the luminance of the spill.

Adjusting the Hue Shift Curve

You can disguise colour spill by shifting its hue so the colour blends better with the background. Sample the colour to which you want to shift the colour spill and then adjust the Hue Shift curve to shift the colour spill accordingly.

To Create a Hue Shift:

- 1 Set the view to Result, so that you can see the changes as you make them.
- 2 Double-click the Colour Curves node in the schematic.
The Colour menu appears.
The Colour menu displays colour curves over a hue spectrum. When you modify the shape of a curve over a region of the spectrum, only those colours are affected.
- 3 Enable Hue to modify the Hue Shift curve.

- 4 Select a pixel within the spill in the Result image.
A red vertical bar appears in the hue spectrum identifying the colour to be shifted.
- 5 Click the colour pot next to the Hue button.
The colour picker appears.
- 6 Select or pick the colour you want to shift the spill to.
- 7 Use the cursor to move the points along the Suppression curve.
- 8 On the Hue Shift curve, drag the point closest to the plotted colour down to a value of 75, intersecting the plotted colour.
The colour spill is shifted toward the Hue colour.
- 9 Continue modifying the shape of the curve until you are satisfied with the result.

Inverting a Matte

Use the Negative node to invert a matte. By inserting the Negative node between the Matte Edge and the GMask nodes in the processing pipeline, the matte is automatically inverted. The Negative node has no settings to configure.

To invert a matte:

- 1 From the Modular Keyer Node bin, drag the Negative node to the schematic.
- 2 Hold Shift and drag the Negative node to the Matte Edge node so their tabs touch and repeat for the GMask node.
The Negative node is inserted to the schematic and your matte is inverted.

Adjusting the Front and Matte Luminance Curves

When you create a matte for the front clip, the Modular Keyer automatically creates a matte for the back clip to specify which part of the back clip is used for the composite. By default, the back matte is the inverse of the front matte.

You can adjust the luminance of the front matte and back matte separately in the Matte Curves menu. For example, increase the luminance of the back matte so that more of the back clip shows through at the edges of the key. This creates a better blend at the edges.

To adjust the luminance curves:

- 1 Click the Result node in the pipeline.
The Matte Curves menu appears.

(a) Result box (b) Front matte curve (c) Matte box (d) View box (e) Back matte curve

- 2 Select Result view from the Result box. This allows you to select a particular image to view as you adjust the curve.
- 3 From the Result box, select the image you want to view as you adjust the curves.

Select:	To view:
Result	The composite clip.
Matte	The front matte. You cannot see changes made to the back matte when this view is selected.
Bmatte	The back matte. You cannot see changes made to the front matte when this view is selected.
Comp	The composite with a coloured background. The default colour is white. To select a different colour, click the colour swatch below the Tools box. The colour picker appears.

- 4 To adjust the luminance curve for the front matte, select Front from the Matte box. To adjust the back matte curve, select Back. Alternatively, click a curve to select it.

(a) 255 (White) (b) Output (remapping of luminance values) (c) 0 (Black) (d) 0 (Black) (e) Input (current luminance values) (f) 255 (White)

In Move edit mode, click a point to display its tangent handle and drag the handle to adjust the curve. Use other modes in the Tools box (Add, Delete, or Break, for example) to further adjust the curve, adding or deleting points, or breaking tangent handles as needed.

Viewing a Key with a Solid Colour Background

The following optional technique can help you create cleaner keys more quickly.

While creating the key, you can view the composite using a solid colour for the background in place of the back clip. This can help you see details in the image, such as colour spill, that you may otherwise miss. You can use the default colour (black) or select a colour using the colour picker.

NOTE This view does not affect the final render.

To use a solid colour background:

- 1 Double-click the Result node.
The Matte Luminance Curves menu appears.
- 2 In the Result box, select Comp.
A colour pot appears.

- 3 Click the colour pot under the Comp view output option.
The colour picker appears.
- 4 Select a colour for the background using the colour picker.
Your key is displayed on a solid colour background in the Result view.

Animating Your Key

The following parameters of a key can be animated:

- The average colour selected using the Average Colour pot in the Keyer menu

- The minimum and maximum Tolerance and Softness values
- The Lift, Gain, Shrink, and Erode values
- The blur factors for the matte and key-in clip
- The Maximum and Minimum Input and Output level values for the histogram

To display the Animation controls in the Keyers, click Animation to the left of the keyer menus. Using the Channel Editor, animate the parameters.

Resetting Your Key

You can reset the individual node within the Modular Keyer processing pipeline. You can also reset the entire Modular Keyer processing pipeline.

To reset individual node within the Modular Keyer processing pipeline:

- 1 Select the node you want to reset.
- 2 Right-click the node and select Reset.
The selected node is reset.

NOTE You can reset multiple nodes by holding the Ctrl key, selecting the nodes and right-clicking to reset.

To reset the entire Modular Keyer processing pipeline:

- 1 Shift+click the Result node.
- 2 Right-click the Result node and select Reset.
The entire Modular Keyer processing pipeline is reset.

Rendering Your Key

To view your key in the timeline, you must render it. You can render the key inside the Batch FX view or in the timeline.

To render your key in the Batch FX view:

- 1 When you are satisfied with your key, exit the Modular Keyer by clicking the Return button.
You are taken to the Batch FX view.
- 2 In the Batch FX view, click the Render Combo box and select Render. If the Render option is already displayed, simply click Render.
The rendering starts. A progress bar appears at the bottom of the screen.
- 3 After the rendering is complete, click EXIT BFX to return to the timeline.
 - If you accessed the Modular Keyer from the timeline, your original source clip is updated in the timeline and in the Viewing panel and displays the result of your key.
 - If you accessed the Modular Keyer from the Tools tab, the result of your key is rendered as new media and is displayed in the Viewing panel.
 A small BFX icon appears on the clip and the timeline segment.

To render your key in the timeline:

- 1 Once you are happy with your key, exit the Modular Keyer by clicking the Return.

You are taken to the Batch FX view.

- 2** In the Batch FX view, click EXIT BFX to return to the timeline.

Your key is displayed in the timeline. A dotted line is displayed on the segment and you cannot view the result, as the segment needs to be rendered.

- 3** From the Editing panel, click the Render Combo box and select Render. If the Render option is already displayed, simply click Render.

The rendering starts. A progress bar appears at the bottom of the screen.

- 4** Once the rendering is complete, the dotted line becomes a full line and you can view the result of your key. Your original source clip is updated in the Viewing panel and displays the result of your key. A small BFX icon appears on the clip and the timeline segment.

Stabilizing and Tracking

18

Use the Stabilizer to remove camera instability and motion jitter, and to track reference points in your clips. You can also use the Stabilizer to produce 2D or, in the context of Action, 3D motion, anchor a surface to the clip's background or anchor the UV points of the surface to features of a clip. With tracking, a point or points on the clip are tracked as they move through the scene. You can then apply the resulting motion path to an object on another layer so that it follows the same path as the object you tracked.

Stabilizing is the inverse of tracking. With stabilizing, the motion path is used to shift the scene so that the point that is tracked remains fixed at one position.

Tracking and stabilizing are often processes of trial and error. It is recommended that you track or stabilize using the default settings. If the tracker box strays from its original point, you can fine-tune the analysis.

Accessing the Stabilizer

Accessing the Stabilizer

Access the Stabilizer from:	To:
The Tools tab	Stabilize.
Action Axis node	Track or stabilize.
GMask	Track a garbage mask or the vertices of a GMask.
Distort	Track vertices or the axis of a spline when warping or morphing.
Warper	Track points or an axis of a mesh when warping or morphing.
Action Analyzer node	Provide a 2D tracking path for 3D manual tracking.
Paint Tool	Track an AutoPaint stroke.
Blur and Glow	Track the center point of the radial blur.
2D Transform	Provide correction for 2D motion, rotation and scaling.

How the Stabilizer Works

The Stabilizer uses trackers to generate tracking data. Each tracker consists of a solid box, called the *reference box*, and a dashed box, called the *tracker box*. The reference box establishes the reference point (the feature to track or stabilize) in any frame of the sequence. The tracker box indicates to the Stabilizer where to locate the reference point. The tracker box follows the frame-to-frame movement of the reference point.

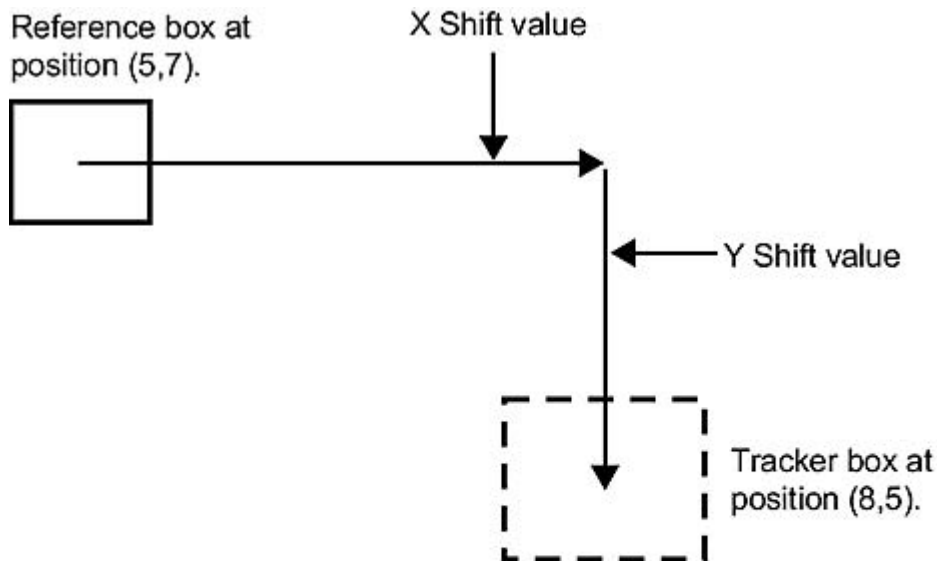

(a) Tracker number (b) Tracker box (c) Reference box

You start by selecting one or more reference points on your clip. Locate the first frame containing the movement to be tracked (the reference frame). In general, the reference frame is the first frame of the sequence. The choice of the reference point depends on whether you are tracking or stabilizing. When tracking, the reference point is a feature you want to track; when stabilizing, the reference point represents the point around which the image is stabilized. See [Selecting a Reference Point](#) (page 872) for details. Place the reference box(es) around the selected feature(s).

Once you have set the tracker positions, start the tracking process, also referred to as analyzing the clip. During the analysis, the tracker box associated with each tracker moves as the Stabilizer looks for a pattern that matches the reference in each frame of the clip.

The Stabilizer calculates the difference between the position of the tracker box and the position of the reference box to produce X and Y Shift values. Shift values represent a measurement in pixels and subpixels of how much the reference point has moved.

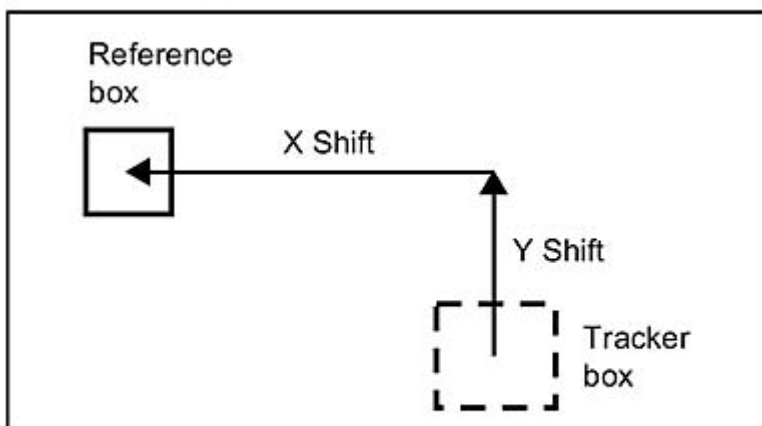

Reference position in X -	8
Tracker position in X	5
Shift value	3

Reference position in Y -	5
Tracker position in Y	7
YShift value	2

When the analysis is complete, you fine-tune it if a tracker box has strayed from the reference it was supposed to follow. Once you are satisfied with the results, you can apply the data to the clip.

To track, the Stabilizer applies the Shift values “as is.” To stabilize, the Stabilizer inverts the X and Y Shift values in each frame of the sequence, and moves the image according to these values. This gives the impression that the reference point stays in the same position throughout the sequence. Because the image is moved during stabilization, a border appears on one or more edges, which means that you lose some pixels. The following illustrations summarize the process.

The Shift values are inverted

The image is moved so that the contents of the tracker box are brought back to the position of the reference box.

Working with Trackers

This section provides information that is common to many procedures. It is recommended that you first read the procedure you want to perform in [Selecting a Stabilizer Method](#) (page 876), and then consult this section when needed.

Selecting a Reference Point

A good reference point is a high-contrast pattern that has good definition both vertically and horizontally.

Selecting a good reference point is a process of trial and error. Play the clip several times to become familiar with the material. Ideally, you should try to find a pattern that is present in every frame. In some cases, this is not always possible and you may have to track two different patterns, track an object that disappears behind another one, or track an object that moves out of the frame. For more information, see [Tracking Difficult Shots and Correcting Errors](#) (page 897).

The frame you use for the reference point should be the frame where the reference image is most representative in terms of shape, size, and rotation. You can select the reference point from a frame in the middle of the

sequence, if the pattern you want to use as a reference is subject to a lot of rotation or scaling. In most cases, you will position the reference box over the reference point in the first frame of the sequence.

Selecting a Tracker

You can use any of the following methods to select a tracker:

- Select any tracker Select Tool, from the Stabilizer Tools menu and click the tracker box, the tracking path, or the reference box of the tracker in the viewer.
- Select a tracker by clicking its corresponding button (Tracker1, Tracker2, and so on).
- Select a tracker by pressing the corresponding number key on your keyboard. You must use the number keys on the alphanumeric keyboard, not the numeric keypad.
- Select any tracker by pressing the up and down arrow keys on your keyboard.
- Select any tracker by selecting its channel in the Channel Editor.

When you select a reference box, a tracker box, or a keyframe in the image window, the sequence automatically updates to the frame where the keyframe was set.

Positioning the Reference and Tracker Boxes

When you position the reference box, the tracker box automatically follows. You can leave the boxes together if you place the reference box in the first or last frame of the clip. However, if you start the analysis on a different frame from where you position the reference box, you should position the tracker box in the first frame of the clip on the pattern you want to track. This way, the Stabilizer knows where to look for the pattern to track when you analyse the clip.

To position the reference and tracker boxes:

- 1 Go to the frame where you want to position the reference and tracker boxes.
- 2 If the tracker and reference boxes do not appear on the image, select the appropriate Tracker, from the Tracker box and enable Active.

(a) Tracker box (b) Active button

NOTE Each tracker is automatically assigned a different colour. However, you can customize the tracker colour at any time.

- 3 Click inside the reference box to select it, and drag it over the pattern you want to track. The reference box changes into a magnifying glass. By default, the tracker box follows the reference box.

- 4 To position the tracker box on a different frame from the reference box, go to that frame and move the tracker box over the pattern to track. To move only the tracker box, click anywhere outside the reference box.

Resetting the Reference and Tracker Boxes

You can reset the Reference, Tracking or Shift values independently for the selected tracker or all these values simultaneously, by selecting the appropriate option in the Reset box.

- 1 Do one of the following:
 - To reset the Reference values of the selected tracker, select Reset Ref from the Tracker box.
 - To reset the Tracking values of the selected tracker, select Reset Track from the Reset box.
 - To reset the Shift values of the selected tracker, select Reset Shift from the Reset box.
 - To reset the Reference, Tracking and Shift values of the selected tracker, select Reset from the Reset box.
- 2 Click Confirm.

Resizing the Reference and Tracker Boxes

Resize the reference box to make it surround the feature you chose to track more closely. By only including the recognizable feature in the box with no other details that may change throughout the clip, you minimize the possibility of the tracker losing the reference point.

TIP Sometimes a small reference point does not give good results. Try enlarging the box to include more of the selected feature. Note that the larger the box, the slower the analysing speed.

Resize the tracker box so that it is large enough to accommodate the most frame-to-frame movement of the reference point. For example, if the movement of the reference point is mostly horizontal, you can increase the width and reduce the height of the tracker box. If there is a large amount of movement both horizontally and vertically, increase both the width and the height of the tracker box. Note that the smaller the tracker box, the faster the analysis.

To resize the reference and tracker boxes:

- 1 Do one of the following:
 - To resize the reference box and tracker box interactively on the frame, press a resize handle on the box and drag.

- To use the menu to move or resize the reference or tracker box for the current tracker, enter values in the Reference or Track fields.
You can also set the position of the offset the position of the reference, via the Offset X and Y fields. See [Offsetting the Tracking Motion of the Reference](#) (page 894).

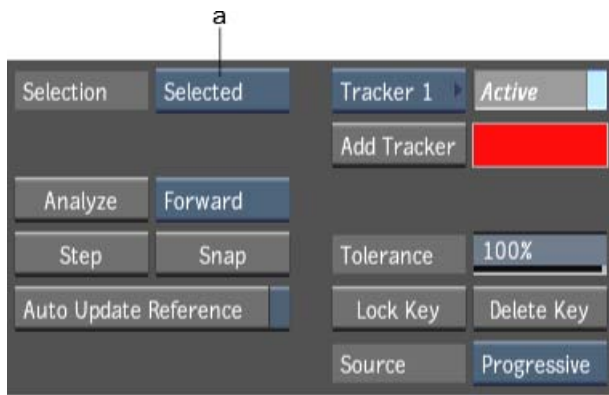

Reference		Track	
X 418.50	Width 26	X 418.50	Width 39
Y 472.50	Height 66	Y 472.50	Height 39
Offset		Import	Export
X 0.00			
Y 0.00			

TIP Use the image window Zoom command to get a closer view of the tracker and reference boxes.

NOTE To reset the reference or tracker box to its default position and size, select either Reset Ref, Reset Track or Reset Shift from the Reset box.

Working with Multiple Trackers

You can change a parameter for all active trackers at once. For example, you can change the dimensions of the tracker box for all trackers or set Fixed to off for all trackers, by selecting Gang, from the Tracker Selection box. Inversely, it can be useful to hide all but a selected tracker, to edit its tracking path, for example. This is achieved by selecting Solo, from the Tracker Selection box. By choosing Selected, only the selected tracker is affected, but the other trackers are still displayed.

(a) Tracker Selection box

Choose:	To affect:
Selected	Only the selected tracker while still showing all trackers in the image window.
Solo	Only the selected tracker and hide all other trackers.
Gang	All the active trackers, except when changing the colour of the trackers.

Selecting a Stabilizer Method

Use the stabilizer to remove unwanted shaky motion and to smooth out the camera motion. The Stabilizer can smooth out motion relative to translation, rotation and scaling in an image sequence to produce a stabilized image.

The first step to stabilizing a clip is to select an appropriate stabilization method.

Auto Stabilize

- Can stabilize simple 2D motion, scaling and rotation, and perspective transformation.
- Can smooth out or pin the detected motion.
- Can remove jitter but keep camera motion.
- Can adapt resolution and advanced padding options.

Stabilizer

- Supports manual trackers.
- Enable simple padding and texture repeat options.
- Can stabilize simple 2D motion.

2D Transform

- Can stabilize simple 2D motion, scaling and rotation.
- Can adapt resolution and advanced padding options.

Simple Stabilization

Use simple stabilization to stabilize a clip where there is no pan or tilt.

To stabilize when there is no pan or tilt with the Stabilizer:

- 1 Position Tracker1 over a pattern that you want to stabilize.
- 2 Click Analyze to generate the stabilization data.
- 3 Fine-tune the data if necessary. See [Tracking Difficult Shots and Correcting Errors](#) (page 897).
- 4 Adjust the framing options as you need (Roll, Fill, Crop Edges, Letterbox, Shift).
- 5 Once you are satisfied with the stabilization, go to frame 1 and click Render.

Auto Stabilize is accessed from either the Tools tab or from Batch .

To stabilize using Auto Stabilize:

- 1 Select 2D Stabilization from the Stabilization Method box.
You are performing a two-dimensional analysis.
- 2 Switch to Front View.
- 3 **Optional:** Enable the Region Of Interest button.
Indicate the region you want to analyze on the front clip.
- 4 Click the Analyze button.
Analysis takes place. This may take some time however you will see the percentage of progress in the analysis in the Progress field.
- 5 Switch to Result view to see the stabilized shot.
- 6 Enable the Components (Position X, Position Y) that you want to stabilize.
- 7 For these components select either Fixed or Smooth.
 - Fixed pins the component during the analysis.
 - Smooth removes the jittering with 0% being the original motion and 100% removing the highest frequency jitter.The analysis is complete.

NOTE The default reference frame is the first frame of the clip. You can change the reference frame of the analysis by defining a new reference point.

To define a new reference point:

- 1 Place the positioner at the desired frame.
- 2 Click the Set Frame button.
The analysis will readapt the timing of the transformation; stabilization will occur before and after the set frame.

2D Transform is accessed from either the Tools tab or from Batch .

To stabilize using 2D Transform:

- 1 Select Pan & Scan from the Transform Type box.
You are now limited to modifying only the position and scale.
- 2 In the Stabilization tab, select the Enter Stabilizer button.
You are in Stabilizer.

- 3 Position Tracker 1 over a pattern that you want to stabilize.
- 4 Click Analyze to generate the stabilization data.
- 5 Fine-tune the data if necessary. See [Tracking Difficult Shots and Correcting Errors](#) (page 897).
- 6 Once you are satisfied with the stabilization, exit back to 2D Transform.
- 7 Enable the Components (Position X, Position Y) that you want to stabilize.
- 8 Adjust the framing options as you need (Roll, Fill, Crop Edges, Letterbox, Shift) .

NOTE The default reference frame is the first frame of the clip. You can change the reference frame of the analysis by defining a new reference point.

To define a new reference point:

- 1 Place the positioner at the desired frame.
 - 2 Click the Set Frame button.
The analysis will readapt the timing of the transformation; stabilization will occur before and after the set frame.
-

Stabilizing Motion, Scaling, and Rotation

Auto Stabilize is accessed either from the Tools tab or from Batch .

To stabilize Motion, Scaling and Rotation using Auto Stabilize:

- 1 Select 2D Stabilization from the Stabilization Method box.
You are performing a two-dimensional analysis.
 - 2 Switch to Front View.
 - 3 **Optional:** Enable the Region Of Interest button.
Indicate the region you want to analyze on the front clip.
 - 4 Click the Analyze button.
Analysis takes place. This may take some time however you will see the percentage of progress in the analysis in the Progress field.
 - 5 Switch to Result view to see the stabilized shot.
 - 6 Enable the Components (Position X, Position Y, Scaling, Rotation) that you want to stabilize.
 - 7 For these components select either Fixed or Smooth.
 - Fixed pins the component during the analysis.
 - Smooth removes the jittering with 0% being the original motion and 100% removing the highest frequency jitter.
- The analysis is complete.

NOTE The default reference frame is the first frame of the clip. You can change the reference frame of the analysis by defining a new reference point.

To define a new reference point:

- 1 Position the positioner to the desired frame.
- 2 Click the Set Frame button.
The analysis will readapt the timing of the transformation; stabilization will occur before and after the set frame.

2D Transform is accessed either from the Tools tab or from Batch .

To stabilize Motion, Scaling and Rotation using 2D Transform:

- 1 Select Pan & Scan from the Transform Type box.
- 2 In the Stabilization tab, select the Enter Stabilizer button.
You are in Stabilizer.
- 3 Position Tracker 1 over a pattern that you want to stabilize.
- 4 For stabilizing scaling and rotation you must position Tracker 2 over a pattern.
- 5 Click Analyze to generate the stabilization data.
- 6 Fine-tune the data if necessary. See [Tracking Difficult Shots and Correcting Errors](#) (page 897).
- 7 Once you are satisfied with the stabilization, exit back to 2D Transform.
- 8 Enable the Components (Position X, Position Y, Scaling, Rotation) that you want to stabilize.
- 9 Adjust the framing options as you need (Roll, Fill, Crop Edges, Letterbox, Shift).

NOTE The default reference frame is the first frame of the clip. You can change the reference frame of the analysis by defining a new reference point.

To define a new reference point:

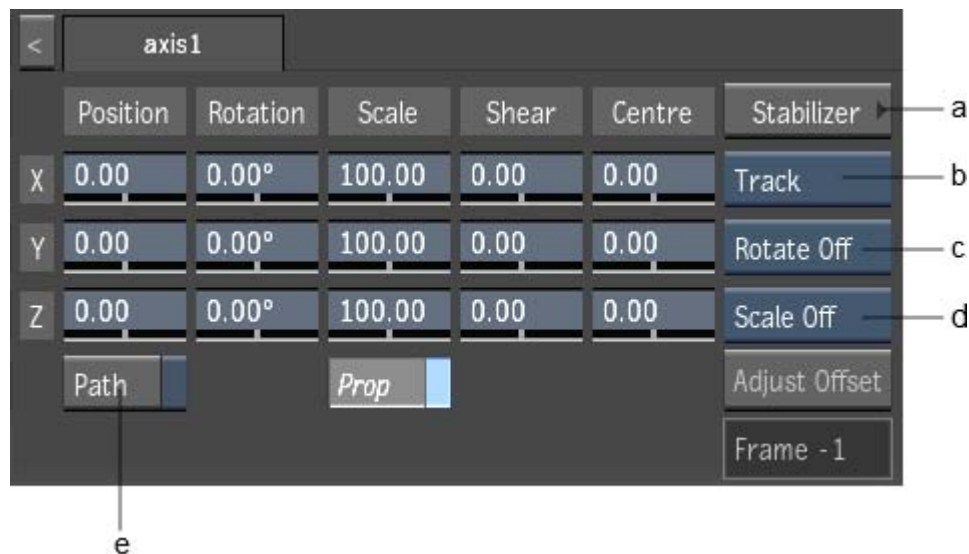

- 1 Position the positioner to the desired frame.
- 2 Click the Set Frame button.
The analysis will readapt the timing of the transformation; stabilization will occur before and after the set frame.

Stabilizing a Clip from Action

You can import stabilizing data to lock the position of an axis in relation to a reference point on the front clip. This means that any movement in the front clip is matched by the axis. You can enter the Stabilizer from Action to stabilize an image so that the axis changes to keep the reference point fixed against the background.

To stabilize a clip from Action:

- 1 Load the clips into Action.
When selecting clips, keep in mind that the front clip is the image that you want to stabilize and the back clip contains the reference point you want to track. Also, the clips must be of the same resolution.
- 2 In the Axis menu for the selected media, make sure that the motion path is disabled (Path button).

(a) Stabilizer button (b) Stabilizer Option box (c) Tracking Rotation Option box (d) Tracking Scale Option box (e) Motion Path button

NOTE Do not move the axis from its default position at the centre of the image window before entering the Stabilizer, or else the tracking data will be overwritten. Use the offset axis to add an offset to the tracker movement instead.

- 3 In the Stabilizer Option box, select Stabilize and click the Stabilizer button.
The front clip is automatically loaded into the Stabilizer and the Stabilizer menu appears.
- 4 In the Stabilizer, position Tracker1 over the reference point that you want to track.
- 5 To help you view your tracking result without any objects blocking the view, enable the Context button. While similar to a result view, the context view allows you to see all of the Action scene, except for the selected node (and any children of the selected node).

- 6 Depending on the performance of your system and the complexity of your Action setup, you can enable Linetest in the setup menu to display the context view at a lower resolution.

When you play the clip in the context of Action, you can see the front image follow the inverse movement of the reference point in the front clip.

- 7 Click Analyze to generate the translation data.
- 8 Once the analysis is complete, click Return.

When you exit the Stabilizer, the X and Y Shift values for the reference position are automatically copied into the X and Y translation channels for the selected axis in Action.

Removing Jitter While Keeping Overall Motion

Use the Jitter option to remove the jitter from a clip while retaining the overall motion. The Stabilizer calculates the difference between an average applied to the channel by using the current Over value and the original tracking data. Applying this curve leaves only the jitter values as keyframes. Copying these curves can also be useful if you want to extract the jitter values to apply to another clip.

The Jitter option removes jitter in a clip on both the X and Y axes simultaneously, and averages the pan over time so that it appears even. Jitter control offers more flexibility than the Remove Vertical Jitter and Remove Horizontal Jitter buttons, which remove motion in one direction only. Use Remove Vertical Jitter and Remove Horizontal Jitter in simple situations, or to produce a result quickly.

Removing jitter is a process of trial and error. Try different Over values until you find one that yields good results. As a general rule, start with a large Over value over n frames to remove slow jitter, and start with a small Over value to remove fast jitter.

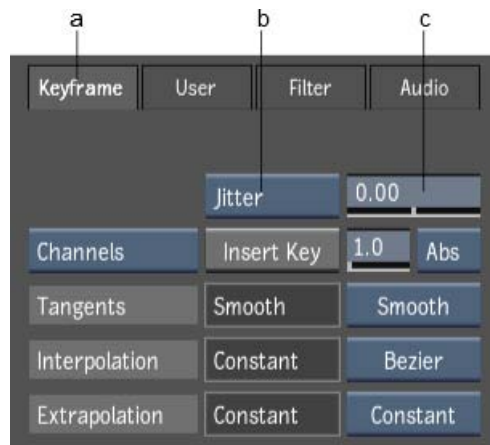

To remove jitter and keep overall motion:

- 1 Position Tracker1 over a pattern you want to stabilize.
- 2 To automatically remove the border at the edges of the clip, select Crop Edges from the Scale and Shift Option box.

(a) Scale and Shift Option box

- 3 Go to the reference frame, and click Analyze to generate the Shift data.
- 4 Click Animation to display the Channel Editor. Select the tracker number and expand the Shift folder. The Shift curves turn white when the Shift channel is selected.
- 5 Select the Keyframe tab from the Animation Controls tabs.

(a) Keyframe tab (b) Curve option box (c) Curve Value field

- 6 Select Jitter from the Curve option box.
- 7 Enter a value in the Curve Value field.

The transformation is applied to the curves. The curves show the amount of motion that the Stabilizer will remove. They should wrap around the zero point and should not be entirely flat; otherwise, the Stabilizer will not remove any jitter.

Quickly Removing Jitter in X and Y

The Remove Vertical Jitter and Remove Horizontal Jitter buttons remove motion in one direction only. Enable the Remove Vertical Jitter button to remove vertical jitter only. Movement on the horizontal (X) axis, such as a camera pan, is not affected. Enable the Remove Horizontal Jitter button to remove horizontal jitter. Movement on the vertical (Y) axis is not affected.

Smoothing Out Camera Motion

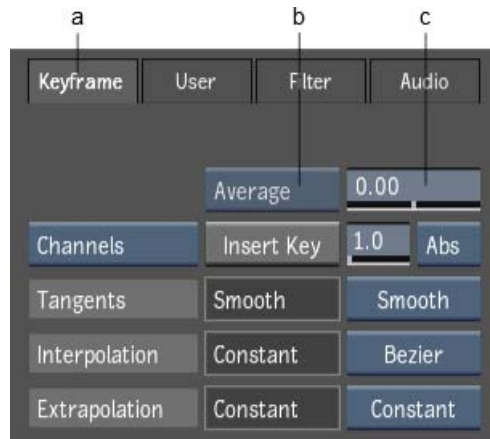

Use the Average curve options to smooth out uneven camera motion. For example, if the camera moves at a certain rate and suddenly drops or increases in speed, the Average option can stabilize the camera motion.

The Average curve smooths out camera motion over a group of keyframes, by affecting the Stabilizer's Shift values. The Shift values represent the amount of movement in a clip. Use the Curve Value field to determine how much stabilizing is applied to the clip. A larger value averages camera motion over more keyframes and increases camera smoothness. This is largely a process of trial and error.

Analyze your clip to generate the initial channel data, then select the channel to apply the average to.

To smooth out camera motion:

- 1 Position the tracker(s) on your image and click Analyse.
- 2 Click Animation to open the Channel Editor and expand the Shift folder for the track(s).
- 3 Do one of the following:
 - To affect the the X and Y Shift values simultaneously, select the Shift folder.
 - To affect the X Shift value, select the X parameter.
 - To affect the Y Shift value, select the Y parameter.
- 4 Select the Keyframe tab from the Animation Controls tabs
- 5 Select Average from the Curve option box.

(a) Keyframe tab (b) Curve option box (c) Curve Value field

- 6 Enter an average value in the Curve Value field.
The transformation is applied to the curves. The Curve Value field defaults back to 0, where 0 always represents the average of the current curve.

One-Point and Two-Point Tracking

In both one-point and two-point tracking, you select the object that follows the pattern on the back clip by assigning the tracking data to its axis in Action.

For one-point tracking, you use only one tracker (usually Tracker1) to generate position information. For two-point tracking, you use a second tracker (usually Tracker2) to generate rotation and/or scaling information. The Stabilizer obtains this information by comparing the position of Tracker2 to that of Tracker1.

Before you select the two reference points on the back clip, note the task of each tracker:

- Tracker1 follows the horizontal and vertical translation of the reference point. You should position Tracker1 over a point on the pattern that you want to track.
- Tracker2 tracks the rotation and/or the change in size of the pattern. In the first frame, the rotation is always 0 and the scaling factor is always 100%. In subsequent frames, a rotation and/or scaling factor is added if the relative position of the two trackers changes. You should position Tracker2 over a point that represents the rotation or change in size of the pattern.

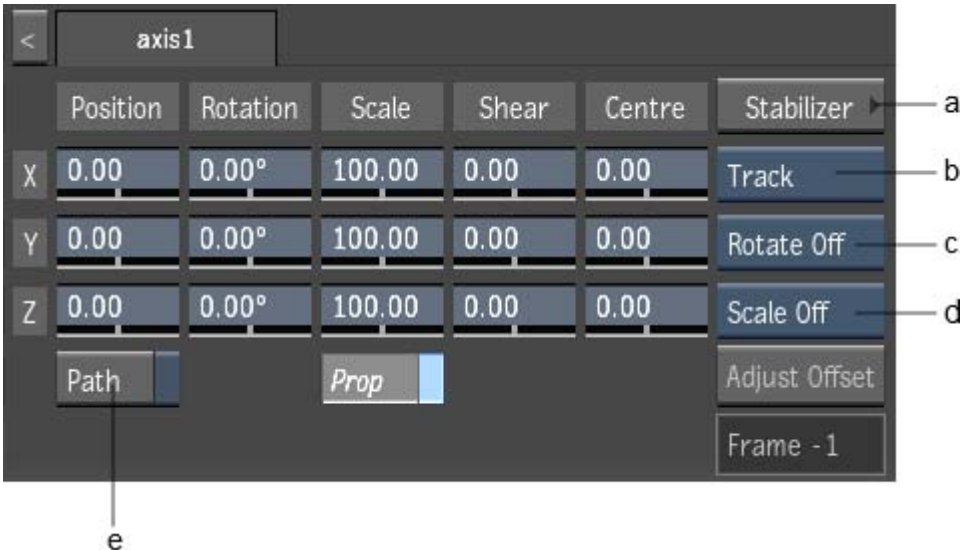

When you open the Stabilizer from Action for two-point tracking, you can select whether you want rotation information, scaling information, or both. The choice depends on the movement of the object to track and on the camera movement in the clip.

To perform one-point or two-point tracking in Action:

- 1 Load a front and back clip in Action.

The front clip contains the object and the back clip supplies the pattern that you want to track.

- 2 In the Axis menu for the selected media, make sure that the motion path is disabled (Path button).

(a) Stabilizer button (b) Stabilizer Option box (c) Tracking Rotation Option box (d) Tracking Scale Option box (e) Motion Path button

NOTE Do not move the axis from its default position at the centre of the image window before entering the Stabilizer, or else the tracking data will be overwritten. Use the offset axis to add an offset to the tracker movement instead.

- 3 In the Stabilizer Option box, select Track.
- 4 From the Tracking Rotation option box and Tracking Scale option box, set the tracking options.

Select:	To:
Rotation Off and Scaling Off	Do one-point tracking.
Rotation On and/or Scaling On	Do two-point tracking.
Rotation Inv	Invert the rotation data.
Scale Inv	Invert the scaling data.

- 5 Click the Stabilizer button.
The Stabilizer opens and the back clip appears.
- 6 Position the tracker(s) over the pattern(s) that you want to track, and click Analyse to generate the tracking data.

NOTE You can fine-tune the tracking data if necessary. See [Tracking Difficult Shots and Correcting Errors](#) (page 897).

- 7 Once you are satisfied with the tracking, click Return.
The Axis menu in Action reappears. The tracking data is applied to the front clip.

Bilinear Surface Tracking

With bilinear tracking, or four-point tracking, you use four trackers in the Stabilizer to generate tracking data.

- For anchoring the four corners of a bilinear surface to the background clip.
- For anchoring the four UV points of the surface to features of the clip.

The bilinear surface then tracked to the horizontal and vertical translation of the reference points.

See [Stabilizer Menu Settings](#) (page 1447) for an overview of the settings and options in the Stabilizer.

To track a bilinear surface:

- 1 Load front and back clips in Action.
- 2 Double-click the image node in the schematic to display the Surface menu.
- 3 Select Bilinear from the Surface Type box.
- 4 Do one of the following:
 - To track the Vertices relative to the background, click the Vertices tab to display the Stabilizer button and tracking options.
 - To track the UV points of the surface to features of the clip, click the UV Points tab to display the Stabilizer button and tracking options.
- 5 Select a tracking mode. Options are:
 - **Each Point:** Track the surface using a tracker for each selected vertex or UV point.
 - **Pos/Rot:** Track the surface using two proxy trackers that extrapolate the position of the selected vertices or UV points, based on changes in the position and rotation.
 - **Pos/Scale:** Track the surface using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on changes in the position and scaling.
 - **Pos/Rot/Scale:** Track the surface using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on changes in the position, scaling and rotation.
- 6 Click Stabilizer.

The Stabilizer menu is displayed.

NOTE The Position, Rotation and Scale settings of the vertices or UV points in Z are reset when entering the Stabilizer.
- 7 Do one of the following:
 - Position the trackers on the background clip (Vertice tracking).
 - Position the trackers on the surface texture (UV points tracking).
- 8 Gang the trackers.
- 9 Enable Auto Update Reference.
- 10 Click Analyze to generate the tracking data.
- 11 After the analysis is complete, click Return.

The Surface menu in Action reappears. The tracking data is automatically applied to the four corners of the bilinear surface or texture.

Extended Bicubic Surface Tracking

When tracking an extended bicubic surface, trackers are placed on each vertex or UV point, enabling you to track complex surfaces that move in 3D space. This is useful for tracking non-rigid objects like faces, bodies, cloth, etc. Extended bicubic tracking is particularly well suited for these types of deformations, as the vertices and the UV points are tracked individually.

With extended bicubic tracking, you use multiple trackers in the Stabilizer, based on the number of subdivisions applied to the surface. This generates tracking data for anchoring the vertices of an extended bicubic surface to the background clip or for anchoring the UV points to the extended bicubic surface.

See [Stabilizer Menu Settings](#) (page 1447) for an overview of the settings and options in the Stabilizer.

To perform extended bicubic surface:

- 1 Load front and back clips in Action.
- 2 Double-click the image node in the schematic to display the Surface menu.
- 3 Select Extended Bicubic from the Surface Type box.
- 4 Subdivide the surface, and position the vertices or UV points as needed.
- 5 Do one of the following:
 - To track the Vertices relative to the background, click the Vertices tab to display the Stabilizer button and tracking options.
 - To track the UV points of the surface to features of the clip, click the UV Points tab to display the Stabilizer button and tracking options.
- 6 Select a tracking mode. Options are:
 - **Each Point:** Track the surface using a tracker for each selected vertex or UV point.
 - **Pos/Rot:** Track the surface using two proxy trackers that extrapolate the position of the selected vertices or UV points, based on changes in the position and rotation.
 - **Pos/Scale:** Track the surface using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on changes in the position and scaling.
 - **Pos/Rot/Scale:** Track the surface using two proxy trackers that extrapolate the movement of the selected vertices or UV points, based on changes in the position, scaling and rotation.
- 7 Click Stabilizer.

The Stabilizer menu is displayed.

NOTE The Position, Rotation and Scale settings of the vertices or UV points in Z are reset when entering the Stabilizer. A notification appears on the screen when this is the case.
- 8 Do one of the following:
 - Position the trackers on the background clip (Vertice tracking).
 - Position the trackers on the surface texture (UV points tracking).
- 9 Gang the trackers.
- 10 Enable Auto Update Reference.
- 11 Click Analyze to generate the tracking data.
- 12 After the analysis is complete, click Return.

The Surface menu in Action reappears. The tracking data is automatically applied to the surface or texture.

Extended Bicubic SurfaceTracking Example

In this example, we want to match the motion of the cloth deformation in this t-shirt clip with the fire clip and superimpose it on top of the t-shirt.

Image courtesy of P. Fua, CVLab, EPFL, Switzerland

Proceed as follows:

- 1 Load front and back clips in Action.
- 2 Select the Fire clip in the Media list and double-click the image proxy to add it to the scene.
- 3 Access the Surface menu and select Extended Bicubic.
- 4 Access the Vertices menu, select all of the vertices and scale the image to match the t-shirt.
- 5 Adjust the four corners to match the t-shirt.

Image courtesy of P. Fua, CVLab, EPFL, Switzerland

- 6 Because the t-shirt deforms much more than the four corners, subdivide the surface, by clicking the Subdivide button twice.

Image courtesy of P. Fua, CVLab, EPFL, Switzerland

- 7 Select Each Point from the Tracking Mode box.
- 8 Select all of the vertices.
- 9 Enter the Stabilizer.
We have one tracker for each vertex.
- 10 Gang the trackers.
- 11 Enable Auto Update Reference.
- 12 Adjust the tracker size, to adjust the sampling area. In this case, we want to make them a little bit bigger.
- 13 Press Analyze.
The motion is tracked.

Image courtesy of P. Fua, CVLab, EPFL, Switzerland

14 Exit the Stabilizer.

The fire surface organically follows the t-shirt displacement.

Image courtesy of P. Fua, CVLab, EPFL, Switzerland

Perspective Surface Tracking

Track a perspective surface to straighten out elements captured at an angle in the scene, to insert surface elements within a scene with camera motion and for logo replacement.

With perspective tracking, you have the ability to either track the perspective using the Vertices or to correct and stabilize the perspective using the UV Points.

See [Stabilizer Menu Settings](#) (page 1447) for an overview of the settings and options in the Stabilizer.

To track the perspective motion:

- 1 Load front and back clips in Action.
- 2 Double-click the image node in the schematic to display the Surface menu.
- 3 Select Perspective from the Surface Type box.
- 4 Click the Vertices tab to display the Stabilizer button and tracking options, to track the Vertices relative to the background (track the perspective).
- 5 Select Perspective from the Tracking Mode box.

This tracking mode allows you to add as many trackers as you want and position them in the same plane as your surface, to cover as much of the perspective transformation as possible.
- 6 Click Stabilizer.

The Stabilizer menu is displayed.

NOTE The Position, Rotation and Scale settings of the vertices or UV points in Z are reset when entering the Stabilizer.
- 7 Position and add trackers on the background clip, as needed.
- 8 Gang the trackers.
- 9 Enable Auto Update Reference.
- 10 Click Analyze to generate the tracking data.

The motion is tracked

- 11 Exit the Stabilizer.

The Surface menu in Action reappears. The tracking data is automatically applied to the perspective surface.
- 12 From the Surface menu, extrapolate the surface in X and Y, as needed.

To correct and stabilize the perspective:

- 1 Access the Surface menu.
- 2 Select Perspective from the Surface Type box.
- 3 Position the UV points to isolate and correct the perspective on the desired portion of the shot.

- 4 Select the four UV points.
- 5 Click the UV Points tab to display the Stabilizer button and the tracking options.
- 6 Select Perspective from the Tracking Mode box.
This tracking mode allows you to add as many trackers as you want and position them in the same plane as your surface, to cover as much of the perspective transformation as possible.
- 7 In the Stabilizer Option box, make sure Track is selected.
- 8 Click Stabilizer.

The Stabilizer menu is displayed.

NOTE The Position, Rotation and Scale settings of the vertices or UV points in Z are reset when entering the Stabilizer.

- 9 Add trackers and position them as needed.

- 10 Gang the trackers.
- 11 Enable Auto Update Reference.
- 12 Click Analyze to generate the tracking data.
The motion is tracked.
- 13 Exit the Stabilizer.
The perspective is corrected and stabilized.

Offsetting the Tracking Motion of the Reference

You can apply the tracking information from one point to another point in the image. A dotted line is displayed between the tracker and the offset target, using the Offset Reference tool. This is useful when you want to track a portion of an image that does not have an adequate tracking anchor point.

In this example, we want to replace the green screen in the TV clip with another shot.

However, when entering the stabilizer, we can see that we don't have proper anchor points on the TV clip, where the four corners of our replacement shot are positioned.

To resolve this, we can offset the reference. To do this, proceed as follows:

- 1 From the Stabilizer Tools menu, select Offset Reference.
This enables you to place the tracker on a proper anchor point, but apply the tracking data to the original portion of the image, which does not have an adequate anchor point.
- 2 Place the trackers on adequate anchor points.

NOTE The trackers should be placed relatively close to the offset target, or on an anchor point that follows the same movement as the offset target, otherwise the detected motion will be off and will drift from the motion of the offset target.

A dotted line is displayed between the tracker and the offset target.

- 3 Gang the trackers.
- 4 Enable Auto Update Reference.
- 5 Press Analyze.

The motion is tracked. The reference is the anchor point on which the tracker was placed, but the motion is applied to the offset target.

6 Exit the Stabilizer.

The tracking data is applied to the offset targets. The corners of the replacement image are still at their original position, where there were no adequate anchor points, but the motion and the positioning is correct.

Adjusting the Surface With the User Shape Channel

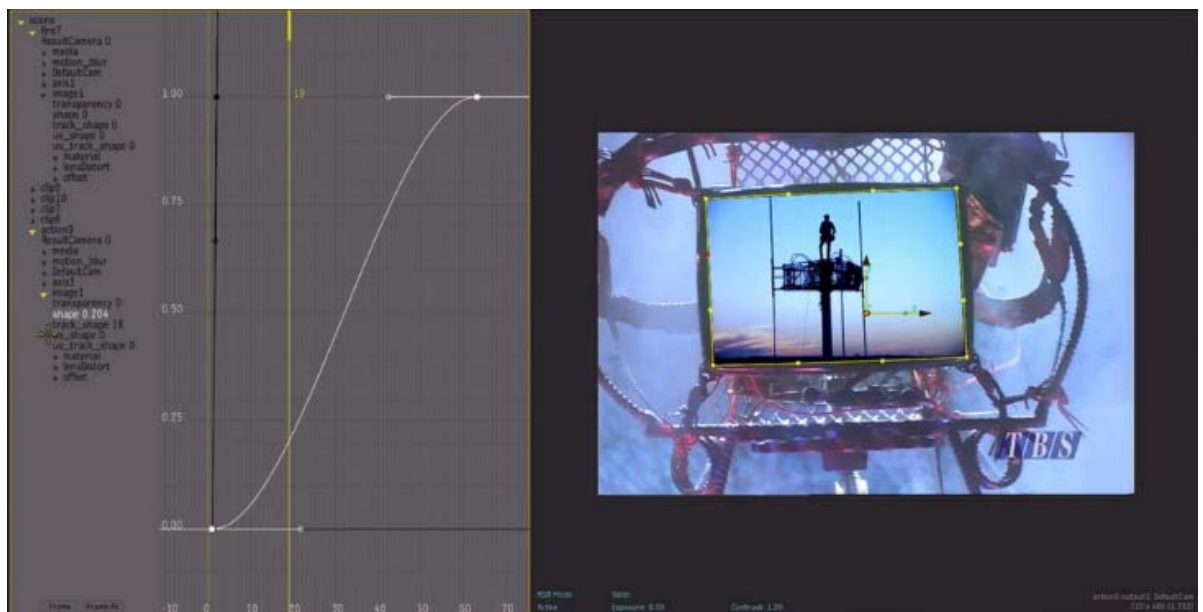

When tracking surfaces, you have access to a user shape channel, that you can use to fine tune or to add additional deformation to the existing tracking animation, without affecting the tracking animation.

Once the surface has been tracked, you can adjust the vertices, the UV points or the tangents of the surface, to add deformation or to adjust the position of the surface. This creates a keyframe at the timecode you specified, which is stored in the user shape channel and does not interfere with the tracking animation.

In this example, we adjust the tangents of the tracked extended bicubic surface, at frame 63, curving the surface for it to fill the TV screen.

Looking at the user shape channel, in the Animation Editor, we see that only one keyframe is added, at frame 63. The adjustment or deformation persists after the last keyframe of the user shape channel and does not interfere with the existing tracking animation.

Tracking Difficult Shots and Correcting Errors

If the tracker box strays from the reference point that it is supposed to be tracking, incorrect shift keyframes result. If such an error occurs, you can stop the analysis, correct it, and restart it at any frame.

This section covers the different strategies you can use to track difficult shots. After trying any of the strategies, you will need to redo the analysis. Click Analyze to generate new keyframes based on the updated information you provide.

Adjusting the Size of the Tracker Box

If the Stabilizer cannot find the reference point within the boundaries of the tracker box during analysis, the tracker box will stray from the reference point and produce incorrect keyframes. Although you can manually correct these keyframes, it is easier to make the tracker box large enough to accommodate the movement of the reference point. Note that processing time increases as the size of the tracker box increases. See [Resizing the Reference and Tracker Boxes](#) (page 874).

To adjust the size of the tracker box:

- 1 Press on the pen or hold down the left mouse button to stop the analysis.
NOTE Make sure to press below the viewer to avoid moving the tracker box.
- 2 Go back to the last good frame before the tracker box strayed from the reference point.
- 3 Adjust the size of the tracker box so that it is large enough to accommodate the largest frame-to-frame movement of the reference point.
- 4 Click Snap, and then click Analyze.

Positioning the Tracker Box Manually During Analysis

When the reference point is temporarily covered by another object, position the tracker box manually.

When you manually position the tracker box, the new position is recorded in the Track X and Track Y channels of the Channel Editor. These values have precedence over the Shift X and Shift Y values.

To manually position the tracker box:

- 1 Press on the pen or hold down the left mouse button to stop the analysis.
NOTE Make sure to press below the viewer to avoid moving the tracker box.
- 2 Advance the clip to the frame where the reference point becomes visible again, and reposition the tracker box over the reference point. Click Analyze to restart the analysis at this frame.
Since the X and Y shifts are recorded as keyframes in channels, the Stabilizer calculates the translation values for the frames in which the reference point was covered. The final result will be a smooth motion.

Locking Keyframes in Place

You can lock Shift keyframes so that they stay in place even if you try to move them manually or perform an analysis. This is useful, for example, when you set keyframes manually and want to prevent Flame Premium from overwriting them when you redo the analysis.

In the following procedure, you select the keyframes directly in the image window. However, you can also select the Shift keyframes in the Channel Editor.

NOTE You cannot lock several keyframes at once. You must lock each keyframe individually.

To lock keyframes in place:

- 1 Zoom in on the image until you can see the points clearly and select the point you want to lock on the tracking path.
The tracking path becomes white when you click it, and the frame that corresponds to the keyframe appears in the image window.

NOTE If the tracking path does not appear in the image window, enable Path in the Setup menu.

(a) The inside of locked keyframes are filled (b) The tracker box appears when you select a keyframe

- 2 Click Lock Key.

- 3 To unlock a keyframe, select it and click Unlock Key. The Lock Key button becomes Unlock Key when a locked frame is selected.

Changing the Reference Point

Change the reference point to another feature if the feature you have been tracking moves out of the frame, or alters such that it is no longer trackable. You should do this before the original reference point moves out of the frame. This allows the Stabilizer to calculate the offset between the two reference points and predict the position of the original reference point. If the Path button in the Setup menu is enabled, you will see the extrapolated path of the original reference point.

Change the reference point before analyzing the clip.

To change the reference point:

- 1 Click Setup and then enable Path.
- 2 Select the tracker for which you want to change the reference point.
- 3 Display the desired frame in the image window.

- 4 Using the Select tool from the Stabilizer Tools menu, drag the reference box and position it on the new reference point.
- 5 Go to the first frame of the sequence and click Analyze.

Finding the Best Tolerance Value

The Tolerance value determines how much discrimination the Stabilizer uses in matching the reference point from frame to frame and in setting a keyframe for that frame. At 100% tolerance (no discrimination), almost anything is considered as a match and a keyframe is set. At 0% tolerance (complete discrimination), only a perfect match is accepted.

If the reference point becomes hidden by another object, you can use the Tolerance value to make the tracker ignore the reference point in parts of the clip where it is hidden, then continue tracking it normally when it reappears. Choosing a good Tolerance value reduces the need to manually reposition the tracker box during analysis.

TIP You can also adjust the tolerance to make a valid keyframe that has been filtered out reappear.

To find the best Tolerance value:

- 1 Click Setup and then enable Path to view the tracking path.
- 2 Analyze the clip with full (100%) tolerance.

- 3 Go to the first frame where the reference point is hidden by another object and adjust the tolerance value until the crosshair reappears in the tracker box.
The crosshair reappears when there is a keyframe.
- 4 Go to the first frame in the sequence and click Analyze.

Once you determine the optimal tolerance value, further analysis automatically discards the unwanted keyframes, and the position of the reference point is extrapolated until the reference point reappears.

Analyzing Backward

Analyze the clip backwards when the pattern you want to track grows larger or when it is off screen at the beginning of the clip.

To analyze backward:

- 1 Select Backward from the Direction box.
- 2 Go to the last frame of the sequence.

- 3 Position the reference and tracker boxes.
- 4 Click Analyze.

Manually Tracking a Pattern that Disappears

Track manually when the pattern you are tracking disappears behind an object for several frames, moves out of the frame, or is difficult to track.

To track a pattern that disappears:

- 1 Go to the last keyframe before the reference point disappears.
- 2 Click Snap to redefine the reference point on this frame.

- 3 Using the Select tool from the Stabilizer Tools menu, drag the tracker box to the required position in the current frame.

Use the reference image you see in transparency as a guide to find the new position. A keyframe is set and the timeline advances one frame forward or backward when you release the pen. The direction of the timeline depends on the setting in the Direction box.

NOTE If you do not see the reference image in transparency, set the Opacity option in the Setup menu to approximately 50%.

- 4 Repeat step 4 as necessary.

TIP Lock the keyframes as you add them.

Analyzing One Frame at a Time

Analyzing one frame at a time is useful for difficult shots because you can adjust the position of the tracker after each frame. Click the Step button to analyse a single frame and advance to the next frame.

Editing the Stabilizer Channels on the Image

You can edit the tracker channels directly on the image instead of editing them in the Channel Editor. Note that the curve on the image shows the X and Y components together and not separately like in the Channel Editor. The tracking path on the image shows the actual displacement of the tracker box.

To edit the curve directly in the image window, Path must be enabled in the Setup menu. When you select a keyframe on the curve, the positioner goes to the frame that corresponds to the keyframe. When you select the reference box, the positioner goes to the frame where you set the reference.

Tracking a Degraded Copy of the Clip

If other options do not work, you can try degrading a copy of the image until the contrast of the pattern to track is high enough. You then generate tracking data from this copy, save the setup, and apply it to the original clip. Try the following methods for degrading the clip:

- Saturate the colours in the Colour Corrector.
- Increase the contrast in the Colour Corrector.
- Apply filters (for example, Emboss).
- Remove film grain using Degrain.

Changing the Colour of Trackers

When you add a new tracker, the system automatically assigns it a unique colour so that you can easily distinguish between multiple trackers. You can change the colour of an individual tracker or of all the trackers at once.

To change the colour of the tracker:

- 1 From the Tracker box, select the tracker you want to change.
TIP To change all trackers, select Gang in the Tracker Selection box.
- 2 Click the Tracker colour pot.
- 3 Select a colour with the colour picker.
- 4 Click in the Tracker colour pot to apply the new colour to the tracker.

Pretracking a Clip

Before analyzing, you can use the Pretracking option in the Setup menu to preview the motion path for a specified number of frames. You can then adjust the tracker position, if necessary, to find the best reference point. The Pretracking option applies only to the selected tracker, regardless of whether you selected Solo, Selected, or Gang in the Tracker Selection box. If you move or resize a tracker with Pretracking enabled, the next frames are analyzed.

To pretrack a clip:

- 1 Position and select a tracker.
- 2 In the Setup menu, make sure that Path is enabled. If it is disabled, Pretracking is not available.
- 3 Enter the number of frames to pretrack.

NOTE If you enter a number larger than the length of the clip, only existing frames are pre-tracked.

- 4 Enable Pretracking.
The motion path appears.

NOTE Frames, not fields, are pretracked. If you are in Fields mode, frames will be pretracked.

Copying Shift Channels

Using the Channel Editor, you can copy a tracker's Shift channel values and paste them into any other channel in any module. For example, you can copy jitter values to the X and Y position channels of an axis to add realism to a static scene, or to a channel to add noise.

To copy and paste a shift channel:

- 1 In the Channel Editor, open the folder of the tracker whose shift values you want to copy.
- 2 Select the X or Y Shift channel, or the entire Shift folder to select both X and Y Shift channels.
- 3 Click Copy.
- 4 If necessary, load the clip to which you want to apply the Shift values into the appropriate tool.
- 5 Open the folder of the channel to receive the copied shift values and select the appropriate channel(s).
- 6 Click Paste.

Importing and Exporting Data

Import and export tracking and shift data values to an ASCII file using the Import and Export buttons located in the Track and Shift areas of the Stabilizer menu.

Track		Shift	
X 360.00	Width 15	X 0.00	Copy
Y 243.00	Height 15	Y 0.00	
Import	Export	Import	Export

The tracking data specifies the X and Y position of the tracker box in relation to the origin point of the image; these are absolute coordinate values. The origin point has coordinates (0,0), and is located at the lower-left corner of the image.

The shift data specifies the difference between the position of the reference box (0,0) and the position of the tracker box in the current frame. These are relative coordinate values.

Both the Tracking values and the Shift values are formatted as follows:

frame#: X position, Y position

NOTE If the position of the reference box is changed during the analysis, the offset is compensated for and the exported tracking data still shows a continuous tracker path.

Masking and Rotoscoping

19

When pulling a key, use garbage masks to isolate particular areas of an image to include with, or exclude from, the opaque area of the matte. Garbage masks are spline-based objects you draw directly on a clip or image. Depending on what you want to accomplish, you can set the area inside each garbage mask to be either opaque (white), transparent (black), or semi-transparent (any shade of grey).

Garbage masks are useful in many situations, such as when removing unwanted elements like equipment or people from a blue-screen shot, when removing unwanted borders from an image, or when creating complex keys by blending portions of the front and back clips. You can animate the shape of a garbage mask, apply motion blur to it, and even use the Stabilizer to make a garbage mask follow a moving element in a clip.

The following example illustrates keying out an unwanted white border using a garbage mask.

Matte before garbage mask is applied

Matte after garbage mask is applied

You can also apply softness to the edge of a mask using a uniform or advanced gradient. Instead of having an abrupt transition from white to black in the matte, you can control the gradations of grey between the key and the background. For example, softness can compensate for uneven edges of a key by blending the front and back clip. You can apply uniform softness around the edge of a mask or vary the softness range for different parts of the mask.

An advanced gradient adds two splines around the garbage mask. By moving points on these splines, you can control the gradient according to how far the surrounding spline is offset from the garbage mask.

Softness applied around edge of garbage mask spline

Image courtesy of Behavior Communications Inc.

Advanced gradient varies softness for different parts of the garbage mask

Image courtesy of Behavior Communications Inc.

Using Region of Interest and the Tracer

Certain garbage mask features are supported only in GMask Timeline FX, and the GMask node in Batch or Batch FX and the Modular Keyer.

In GMask Timeline FX, and the GMask node in Batch or Batch FX and the Modular Keyer, you can use a parameter called Region of Interest (ROI) when drawing multiple garbage masks on a clip to remove the portion of the matte that falls outside of each mask while respecting the area defined by all masks.

ROI enables you to reveal multiple parts of the matte.

Image courtesy of The Post Group

In the GMask node in Batch or Batch FX and the Modular Keyer, you also have the option of using the Tracer with an advanced gradient. The Tracer is an additional softness tool you can use to pull a key from scratch. This allows you to key images with a lot of detail at the edges. It uses a system of localized keys, called *pickers*,

which analyse the colour information both inside and outside the mask to derive a key for the mask edge. You can use both the Tracer and the advanced gradient within the same garbage mask.

The Tracer is particularly useful for keying challenges such as:

- Very fine, wispy talent edges (hair, fur, or lace) where a blue or green screen may show through.
- An object not shot on a blue or green screen.

Garbage mask with pickers sampling image for more advanced softness

Image courtesy of Behavior Communications Inc.

Garbage mask with pickers applied to only select vertices, the remainder using an advanced gradient

Image courtesy of Behavior Communications Inc.

The Stabilizer and pickers are not available when this type of input is attached to the node.

Accessing the Garbage Mask Menu

Access the Garbage Mask menu from the Modular Keyer or the GMask node when you want to use multiple garbage masks or use the Tracer for detailed masks.

To access the garbage mask, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

Accessing the Garbage Mask from Batch

To access the Garbage Mask from Batch;

- 1 Go to Batch.
- 2 Double-click on, or drag, the GMask Node from the node bar and add it to the schematic.

- 3 Double-click the GMask Node.
The GMask Node editor opens.

Accessing the Garbage Mask from Batch FX

To access the Garbage Mask from the Timeline through Batch FX;

- 1 Select Timeline.
- 2 Select the segment.
- 3 Click the FX button.
- 4 Click the Create Batch FX button.
- 5 Double-click on, or drag, a GMask node into the schematic.
The GMask node is now in the schematic.
- 6 Double-click the GMask node.
You are in the GMask node editor.

Accessing the Garbage Mask from the Timeline

To access the Garbage Mask from the timeline:

- 1 Select the Timeline tab.
 - 2 Do one of the following:
 - Click the FX button.
 - Right-click on a segment in the timeline and choose Add Effect.
The Effects ribbon appears.
- NOTE** Effects that are enabled have already been added to the current Timeline FX pipeline.
- 3 Enable GM (GMask).
 - 4 You can adjust the effect's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

Accessing the Garbage Mask from Modular Keyer

To access the Garbage Mask from the Modular Keyer;

- 1 Once inside the Modular Keyer, select the Gmask start Mode, from the Start Mode box.
A simple GMask schematic, with Front, Back and Key In clips is displayed.
- 2 Double-click the GMask node.
You are in the GMask node editor.

About Garbage Mask Options

You can customize a mask's properties in the Garbage Mask menu.

Render Mask button Turns masks on or off as you work. A mask that is turned off can be seen in the image window, but it has no effect on the image. Masks are turned on by default. **garbage masks: turning on and off** Constant shape, for garbage masks

NOTE This parameter cannot be animated.

Outside button Applies the effect to the part of the image that is outside the mask.

Colour field Sets the blend value between the front and back image in the area that the mask is affecting (that is, either outside or inside the mask). A value of 50% is a 50/50 blend between the front and back clip. A value of 100% is the front clip. A value of 0% is the back clip.

Mask with 25% colour

Mask with 75% colour

Opacity field Sets the opacity of the matte in the area affected by the mask (that is, either inside or outside the mask). A value of 100% means the matte is completely opaque; 50% means the matte is 50% transparent; and 0% has no effect on the image.

Mask with 0% opacity

Mask with 100% opacity

Lasso Fit field Increase or decrease the number of points in the segments of the mask that are drawn freehand. See [Adjusting the Number of Points in Freehand Segments](#) (page 915).

Edge Softness box Apply a uniform gradient or use an advanced gradient to set different levels of softness for different parts of the mask edge. In the GMask node in Batch or Batch FX or the Modular Keyer, use the Tracer to set variable softness around the mask edge using pickers. See [Refining the Mask](#) (page 930).

Alpha field Defines the transparency of the gradient from the edge of the mask.

Offset field Defines the border position of the gradient from the edge of the mask.

Inner Edge, Outer Edge, Distance fields Applies the distance and degree of change between the opaque and transparent part of the mask edge.

Linear Interp Enable to use linear interpolation of the mask border between keyframes. Disable to use rounded interpolation.

Constant Shape button Enable to modify the mask's shape without setting keyframes. This forces all animatable parameters (except the Tracer parameter Sample On) to be set for the whole clip rather than for only the current frame. It also removes any existing keyframes and applies the shape of the current frame to the rest of the clip.

Splines button Enable the display of softness, borders and pickers.

Borders button Enable the display of borders. The Border button is active when the Advanced Gradient and Tracer menus are displayed.

Pickers button Enable the display of pickers. This element is only available when accessing the Tracer tool in the Garbage Mask menu from the GMask node in Batch or Batch FX or the Modular Keyer.

X/Y fields Defines the mask's X and Y offset from its axis.

Setting Mask Options

You can control how a mask affects the matte. For example:

- Set the opacity, colour, and edge softness of the mask.
- Specify whether the effect is applied to the inside or outside of the mask.
- Adjust the offset of the mask from its axis.
- Turn a mask on or off.

To set mask options:

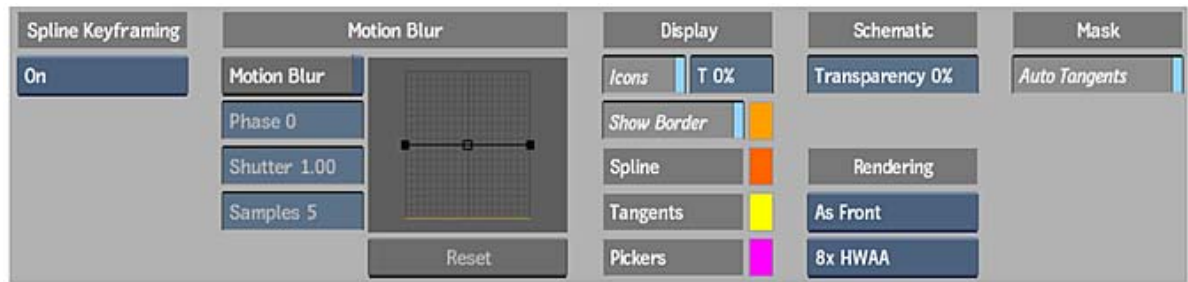

- 1 Display the Matte or Result view.

- 2 Select the mask in the image window:
 - Click anywhere on the garbage mask spline.
 - Click the Geom node in the schematic.
- 3 Access the Garbage Mask menu.
- 4 Set the mask options. See [About Garbage Mask Options](#) (page 908).

About Drawing Options

Use the Mask Setup menu to access mask drawing options.

Spline Keyframing box Determines under what conditions keys are set, and for which parameters, when you are animating a garbage mask spline. See [Animating Masks Using Spline Keyframing](#) (page 921).

Motion Blur settings Controls motion blur applied to garbage masks that can be used to match the movement of objects in a clip. See [Applying Motion Blur to Garbage Masks](#) (page 926).

NOTE There are additional setup options to do with animating garbage masks. These only appear when you disable Shape Animation in the Garbage Mask menu. For more information, see [Animating Masks Using Spline Keyframing](#) (page 921).

Icons button Globally displays or hides the garbage mask splines and axes.

NOTE If you hide garbage masks splines and axes with the Icons button, the Widget All / Widget Sel button in the View menu has no effect.

Transparency field Sets the transparency for the garbage mask splines and axes.

Show Border button Displays the Softness Offset wireframe border, defined in the Shape menu.wireframe:in garbage masks

Show Border colour pot Sets the colour for the Softness Offset wireframe.

Spline colour pot Sets the colour for the wireframe of the garbage mask.

Tangents colour pot Sets the colour of the garbage mask tangents and vertices.

Pickers Display colour pot Sets the colour of the Tracer's pickers. This element is only available when accessing the Garbage Mask Setup menu from the GMask node.

Schematic Display Transparency field Sets the transparency of the nodes in the garbage mask schematic.

Rendering box Select the rendering method.

Hardware Anti-aliasing Sample box Select a hardware anti-aliasing sampling level to accelerate edge anti-aliasing with no performance penalty. The graphics hardware automatically renders the image at full speed with approximately the equivalent of up to 32 samples of anti-aliasing (depending on your graphics card and project graphic bit depth). Hardware anti-aliasing also gives anti-aliasing during normal interaction instead of only while rendering.

Auto Tangents button Positions a tangent for each vertex set to create a smooth curve between the vertices. When Auto Tangents is disabled, the tangents are positioned under the vertex, resulting in straight lines between vertices. When you draw freehand segments in a mask with Auto Tangents off, vertices are added with broken tangents, allowing the mask to follow your cursor movement.

Drawing a Mask

After setting the drawing options, you can draw the mask.

To draw a garbage mask:

- 1 Access the Garbage Mask menu.
- 2 Select the view where you want to draw the mask from the View box.

Which view you use depends on the context of your key and why you are drawing the mask. For example, if you want to crop the edges of a clip by drawing an opaque mask around the subject and then turning on Outside, try drawing the mask using the Matte view. Or, if you are rotoscoping a subject that has not been shot on a blue or green screen, try either the Front or Result view.

TIP In Batch or Batch FX or the Modular Keyer, you can use multiple viewports as you draw the garbage mask. For example, you can draw the mask in Matte view, while also displaying Result view. Using multiple viewports, you can immediately see how your mask affects the clip.

- 3 Do one of the following:
 - Click Add.
 - Select Create from the Tools box.
 - Press N.
- 4 Do any of the following to draw the garbage mask:
 - Click to add vertices.

(a) Vertex added by first click (b) Vertex added by third click

- Press **Shift** to temporarily hide the vertices and tangents as you are drawing the mask.

(a) Vertices are temporarily hidden while holding **Shift**

- Click-drag to control the tangency of any vertex as you are drawing the mask. When you release, you can continue to add vertices.

Tangency handles extend as you drag from a vertex

- Shift-drag to add freehand segments to the mask. The vertices and tangents of the mask you are drawing are temporarily hidden. Vertices are added where you drag, and appear when you release Shift. After closing the mask, you can use the Lasso Fit parameter to increase or decrease the number of vertices that define the freehand segments of the mask. See [Adjusting the Number of Points in Freehand Segments](#) (page 915).

Segments of garbage mask drawn freehand

NOTE If you are drawing the mask with Auto Tangents turned off, freehand segments are drawn with broken tangents. See [Breaking Tangents](#) (page 918).

- 5 To close the mask, do one of the following:
 - Click Close.
 - Click the first vertex.
 - Drag to the first vertex.

TIP You can also close the mask by pressing the keyboard shortcut for the edit mode you want to use next: **M** for Move, **S** for Select, or **B** for Break. The mask closes and you are ready to work in that mode.

When the garbage mask is closed, its vertices and tangents can be edited and animated.

(a) Vertex (b) Tangent

If you want to view the nodes that are added with each new garbage mask, select Schematic from the World View box. You can use the Schematic view to access a menu, create parent-child relationships between masks and axes, delete masks, as well as perform other organizational tasks.

(a) World View box

Adjusting the Number of Points in Freehand Segments

You can increase or decrease the number of points in freehand segments of a mask by adjusting the Lasso Fit value. An entire garbage mask can consist of freehand segments, in which case the Lasso Fit value affects the whole garbage mask. Otherwise, the Lasso Fit value only affects the part of the mask drawn freehand.

The Lasso Fit parameter loses its influence over freehand segments of a mask if you have edited points as follows:

- Added or deleted points using the Add or Delete Edit modes
- Saved and loaded a garbage mask
- Started a new session with the application

To adjust the number of vertices using Lasso Fit:

- 1 If necessary, select the garbage mask you want to affect.
- 2 Drag the Lasso Fit field. Increase the value to decrease the number of points in the freehand segments of the mask. Decrease the value to increase the number of points in the freehand segments.

Segments of the mask that have been drawn freehand are affected, while segments created by simple clicks remain unaffected.

NOTE If you move vertices of a garbage mask and then change the Lasso Fit value, all the vertices snap back to the original position where they were first drawn, and all animation is lost. This occurs only if the Lasso Fit value retains its influence on the garbage mask.

Garbage Mask Nodes

When you create a garbage mask, an Axis node and a Geom node are added to the schematic. The Axis node contains rotation, position and scaling data. The Geom node contains information about how the mask will affect the image. There is also a Camera node, which is always part of the scene. The Camera node can parent the Axis node for greater precision over the garbage mask, particularly if you want to rotate or orbit the camera with respect to the garbage mask.

To view the schematic, select Schematic from the World View box to toggle between the Schematic view and the previous view.

(a) Axis node (b) Geom node

Changing the Priority Order of Masks

When you create several garbage masks on an image, you can change the order in which they are drawn, or layered in the scene. This affects the resulting image because a mask with a higher priority has precedence over one with a lower priority. You can use the priority order to create complex effects involving multiple garbage masks.

To set the priority of a mask:

- 1 Select the mask.
- 2 Click Push to move the mask down a layer; click Pop to move the mask up a layer.

NOTE You cannot animate the priority by setting Push and Pop at different frames. When you set a mask's priority with Push or Pop, it is set for the entire clip.

Transforming the Mask

You can apply transformations such as translation, rotation, scaling, shearing, and centre changes to a garbage mask. The transformation data for the mask is stored in its Axis node. You apply transformations to the mask using the Axis controls.

All transformation parameters in the Axis menu can be animated. You can use a motion path to animate the position of a mask.

You can also apply motion blur to a garbage mask. See [Applying Motion Blur to Garbage Masks](#) (page 926).

To transform a mask:

- 1 Access the Garbage Mask menu.
The Axis controls appear.
NOTE The Axis controls are similar to the Axis menu in Action.
- 2 Use the Transformation fields to modify the position, shape, and size of the mask.

Manipulating Vertices and Tangents

Use the options in the Tools box to manipulate the vertices on the mask. You can edit the mask most easily in Front, Key-In, or Matte view.

Selecting Vertices and Tangents

You can select vertices and tangent handles when Select, Move, or Scale is selected in the Tools box:

- To select an individual vertex or tangent handle, click the vertex or tangent handle.
- To select multiple vertices, **Ctrl**-drag a selection box over a series of vertices.
- To select multiple vertices using the pen, press the pen button and drag a selection box over a series of vertices.
- To add another vertex to a multiple selection, **Shift**-click the vertex.

- To add several more vertices, press `Shift+Ctrl` and drag a selection box over the additional vertices.
- To deselect all vertices, click anywhere outside the mask.

Selecting Pickers and Softness Vertices

You can select pickers or softness vertices using the following techniques. Pickers are an element of the Tracer tool, which is only available in the GMask node in Batch or Batch FX and the Modular Keyer. See [Applying Softness Using Pickers](#) (page 932).

To select a single picker or softness vertex:

- 1 Click the picker or vertex that you want to select.

To select multiple pickers or softness vertices:

- 1 Select the mask vertices that the pickers or softness vertices are associated with (see previous section).
- 2 Click a picker or softness vertex corresponding to one of the selected mask vertices.
The pickers or softness vertices are selected for all the selected mask vertices.

Moving Vertices and Tangents

You can move vertices and tangents using the Move and Scale options of the Tools box:

- To move a vertex or tangent in any direction, select Move. Click the vertex or tangent and drag.
TIP If you have trouble selecting a tangent handle that is very close to the vertex, hold `Q` then select it.
- To move selected vertices in any direction, select Move. Click one of the selected vertices and drag.
- To move one or more selected vertices in the direction perpendicular to their tangents, select Scale. Click one of the selected vertices and drag.
- To ensure better continuity on a garbage mask, automatically adjust tangents as you move vertices or scale the mask. Press and hold `G` and then drag a vertex. See [Automatically Adjusting Tangent Handles of Adjacent Vertices](#) (page 919).

Breaking Tangents

You can separate two tangent handles (“break” the tangent) and move them separately using the Break option from the Tools box:

- To break and move a tangent handle, select Break and click the tangent handle. The tangent is displayed as a solid line, indicating it is “broken.”
- To reconnect two broken tangent handles, select Auto and click either of the two tangent handles. The tangent is displayed as a dotted line.
- To change the position of an individual tangent handle after releasing the cursor, select Move.

Removing and Adding Tangents

You can also use the Break option to remove tangents from vertices by clicking the vertex while in Break mode. When you remove a tangent, the curve defined by the tangent is removed.

The shape of the border line differs depending on whether adjacent vertices are broken:

- If adjacent vertices are unbroken, the border line curves as it approaches the vertices.
- If adjacent vertices are broken, the border line is straight as it approaches the vertices.

You can create a garbage mask composed entirely of straight edges by removing the tangents from all the vertices:

- To remove the tangent of a vertex, select Break and click the vertex.
- To add a tangent back to a vertex, select Auto and click the vertex. Alternatively, using the Break option, click the vertex and “drag” the tangent out again.

Automatically Adjusting Tangent Handles of Adjacent Vertices

When you move vertices, the tangent handles of the two adjacent vertices remain fixed in their current position. You can make them automatically adjust to create smooth curves between the vertices by pressing the **G** keyboard shortcut as you move vertices.

You can reverse the behaviour so that dragging vertices automatically adjusts tangents without using the keyboard shortcut. You reverse the behaviour by setting the following environment variable:

```
DL_GMASK_AUTO_MOVE_MODE
```

To reverse functionality of the **G** keyboard shortcut:

- 1 From the home directory of the application, open the `.cshrc` file in a text editor.
- 2 Add the following line to the end of the `.cshrc` file:

```
setenv DL_GMASK_AUTO_MOVE_MODE
```
- 3 Save and close the `.cshrc` file.
- 4 In the home directory, type:
source .cshrc
- 5 Launch or restart the application.

When you click or move a vertex on a garbage mask, the tangents are automatically repositioned. When you press **G** and click or move a vertex, the tangents are not repositioned.

TIP Alternatively, you can set the environment variable in the shell pointing to the home directory of the application. When you set an environment variable in the shell, the environment variable is enabled for the current session only.

Creating Right-Angled Vertices

You can create right-angled vertices using the following technique.

Press:	To:
Ctrl+A	Select all vertices.
B	Break apart tangents.
G	Create right-angled vertices of selected vertices.

Animating Garbage Masks

You can animate a garbage mask using the Shape channel in the Channel Editor or using spline keyframing, which animates individual Vertex channels. Vertex channels correspond to the vertices—or handles—that appear along the perimeter of the garbage mask. The Vertex channel names are contained in the Spline folder in the Channel Editor.

You can apply tracking data to a mask's axis to animate a garbage mask. Existing keyframes are disregarded, after applying tracking data, you can animate individual vertices and make adjustments.

Animating Masks Using the Shape Channel

The Shape channel shows when the shape of the garbage mask changes during the animation.

To animate a garbage mask using the Shape channel:

- 1 In the Garbage Mask menu, click Mask Setup.
- 2 In the Garbage Mask Setup menu, turn on Spline Keyframing.
Each time you move a vertex, a shape key is added at the current frame.

NOTE Disable Spline Keyframing if you do not want a keyframe added to the Shape channel.

- 3 Click Mask Setup again.
The Garbage Mask menu appears.

(a) Shape Animation button **(b)** Linear Interpolation button

- 4 Enable Shape Animation.
If keyframes are already set for specific vertex channels, the following message appears: "Convert explicit channels to a single shape channel?"
- 5 Click Confirm.
The Shape channel appears in the Channel Editor and any Vertex channel keyframes are converted.

(a) Shape channel with 4 keyframes

NOTE Enabling Shape Animation disables the Vertex Keyframing and Channel Selecting boxes in the Garbage Mask Setup menu. These contain options for animating individual vertex channels. See [Animating Masks Using Spline Keyframing](#) (page 921).

- Depending on how you want to animate the garbage mask, use the Linear Interpolation and Constant Shape buttons as follows.

Enable:	To:
Linear Interpolation	Make the garbage mask trajectory linear. Enable this button when rotoscoping. For smooth garbage mask animation, disable this button.
Constant Shape	Keep the garbage mask shape the same for all frames. When you enable this button, the following message appears: "Remove all keyframes except current one?" Click Confirm.

Animating Masks Using Spline Keyframing

You can animate the shape of a mask by moving the vertices of a garbage mask spline at different frames throughout the clip. Each vertex has its own X, Y and Z position channels in the Channel Editor, as well as several other parameters, as shown in the following table.

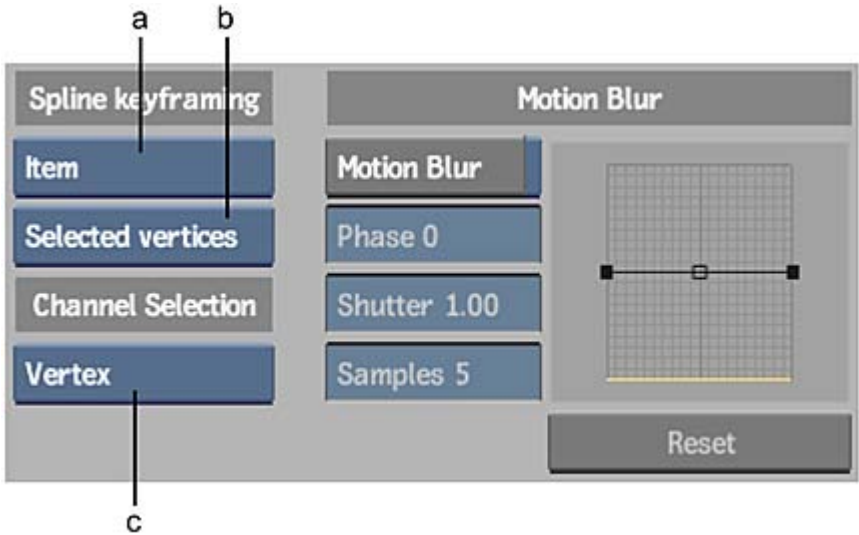

Parameter	Channel Editor Folder & Name(s)	Channel Editor Values
The position of the mask vertices.	<i>position: X, Y, Z</i>	
The position of the left and right tangent handles relative to the mask vertex.	<i>tangents: left, right</i>	
The tangent continuity (handles broken or unbroken).	<i>tangents: continuity</i>	0 = broken handles 1 = unbroken handles
The active/inactive status of mask vertices. See Adding and Removing Vertices (page 923).	<i>Vertex_x: active</i>	0= inactive 1 = active

Before you start to animate the mask, set the Spline Keyframing options in the Garbage Mask Setup menu. In the GMask node in Batch or Batch FX, these options are located in the Node Setup menu. Use these options to specify which elements will get a keyframe as you animate the mask.

As you adjust the mask, you can opt to apply keyframes to selected vertices or to all vertices. To quickly animate a mask, keyframe all vertices every time you adjust a single vertex. This way, what you see at a given frame will be exactly what you get no matter how you animate the “surrounding” frames.

To have more control over the shape of the mask frame by frame, animate one vertex at a time. This method is useful for tracking garbage masks and keeping control over tangent animation. See [Animating Masks Using Tracking](#) (page 925).

By combining the Spline and Vertex Keyframing options in different ways, you can set an animation mode to suit the task at hand. For example, by selecting Item and All Vertices, you could animate just the tangent handles of all vertices on the mask.

(a) Spline Keyframing box (b) Vertex Keyframing box (c) Channel Selecting box

Spline Keyframing box Sets the conditions under which keyframes are set, and for which parameters.

NOTE The Spline & Tracer, Spline only, and Item options are only available if you disable Shape Animation in the Garbage Mask menu.

Select:	To:
Spline & Tracer	Set a keyframe for all the parameters of the vertex or vertices and related elements, with the exception of the Sample On parameter. This option is only available when accessing the Garbage Mask Setup menu from the GMask node.
Spline only	Set a keyframe for one or more vertices, or related elements, for the specified parameter, as well as for the mask vertex position and the tangent position channels.
Item	Set a keyframe for a parameter of a vertex, or of a related element. Only the particular parameter gets a keyframe.
On	Set a keyframe for the shape channel when a change to a vertex is made (such as moving a vertex or tangent handle, breaking tangent handles, or changing the Active/Inactive status of a vertex). This option is only available when Shape Animation is enabled in the Garbage Mask menu.

Select:	To:
Off	No keyframes are set.

Vertex Keyframing box Sets the conditions under which parameters are applied to specified vertices in the mask.

NOTE The Vertex Keyframing box is only available if you disable Shape Animation from the Garbage Mask menu.

Select:	To:
All Vertices	Set a keyframe for the parameter you are animating for all the vertices of the mask. Related elements, such as tangents, also all get a keyframe when you animate a parameter on the mask.
Selected Vertices	Set a keyframe for the parameter you are animating for all selected vertices on the mask. Related elements, such as tangents, that are selected, also all get a keyframe when you animate one on the mask.

Channel Selecting box Determines which channels are selected in the Channel Editor when you select one or more vertices.

NOTE The Channel Selecting box is only available if you disable Shape Animation from the Garbage Mask menu.

Select:	To:
Vertex	Select all the channels related to the vertices you select on the garbage mask. For example, whether you select a vertex or one of its tangents, its active, position, and tangent channels are also selected in the Channel Editor.
Item	Select only the particular channel corresponding to the selected vertices. For example, if you select the right tangent handle of a vertex, only the corresponding right channel is selected in the Channel Editor.

Adding and Removing Vertices

To further control the shape of a mask throughout the clip, you can add and remove vertices from your mask at any frame of the clip. For example, if the shape changes radically or gets bigger part way through the clip, you can add vertices to reshape the mask at that frame. When you add a vertex part way through the clip, it is added to the whole clip but respects the existing shape of the mask in all previous and subsequent frames. Therefore, any reshaping that you have done to the mask is not affected by the new vertices.

NOTE Adding or deleting vertices on masks with freehand segments causes the Lasso Fit value to lose influence. See [Adjusting the Number of Points in Freehand Segments](#) (page 915).

If you delete a vertex, it becomes “inactive” from that frame to the next active/inactive keyframe set for that vertex, or, if there are no keyframes, to the end of the clip. An inactive vertex has no effect on the shape of the mask. On previous frames, the vertex is still active, so the mask shape is unchanged by the deletion. To delete the vertex completely (that is, throughout the whole clip), click it a second time.

(a) Active vertices (b) Inactive vertices

Use the options in the Tools box to add and delete vertices from the mask, and to control which vertices are active and inactive.

To add a vertex to the entire mask:

- 1 Select Add from the Tools box.
- 2 On any frame in the clip, click the mask where you want to add the vertex.

The new vertex is added and is active throughout the clip. It does not affect the existing mask animation, regardless of where in the clip you add the vertex.

To make an active vertex inactive:

- 1 Switch to Delete mode.
- 2 Click the vertex.

The vertex is inactive from the current frame to the next frame where an Active/Inactive keyframe has been set, or, if there are no keyframes, to the end of the clip. The status of the vertex on previous frames is unchanged.

NOTE Alternatively, use the Active button in the Shape menu to make vertices inactive. Select the vertex you want to make inactive (you must be in Select, Move, or Scale mode), and then click Active.

To make an inactive vertex active:

- 1 Switch to Add mode.
- 2 Click the inactive vertex.

The vertex is active from the current frame to the next frame where an Active/Inactive keyframe has been set, or, if there are no keyframes, to the end of the clip. The status of the vertex on previous frames is unchanged.

NOTE Alternatively, use the Active button in the Shape menu to make vertices active. Select the vertex you want to make active (you must be in Select, Move, or Scale mode), and then click Active.

To delete a vertex from the mask:

- 1 At any frame, switch to Delete mode.
- 2 Click the vertex.
It becomes inactive.
- 3 Click the vertex a second time.
It is removed from the mask for the duration of the clip.

NOTE You cannot delete the last three vertices of a mask, as they are the minimum necessary to define it. If you want to delete the mask, you delete its Geom node in the Garbage Mask Schematic.

Animating Masks Using Tracking

You can animate a mask by applying tracking data to it. This is useful when you want a garbage mask to follow a moving element in a clip. To do this, you can either:

- Animate the entire mask by applying the data to the mask's axis.
You can track an object on the front or back clip and apply the tracking data to the axis of a mask, or to a hierarchy of masks.
- Animate selected vertices according to reference points that you set in the Stabilizer.
Each vertex you select is assigned a tracker in the Stabilizer. The vertices are repositioned according to the reference points that you set in the Stabilizer.

When you apply tracking data to a mask, only the mask axis, or position of selected vertices, is animated. Any other keyframes set for the mask are disregarded. You can, however, animate individual vertices after applying tracking data to your mask's axis or to individual vertices. It is especially useful to manually adjust the tangent handles of the vertices at different frames where needed.

To animate an entire mask with tracking:

- 1 Access the Garbage Mask menu.
The Garbage Mask menu appears.
- 2 Select the mask.
- 3 From the Clip box, select the clip you want to track.
- 4 If necessary, adjust the mask using the Position, Rotation, Scale, Shear, and Centre fields.
- 5 Set the Rotation and Scaling options. To track rotation, select Rotation On; to track scaling, select Scaling On.
- 6 Select an option from the Adjust box.

Select:	If the selected mask is:
Adj Offset	Parented to one axis.
Adj Axis	Parented to a hierarchy of objects.

- 7 Go to the frame where you want to start tracking.
- 8 Click S.
The Stabilizer appears.
- 9 Position of the trackers.

NOTE The first tracker is for position data and the second tracker is for rotation and scaling data. If rotation and scaling were not selected, the second tracker has no effect.

- 10 Click Analyse.

Fine-tune your analysis if necessary. For more information, see [Stabilizing and Tracking](#) (page 869).

- 11 Click Return.

The Garbage Mask menu reappears. The tracking data is applied to the mask.

- 12 Fine-tune your mask if necessary.

To animate individual vertices on a mask with tracking:

- 1 Select a vertex or a group of vertices on a mask.

- 2 Access the Garbage Mask menu.

The Garbage Mask menu appears.

(a) Clip box (b) Adjust box

- 3 From the Clip box, select the clip you want to track.

NOTE When tracking vertices on a mask using the Garbage Mask menu in the GMask node in Batch or Batch FX or the Modular Keyer, you can only track the front clip.

- 4 From the Adjust box, select Adj Tangents.

The tangents for the selected vertices are adjusted while the points are being tracked.

- 5 Go to the frame where you want to start tracking.

- 6 Click S.

The Stabilizer appears. The trackers are automatically placed in the position of the selected vertices. Reposition if needed.

- 7 Click Analyse.

Fine-tune your analysis if necessary.

- 8 Click Return.

The Garbage Mask menu reappears. The tracking data is applied to the selected vertices on the mask.

- 9 Fine-tune your mask if necessary.

Applying Motion Blur to Garbage Masks

Use motion blur on a garbage mask to compensate for the movement of an object in a clip. Motion blur is created according to the animated movement of a mask's vertices. The amount of blurring is affected by the speed of the mask's movement.

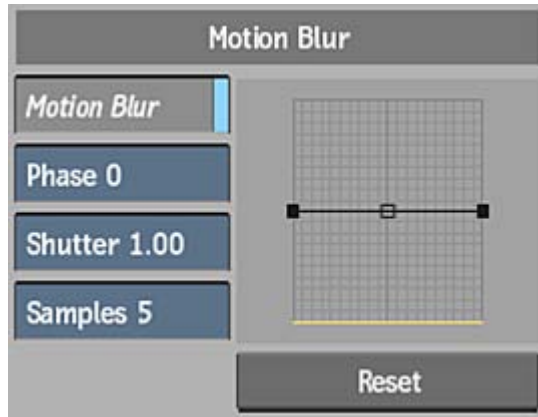

Motion blur can account for the natural blurring of an object as it moves or rotates in space. For example, assume you are drawing a garbage mask around a car as it turns a corner. Because you are using an overhead shot, the edges of the car where motion blur occurs change as the car accelerates and rounds the corner. By

applying motion blur to the mask, which has animated position and rotation values to match the car's movement, appropriate blurring of the car's edges into the background clip occurs.

TIP Besides the practical use of blurring a garbage mask, that is, to match the movement of an object you are keying, you can try blurring masks for artistic effects in multi-layered composites.

To apply motion blur to a garbage mask:

- 1 Access the Garbage Mask Setup menu.

- 2 Set the motion blur as follows.

Motion Blur button Enable to apply motion blur to garbage masks.

Phase field Specifies whether the motion blur is based on the movement before or after the current frame. A value of -100 places the motion blur before the frame, while a value of 100 places the motion blur after the frame. A value of 0 is centred, which evenly distributes the motion blur. The default value is 0.

Shutter field Controls the duration of the motion blur at each frame, which affects the size of the motion blur. Increasing Shutter value does not increase the processing time.

Samples field Determines the quality of the motion blur produced by the number of samples taken at each frame. Increasing the Samples value causes the processing time to increase linearly.

NOTE You can animate the Motion blur button, as well as the Phase, Shutter, and Samples fields. They can be found in the Channel Editor under the *motion_blur* folder.

Motion Blur curve Determines the transparency of the samples that create the blurring effect. The left side of the curve controls the samples of the incoming movement of the subject in the frame. The right side of the curve controls the samples of the outgoing movement of the subject in the frame.

For example, to add blur to the left edge of the mask as it travels from left to right in the clip, adjust the motion blur curve so it slopes down. If you want to add a bit of blur on each side of the mask, adjust the motion blur curve so it peaks in the middle.

Select one of the three vertices on the curve to move it. When you select a vertex, its tangent handle is displayed. You use the tangent handle to adjust the slope of the curve.

NOTE The garbage mask motion blur settings are similar to those in the Axis menu in Action.

Motion blur occurs on the mask according to the settings you select and the speed its vertices traverse the clip.

- 3 Enable Motion Blur. This makes the motion blur available for application on any garbage mask or axis in the setup.

NOTE Motion blur settings are applied uniformly to all garbage masks in the setup.

- 4 To reset all motion blur settings back to their default settings, click Reset and then click Confirm.
- 5 To apply motion blur to a garbage mask, access the Garbage Mask Shape controls, select the garbage mask, and then enable MBlur.
The settings specified in the Garbage Mask Setup menu will be used to create the motion blur effect on the garbage mask. You can select one garbage mask at a time.
- 6 To apply motion blur to an axis, select the axis, and then enable MBlur.
The settings specified in the Garbage Mask Setup menu will be used to create the motion blur effect on the axis. You can select one axis at a time.

Blurring a Stationary Garbage Mask

You can create a motion blur effect for a garbage mask without having the mask actually change position. This could be useful, for example, if you would like to simulate movement in a stationary image.

To apply axis motion blur:

- 1 Toggle to schematic view and add a new axis.
- 2 Parent the new axis to the garbage mask axis.
The garbage mask and the new axis should now both be parented to the garbage mask axis.

- 3 Apply motion blur to the new axis.
Motion blur is applied to the stationary garbage mask.

Rendering Garbage Masks in Interlaced Mode

Using the GMask node, you can render garbage masks in Interlaced mode to accommodate video material.

To render garbage masks in Interlaced mode:

- 1 From the GMask node's menu, select Interlaced from the Rendering box.

Using Multiple Garbage Masks

Use the Region of Interest feature on clips containing multiple garbage masks that each hide a portion of the matte. Region of Interest ensures that multiple overlapping or non-overlapping garbage masks all respect the areas defined by one another. Furthermore, you can individually modify the opacity of each mask.

Region of Interest is only available when accessing the Garbage Mask menu from the GMask node in Batch or Batch FX.

Two garbage masks with Region of Interest enabled

To draw more than one garbage mask revealing a matte:

- 1 In the Garbage Mask menu, select Geom from the Object box and click Add.

(a) Add button (b) Object box

2 Draw the first garbage mask.

3 Switch to Result view.

4 Enable Region of Interest.

Outside is enabled and the Colour is set to 0.0 for the mask.

NOTE Disabling Region of Interest toggles the Colour setting back to what it was before.

5 Adjust offsets and softness as required.

6 To adjust the individual opacity for each mask, select the mask and then adjust the value in the Opacity field.

7 Draw any other garbage masks as needed.

NOTE Each time you add a garbage mask with ROI enabled, Result view is temporarily cleared of all masks so that you see the entire matte. This way you have a better view of what you want to reveal and mask.

Refining the Mask

You can adjust the softness gradient of a mask to smoothen its edges. You can smoothen the gradient towards the inside edge, the outside edge, as well as the area where the inside and outside adjustments have an effect. You can create a uniform gradient around the edge of the mask, or use an advanced gradient to control the shape of the gradient at different parts of the mask.

To create a uniform gradient, you define how far you want the gradient to be offset from the edge of the mask and then set its transparency. To vary the shape of the gradient, you move vertices on inner and outer softness splines. The gradient will be based on how far each vertex point is offset from the mask.

(a) Alpha region (b) Inner offset

Advanced gradient provides a versatile method for setting the softness of the mask edge. It applies a gradient according to the distance of the softness borders from the garbage mask spline. It allows you to customize the softness gradient at different parts of the mask. The advanced gradient has two softness borders, one inside and one outside the mask border. It also includes inner and outer softness vertices for each regular mask vertex.

(a) Outer Softness border (b) Inner Softness border (c) Softness vertices (d) Mask border

Some potential uses for the advanced gradient are:

- Creating compositing effects when using Action
- Removing wires
- Pulling a key on areas of the mask where pickers are not needed

When using the Tracer in the GMask node in Batch or Batch FX or the Modular Keyer, you can work in two modes: advanced gradient and pickers. Individual vertices can be set to either of these modes.

You can change the default mode of the Tracer from advanced gradient to pickers, a system of localized keys. Tracer analyses the colour information both inside and outside the mask, then compares the values and uses a keying algorithm (the same one used in the 3D Keyer) to derive a key for the mask edge. This system allows you to key images with a lot of detail at the edges.

NOTE For good results with the Tracer, the object must have sufficient (and relatively consistent) chroma and luma differences between its foreground and background.

To control softness and advanced gradients, use the Garbage Mask Shape controls.

(a) Edge Softness box (b) Alpha field (c) Offset field (d) Distance field (e) Inner Edge field (f) Outer Edge field

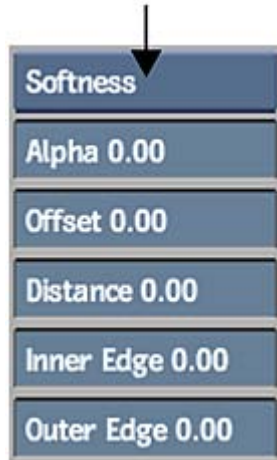

Applying Softness Using a Uniform Gradient

Use the Softness fields to apply a constant range of softness to the edge of the mask. The Alpha and Offset fields define the fade-out of the softness gradient from the edge of the mask.

Once gradient transparency and offset have been determined, the degree of smoothness can be set using the Inner Edge and Outer Edge fields. You can then use the Distance field to determine the area where Inner Edge and Outer Edge settings have an effect.

To apply uniform softness:

- 1 Access the Garbage Mask menu.
- 2 Select a mask in the image window.
- 3 If necessary, toggle the Edge Softness box to Softness.

- 4 Set the border of the softness gradient using the Offset field. The gradient will be affected by how far the softness border is offset from the edge of the mask.
- 5 Set the transparency of the gradient using the Alpha field.
- 6 Use the Inner Edge field to smoothen the softness gradient towards the inside.
- 7 Use the Outer Edge field to smoothen the softness gradient towards the outside. Adjusting this value is especially noticeable if you are smoothening a transition from a black inside edge to a white outside edge.
- 8 Use the Distance field to modify the area of which the Inner and Outer Edge adjustments have an effect.

Applying Softness Using Pickers

You can change the default mode of the Tracer from advanced gradient to pickers, allowing you to sample colours inside and outside the garbage mask spline, to apply softness according to the colour transition in the clip. Individual vertices can be set to either of these modes.

When great control over the mask edge is needed, for example, for fine edge detail, use pickers to effectively key out the background. The Tracer uses pairs of pickers to do luma and chroma analysis of the area inside and outside of the mask and derives localized edge keys from this information.

(a) Pickers—Colour analysis is done in the area inside the pickers.

The area that each picker affects extends halfway towards the two adjacent mask vertices, and up to the two softness borders, as shown in the following example.

(a) Borders of area of pickers' influence.

Using pickers, you can key objects that otherwise would be extremely difficult to key. Imagine a golden horse with a very fine mane on an unfocused background of various colours. As long as you have some chroma/luma differences in the background (green vegetation, blue sky, black earth or rocks), you can 'force' the outside pickers to sample these colour values. The inside pickers can sample the golden average values, and the Tracer can generate a soft-edged matte based on the difference between the two sets of values.

Pickers can be selected and manipulated independently of the vertices they are associated with. See [Selecting Pickers and Softness Vertices](#) (page 918).

Mixing Advanced Gradient and Pickers

When the subject has a mixture of fine, wispy edges and hard, clean edges, use a mix of localized keys and advanced gradients. Pickers are better for the fine edge areas and advanced gradient is sometimes better for the hard edge areas. You can set the state of each vertex to advanced gradient (pickers off) or localized key (pickers on) mode.

- To convert a section of a mask from advanced gradient to pickers, select one or more vertices with no pickers and enable the Picker button. Adjust the pickers as needed.

- To convert a section of a mask from pickers to advanced gradient, select one or more vertices with pickers and disable the Picker button.
- To toggle selected vertices between the two modes, use the 0 (zero) keyboard shortcut.

To completely remove gradient (for hard edges):

- 1 Select the mask vertices in the area of the mask border where you want to remove the gradient.
- 2 Click any one softness vertex corresponding to one of the selected mask vertices (either an inner or outer vertex).
All the corresponding inner or outer softness vertices are selected.
- 3 From the Tools box, select Scale.
- 4 Click any one of the selected softness vertices and drag until the softness border is lined up with the mask border.
- 5 Repeat for the second softness border (inner or outer).

To separate the softness border from the mask border:

- 1 Click a mask vertex, and then drag to the right to move the softness vertex out.

Applying Softness Using the Tracer

Drawing a Tracer-aided matte entails four basic steps.

To draw a Tracer-aided matte:

- 1 Analyse the image to determine which areas are appropriate for pickers and which areas are better served by advanced gradients.
- 2 Draw the garbage mask.
- 3 Assign pickers to vertices where they are needed.
- 4 Adjust the softness borders, offsets, tangents, vertices, and pickers (where used).

To analyse the image:

- 1 Examine the edges of your talent to decide which portions would benefit from advanced gradient treatment and which would respond better to localized key treatment. If your clip has colours that change greatly throughout the clip, using pickers may be difficult.

For more information, see [Applying Softness Using Pickers](#) (page 932).

To draw the garbage mask:

- 1 In the Modular Keyer or Batch or Batch FX, add a context point further down the processing pipeline or processing tree. You can then use the Context view to see the effect of the matte on the result image.

NOTE When using the Tracer to pull a key from the Modular Keyer, remove the nodes before the GMask node in the default pipeline.

- 2 Display the Garbage Mask menu.
- 3 From the View box, select Reference.
This view is a reference image of the clip.

- 4 Draw a garbage mask around the subject and close it by clicking the first vertex drawn. Use as many vertices as required to adequately enclose the subject, but try to avoid excessive vertices. This will minimize unnecessary tweaking and manipulation later.

TIP Place more vertices in areas with variation in the background.

To assign pickers to selected vertices:

- 1 From the Edge Softness box, select Tracer.

The Tracer menu appears, and two softness borders (the green lines) are added to the mask.

(a) Edge Softness box

- 2 Select the vertices to which you want to apply pickers. See [Selecting Vertices and Tangents](#) (page 917).
- 3 Enable Pickers.

NOTE When one or more pickers are enabled, mask characteristics are automatically set to Outside disabled and a Colour value of 0 so that the mask will be white inside and black outside. Do not set the Outside button unless you want to reverse the effect.

A pair of pickers is provided for each selected vertex.

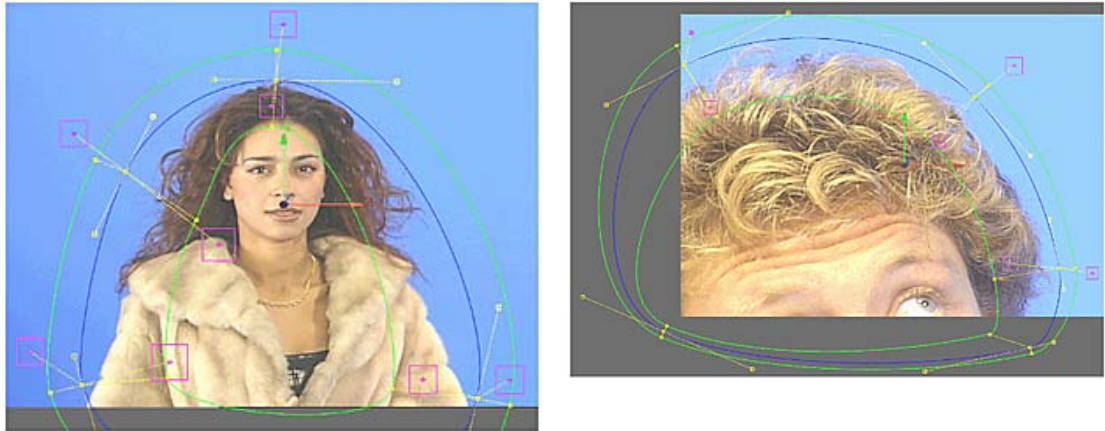

(a) Softness borders (b) Picker

- On vertices without pickers, the softness borders delineate the area where a softness gradient is applied.
- On vertices with pickers, the softness borders delineate the area to which softness is applied according to the picker values.

To fine-tune the matte:

- 1 Adjust the softness borders and mask border by moving the vertices and tangents:
 - The mask border should follow the general contour of the subject as closely as possible.
 - The outer softness border should completely surround all details that you want to include in the matte—all wispy details and edges must be within this line.
 - The inner softness border should be well within the area where softness control is needed.

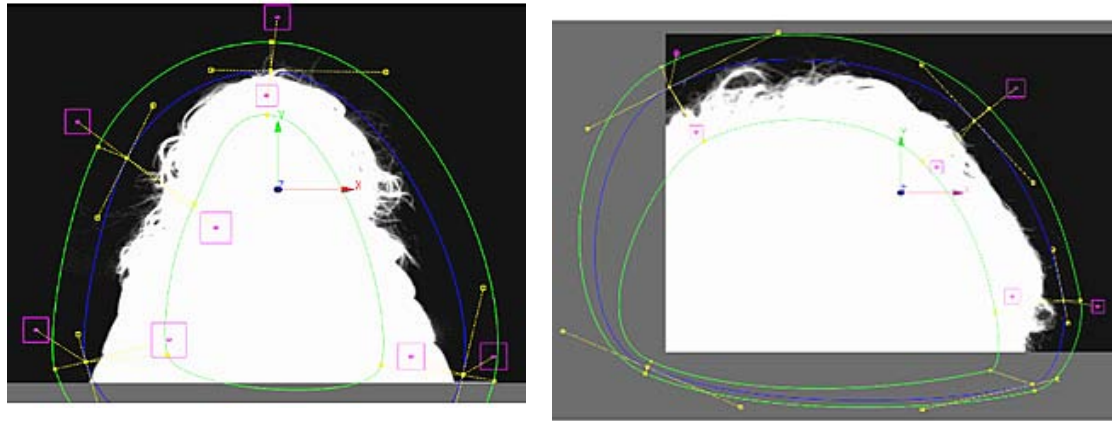

When moving tangents, you can opt to have the pickers follow the tangent movement (the default behaviour), or be independent of tangent movement. To make pickers independent of tangents, switch to Break mode and click either picker. You can animate this behaviour. See [Animating a Tracer Mask](#) (page 937).

NOTE If the tangents are broken, the pickers are automatically unlinked from the tangents.

- 2 For each pair of pickers, one requires a sample of the area outside the mask, while the other requires a sample of the mask interior.
Place one picker outside the subject to sample values you do not want to include in the matte (for example, a blue screen). Place the other picker within the subject for a colour value sample of an area you do want included in the matte. Try to select areas where the colour values do not change too much throughout the clip.
- 3 Click Matte or Result (Matte will provide a clearer view) to see your progress.
- 4 Scale the pickers by doing one of the following:
 - Select Scale edit mode, click within the picker, and drag to the left to reduce the size or to the right to increase the size.
 - Select the picker and then drag the cursor over the Sample Size field.
- 5 Move the pickers around and enlarge or reduce them to interactively see how you can obtain the best results. This will require toggling between the Front and Matte views.

The following figure illustrates the Matte view result of the pickers placed in the previous figures.

Animating a Tracer Mask

When using the Tracer, you can animate the basic vertex parameters, as well as the following additional parameters.

Parameter	Channel Folder and Name(s)	Channel Values
The position of the two softness vertices relative to the mask vertex.	border: upper = outer vertex* bottom = inner vertex*	
Whether pickers are linked to tangents or not. Linked—Pickers move with tangents. Unlinked—Pickers remain in their current position when tangents are moved.	pickers: fixed	0 = unlinked 1 = linked
The on/off status of pickers.	pickers: active	0 = off, 1 = on
The position of the pickers relative to the mask vertex.	pickers: upper = outer picker* bottom = inner picker*	
The picker size.	pickers: u-size = outer picker size* b-size = inner picker size*	
The Sample on/off status of pickers. See Animating Picker Values (page 938).	sample: active	0 = Sample off 1 = Sample on
The interpolation mode for picker values when Sample is off. See Animating Picker Values (page 938).	sample: interp.	0 = Constant 1 = Linear

*Channel Editor designations for “upper” and “bottom” assume the mask was drawn clockwise.

Animating Picker Values

Two options are available to control how picker values (that is, the sampled colour values) are animated: Sample On and Interpolation mode.

(a) Sample box (b) Interpolation button

Sample box Active resamples picker values at every frame (the default). Passive disables resampling for one or more frames. When Passive at a particular frame, the picker values previously sampled at another frame are used. It is useful to adjust the size and position of pickers at one particular frame until the result is optimal, and then apply these values to other frames. In this way, if movement in the clip in other frames causes the area being sampled to move away from the pickers, you do not need to readjust the pickers to get a good reading.

You can select Active or Passive for one or more selected pickers.

Selecting Passive works best when colour values remain fairly consistent throughout the clip. In this case, one picker sampling will often be enough for the entire clip.

Typical technique for using Sample On: one sample is used for the entire clip

(a) Sample Off (b) Sample On (c) Sample Off

When there is more colour variation in the clip, you may need to take samples at several frames.

To use one picker sampling throughout a clip:

- 1 Choose a frame in which the colour values are representative of the average colour values found in the clip.
- 2 Select the pickers you want to sample. See [Selecting Pickers and Softness Vertices](#) (page 918).
- 3 At that frame, make sure Active is selected from the Sample box (the default).
- 4 Set the picker values by setting their position and size until you get the optimal result.
- 5 Go to the next frame and select Passive from the Sample box.
The sample values read at the frame you chose will be used to compute the softness for all other frames in the clip.

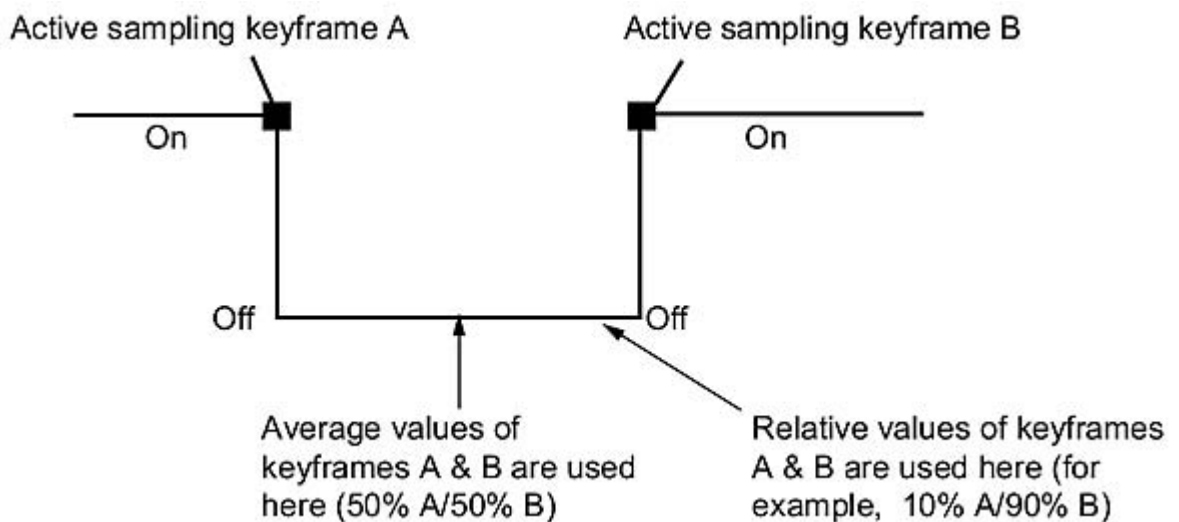

To take samples at several frames:

- 1 Follow the steps in the previous procedure to set a picker sampling for the clip.

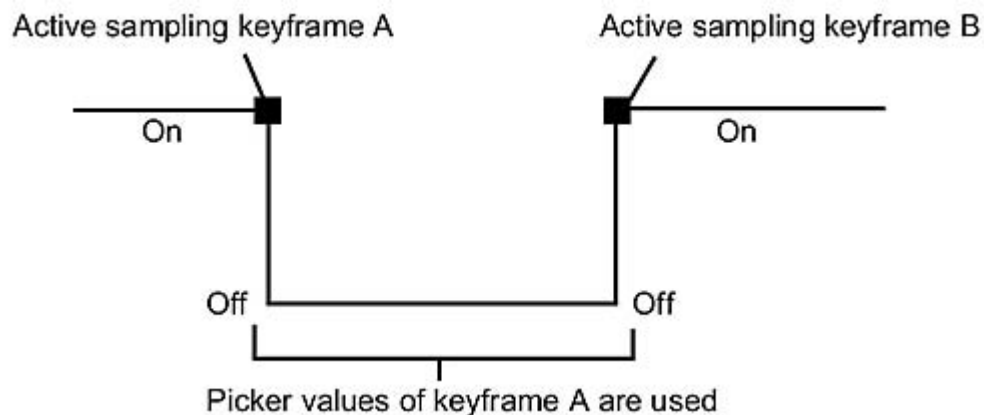

- 2 Starting at the first frame sampled, examine your results frame by frame (either forward or backward through the clip).
- 3 When you come to an unsatisfactory result, select the pickers you want to re-sample and select Active.
- 4 Adjust the picker position and size until you get a good result.
- 5 Go to the next frame and select Passive from the Sample box.
- 6 Continue verifying frames until you come to one that needs to be adjusted.
- 7 Repeat steps 3-5.
- 8 Repeat for the remainder of the clip.

Interpolation button Displays the interpolation between keyframes that have Active selected as the Sampling option.

- **Linear (enabled):** Picker values are interpolated between keyframes with active sampling. The picker values for each frame are computed based on the values of the previous and next active sampling keyframes and the proximity of the frame to those keyframes.

- **Constant (disabled):** Picker values are fixed between keyframes with active sampling. This means that the picker values at the first active sampling keyframe will be used for all subsequent frames up until the sampling is active again.

Tracking with the Tracer

Tracking with the Tracer is done using the same method as with regular garbage masks. See [Animating Masks Using Tracking](#) (page 925).

NOTE When animating selected vertices with the Stabilizer, the vertices do the tracking, not the pickers. Once you obtain the tracking data, you will need to go back through your clip from frame 1 onwards, making adjustments to the pickers where necessary.

Troubleshooting the Tracer

Every clip has its own challenges and requires a certain amount of tweaking and fine-tuning to achieve the best results.

Problem	One of the Tracer segments (localized keys) on my matte shows noisy black and white artefacts and nothing else. What's wrong?
Possible Cause	The two pickers are sampling luma and/or chroma values that are too similar.
Solution	Try moving one of the pickers to a differently coloured area, or enlarge or reduce the size of one or both of the pickers to include more varied colour information. If there is simply no area in the clip that differs enough, you will need to use an advanced gradient for that segment.
Problem	One of the Tracer segments (localized keys) on my matte appears to be showing the black/white matte information reversed, or as a negative. What's wrong?
Possible Cause	You may have reversed the position of the two pickers.
Solution	Try exchanging the inside picker for the outside one and vice-versa.
Problem	I can't get a good colour sample from the area outside the mask edge in a certain portion of the image. What can I do?
Possible Cause	There is simply none (or not enough) of the needed colour in the immediate area of that particular picker.
Solution	You can drag the picker somewhere further away from the vertex to get a better colour sample. The picker can be located anywhere on the image in order to facilitate the best possible colour sample. Do not, however, place a picker outside the image.
Problem	I'm getting really nice edge detail on my matte, but I'm also getting black/white holes in my matte. Is there anything I can do?
Possible Cause	This may be caused by the generation of random noise and/or artefacts.

Solution 1	Try the Clean algorithm by clicking the box labelled Clean. You may want to try several different percentages to find the optimal level of cleaning that doesn't effect your edges (the default percentage is 70%). The Clean algorithm works only with the Tracer and pickers on. If you have advanced gradient segments, they will be unaffected. The Clean command works on all vertices with pickers, whether or not they are selected. The area affected by the Clean command is the same area that the pickers affect (see Applying Softness Using Pickers (page 932)).
Solution 2	Use the inner border to isolate the problem areas.
Solution 3	Add a second garbage mask.
Problem	I'm repositioning and rescaling the pickers and the matte goes from having too much softness (overly transparent) to having too little (overly opaque). What can I do?
Possible Cause	The sampled colour range is either too broad or too narrow.
Solution	Locate the areas that have a tendency to become too softened and the picker that is 'responsible' for this by moving the pickers until the matte results change for the worse. Include a larger portion of these softer areas in a picker box. By sampling a fuller range of chroma/luma in this area, a more uniform, averaged effect is created.

Saving Garbage Mask Setups

Garbage masks can be saved and loaded as setup files, with all vertex and animation information preserved.

To save garbage masks as a setup:

- 1 In the Garbage Mask menu, click Save to open the file browser.

- 2 From the GMask Type box, select Save GMask.

- 3 Type the name of the setup, and click Save.

Loading Garbage Mask Setups

In the file browser, when loading garbage mask setups, you can quickly navigate to either the default gmask directory or a custom directory for the current project.

In Action, you can load a garbage mask as a 3D model. See [Using Garbage Masks as 3D Geometry](#) (page 562).

To navigate to the default or custom directory when loading garbage mask setups:

- 1 Select Default or Custom from the GMask Directory box.

NOTE The custom directory is updated every time you navigate to a new directory.

To load a garbage mask setup:

- 1 In the Garbage Mask menu, click Load to open the file browser.

- 2 From the GMask Type box, select Load GMask.

- 3 From the file browser and select the name of the setup to load.

If the GMask setup you are loading was created in a different resolution than the current project, click Scale Setup to scale the GMask.

NOTE The Scale Setup button is available on the GMask Setup menu only when accessed from the GMask node in Batch or Batch FX or the Modular Keyer.

Preset Garbage Mask Setups

A library of preset garbage mask setups is available. To load a preset garbage mask, navigate to the `/usr/discreet/<product home>/gmask` directory and select one of the following:

- | | | | |
|----------------|----------------|-------------------|-------------|
| ■ 4_point_star | ■ 5_point_star | ■ 6_point_star | ■ arrowhead |
| ■ cat_eye | ■ circle | ■ diagonal | ■ diamond |
| ■ heart | ■ hexagon | ■ keyhole | ■ oval |
| ■ pentagon | ■ rectangle | ■ round_rectangle | ■ s_shape |
| ■ square | ■ triangle | ■ v_shape | |

You can also view proxies for each of these setups using the file browser.

Importing and Exporting Raw Setup Files

You can import and export raw setup files for animated garbage masks. A garbage mask exported as a raw setup file includes the following information:

- The number of keyframes in the animation of the spline
- The number of vertices in the shape
- The x, y, and z position of every vertex at each keyframe

To export a raw setup file:

- 1 In the Garbage Mask menu, click Save to open the file browser.
- 2 From the GMask Type box, select Export RAW.
- 3 Type the name of the file to be exported, and click Save.

To import a raw setup file:

- 1 In the Garbage Mask menu, click Load to open the file browser.
- 2 From the GMask Type box, select Import RAW.
- 3 Navigate to the appropriate directory and select the raw setup file to import.
The raw setup file is imported into the Keyer.

To import a raw setup file in the Modular Keyer:

- 1 In the Modular Keyer, click the GMask node in the processing pipeline. See [Accessing the Garbage Mask Menu](#) (page 907).
- 2 In the GMask menu, click Load.
The Load menu and file browser appear.
- 3 In the Load menu, select Import Raw and Default from the Load option boxes.

- 4 Enable Append or Replace.
- 5 In the file browser, specify the name and path of the file to import.

To export a raw setup file in the Modular Keyer:

- 1 In the Modular Keyer, click the GMask node in the processing pipeline. See [Accessing the Garbage Mask Menu](#) (page 907).
- 2 In the GMask Setup menu, click Save.
The Save menu and file browser appear.

(a) Save option box

- 3 In the Save menu, select Export Raw from the Save option box.
- 4 In the file browser, specify the name and path of the file to export.
- 5 Click Save.

Creating Customized Wipes with Garbage Masks

Use masks on the incoming clip to create a customized transition that wipes into the outgoing clip.

Setting the Mask Drawing Options

Before you create a mask, set how the points of the mask are drawn.

To set the drawing options:

- 1 From the Wipe Editor, click Setup.

2 Specify the setup options.

Enable:	To:
Auto Tangents	Create tangents for every new point you set.
Show Border	View the border defined in the Offset field of the Shape menu. The colour pot next to the Show Border button defines the colour of the border.
Invert	Reverse your wipe. For instance, if you originally create an expanding box wipe, enabling Invert creates a shrinking box.
Spline Keyframing	Allow animation of points on the mask.

3 To change the colour of the mask's wireframe, colour points, or offset border, click a colour pot and pick a colour.

About Colour Correcting

The Colour Corrector includes tools that provide precise control over colour values. You can modify luma ranges in a clip (shadows, midtones, and highlights), sample colours, and adjust the colour balance. You can rewire colour channels and suppress colours, as well as animate a colour correction by manipulating the animation curve in the Channel Editor.

When working with large images, you can free up additional screen space with the Overlay user interface. This feature is exclusive to the Colour Corrector and the Colour Warper. The Colour Warper's Overlay user interface is not available when accessing the Colour Warper as a Batch or Batch FX node.

For details on using the Overlay user interface, see [Overlay User Interface](#) (page 949).

Accessing the Colour Corrector

To access the Colour Corrector, you must load clips of the same resolution. If the clips you want to load have different resolutions, resize them so that they have the same resolution.

You can load a front clip, a front and back clip, or a front, back, and matte clip for colour correction. Changes in colour are applied to the front clip.

To access the Colour Corrector menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- Modular Keyer, Action or Paint tool.

Accessing the Colour Corrector from Batch

To access the Colour Corrector from Batch:

- 1 Double-click on, or drag, the Colour Correct node from the node bar and place it in the schematic. Make sure you connect to other nodes or clips in the process tree.
- 2 Click the Colour Correct node.
The Colour Correct Node editor appears.

Accessing the Colour Correct from Batch FX

To access Colour Correct through Batch FX:

- 1 Select Timeline.
- 2 Select the segment.
- 3 Click the FX button.
- 4 Click the Create Batch FX button.
- 5 Double-click on, or drag, a Colour Correct node into the schematic.
The Colour Correct node is now in the schematic.
- 6 Double-click the Colour Correct node.
You are in the Colour Correct node editor.

Accessing the Colour Corrector from the Timeline

To access the Colour Corrector from the timeline:

- 1 Select the Timeline tab.
- 2 Do one of the following:
 - Click the FX button.
 - Right-click on a segment in the timeline and choose Add Effect.
The Effects ribbon appears.

NOTE Effects that are enabled have already been added to the current Timeline FX pipeline.
- 3 Enable CC (Colour Correct).
- 4 You can adjust the effect's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

Accessing the Colour Corrector from Modular Keyer, Action, or Paint

You can colour correct clips loaded into the MODular Keyer, Action or Paint.

Back clips and key-in clips cannot be colour corrected.

To access the Colour Corrector from the Modular Keyer:

- 1 Double-click on, or drag, the Colour Correct node from the node bar to the schematic.

- 2 Double-click the Colour Correct node.
You are in the Colour Correct editor.

To access the Colour Corrector from Action:

- 1 From the Media menu, select the media containing the clip you want to colour correct.
- 2 Double-click the CC field for the media you want to colour correct.
The clip is loaded into the Colour Corrector.

To access the Colour Corrector from Paint:

- 1 Do one of the following:
 - To colour correct a clip, click Setup in the Paint menu. In a Colour Correction field, enable CC.
The clip is loaded into the Colour Corrector.
 - To colour correct a cutout, click Texture in the Paint menu, create a cutout. Click CC.
The cutout is loaded into the Colour Corrector.

Hiding the Colour Corrector Menu

You can hide the Colour Corrector menu while adjusting an image if you find the menu distracting. With the menu hidden you can modify numeric fields, use the colour wheel, or access buttons via their corresponding keyboard shortcuts.

To hide the Colour Corrector menu while modifying a numeric field or the colour wheel:

- 1 Click and hold any numeric field or the colour wheel. For example, click and hold the Hue field.
- 2 Press **Alt+`** (on the Tilde key) while continuing to hold the cursor.
The Colour Corrector menu is hidden.
- 3 Drag the cursor to modify the field value or adjust the colour wheel.
The changes you apply will be visible in the image as you drag if Regen is enabled (see [Dynamic Updating](#) (page 955)). Otherwise, the changes appear when you release the mouse.
- 4 Press **Alt+`** (on the Tilde key) to display the menu.

To hide the Colour Corrector menu while accessing buttons via their corresponding keyboard shortcuts:

- 1 Press **Alt+`** (on the Tilde key).
- 2 Use the Colour Corrector keyboard shortcuts.
- 3 Press **Alt+`** (on the Tilde key) to display the menu.

Overlay User Interface

The Overlay user interface is specific to the Colour Corrector and Colour Warper. Its controls are identical to those on the regular user interface except that they are transparent and appear on top of the image. This allows you a greater viewing area when working with large or zoomed-in images.

The Overlay user interface is available when accessing Colour Corrector or Colour Warper from Tools. It is not available when accessing the Colour Corrector or Colour Warper as a node or as a timeline effect.

To toggle between the Overlay user interface and the regular user interface:

- 1 Press **Ctrl+`** (on the Tilde key).

To hide the Overlay user interface:

- 1 Press **Alt+`** (on the Tilde key).

In addition to the increased area provided by the transparent controls, you can view even more of your image depending on the action you are performing. For example:

- Panning and zooming in the clip causes the Overlay user interface to disappear completely until the pan or zoom is complete.
- When you play the clip, the Overlay user interface disappears except for the timebar and the current frame number.
- When adjusting a menu parameter, all other user interface elements disappear.

The Overlay user interface does not support multiple views. When you switch to Overlay user interface while using multiple views, your viewport automatically goes to 1-Up until you toggle back to the regular user interface.

When you access a submenu in the Colour Corrector that does not support Overlay user interface, such as Load or Save, the Overlay user interface is restored when you return to the Colour Corrector.

Changing the Look of the Overlay User Interface Buttons

You can adjust the opacity of the Overlay user interface buttons to suit your preference, and even invert the elements in the interface so that white outlines and text appear in a muted grey.

To set preferences for the Overlay user interface:

- 1 While in the Overlay user interface from the Colour Corrector tool, click View.

	Gamma	Gain	Offset	Contrast
RGB	1.000	100.0	0.000	100.0
Red	1.000	100.0	0.000	100.0
Green	1.000	100.0	0.000	100.0
Blue	1.000	100.0	0.000	100.0

The Overlay user interface preferences are displayed.

Use the Opacity field to increase or decrease the opacity of the buttons. An opacity of 1.0 displays the buttons as they look in the regular user interface. You can also use the following keyboard shortcuts.

Press:	To:
Ctrl+Alt+(num pad) +	Increase the opacity of the Overlay user interface.
Ctrl+Alt+(num pad) -	Decrease the opacity of the Overlay user interface.

TIP You can repeatedly press the keyboard shortcuts to increase or decrease opacity, or simply hold down the keyboard shortcuts until the desired opacity is reached.

Enable Invert (or press Ctrl+Alt+(num pad) * to switch the Overlay user interface outlines and text from white to grey.

Viewing Clips

You can view a front, back, matte, or result clip in the image window. The front, back, and matte clips show the source clips used. The result clip shows your colour corrections as you apply them.

You can also view the following information for the clip:

- Channel: displays the numerical data used by the components in the clip.
- Reference: displays any referenced clips.
- Tracks: displays when an effect is used in the timeline
- Info: lists the channel, components, any related values, and the number of keys used in each effect in the clip.

To display a clip:

- 1 From the View box, select the clip you want to view. For example, select Result to view the result clip.

TIP Use the controls below the image window to change the frame displayed in the image window. Use the viewing tools in the upper-right corner of the panel to enlarge and pan images.

To change the clip that is displayed using the keyboard shortcuts:

- 1 Consult the following table.

To display:	Press:
The front clip	F1
The back clip	F2
The matte clip	F3

To display:	Press:
The result clip	F4
The channel data	F5
The track timeline	F5
The Info table	F5
The Referenced clips	Select Reference from the View box

Colour Corrector Settings

In the Colour Corrector Setup menu, you can change matte clip settings, the way that colour changes are updated, background brightness, and cropping. You can also reset colour corrections made from the Colour Corrector, Colour Warper, or both.

Inverting the Matte

You can invert the matte clip. Inverting the matte swaps the transparent and opaque areas of the matte and redefines the area of the front image that can be colour corrected, as well as the area of the back image that is shown.

To invert the matte clip:

- 1 Click Setup in the Colour Corrector menu.
- 2 Enable Invert Matte.

Changing the Background Brightness

You can adjust the brightness of your work area background. Changing the background brightness is a global setting. Changing the brightness through the Colour Corrector menu has the same effect as changing it through the Flame Premium Preferences menu.

To change the background brightness:

- 1 Click Setup in the Colour Corrector menu.

- 2 Enter a value in the Background field.

Creating a Crop Box

Use a crop box to view the colour changes to a limited region of the front clip. Colour changes only appear in the area within the crop box. This feature speeds up processing and lets you see the difference between the source clip and the result clip.

For example, while colour correcting, you can use the crop box to split the image window. The split window allows you to view the front clip and the result or matte clip at the same time.

To create a crop box:

- 1 Do one of the following:
 - Hold down the **Ctrl** key or hold the pen button and drag the box across the image.
 - From the Setup menu, enable the Crop button and enter the dimensions for the crop box in the Left, Right, Bottom, and Top fields.

The crop box appears in the image window. The display inside and outside the crop box depends on how many clips are loaded.

If you loaded:	Inside the crop box:	Outside the crop box:
A front, back, and matte clip	Shows the front clip in the opaque area of the matte and the back clip in the transparent area of the matte.	Shows the back clip.
A front and back clip	Shows the front clip.	Shows the back clip.
A front clip only	Shows the colour-corrected clip.	Shows the non-colour corrected clip.

- 2 To adjust the size of the crop box, drag on the corner points of the box, or modify the values in the Left, Right, Bottom, and Top fields in the Setup menu.
- 3 To move the crop box in the image window, click a side of the box and drag to a new location. Alternatively, press **Ctrl** and redraw the crop box.

TIP If Overlay user interface is enabled, the crop box will extend beneath the Overlay user interface. To access the bottom edge, be sure to grab from an area where there are no user interface elements.

To disable a crop box:

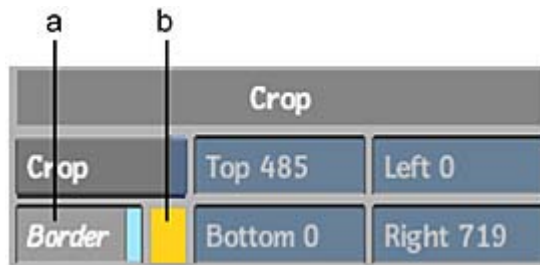

- 1 From any Colour Corrector menu, disable the Crop button.
When you disable the Crop button in a Colour Corrector menu, it is also disabled in the Setup menu.

Changing the Colour of the Crop Box

You can change the colour of the crop box so that it is easier to distinguish from the rest of your image.

To change the colour of the crop box:

- 1 In the Colour Corrector Setup menu, click the colour pot beside Border.

(a) Border button (b) Colour pot

- 2 Select a colour with the colour picker.
- 3 Click in the Border colour pot to apply the new colour to the border.

Hiding the Crop Box

You can hide the crop box to prevent it from affecting your colour correction.

To hide the crop box:

- 1 In the Setup menu, disable Border.

Dynamic Updating

Use the Regen button to enable dynamic updating of changes you make in the Colour Corrector. When Regen is enabled, you see the changes interactively as you adjust the values in the various displays. When Regen is disabled, you do not see changes until values are entered after releasing the cursor, or by clicking the `Enter` key in the calculator.

To enable dynamic updating:

- 1 Select **Setup > Master**.
- 2 Enable Regen.

Viewing Reference Clips

You can use the split bar to view and sample a reference clip while you work. Reference clips are particularly useful when you want to match colours or compare colour corrections. Carefully selecting a suitable reference clip will help you make your colour corrections quickly and efficiently. For example, you can use a reference clip from the Batch or Batch FX schematic to match saturation, whites and blacks, or colours. You can also switch between different references to ensure continuity throughout the project.

(a) Focus clip (b) Split bar (c) Reference clip

TIP If the Overlay user interface is enabled, the split bar can extend beneath the Overlay user interface. To access it, grab from an area where there are no menu elements.

Resetting Colour Corrections

You can reset colour corrections created with the Colour Corrector. You can also reset the corrections you make inside the Colour Corrector using the Reset Basics button, or by using the Range, Histogram, or Curve graphs.

To reset a colour correction:

- 1 Do one of the following:
 - In the Colour Corrector Timeline FX or Tools editor, click Reset All. Click Confirm.
 - In Batch or Batch FX, right-click the Colour Correct node in the schematic, and select Reset.

To reset a colour correction within the Colour Corrector:

- 1 Select one of the reset buttons depending on what you want to reset.

Select:	To reset:
Reset Basics	The basic properties of the Colour Corrector. Any changes made using the Curve, Histogram, or Range charts are unaffected.
Reset in the Curve menu	The settings defined by the Curve chart. The Basic properties of the Colour Corrector are unaffected.
Reset in the Histogram menu	The settings defined by the Histogram. The Basic properties of the Colour Corrector are unaffected.
Reset in the Range menu	The settings defined by the Range chart. The Basic properties of the Colour Corrector are unaffected.

Saving Setups and Preferences

In the Colour Corrector or Colour Warper, you can save or load colour correction or colour warper setups using the Save or Load button. Any setup can be loaded from the file browser for use with another set of clips using the same effect. You can also save or load colour correction or colour warper preferences using the Load or Save button.

- To save setups or preferences, click Save.
- To load setups or preferences, click Load.

TIP Click Revert to revert to the last saved setup. All changes made since the previous Save operation are undone.

Colour Sampling

You can sample colours from the front and back clips, and instantly see how the front clip will be affected by the colour correction.

Colours are sampled using colour patches. The sampled colours appear in the patches with their colour values. You can display the RGB, HLS, or Y (luma) values for the sampled colours. You can choose to display numerical sample data as either RGB bit values or percentages.

To sample a colour:

- 1 Below the colour patches, select the sample option you want to use.

Select:	To:
Y	Display the NTSC luma values for the colours sampled. Either NTSC 601 or HD 709 luma values are displayed, depending on the settings in the configuration file.
HLS	Display the hue, lightness, and saturation values for the colours sampled.
RGB	Display the red, green, and blue values for the colours sampled.
Off	Turn off the colour information display.

- 2 Click the Front colour patch to sample a colour from the front clip. Click the Back colour patch to sample a colour from the back clip. Click both patches to sample front and back clips simultaneously. The cursor becomes a colour picker.
- 3 To sample an individual pixel, click a colour in the image.
- 4 To sample an average colour, Alt-drag in the image, or press Ctrl and draw a selection box.

TIP Zoom in for more precise colour sampling.

The sampled colour appears in the colour patch. The sampled colour also appears in each menu.

In the:	A sample is displayed:
Colour Wheel	As a reference point on the colour wheel. A black reference point indicates the colour you sampled from the front clip. A white reference point indicates the sample from the back clip.
Histogram menu	As a red vertical line on the gradient bar, indicating the luma value. Only the front sample is displayed.
Curves menu	As red, green, and blue values mapped to the colour curves.
Ranges menu	As a red vertical line on the Luminance gradient bar, indicating the luma value. Only the front sample is displayed.

Colour Sampling and Processing Order

You can use any combination of colour correction commands to modify the front clip. The commands are processed in the following order:

- RGB Rewiring, Monochrome, Negative
- Hue Shifting
- Saturation
- Colour Balancing
- Gamma, Gain, Offset, and Contrast
- Histogram
- Colour Curves
- Chroma Suppression

The processing order is important in determining the colour that appears in the middle (result) section of the colour patch. The middle section displays the colour resulting from the application of all colour correction setups; in other words, the colour at the end of the processing order. This colour is updated as you change any parameter value. The original front colour appears in the left section of the patch.

Matching Colours

You can match and colour correct the colours of the front clip using the back clip as a reference. To perform a match operation, sample colours from the front and back clip and then use the Match button in the Curves menu.

To match colours between two clips:

- 1 Load a front and back clip from the Thumbnail view.
- 2 Use the split bar to view the front and back clips in the image window.
- 3 Click the Curves tab to display the Curves menu.
- 4 Click the Front colour patch.

The colour picker appears.

- 5 Using the colour picker, select a colour in the front clip to be corrected.
The colour is added to the Front and Result colour patches.
- 6 Click the Back colour patch.

The colour picker appears.

- 7 Using the colour picker, select a colour in the back clip to use as a reference colour.
- 8 Click Match.

The reference colour is applied to the result clip. The reference colour is also added to the Result colour patch and points are added to the colour curves.

When you use Match, a number is displayed in the numerical field beside the Rematch button. The first match you perform is indicated by a 1 in the field, the second by a 2, and so on. To revert to a previous match, click the numerical field and type the number of the match you want to recall. The colour patches and colour curves reset to the values stored in the specified match.

To reset the red, green, blue, or luminance curve, select a curve and click Reset in the Curve menu. The Curves menu also has its own Undo button that is separate from the overall Colour Corrector Undo.

Colour Correcting

Use the colour correction controls to perform many operations. You can:

- Colour correct shadows, midtones, and highlights separately or together.
- Adjust the hue, saturation, or contrast pivot point of an image.
- Rewire the red, green, or blue channels of an image.
- Create a negative or monochrome image.
- Adjust the gamma of the individual red, green, blue, or RGB channels.
- Adjust the red, green, blue, or RGB values in an image by modifying the gain, offset and contrast values for the channel.
- Perform colour suppression.
- Adjust the colour balance.

To reset any of these changes, click Reset Basics. To reset all the changes in the Colour Corrector, click Reset All.

Colour Correcting Shadows, Midtones, and Highlights

When you modify Saturation, Gamma, Gain, Offset, and Contrast, you can colour correct the shadows, midtones, and highlights ranges in the image individually or all together.

To colour correct shadows, midtones, or highlights:

- 1 Select the luma range you want to modify.

Click:	To modify:
Shadows	Dark areas in the image.
Midtones	Midlevel areas in the image.
Highlights	Light areas in the image.
Master	The entire image. Modification made in the Master range are applied after individual range modifications.

NOTE Monochrome, Negative, Chroma Suppression, and RGB Rewiring always affect the Master tonal range.

Adjusting the Hue

Hue is the main attribute that distinguishes one colour from another. When you adjust the hue, you also change the colours in the image.

NOTE Hue shift can be applied to individual ranges (highlights, midtones, and shadows) or to the Master tonal range.

To adjust the hue of an image:

- 1 Select the range you want to modify: Master, Shadows, Midtones, or Highlights.
- 2 Drag the Hue field to adjust the level of hue and saturation until you are satisfied with the result.

- 3 Click Process to apply the changes to the clip.

Adjusting the Saturation

You can adjust the purity of colour in an image by adjusting the saturation level. Increasing the level of saturation decreases the amount of grey and produces purer colours. Decreasing the level of saturation increases the amount of grey and reduces the purity of colours.

To adjust the saturation of an image:

- 1 Select the range you want to modify.
- 2 Drag the Saturation field to decrease or increase the level of saturation until you are satisfied with the result.

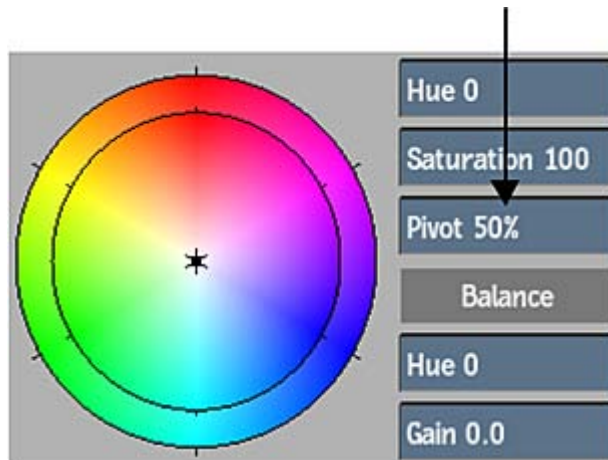

- 3 Click Process to apply the changes to the clip.

Adjusting the Pivot

Adjust the point at which contrast pixel value is equal to that of the pivot value. Colour values darker than the pivot are further darkened and colours that brighter than the pivot are further brightened.

To adjust the pivot in an image:

- 1 Select the range you want to modify.
- 2 Click the Pivot field and adjust the pivot percentage value of the colour range around which the contrast pivots. The default value is 50% for integer input and 18% for floating point input.

- 3 Click Process to apply the changes to the clip.

Rewiring the RGB Channels

Use the Red, Green, and Blue Channel Rewiring fields to rewire the red, green, and blue channels of an image. Use the Rewire option box to create a monochrome or negative image.

When you rewire a channel, the values for the current colour channel are replaced with those of the new channel. For example, if you select the R

G option in the Red Channel Rewiring field, the colour values of the red channel are replaced with those of the green channel.

The RGB Rewiring commands can be applied to the Master range only.

To rewire the red channel:

- 1 Select an option from the Red Channel Rewiring box.

Select:	To:
$R \leftarrow R$	Use colour values for the red channel.
$R \leftarrow G$	Replace colour values of the red channel with those of the green channel.
$R \leftarrow B$	Replace colour values of the red channel with those of the blue channel.
$R \leftarrow Y$	Replace colour values of the red channel with the luma of all channels.
$R \leftarrow 1-R$	Replace colour values of the red channel with its inverse. For example, 1 corresponds to the maximum value of the given colour channel. In 8 bits, this value is 255.

- 2 Click Process to apply the changes to the clip.

NOTE The green and blue channels are rewired in the same way as the red channel (described in the previous table).

Creating a Negative or Monochrome Image

You can convert a colour image into a monochrome or negative image using the Rewire option box.

TIP You can also convert the image manually by clicking the appropriate Rewire selection box (R, G or B) and selecting the Y option for monochrome or 1 - R for a negative image.

To convert a colour image into a monochrome or negative image:

- 1 Select Mono or Negative from the Rewire option box.

The image is automatically converted to a monochrome or negative image.

- 2 Click Process to apply the changes to the clip. To cancel the changes, click Reset Basics.

TIP You can also create a monochrome or negative image using the Monochrome and Negative buttons in the Processing menu.

Adjusting the Gamma

You can adjust the grey values of an image by adjusting the gamma. This allows you to brighten or darken an image without greatly affecting the shadows or highlights.

To adjust the gamma of the image:

- 1 Select the tonal range you want to modify.
- 2 Click a Gamma field and enter a value. Lower the gamma value to increase the contrast or raise the gamma value to decrease the contrast.

	Gamma	Gain	Offset	Contrast
RGB	1.000	100.0	0.000	100.0
Red	1.000	100.0	0.000	100.0
Green	1.000	100.0	0.000	100.0
Blue	1.000	100.0	0.000	100.0

Adjusting the Gain and Offset

You can boost the colours in an image by increasing the Gain and Offset values. The Colour Corrector multiplies the pixel colour values by the Gain and then adds the Offset value. The resulting colour values are clipped at the maximum value of 255 in 8-bit mode, or 4095 in 12-bit mode.

You can also reduce the colours in the image by decreasing the Gain and Offset values. The resulting colour values are clipped at the minimum value of 0.

Gain is expressed as a percentage value. The default value of 100% has no effect on the image since the colour values are multiplied by 1.

NOTE You can adjust the Gain for individual ranges, or across all ranges simultaneously (by using the Gain fields in the Global controls). However, changes in gain mostly affect the highlights in the image.

To boost or reduce the colours in the image:

- 1 Select the range you want to modify.
- 2 Enter a value in the Gain field for the colour channel you want to modify.

	Gamma	Gain	Offset	Contrast
RGB	1.000	100.0	0.000	100.0
Red	1.000	100.0	0.000	100.0
Green	1.000	100.0	0.000	100.0
Blue	1.000	100.0	0.000	100.0

- 3 Enter a value in the Offset field for the channel you want to modify.

	Gamma	Gain	Offset	Contrast
RGB	1.000	100.0	0.000	100.0
Red	1.000	100.0	0.000	100.0
Green	1.000	100.0	0.000	100.0
Blue	1.000	100.0	0.000	100.0

- 4 Click Process to apply the changes to the clip.

Adjusting the Contrast

You can control the gradations between the light and dark areas of an image by adjusting the contrast. The pivot value affects the contrast behaviour. See [Adjusting the Pivot](#) (page 963).

To adjust the contrast of the image:

- 1 Select the range you want to modify.
- 2 Click a Contrast field and enter a value.

Suppressing Colours

You can suppress the RGB or CMYw colours in an image. Chroma suppression is useful for removing blue spill from a blue-screen composite.

To suppress a colour:

- 1 Click Master.

NOTE Chroma suppression can only be applied to the Master tonal range.

- 2 Enable the appropriate button for the colour to suppress.

Enable:	To suppress:
R	Red
G	Green
B	Blue
C	Cyan
M	Magenta
Yw	Yellow

The status box on the button is light blue when the button is enabled.

NOTE Suppression of RGB and CMYw always reduces luma.

Adjusting the Colour Balance

You can adjust the colour balance in an image using the colour wheel or the Balance Tools Hue and Gain fields. The value of Hue determines the colour to add and the value of Gain specifies the amount of colour to use.

(a) Colour wheel (b) Hue field (c) Gain field

Pure red is the 0-degree point for hue on the colour wheel. When you increase the Hue value, you move counterclockwise on the colour wheel. When you decrease the Hue, you move clockwise on the colour wheel.

The centre of the colour wheel represents 0 Gain. As you increase the value of Gain, you move towards the edge of the colour wheel and add more of the selected colour to the image.

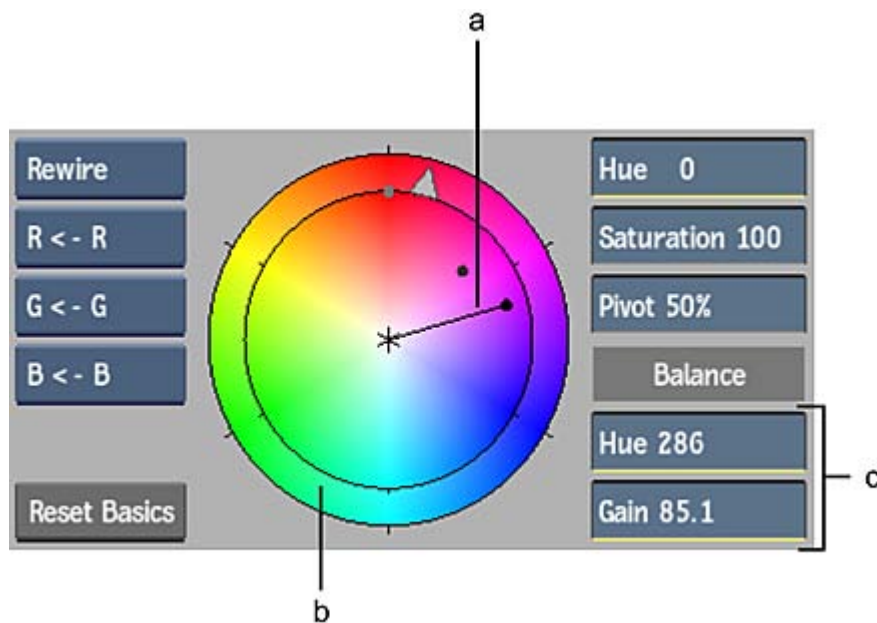

NOTE If Saturation is set to 0, no colour balancing is performed, regardless of the Gain value. In the Channel Editor, Balance channels are labelled hue_balance and gain_balance, respectively.

Creating and Modifying a Colour Balance Point

You can make colour balance points for each range (highlights, midtones, and shadows) or for all ranges simultaneously (master). Click inside the colour wheel to create a balance point for the current tonal range.

The current range's colour balance point is connected to the hub of the colour wheel by a line. You can constrain how the point is modified according to how you select it. If you select the line, the radius of the line Strength is constrained. If you select the point, the direction of the line Tint is constrained. You can make unconstrained modifications by clicking anywhere in the wheel, or by entering values in the Balance fields.

NOTE As you move the colour balance point on the colour wheel, the values in the Balance Tools Hue and Gain fields update automatically. You can also set the values for Tint and Strength directly in these fields.

(a) Current colour balance point (b) Hue shift/saturation comparison (outside ring is Result; inside ring is Source)
(c) Balance tools

Colour balancing is performed in RGB colour space. The luma of the image is not changed. For example, if Hue (tint) is set to 0 and Gain (strength) is set to 100%, pure red is added to the image. However, a black pixel remains black since it keeps the same luma value.

To change the colour balance in the image:

- 1 Enable Regen so that the image will update as you change the colour balance.
- 2 Select the range you want to modify.
- 3 On the colour wheel, click and drag toward the colour you want to use.

As you drag the cursor, a colour balance point follows the cursor. Depending on the range you are modifying, the colour balance points are shaded to make for easier identification (from light grey to black, in this order: Highlights, Shadows, Midtones, Master).

You can continue dragging outside of the colour wheel. The colour balance point is replaced by a triangle in the outer circle of the colour wheel. The triangles are also shaded depending on the range selected (from white to grey, in this order: Master, Highlights, Shadows, Midtones).

The image dynamically updates as you drag.

TIP You can interact directly in the image window to change the colour balance. While holding the range keyboard shortcut (V for Master; Z for Shadows; X for Midtones; or C for Highlights), drag directly in the image window. The colour wheel and Balance Tools fields update accordingly.

- 4 If you are not satisfied with the resulting image, click and drag the colour balance point or triangle again. You can continue to move the colour balance point or triangle until the desired effect is achieved.
- 5 Click Process to apply the changes to the clip.

Adjusting the Colour Range

You can use the Histogram menu to adjust the range of values used for the red, green, blue, or luminance channels of an image. The histogram shows the colour distribution of pixels in the front and result image for the selected channel. The horizontal axis represents the values of pixels, from black at the left to white at the right. The vertical axis represents the number of pixels with these colour values.

When working with 16-bit floating point images, the values of the histogram are represented on a logarithmic scale. When working with integer images (8, 10, or 12-bit), the values of the histogram are represented on a linear scale.

To access the Histogram menu:

- 1 Click the Histogram tab.

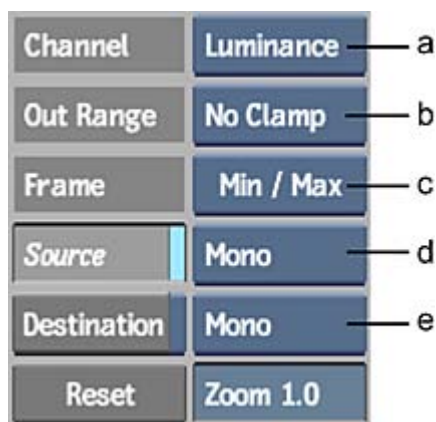

The Histogram menu options are described as follows.

(a) Minimum Input slider (b) Minimum Output slider (c) Minimum Input field box (d) Minimum Output field (e) Maximum Input field (f) Maximum Output field (g) Maximum Output slider (h) Maximum Input slider

Input controls Use the minimum and maximum input sliders or fields to set the input levels of your image.

Output controls Use the minimum and maximum output sliders or fields to set the output levels of your image.

(a) Channel Selection box (b) Out Range Option box (c) Frame Selection box (d) Source View Option box (e) Destination View Option box

Select	To Frame:
Min / Max	Based on the minimum and maximum slider values.
Full Range	The complete range of histogram values.
Plot Colour	The plot and reference colours.
Home	Based on a [0:1] horizontal and vertical range.

Increasing Image Contrast

The slider controls directly below the histogram are the Input Level controls. These controls are used to set the range of colour values used in the image:

- The white triangle on the right sets the maximum value for the range.
- The black triangle on the left sets the minimum value for the range.

You can use the Input Level controls to increase the contrast in the image. For example, if you set the minimum value to 50, pixels with colour values less than 50 are remapped to 0 (black). Pixels with colour values greater than 50 are remapped to the appropriate values. This darkens the image and increases the contrast in the shadow areas.

You can also set the maximum and minimum limits for the colour range by entering the values directly in the Minimum and Maximum Input fields on either side of the histogram.

To increase the contrast in an image:

- 1 Display the Histogram menu.
- 2 Click the Master, Shadows, Midtones, or Highlights button to select the parts of the image you want to modify.
- 3 From the Channel Selection box, select Luminance, Red, Green, or Blue as the channel you want to work with.
- 4 Position the cursor on the black triangle below the histogram. Drag right to darken the shadow areas in the image.

The value of the lower limit for the colour range appears in the Minimum Input field.

- 5 Position the cursor on the white triangle below the histogram. Drag left to brighten in the highlight areas in the image.

The value of the upper limit for the colour range appears in the Maximum Input field.

NOTE If you are in Luminance, you can invert the image by reversing the order of the black and white triangles.

- 6 Click Process to apply the changes to the clip. To cancel the changes, click Reset Basics.

Reducing Image Contrast

The slider controls on the gradient bar below the histogram are the Output Level controls. These controls are used to set the range of colours used in the image:

- The white triangle on the right sets the maximum value for the range.
- The black triangle on the left sets the minimum value for the range.

You can use the Output Level controls to decrease the contrast in the image. For example, suppose that you set the minimum value to 100. A pixel with a colour value of 0 is remapped to 100. Pixels with colour values greater than 0 are remapped to the appropriate values. This has the effect of lightening the image and decreasing the contrast in the shadow areas.

Suppose that you set the maximum value for the range to 200. A pixel with a colour value of 255 is remapped to 200. Pixels with colour values less than 255 are remapped to the corresponding values. This has the effect of darkening the image and decreasing the contrast in the highlight areas.

You can also set the maximum and minimum limits for the colour range by setting the values directly in the Minimum and Maximum Output fields.

To reduce the contrast in an image:

- 1 Display the Histogram menu.
- 2 Click the Master, Shadows, Midtones, or Highlights button to select the parts of the image you want to modify.
- 3 From the Channel Selection box, select Luminance, Red, Green, or Blue as the channel you want to work with.
- 4 Position the cursor on the black triangle below the Output Level bar. Drag right to lighten the shadow areas in the image.
The value of the lower limit for the colour range appears in the Minimum Output field.
- 5 Position the cursor on the white triangle below the gradient bar. Drag left to decrease the brightness in the highlight areas.
The value of the upper limit appears in the Maximum Output field.

Defining Luma Ranges

Use the histogram in the Ranges menu to modify the shadow, midtone, or highlight ranges.

When working with 16-bit floating point images, the values of the histogram are represented on a logarithmic scale. When working with integer images (8, 10, or 12-bit), the values of the histogram are represented on a linear scale.

To access the Ranges menu:

- 1 Click the Ranges tab.

The Ranges menu options are described as follows.

(a) Shadows curve (b) Midtones curve (c) Highlights curve

The X-axis is luma and the Y-axis is weight. The Shadow curve is labelled “S”, the Highlight curve is labelled “H”, and the Midtones curve is not labelled.

(a) Frame Selection box (b) Source View option box (c) Destination View option box

Frame Selection box Choose how you want to frame the Ranges Histogram.

Select	To Frame:
Min / Max	Based on the minimum and maximum slider values.
Full Range	The complete range of histogram values.
Plot Colour	The plot and reference colours.
Home	Based on a [0:1] horizontal and vertical range.

To see the effect of adjusting these curves:

- 1 Adjust the colour balance for each of the Shadows, Midtones, and Highlights channels. Note the effect that this setup has on the image.
- 2 Display the Ranges menu. Adjust the curves using the tangent handles.
You should see that the resulting image is different from that in step 1. The difference is the result of the changes you made to the luma curves for the shadows, midtones, and highlights.

Remapping Colour Values

Like the Histogram menu, the Curves menu allows you to remap the colour values for the individual red, green, blue, and luminance channels of the image. However, instead of adjusting the colour values by resetting just the maximum and minimum values for the colour range, the Curves menu allows you to remap any value in the colour range precisely.

To reset any changes to the Curves chart, click Reset. To reset all the changes in the Colour Corrector, click Reset All. The Curves menu also has its own Undo button that is separate from the overall Colour Corrector Undo.

To access the Curves menu:

- 1 Click the Curves tab.

There is one colour curve for each of the red, green, blue, and luminance channels of an image. The colour curves are generated by plotting the input values for the source image versus the output values for the resulting image.

For integer images, the input values range from 0 to 255, and are plotted along the horizontal axis. The output values range from 0 to 255, and are plotted along the vertical axis. The range for both the input values and the output values is from 0 to 255 in 8-bit mode, and from 0 to 4095 in 12-bit mode.

For 16-bit floating point images, the input values range from 0 to 1, and are plotted along the horizontal axis. The output values range from 0 to 1, and are plotted along the vertical axis. By default, there are 2 points on the curve, mapping 0 to 0 and 1 to 1. Use the Out Range option box to define whether the curves are constant (select Clamp) or linear (select No Clamp) before the first point of the curve and after the last point of the curve.

The default curve for each channel is a diagonal line that extends from the lower-left corner to the upper-right corner of the graph. The default curve represents the initial state in which the colour values for the pixels of the source image are equal to the values for the corresponding pixels of the resulting image. For example, all pixels that have a value of 100 in the source image also have a value of 100 in the resulting image.

The colour values of an image are remapped when you change the shape of a colour curve. Use the Curves Editor to add, delete, or move vertices on the curve. For example, move the end vertices on the curve to change the maximum and minimum values for the colour range. Add a vertex anywhere on the curve to remap a particular colour value.

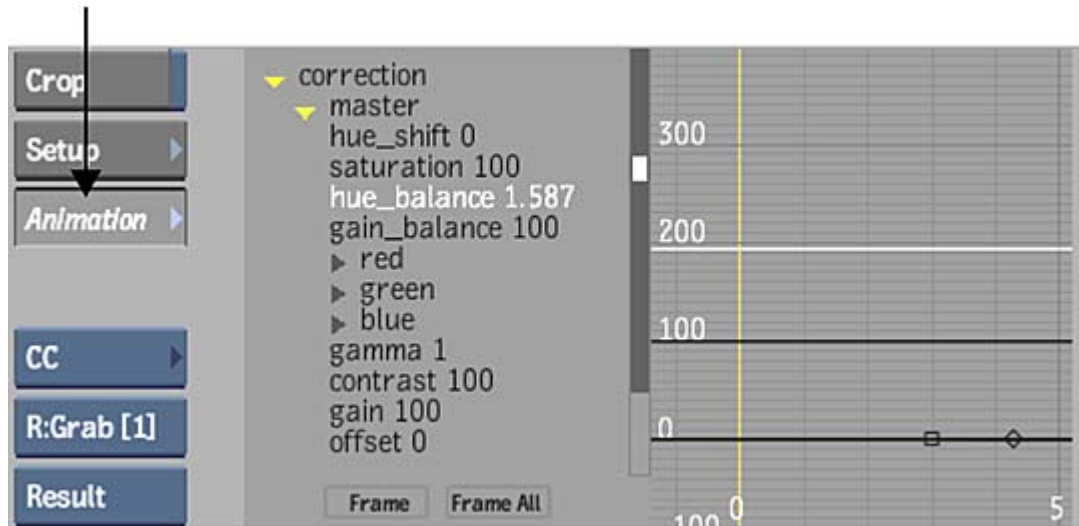

The Curves Editor behaves in much the same way as an animation curve in the Channel Editor. To edit colour curves, select Add, Delete, or Move from the Tools box.

Animating a Colour Correction

Use the Animation controls to animate a colour correction that has been applied to a clip. You can animate any value in the Colour Corrector.

To access the Animation controls:

- 1 In the Colour Corrector menu, click Animation.

About the Colour Warper

When you colour correct an image or clip, use the Colour Warper to perform advanced colour corrections and create artistic colour effects. The way in which you approach these tasks depends on your goal, the number of clips you are using, and the type of clips being used.

Clips created from source material shot with the same camera equipment under the same lighting conditions may be colour corrected quickly and easily to correct lighting and colour imbalances. Clips created from source material shot at different times of the day, in different seasons, at different locations, or using different equipment require more work. With the Colour Warper, you can manipulate colours with precision and ease, working on the entire clip as you would with traditional tools or working with a matte to adjust a range of colour in the clip.

Use the Colour Warper to gesturally set black and white levels, adjust specific colours and colour ranges, and accurately match colours in one clip to another. You can also perform hue shifts and suppress colour to remove colour spill or create visual effects such as a colour cast. While you manipulate the colour content of a clip, you can monitor reference clips as well as changes in the colour distribution to ensure that you achieve the result you want. Original data is always preserved, so you can adjust colours without the risk of permanently losing colour information.

When working with 16-bit floating point images in the Colour Warper, you can plot colours outside of the 0 to 1 range. Even when working with integer images, clamped colour information (colours that go beyond the RGB range) can be retrieved using the Colour Warper controls.

(a) Clamped colour

(a) Colour information restored

When working with large images, you can free up additional screen space with the Overlay user interface. This feature is exclusive to the Colour Corrector and the Colour Warper. The Colour Warper's Overlay user interface is not available when accessing the Colour Warper as a Batch or Batch FX node.

For details on using the Overlay user interface, see [Overlay User Interface](#) (page 949).

Accessing the Colour Warper

Use the Colour Warper to modify the colour content in your clips. You can manipulate colour content with intuitive controls that provide precise colour correction, and view histograms that help you visualize your image's colours. You can also output a matte corresponding to selected colours.

You can access the Colour Warper as a Batch or Batch FX node that you drag and drop into the process tree or the Modular Keyer's processing pipeline. Access the Colour Warper from the Modular Keyer to remove colour spill, or access it from Batch or Batch FX to modify the colour content of your clips.

To access the Colour Warper menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).

- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- Modular Keyer, Action or Paint tool.

Accessing the Colour Warper node from Batch

To add a Colour Warper Node in Batch:

- 1 Go to Batch.
- 2 Double-click on, or drag, the Colour Warper Node from the node bar and add it to the schematic.
- 3 Double-click the Colour Warper Node.
The Colour Warper Node editor opens.

Accessing the Colour Warper from Batch FX

To access Colour Warper through Batch FX:

- 1 Select Timeline.
- 2 Select the segment.
- 3 Click the FX button.
- 4 Click the Create Batch FX button.
- 5 Double-click on, or drag, a Colour Warper node into the schematic.
The Colour Warper node is now in the schematic.
- 6 Double-click the Colour Warper node.
You are in the Colour Warper node editor.

Accessing Colour Warper from the Timeline

To access the Colour Warper from the timeline:

- 1 Select the Timeline tab.
- 2 Do one of the following:
 - Click the FX button.
 - Right-click on a segment in the timeline and choose Add Effect.
The Effects ribbon appears.

NOTE Effects that are enabled have already been added to the current Timeline FX pipeline.
- 3 Enable CW (Colour Warper).
- 4 You can adjust the effect's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

Accessing the Colour Warper from Modular Keyer, Action, or Paint

To access the Colour Warper from the Modular Keyer:

- 1 Double-click on, or drag, the Colour Warper node from the node bar to the schematic.
- 2 Double-click the Colour Warper node.

To access the Colour Warper from Action:

- 1 From the Media menu, select the media containing the clip you want to colour correct.
- 2 Double-click the CC field for the media you want to colour warp.
- 3 Click the Colour box.
The Colour box changes to CW. You are in the Colour Warper.

To access the Colour Warper from Paint:

- 1 Do one of the following:
 - To colour correct a clip, click Setup in the Paint menu. In a Colour Correction field, enable CC.
 - To colour correct a cutout, click Texture in the Paint menu, create a cutout. Click CC.

The Colour box changes to CW. You are in the Colour Warper.

Setting Up Your Work Environment

Set up your work environment to streamline the colour correction process. Use the tools provided to examine the clip or image and efficiently perform advanced colour corrections. As your work progresses, you can modify the Colour Warper environment to suit the task at hand.

You can:

- Display multiple viewports.
- View reference clips.
- View the colour and luma content of a source (front) clip and result clip.
- Apply a colour correction to all or part of a clip.
- Crop the colour correction area (when accessed from the Colour Corrector).
- Invert the matte (when accessed from the Colour Corrector).
- Dynamically update colour information as you work.
- Reset entire colour corrections.
- Clear or reset individual values.
- Save and load colour correction setups and preferences.
- Use the Undo/Redo list.

Multiple Viewports

When working in the Colour Warper, you can display up to four viewports at a time in the image window, including a view of the Channel Editor. Multiple viewports are convenient when you want to modify colour values, create mattes, and compare your result with other images in different viewports simultaneously.

NOTE The Overlay user interface cannot be used with multiple views in the Colour Warper tool.

Viewing Reference Clips

You can use the split bar to view and sample a reference clip while you work. Reference clips are particularly useful when you want to match colours or compare colour corrections. Carefully selecting a suitable reference clip will help you make your colour corrections quickly and efficiently. For example, you can use a reference clip from the Batch or Batch FX schematic to match saturation, whites and blacks, or colours. You can also switch between different references to ensure continuity throughout the project.

(a) Focus clip (b) Split bar (c) Reference clip

TIP If the Overlay user interface is enabled, the split bar can extend beneath the Overlay user interface. To access it, grab from an area where there are no menu elements.

Viewing Colour Information with a Vectorscope

In the Colour Warper, you can use a 2D or 3D vectorscope to help match colours, adjust shadows and highlights, view colour distribution, and ensure that broadcast standards are met. The vectorscopes show the changes you make to colour content in a clip or image.

Each vectorscope can display:

- A histogram showing the distribution of image pixels across luma and hue ranges. The histogram dynamically updates to reflect your changes as you modify colours in the image. Exposure and contrast settings in the image display viewer are taken into account.
- Source and destination colours. Source colours are the colour values in the front clip and destination colours are the colour values in the result clip.
- Plotted and reference colours that are obtained by sampling images in the image window. See [Sampling Clips in the Image Window](#) (page 989).

NOTE The 2D and 3D vectorscopes only appear in Result view.

To view colour information in either the 2D or 3D vectorscope:

- 1 In the Colour Warper menu, enable Scope.
The vectorscope appears in the image window.

NOTE You can only view one vectorscope at a time.

- 2 Click Setup.
- 3 From the Scope box, select the vectorscope you want to use to view the clip.

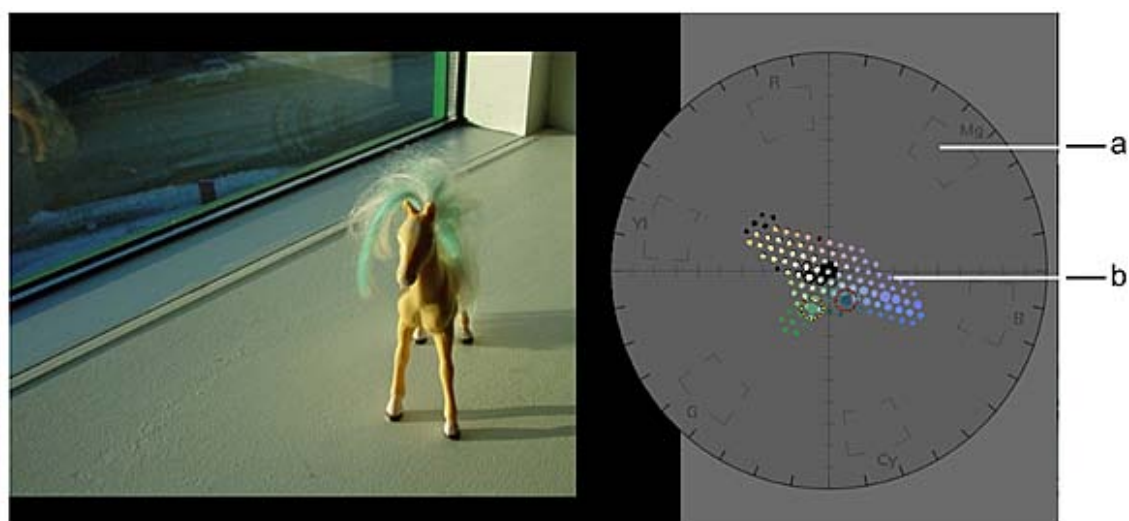

2D Displays the 2D vectorscope. Use the 2D vectorscope to analyse the colour content of the clip and locate specific colours in terms of their chroma values. When you view a clip in the 2D vectorscope, you see it in terms of hue and saturation. The size and placement of the colour squares in the 2D vectorscope show the distribution of all the colours in the clip—like a colour wheel; the distance from the centre to the perimeter of the scope maps colour saturation, with the outside edge of the scope delineating pure colour.

3D Displays the 3D vectorscope. Use the 3D vectorscope to both analyse the colour content of the clip and to locate specific colours in terms of their chroma and luma values. When you view a clip in the 3D vectorscope, you see it in terms of HLS (hue, lightness, and saturation). Its X, Y, and Z axes represent red, green, and blue, and the size and placement of the colour cubes show the distribution of all the colours of the clip in RGB colour space.

The selected vectorscope is displayed in the image window. As you scroll through a clip, the histogram is updated to display the colour distribution of each frame.

(a) 3D vectorscope **(b)** 3D histogram

(a) 2D vectorscope (b) Histogram

- 4 Set the following options to customize the display of the 2D or 3D vectorscope.

Enable:	To:
Canvas	Show the vectorscope canvas. When the canvas is off, the vectorscope is transparent, but can be outlined.
Lines	Show the vectorscope outline.

- 5 Set the following histogram options to show clip colour information.

Enable:	To:
Source	Show a histogram of the colour values in the front, or source clip. The source colour values are obtained from the current frame. If you input both front and matte clips, the colour values in the front clip that are defined by the white part of the matte are displayed.
Destination	Show a histogram of the colour values in the result clip. The destination colour values are obtained from the current frame. If you input both front and matte clips, the colour values in the front clip that are defined by the white part of the matte are displayed.

When both Source and Destination are enabled, you see both the source and destination colour values. The source clip's colour values are displayed in black and the result clip's colour values are displayed in colour. When only Source is enabled, the source clip's colour values are displayed in colour.

(a) Result clip (in colour) (b) Source clip (in black)

NOTE You can also toggle the Source and Destination buttons in the Basics menu to show or hide source and destination colours in the histograms.

- 6 From the Size box, select the size of the coloured squares or cubes that make up the histogram. You can display 8x8, 16x16, or 32x32 coloured dots.
- 7 To set SMPTE bars for the 2D vectorscope, select an option from the Bars box.

Select:	To match:
Bars 75%	75% SMPTE bars. If the current project is NTSC, the bars are set to 75% by default.
Bars 100%	100% SMPTE bars.

The parameters of the histogram of the 2D vectorscope update accordingly.

- 8 To toggle between the vectorscopes, double-click the vectorscope in the image window. Use these other shortcuts to interact with the vectorscopes.

Press:	To:
Alt-drag	Move the 2D or 3D vectorscope
Shift-drag	Zoom the 2D or 3D vectorscope
Ctrl-drag	Rotate the 3D vectorscope. If you Ctrl-drag the 2D vectorscope, the 3D vectorscope appears and rotates.

- 9 To position a vectorscope at its default location and size, click Home.

Viewing Luma Information with the 2D Luma Histogram

The 2D luma histogram shows the changes you make to luma content in a clip. Use the 2D luma histogram when you want to adjust the lightness of a sample. The 2D luma histogram is displayed in the Basics menu of the Colour Warper.

The 2D luma histogram can display:

- A histogram showing the distribution of image pixels across the luma range—the size and distribution of the vertical bars show the luma distribution.
- Source and destination colour values. Source colour values are the luma values in the front clip and destination colours are the luma values in the result clip.
- Plotted and reference colours that are obtained by sampling images in the image window. See [Sampling Clips in the Image Window](#) (page 989).

To view luma information in the 2D luma histogram:

- 1 In the Colour Warper menu, click Basics.

The 2D luma histogram appears in the Basics menu. R, G, and B values that are modified by the Midtones trackball are displayed as curves in the histogram.

(a) RGB curves (b) Midtone triangle

- 2 Set the following options to show clip luma information.

Enable:	To:
Source	Show a histogram of the luma values in the front, or source, clip. The source luma values are obtained from the current frame.
Destination	Show a histogram of the luma values in the result clip. The destination colour values are obtained from the current frame.

When both Source and Destination are enabled, you see both the source and destination luma values in the histogram. Source clip colour values are displayed in black and result clip colour values are displayed in off-white.

NOTE You can also toggle the Source and Destination buttons in the Setup menu to show or hide source and destination colours in the histograms.

Colour Correcting All or Part of an Image

Use the options in the Work On box to apply colour corrections to all or part of an image. You can select an option from the Work On box at any time to further modify the image. Use Master to apply colour corrections to the entire image and use a selective to generate a matte and perform selective colour correction—apply the colour correction to a selected range of colour. The Work On box is available in every menu of the Colour Warper.

(a) Work On box

To colour correct all or part of a clip:

- 1 Select an option from the Work On box.

Select:	To:
Master	Use the Basics menu to modify the entire image. In Master mode, you cannot output a matte.

Select:	To:
Sel. 1, Sel.2, or Sel. 3	Generate a matte from the front clip selective colour correction. You can then use the Basics menu to modify the range of colour defined by the matte. In a selective mode, you can output the matte, selective, or result. See Selecting Colour Ranges for Colour Correction (page 991).

Cropping the Colour Correction Area

When you access the Colour Warper from the Colour Corrector, you can create a crop box to limit the area where the colour correction is applied.

Using a crop box as you colour correct a clip speeds up interactivity, which is especially useful when working at high resolutions. You can also process the clip with a crop box. Everything outside the crop box will be processed as black on the matte.

To use a crop box:

- 1 In the Colour Warper menu, click Setup.
- 2 Do one of the following:
 - Hold down the **Ctrl** key or hold the pen button and drag the box across the image.
 - Turn on the Crop button and enter the dimensions for the crop box in the Left, Right, Bottom, and Top fields.

The crop box appears in the image window. By default, the crop box has the same dimensions as the clip. The display inside and outside the crop box depends on how many clips are loaded.

If you loaded:	Inside the crop box:	Outside the crop box:
A front, back, and matte clip	Shows the front clip in the opaque area of the matte and the back clip in the transparent area of the matte.	Shows the back clip.
A front and back clip	Shows the front clip.	Shows the back clip.
A front clip only	Shows the colour-corrected clip.	Shows the non-colour corrected clip.

- 3 To adjust the size of the crop box, drag on the corner points of the box, or modify the values in the Left, Right, Bottom, and Top fields in the Setup menu.
- 4 To move the crop box in the image window, click a side of the box and drag to a new location. Alternatively, press **Ctrl** and redraw the crop box.

TIP If the Overlay user interface is enabled, the crop box will extend beneath the Overlay user interface. To access the bottom edge, be sure to grab from an area where there are no user interface elements.

- 5 You can now use any Colour Warper menu and colour correct the area of the clip that is defined by the crop box. You will only see the results of your changes within the crop box.
- 6 If you want to process the clip with the crop box, leave the Crop button enabled when you process.

To disable a crop box:

- 1 From any Colour Warper menu, disable Crop.
When you disable the Crop button in a Colour Warper menu, the Crop button in the Setup menu is also disabled.

To change the colour of the crop box:

- 1 In the Colour Warper Setup menu, click the colour pot beside Border.

The colour picker appears.

- 2 Select a colour with the colour picker.
- 3 Click in the Border colour pot to apply the new colour to the border.

To hide the crop box:

- 1 In the Setup menu, disable Border.

Resetting Colour Warper Effects

Resetting the Colour Warper

You can reset colour effects created with the Colour Warper.

To reset a colour correction:

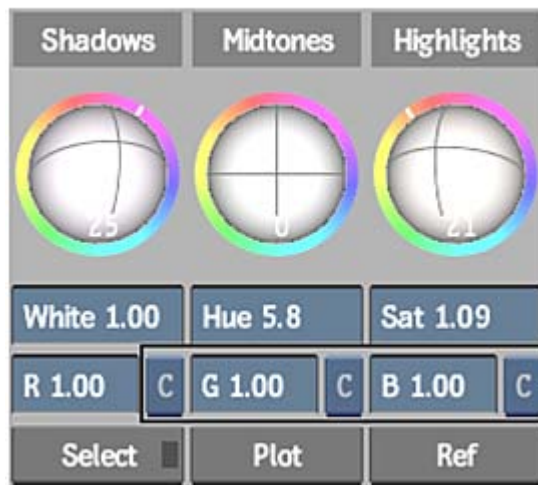

- 1 Do one of the following:
 - In the Timeline FX or Tools Colour Warper editor, click Reset All. Click Confirm.
 - In Batch, Batch FX or the Modular Keyer, right-click the Colour Warper node and select Delete.

Resetting and Clearing Values

You can clear or reset several Colour Warper values in the Basics menu using individual Clear/Reset boxes. C resets the value for the current frame by setting a keyframe. R resets the value for the entire animation curve.

To reset a Colour Warper value:

- 1 In the Basics menu, do one of the following:
 - Select C from the Clear/Reset box next to a control.

The value is reset at the current frame.

- Select R from the Clear/Reset box.

The value is reset for the entire animation curve.

NOTE Fields that do not have Clear/Reset boxes next to them cannot be reset. Use the Undo box instead.

Saving Setups and Preferences

In the Colour Corrector or Colour Warper, you can save or load colour correction or colour warper setups using the Save or Load button. Any setup can be loaded from the file browser for use with another set of clips using the same effect. You can also save or load colour correction or colour warper preferences using the Load or Save button.

- To save setups or preferences, click Save.
- To load setups or preferences, click Load.

TIP Click Revert to revert to the last saved setup. All changes made since the previous Save operation are undone.

Using Undo and Redo

Use the Undo and Redo boxes to remove or redo colour modifications. To undo or redo a modification, click a box and select an option from the list. Set the number of undo levels in the Setup menu.

NOTE You also set the number of undo levels for the Modular Keyer in the Setup menu of Batch or Batch FX.

(a) Redo option box

Sampling Clips in the Image Window

When you generate mattes, modify clips, or match colours between clips, you can sample colours in both the result clip and a reference clip. Use Plot to sample a colour from the result clip and Ref to sample one from a reference clip. The Plot and Ref buttons appear on every menu in the Colour Warper.

NOTE Ref samples cannot be adjusted.

Samples appear in the histograms. In the 2D luma histogram, the Plot sample is represented by a red bar and the Ref sample is represented by a yellow bar.

(a) Reference colour (yellow vertical line) (b) Plotted colour (red vertical line)

In the vectorscope, the Plot sample is outlined in red and the Ref sample is outlined in yellow.

(a) Plotted colour (outlined in red) (b) Reference colour (outlined in yellow)

You can use Plot to get more information on colours you want to change. When you are adjusting colours and levels and are not sure which controls to use, click Plot and select a colour in the image. You can then view the histograms to determine which control you should use. For example, if the plotted colour appears in the middle of the 2D luma histogram, you can modify the colour in the image using the Midtones trackball while viewing the plotted colour in the 2D vectorscope.

To sample clips:

- 1 Load a reference clip and position the split bar so that both the reference clip and the result clip appear in the image window.
- 2 Do one or both of the following:
 - Enable Plot and then sample the result clip.

You can:	To:
Click-drag	Sample a single pixel in the image. You can drag through the image until you locate the pixel you want to sample.
Ctrl-drag	Sample an average taken from a range of colours in the image.

A red vertical line appears in the 2D luma histogram indicating the luma of the sample. The sampled colour is also outlined in red in the 2D or 3D vectorscope. In the 2D vectorscope, you see the sample in terms of hue and saturation. In the 3D vectorscope, you see it in terms of HLS. If you are plotting a colour in a 16-bit floating point image that is out of the 0:1 range, the red outline appears outside of the vectorscope.

- Enable Ref and then sample the reference clip.

You can:	To:
Click-drag	Sample a single pixel in the image. You can drag through the image until you locate the pixel you want to sample.

You can:	To:
Ctrl-drag	Sample an average taken from a range of colours in the image.

A yellow vertical line appears in the 2D luma histogram and the sampled colour is outlined in yellow in the 2D or 3D vectorscope. If you are referencing a colour in a 16-bit floating point image that is out of the 0:1 range, the yellow outline appears outside of the vectorscope.

Selecting Colour Ranges for Colour Correction

With some images or clips, you may need to perform selective colour correction—where you modify a range of colour, as opposed to the entire clip or image. Use the tools in the Selective menu to create selectives. Selectives are generated mattes used to isolate colour ranges for selective colour correction.

In the Selective menu, you can:

- Create and refine a matte using tolerance and softness to define the range you want to modify.
- View a matte, a selected colour range, or the result.
- Enable mattes to apply the selective colour correction to the result image. Disable mattes to remove the selective colour correction from the result image.

TIP Set the image window to 2-Up view (Alt+2) so that you can create your matte in one viewport while simultaneously monitoring the result in the other.

Generating Mattes

Mattes can be used for several purposes. For instance, use a matte to remove colour spill, hue shift an object in an image for artistic effect, or match colours in a specific range. Use mattes to define the range of colour you want to modify in the result clip.

You can generate up to three mattes using the Selective menu.

TIP To get the best key, make sure you have enough processing speed to see the result in real time while interacting with the Tolerance and Softness boundary handles. In the Modular Keyer, you can use the Crop feature to improve interaction.

To generate a matte for selective colour correction:

- 1 Enable Plot and then sample the image.
A black dot representing the sample appears on the hue cube. A red line also appears in the luma range and the sample is outlined in the 2D or 3D vectorscope. When you create the matte, you can modify the softness and tolerance boundaries to include or exclude the plotted colour.
- 2 From the Work On box, select a selective (Sel 1, Sel 2, or Sel 3). With each selective, you define a range for a matte by selecting colours in the front clip.
- 3 From the Selective View box that appears, select Sel.

The front clip is displayed as a greyscale image.

- 4 Click one of the Define controls to set the initial softness and tolerance for the matte.

Click:	To define:
Pick Custom	The tolerance range based on a sample from the image. You must drag the cursor over the image to define initial tolerance.
R, G, B, C, M, or Yw	The tolerance range based on the selected colour channel. For example, click Yw to use the yellow channel to set the tolerance. The luma range is set to default tolerance and softness values.
Shadows, Midtones, Highlights	The tolerance range based on the selected luma range. These buttons expand the tolerance and softness boundaries to include all ranges of colours in the image.

The initial softness and tolerance is set for the matte. The range you use to define the matte becomes visible through the greyscale image. The unselected colours remain greyscale.

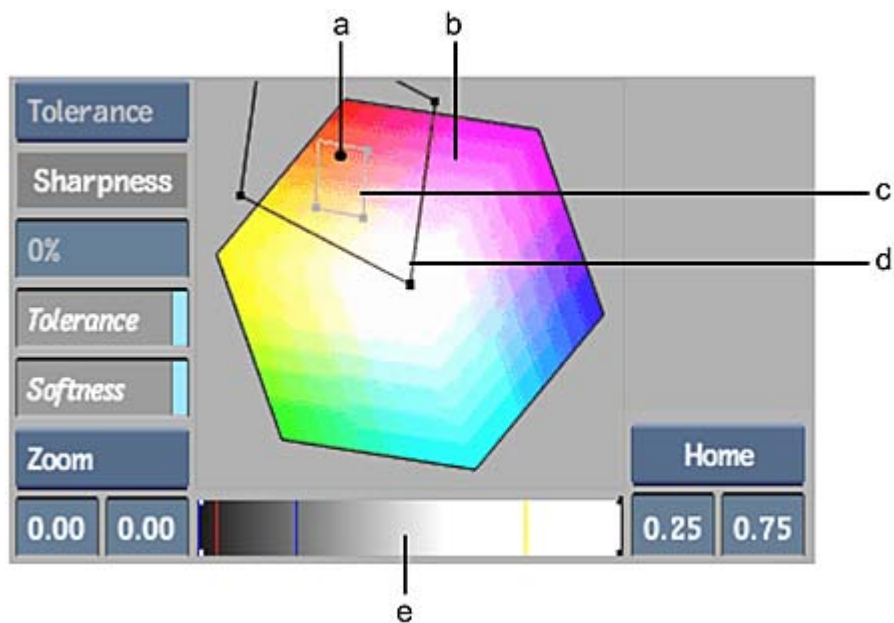

(a) Original colour visible through the greyscale display.

The Active button associated with the selective is enabled when you set the initial softness and tolerance. When an Active button is enabled, the selective's matte will be applied to the result clip. You can disable the Active button at any time if you do not want to apply this matte to the result clip.

TIP To redefine a matte based on a different Define control, click the control you want to use. The matte is reset according to your selection.

5 Enable Tolerance and Softness.

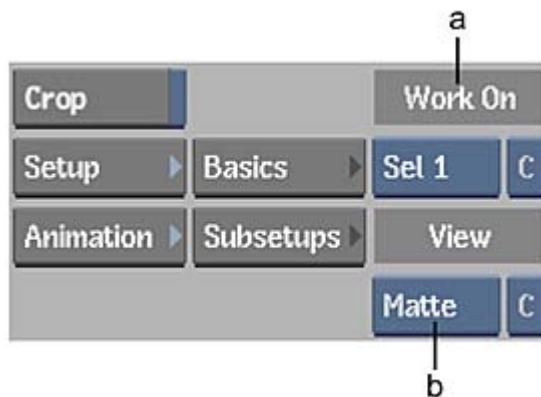

The range of colour used to define the matte is shown on the hue cube with tolerance and softness indicators. The light grey outline shows tolerance and the black outline shows softness. When you define a matte with a luma range, it is shown in the luma range—the white line indicates the tolerance and the yellow line indicates softness.

(a) Plotted colour (black dot) (b) Hue cube (c) Tolerance range (d) Softness range (e) Luma range

TIP Select Home from the Frame Options box to reset the hue cube to its original size and position.

- 6 To view the matte while you refine it, select Matte from the Selective View box.

(a) Work On box (b) Selective View box

The matte appears in the image window. The black and grey areas of the matte can be colour corrected. The white areas will remain unaffected.

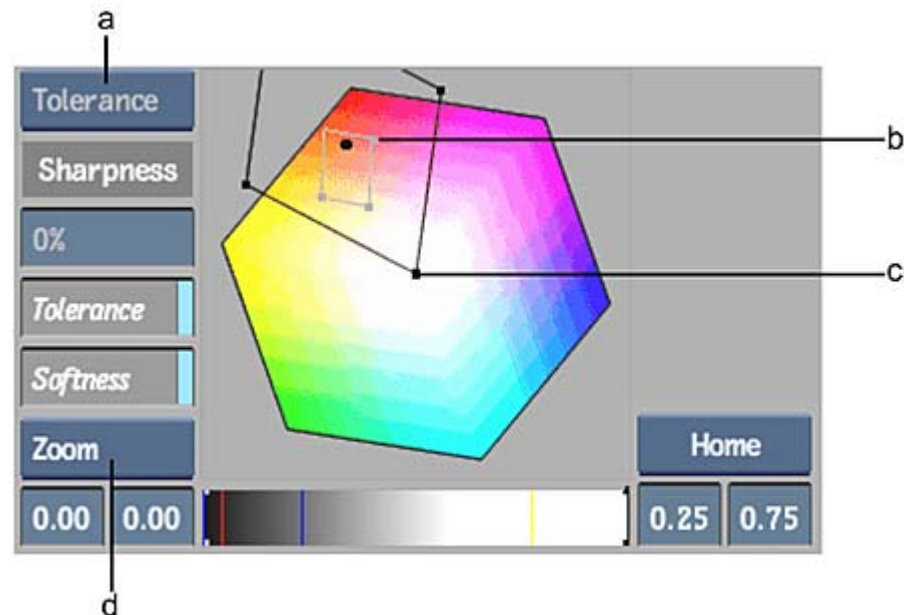

TIP Select Matte view to output a matte for use in another tool in Batch or Batch FX. The selective must also be selected in the Work On box.

- 7 To refine the matte, do any of the following:
 - Adjust softness and tolerance by selecting options from the Adjusting box and then sampling the result clip.

Select:	To:
Tolerance	Add tolerance to the matte.
+Softness	Add softness to the matte.

Select:	To:
-Softness	Remove softness from the matte.

- Adjust softness and tolerance by selecting Move from the Move/Zoom box and then moving the handles of the tolerance or softness outlines on the hue cube. The Tolerance and Softness buttons must also be enabled.

(a) Adjusting box (b) Tolerance handle (c) Softness handle (d) Move/Zoom box

TIP You can zoom the hue cube by selecting Zoom in the Move/Zoom box and then dragging the cube. Alternatively, `Ctrl+spacebar`-drag to zoom. You can pan the hue cube by pressing `spacebar` and dragging.

- Adjust the softness and tolerance in the luma range by dragging the Softness and Tolerance fields.

(a) Softness range (b) Low Softness field (c) Low Tolerance field (d) Low bracket (e) Tolerance range (f) Plot line (g) High bracket (h) High Tolerance field (i) High Softness field

When working with 16-bit floating point images, you can press `spacebar` to pan the gradient bar, and `Ctrl+spacebar` to zoom the gradient. Select Home from the Frame Options box to reset the gradient to the default 0:1 position. If you have softness or tolerance values out of the 0:1 range, select Autoframe from the Frame Options box to view the complete gradient range. Select Plot Colour from the Frame Options box to enlarge the gradient to include the plot and reference colours.

- If the matte appears grainy, drag the Sharpness field to adjust softness and reduce noise.
- 8 To apply a Gaussian blur, enable G. To apply a box blur, disable G and set the width and height of the blur with the X and Y fields.
 - 9 To invert the matte, enable Inv Selection.

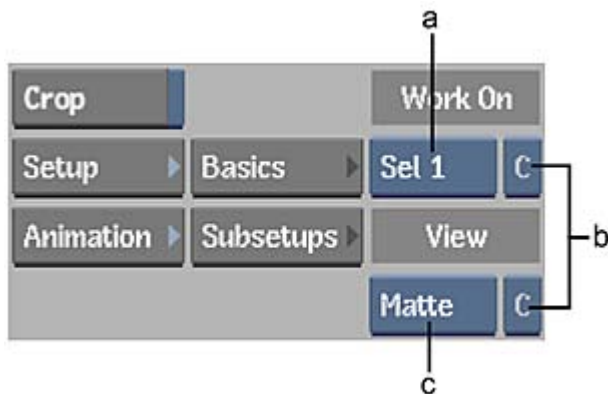

- 10 Continue fine-tuning the matte until you are satisfied.

You can select the selective in the Work On box from any menu in the Colour Warper to perform advanced colour corrections on the range defined by the matte. You can also change the view in the Selective View box.

TIP When you switch from the Selective menu to any other menu in the Colour Warper, Result appears in the Selective View box. Select Result to view the result clip.

Clearing and Deleting Mattes and Colour Corrections

Use the C/R boxes next to the Work On box and Selective View box to reset a matte or a colour correction. C deletes the matte or colour correction at the current frame by setting a keyframe. R deletes the matte or colour correction for the entire animation curve.

(a) Work On box (b) C/R boxes (c) Selective View box

NOTE If there is no matte or colour correction associated with the correction, the C/R button is disabled.

To delete a matte for the entire animation curve:

- 1 Select the matte from the Work On box (Sel 1, Sel 2, or Sel 3).
- 2 Select R from the C/R box next to the Selective View box.
The matte is deleted. All keyframes and colour corrections associated with the matte are also cleared.

NOTE Keyframes associated with the colour correction are not cleared.

To delete a matte at the current frame:

- 1 Select the matte from the Work On box (Sel 1, Sel 2, or Sel 3).
- 2 Select C from the C/R box next to the Selective View box.
The matte is deleted at the current frame and a keyframe is set.

To delete a colour correction for the entire animation curve:

- 1 Select a matte or the entire image from the Work On box (Master, Sel 1, Sel 2, or Sel 3).
- 2 Select R from the C/R box next to the Work On box.
The colour correction is deleted and all keyframes are cleared. If you selected a matte (Sel 1, Sel 2, or Sel 3) from the Work On box, the matte is unaffected and its keyframes are not cleared.

To delete a colour correction at the current frame:

- 1 Select a matte or the entire image from the Work On box (Master, Sel 1, Sel 2, or Sel 3).
- 2 Select C from the C/R box next to the Work On box.

The colour correction is cleared at the current frame and a keyframe is set. If you selected a matte (Sel 1, Sel 2, or Sel 3) from the Work On box, the matte is unaffected and its keyframes are not cleared.

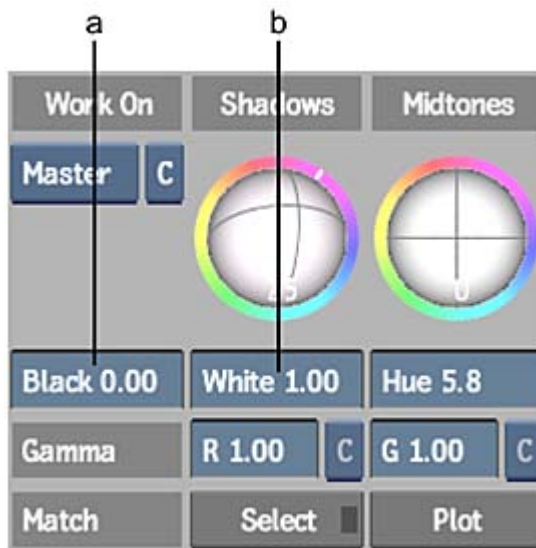

Correcting Colour Imbalances

During production, differences in lighting and equipment often create colour imbalances in and between clips. When you work on these clips in the Colour Warper, you should perform a basic colour correction to colour balance them. You can balance colours using the tools in the Basics menu. Perform your tasks in the following order:

- Set black and white levels.
- Remove unwanted colour.

Setting Black and White Levels

When you balance the colours in a clip, you should always start with the darkest and lightest parts of the image. You may, for example, need to establish parameters for the black and white (luma) content to ensure that the intensity of the image is in accordance with established broadcast parameters. These parameters are known as *black points* and *white points*. You use the Black and White fields to establish black and white points.

(a) Black field (b) White field

Black field Modifies the luma in the image's shadows without affecting the chroma.

White field Modifies the luma in the image's highlights without affecting the chroma.

To set black and white levels:

- 1 Sample the highlights in the image. To determine the white point, select a white that appears to be flat rather than reflective so that you obtain a more accurate reading. Do not use a highly reflective

surface such as a window or metal surface as they are often too bright. Enable Plot and then sample the whites in the result clip.

In the Basics menu, a red plot line is displayed in the 2D luma histogram indicating the luma value of the sampled whites in the result clip.

- 2 While viewing the 2D luma histogram and the image, adjust the white level to modify the luma value and set the white point—drag left to darken the highlights and right to lighten them. The Plot sample is updated as you drag the field.

TIP You can view both the 2D luma histogram and 2D vectorscope to determine what adjustments you need to make to the highlights. For example, if the white point is set to an acceptable level in the 2D luma histogram but the sampled chroma value shows an unwanted colour cast in the 2D vectorscope, use the Highlights trackball to modify the chroma value in the highlights. See [Removing Unwanted Colour](#) (page 998).

- 3 Enable Plot and sample the shadows in the result clip to determine the black level. Sample the darkest part of the image to determine the black point.

A red plot line is displayed in the 2D luma histogram indicating the luma value of the sampled blacks in the result clip.

- 4 While viewing the 2D luma histogram and the image, adjust the black level to modify the luma value—drag left to darken the shadows and right to lighten them. The Plot sample is updated as you drag the field.

TIP Once the black level is set, you can use the Shadows trackball to adjust the chroma values in the highlights while viewing the plot sample in the 2D vectorscope. See [Removing Unwanted Colour](#) (page 998).

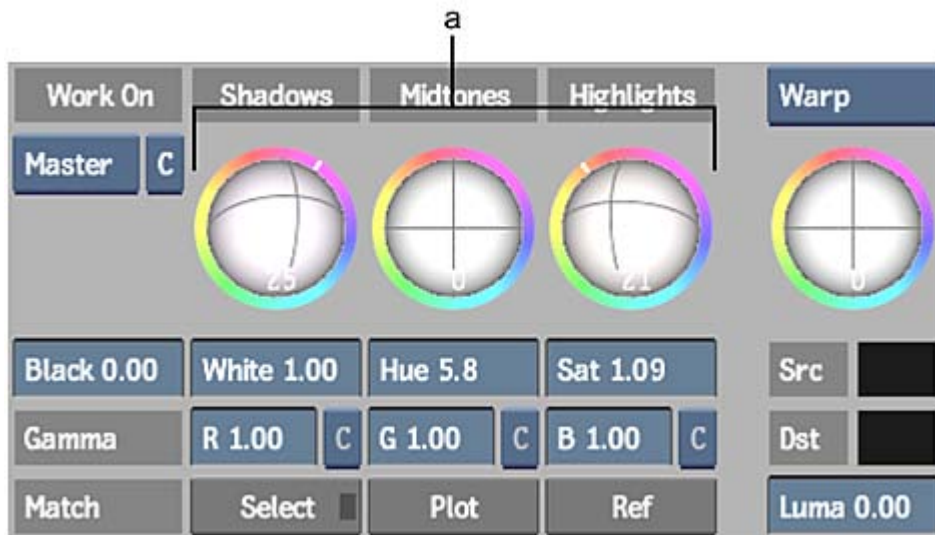

Removing Unwanted Colour

Unwanted colour can be caused by factors such as inconsistent lighting conditions during a shoot or incongruities between the white levels set on a video camera and the given lighting conditions. Factors such as these can result in clips or images that contain unnatural looking colours or one predominant colour, which gives the image an unwanted colour cast. After setting black and white points, you can remove the unwanted colour without affecting the black and white levels. You can:

- Use the Shadows, Midtones, and Highlights trackballs to remove colour from the shadows, midtones, and highlights ranges.
- Use the Suppress trackball to remove a range of colour, such as a colour cast that pervades the entire image.

Not all colour casts detract from the natural appearance of the image. Before you remove a colour cast, it is best to analyse the image or clip, both in relation to other clips in the project and with an eye on maintaining the atmosphere, or mood inherent to the clip. For example, images of sunny summer days should have a reddish cast to convey an atmosphere of warmth. Completely removing the reddish cast may result in a colder feel than you want. In cases where the cast is a complementary one, you may want to refine it to improve the overall effect. See [Creating Colour Casts](#) (page 1009).

The shadows, midtones, and highlights trackballs in the Basics menu are described as follows.

(a) Trackballs

NOTE To make the trackballs respond to changes in pressure, use the Pointer preferences in the Preferences menu.

Shadows trackball Modifies the chroma in the low luminance area without affecting the luma.

Midtones trackball Modifies horizontal RGB curves in the 2D luma histogram. These curves represent the amount of chroma tint you apply to the image. For example, if the red and green curves are above the middle line while the blue curve is below the middle line, you are adding a yellow tint to the midtones components of your image.

By default, the Midtones trackball affects all ranges except white and black, as shown by the histogram's RGB curves. To set the luma range affected by the Midtones trackball, use the two midtones triangles below the 2D luma histogram. Drag the triangles closer together to decrease the range and further apart to increase it. You can modify the range as many times as you like. When working with 16-bit floating point images, the midtones range is set to 0:1, and the midtones triangles can only be moved in this range.

(a) RGB curves (b) Midtones triangle (c) Midtones triangle

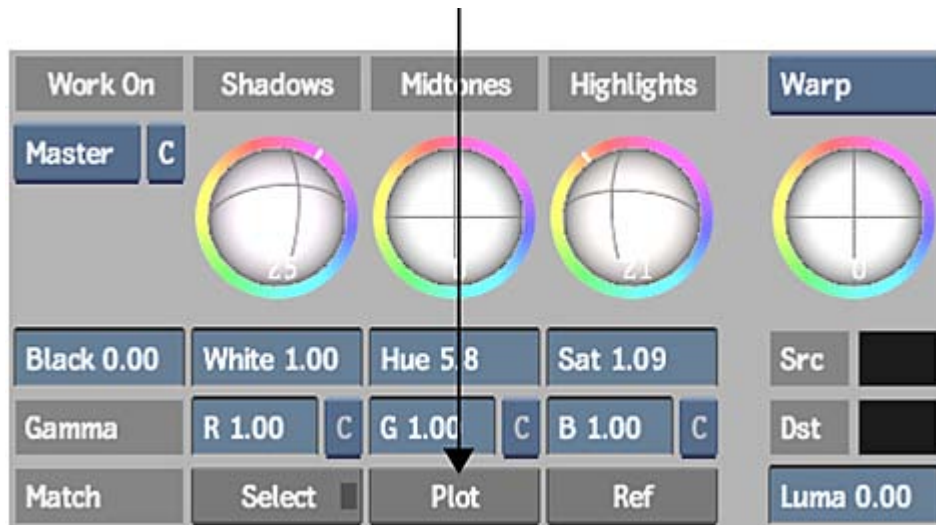

Because you can modify the range that the Midtones trackball affects, the trackball will always return to its default reference value—when you release the Midtones trackball and apply the change, it will return to 0.

NOTE You can animate the curve using the Shape channel under Midtone in the Channel Editor. Click Animation to view the Channel Editor.

Highlights trackball Modifies the chroma in the high luminance area without affecting the luma.

To remove unwanted colour using the Shadows, Midtones, and Highlights trackballs:

- 1 Click Basics to display the Basics menu.
- 2 Enable Plot and then sample the image's highlights.

The sample (outlined in red) appears in the 2D or 3D vectorscope.

TIP You can determine the colour of a sample by dragging right in the Saturation field to temporarily increase the saturation while monitoring the sample in the 2D vectorscope. When you release the mouse, the level that appears in the field resets to its default reference value. Once you determine the cast of the colour, click Undo to reset the saturation level and then resample the image.

- 3 If necessary, double-click the 3D vectorscope to display the 2D vectorscope.
- 4 While viewing the 2D vectorscope, drag the Highlights trackball to move the sample towards the centre of the 2D vectorscope.

The chroma in the high luminance area of the clip is modified without affecting the luma.

- 5 Drag the Midtones trackball to make minor adjustments to the chroma content.

TIP Drag the left midtones triangle to decrease the range affected by the Midtones trackball. Make sure the range includes the sampled colour.

The RGB curves in the 2D luma histogram reflect the changes you make. More of the unwanted colour is removed from the image (while still preserving luma) without affecting the black and white points.

TIP To achieve true white, drag the Highlights and Midtones trackball to move the plot sample to the centre of the 2D vectorscope.

- 6 Continue modifying the highlights and midtones until you are satisfied with the result.
- 7 Enable Plot and then sample the image's shadows.
- 8 Repeat steps 2 to 6 using the Shadows and Midtones trackballs to remove unwanted colour from the shadows (and midtones) in the image.

To remove unwanted colour using the **Suppression** trackball:

- 1 Click Basics to display the Basics menu.
- 2 Select Suppress from the Trackball option box.

- 3 To sample the colour you want to suppress, enable Plot and then sample the image. The sample (outlined in red) appears in the 2D or 3D vectorscope.
 - 4 While monitoring the 2D vectorscope and image, drag the Suppress trackball towards the colour you want to suppress to move it closer to the centre of the 2D vectorscope. For example, to suppress yellows, move the trackball towards yellow.
- TIP** Disable Source and Destination to only view the sample.
- 5 Release the trackball.
 - 6 To further increase the suppression of the same colour, use the trackball to move the colour closer to the centre of the 2D vectorscope.

Improving Contrast

Poor image contrast can be caused by various factors. For example, when you remove a colour cast from a clip, it may become washed out. Washed out clips usually occur when the image contrast and saturation levels are too low. To complete the task of balancing the colours in the clip, use the tools in the Basics menu to correct the poor contrast. To improve contrast and the overall look of the clip, you can:

- Adjust the luma and chroma content in the shadows and highlights, including the black and white point.
- Increase colour saturation without changing luma.
- Modify the luma and chroma content using the Gamma controls.

Adjusting Shadows and Highlights to Improve Contrast

When there is not enough, or too much, black or white in a clip, it will lack contrast. If you want to improve the contrast by changing both the chroma and luma content, including the black and white points, use the controls in the Basics menu to adjust the shadows and highlights in the image.

To adjust the shadows and highlights to improve contrast:

- 1 Click Basics to display the Basics menu.
- 2 Enable Plot and then **Ctrl**-drag the cursor over the portion of the result clip containing black or white. In the Basics menu, a red plot line is displayed in the 2D luma histogram indicating the luma value of the sampled blacks. In the vectorscope, you can view the saturation and hue.
- 3 Use the 2D luma histogram and 2D vectorscope to determine which controls you need to use (such as the Black field, and Shadows and Midtones trackballs).
- 4 While viewing the 2D luma histogram, adjust the black level to modify the luma value. The Plot sample is updated as you drag the field.
- 5 While viewing the 2D vectorscope, drag the Midtones and Shadows (Highlights) trackballs towards the colour you want to increase in the blacks or whites. The Plot sample is updated as you drag the trackball.

TIP To achieve true black or white, drag the Midtones and Shadows trackball to move the plot sample to the centre of the 2D vectorscope.

- 6 Continue modifying the shadows until you are satisfied with the result.

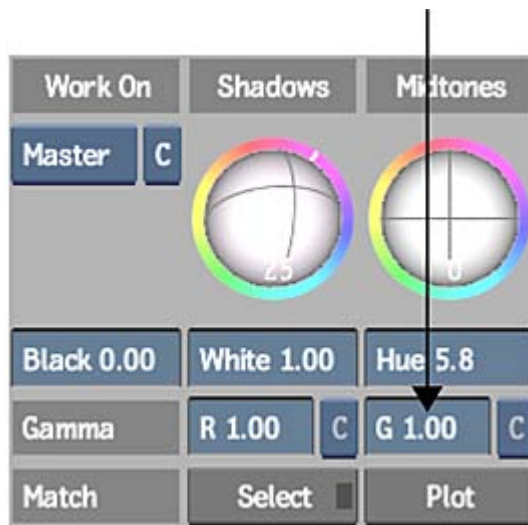

TIP View the sample in the 3D vectorscope to make more refined modifications.

Increasing Saturation

When an image is desaturated, the colours can appear washed out. To improve contrast, you can increase the colour saturation globally, saturate specific hues, or do both. Increasing saturation levels increases the colour intensity and causes minor changes to the hue. The luma content is virtually unaffected when you modify saturation.

To increase saturation globally:

- 1 Click Basics to display the Basics menu.
- 2 Drag right in the Saturation field while monitoring the 2D or 3D vectorscope and the image.

The selected colour range (or entire image) moves towards the perimeter of the 2D luma histogram. There is also an increase in colour saturation in the image.

To saturate specific hues of an image:

- 1 Click Basics to display the Basics menu.
- 2 Select Saturate from the Trackball option box.

- 3 Drag the Saturate trackball towards the colour you want to saturate while monitoring the 2D vectorscope. Drag until the colour is closer to the edge of the 2D vectorscope. For example, to saturate reds, move the trackball towards red.

NOTE To make the trackballs respond to changes in pressure, use the Pointer preferences in the Preferences menu.

- 4 Release the trackball.
- 5 To further increase the saturation of the same colour, use the trackball to move the colour closer to the edge of the 2D vectorscope.

Improving Contrast Using Gamma

When you want to improve contrast by modifying both the chroma and luma content simultaneously without changing the black and white points, use the Gamma controls. You only need to make small adjustments to the RGB gamma curves to improve the contrast.

You can adjust the RGB gamma curves uniformly using the RGB Gamma fields.

You can also use a second set of adjustment curves to tweak each colour channel, as well as the luminance channel, regionally.

After making uniform or regional adjustments, if you are not satisfied with the result, you can reset each channel's gamma or adjustment curve, or clear edited curve values for individual frames.

(a) Trackball option box (b) Gamma curves (c) Reset box (d) Luma range

To improve contrast using gamma:

- 1 Click Basics to display the Basics menu.
- 2 Select Gamma from the Trackball option box.
- 3 Display the gamma curve(s) you want to adjust.

Enable:	To display:
RGB	The R, G, and B gamma curves at the same time.
Red, Green, or Blue	The R, G, or B gamma curve individually.
Luminance	The Luminance curve. Use this curve to modify luminance levels locally without affecting the overall luminance.

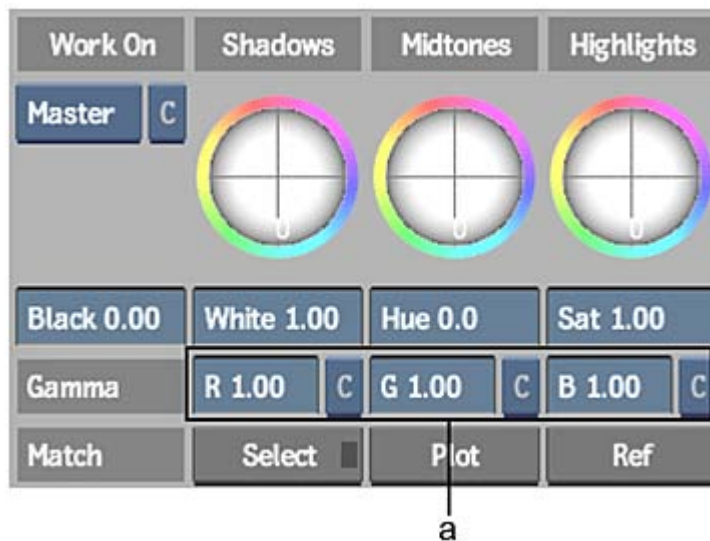

Two curves are displayed for each channel, the original gamma curve, and an adjustment curve with control points for regional control. Initially these curves overlap.

(a) Red channel's gamma curve (b) Red channel's adjustment curve (c) Added control points on adjustment curve

- 4 While monitoring the 2D vectorscope and image, make a minor adjustment to the gamma curves by doing one of the following:
 - To modify R, G, and B gamma values individually across the entire luma range (from black to white), click and drag in the Gamma R, G, and B fields. Drag left to increase contrast or right to decrease contrast. You can also enter a value directly in these fields. Enter a low value to increase contrast or a high value to decrease contrast.

Only the field you modified is updated. The gamma curves are also updated to reflect your changes. The gamma curve is offset from its dotted adjustment curve. Use the adjustment curve to make regional adjustments to the channel.

(a) RGB Gamma Fields

- To modify R, G, and B gamma values proportionally across the entire luma range (from black to white), **Alt**-drag the Gamma R, G, or B field. Drag left to increase contrast or right to decrease contrast.

All three fields are updated. The gamma curves are also updated to reflect your changes. The gamma curves are offset from their dotted adjustment curves. Use the adjustment curve to make regional adjustments to the channel.

TIP To smooth the contrast, you can increase the gamma (raise the curves) and then adjust the Black and White levels in the Basics menu.

- To modify part of the RGB gamma or luminance range rather than the entire range, use the Tools box to modify the adjustment curves.

Select:	To:
Add	Add control points to an adjustment curve. With Add selected, click either the red, green, blue or luminance adjustment curve to add a control point.
Delete	Delete control points from an adjustment curve. With Delete selected, click a point on the red, green, blue or luminance adjustment curve to delete it.
Move	Move the control points. With Move selected, drag the points to move them.
Zoom	Zoom in on the curves. With Zoom selected, drag over the curves right or left to zoom in or out. You can also press <code>Ctrl+spacebar</code> and drag in the curves to zoom.
Rect Zoom	Zoom in on a section of the curves. With Rect Zoom selected, drag a selection box to zoom in on the area of the curves contained by the selection box.
Pan	Pan the curves. With Pan selected, drag over the curves to pan the curves in any direction. You can also press <code>spacebar</code> and drag in the curves to pan.

After dragging control points, the image and 2D vectorscope update accordingly.

To reset RGB gamma or luminance curves for all frames in the clip:

- 1 Do one of the following:

- To reset individual RGB gamma curves, select R in one of the Channel Reset boxes next to the Gamma R, B, or C field.

The gamma curve is reset along with its adjustment curve for all frames in the clip. Any control points added to the adjustment curve are removed.

- To reset the R, G, or B gamma value for the current frame, `Ctrl`-click the GamR, GamB, or GamC field.
- To reset RGB adjustment or luminance curve values for all frames in the clip, click one of the channel buttons (RGB, Red, Green, or Blue) or the Luminance button to display the curves you want to affect, then select Reset in the Reset box.

The values for the displayed adjustment curves or luminance curve are reset. Any control points added to the adjustment curves or luminance curve are removed.

To clear RGB gamma or luminance curve values for the current frame:

- 1 Do one of the following:

- To clear individual RGB gamma curve values for the current frame, select C in one of the Channel Reset boxes next to the Gamma R, B, or G field.

The gamma curve value is cleared for the current frame, and the gamma curve is updated without affecting its adjustment curve. A keyframe is set with the reset values.

- To clear RGB adjustment or luminance curve values for the current frame, click one of the channel buttons (RGB, Red, Green, or Blue) or the Luminance button to display the curves you want to affect, then select Clear in the Reset box.

The values for the displayed adjustment curves or luminance curve are reset for the current frame. The curves' control points are distributed equidistantly along each curve. A keyframe is set with the reset values.

Matching Colours in Clips

You can match a sample from the result clip to one from a reference clip. Matching clips can improve continuity between clips. You can:

- Match specific colours.
- Match shadows, highlights and overall saturation.

Matching Specific Colours

You can match plot samples to reference samples using the trackballs and by aligning the colours in the vectorscope. For example, you may want to match a red in one image to a different shade of red in another clip. For information on using Plot and Ref controls, see [Sampling Clips in the Image Window](#) (page 989).

To match specific colours:

- 1 Select Result from the View box.
The result clip is displayed in the image window.
- 2 If necessary, position the split bar so that both a reference clip and the result clip appear.
- 3 Enable Plot and then sample a colour in the clip you want to modify (the result clip).
A red plot line is displayed in the 2D luma histogram indicating the luma value of the sample. In the 2D vectorscope, you can view the saturation and hue of the sample (outlined in red). In the 3D vectorscope, you can view the sample in terms of HLS.
- 4 Enable Ref and then sample the colour in the reference image you want to match.
A yellow reference line is displayed in the 2D luma histogram indicating the luma value of the sample. In the 2D vectorscope, you can view the saturation and hue of the sample (outlined in yellow). In the 3D vectorscope, you can view the sample in terms of HLS.
- 5 Use the 2D luma histogram in the Basics menu and 2D vectorscope in the image window to determine which controls you need to use.

Drag:	When:
White or Black field	You need to adjust the luma values in the highlights or shadows without modifying the chroma. Drag the field so that the plot line in the 2D luma histogram moves towards the reference line.
Highlights, Midtones, or Shadows trackball	You need to adjust the chroma values in the image without modifying the luma. Drag the trackball(s) so that the plot sample in the 2D vectorscope moves towards the reference sample.

- 6 Use the necessary controls to modify the clip until the plotted sample is aligned with the reference colour in the 2D luma histogram and 2D vectorscope. If necessary, increase or decrease the saturation as well as shift the hue.

TIP View the sample in the 3D vectorscope to make more refined modifications.

Matching Shadows, Highlights, or Overall Saturation

Use the Match feature to match a range of colours in the result clip to a range of colours in a reference clip. You can match highlights, shadows, or the overall saturation of an image.

NOTE Match is not designed to match specific colours.

To match shadows, highlights, or overall saturation:

- 1 Select Result from the View box.
The result clip is displayed in the image window.
- 2 Position the split bar so that both a reference clip and the result clip appear.
- 3 Click Match.
The following message appears in the message bar: “MATCHING: Select an area to be modified.”
- 4 Click and drag on the result clip to draw a box around a range of colours. You can select an area of the image that is predominantly black, white, or contains a wide spectrum of colours. To match the overall saturation of an image, select a larger area of the image.
The blue indicator on the Match button is enabled, indicating that you need to select a destination sample.
- 5 If necessary, position the split bar to show more of the reference image.
- 6 Click Match.
The following message appears in the message bar: “MATCHING: Select an area to match to.”
- 7 Click and drag to draw a box around a range of colours in the reference clip. You should match whites with whites, blacks with blacks, or select a broad range of colours on both images to match saturation. Trying to match completely different colours will produce unpredictable results.
The range in the result clip is matched to the range in the reference clip.
- 8 Repeat these steps as often as necessary to obtain the best possible match between colours. You can use Match repeatedly to make your colour match more precise.
- 9 To refine the result, use other controls in the Basics menu (such as the Saturation field), and then reuse Match.

To clear a Match operation:

- 1 Click the Undo box.

To cancel a Match operation in progress:

- 1 If you begin using Match and want to cancel the matching process, adjust any value using the trackballs or fields.
The blue indicator on the Match button will be disabled, indicating that the matching process has been cancelled.

Performing Hue Shifts

You can use the Hue field in the Basics menu to perform hue shifts on the entire image or a range in the image defined by a selective's matte. Perform hue shifts when you want to change the colour of an object or create other artistic effects. Hue shifts do not affect the luma.

You can also perform hue shifts when you want to suppress colour spill. See [Removing Colour Spill](#) (page 1011).

To perform a hue shift:

- 1 If necessary, create a matte for the range of colour you want to change. See [Selecting Colour Ranges for Colour Correction](#) (page 991).
- 2 Click Basics to display the Basics menu.
If you are using a selective, the Selective View box should display Result when you display the Basics menu.
- 3 Sample the image to see the hue shift in the 2D luma vectorscope. Enable Plot and then sample the colour range in the image you want to hue shift.
A red line also appears in the 2D luma histogram and the sample is outlined in the 2D or 3D vectorscope.
- 4 Drag the Hue field while monitoring the 2D or 3D vectorscope and the image.
The selected colour content (or entire image) shifts through the colour range.
- 5 If necessary, you can change the saturation of the hue by dragging the Saturation field—drag right to increase saturation or left to decrease it.
The selected colour range moves towards the perimeter or centre of the 2D luma histogram.

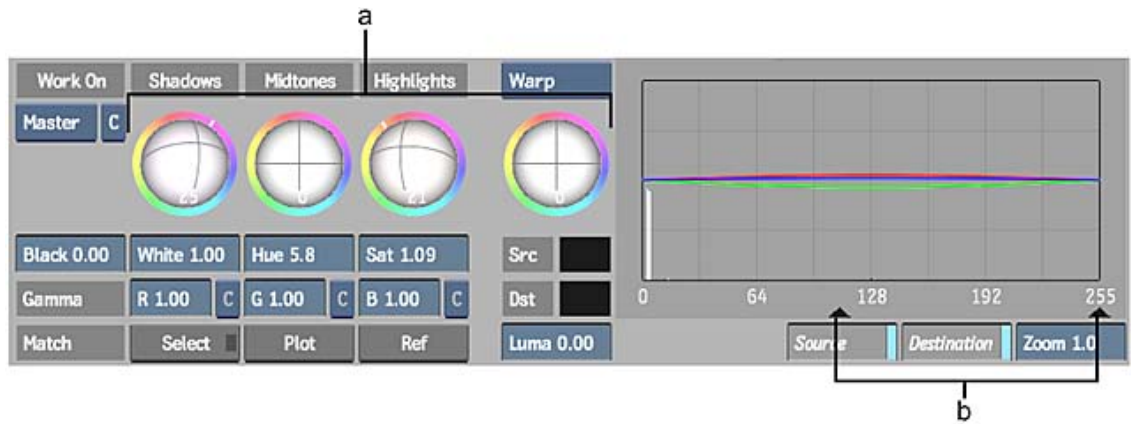

Creating Colour Casts

You can use the Midtones trackball to create a colour cast that affects the chroma in the entire image without affecting the luma. Create a colour cast when you want to emphasize a colour range to create an artistic effect or when you want to refine an existing cast. For example, create or refine a bluish cast to convey a cooler atmosphere.

NOTE Before you create a colour cast, you should correct colour imbalances in the image or clip. See [Correcting Colour Imbalances](#) (page 997).

To create a colour cast:

- 1 Click Basics.

(a) Trackballs (b) Midtones triangles

TIP You can determine the colour of an existing cast by dragging right in the Saturation field to temporarily increase the saturation while monitoring the sample in the 2D vectorscope. Click Undo once you determine the colour of the cast.

- 2 To add a colour cast to the entire image, drag the midtones triangles so that they span the entire luma range.
- 3 While viewing a vectorscope and the image, drag the Midtones trackball towards the colour you want to increase in the clip or image. For example, to add more yellow to the image, drag the Midtones trackball towards yellow.

In the 2D or 3D vectorscope, the colours update to reflect your changes. In the image window, the colour in your clip changes according to the direction the trackball is being dragged.

NOTE When you drag the Midtones trackball, the RGB curves in the 2D luma histogram also reflect the changes you make.

- 4 To increase a range of colour in the highlights or shadows of the image, drag the Highlights or Shadows trackball.
- 5 To increase or decrease the saturation of the cast, drag the Saturation field—drag right to increase saturation and left to decrease it.

TIP You can make slight modifications to the hue of the cast using the Hue field.

Readjusting Colour After a Colour Correction

When colour correcting clips, colours that you do not want to alter may be modified in the colour correction process. Use the Warp trackball in the Basics menu to readjust a specific range of colour.

You can also adjust the luminance of the selected colour using the Luma field.

To readjust colours after a colour correction:

- 1 Click Basics.
The Basics menu appears.

(a) Trackball option box (b) Source Colour pot (c) Destination Colour pot (d) Luma field

- 2 Select Warp from the Trackball option box.
 - 3 Click Pick and then sample a colour in the clip you want to modify.
The colour you select is outlined in white in the 2D or 3D vectorscope. A cyan bar representing the colour appears in the 2D luma histogram. The Src Colour pot displays the colour.
 - 4 Click the Src Colour pot to set the source colour.
The Dst (destination) Colour pot is updated to match the source colour.
 - 5 Move the Warp trackball towards the destination colour.
The Dst Colour pot dynamically updates to reflect your changes. When you release the mouse, the Src Colour pot is updated to match the destination colour. In the 2D or 3D vectorscope, the selected colour moves to reflect the changes you are making to the image.
- NOTE** To make the trackballs respond to changes in pressure, use the Pointer preferences in the Preferences menu.
- 6 To adjust the luminance of the destination colour, adjust the Luma field. When you adjust the luma of the destination colour, the entire luma content of the image is adjusted around the selection. The selected luma value changes the most.
The Dst Colour pot dynamically updates to reflect your changes. When you release the mouse, the Src Colour pot is updated to match the destination colour. In the 2D luma histogram, the cyan bar moves to reflect the changes you are making to the luma content.
 - 7 Release the trackball or click the Luma field.
The Src Colour pot is set to the Dst box colour.

Removing Colour Spill

When you key clips in the Modular Keyer, there can be colour spill. You can refine the key by suppressing colour spill in the Colour Warper. Use the Saturate and Suppress trackballs in the Basics menu. Use the Suppress trackball to suppress the colour spill and the Saturate trackball to correct any unwanted colour suppression. When you use these trackballs to modify colour in the image or clip, a range of colour is affected.

In the Modular Keyer, place the Colour Warper node in the CBlend pipe.

To remove a colour spill:

- 1 Click Basics to display the Basics menu.

- 2 Select Suppress from the Trackball option box.

NOTE To make the trackballs respond to changes in pressure, use the Pointer preferences in the Preferences menu.

- 3 Move the Suppress trackball towards the colour that you want to suppress. For example, to remove a blue background, move the trackball so that the blue colours appear in the centre of the 2D vectorscope.

NOTE The colour you are suppressing appears in the middle of the 2D vectorscope at full suppression.

By comparing the Result clip and the Front clip, you may notice some unwanted colour suppression to the colour that is opposite (on the colour wheel) the one you just suppressed. You can fix such suppression with the Saturate trackball.

- 4 Select Saturate from the Trackball option box.

- 5 Move the Saturate trackball towards the colour that you want to saturate. The colour that you are saturating moves closer to the edge of the 2D vectorscope.

- 6 It may be necessary to adjust colours in the image using the Suppress and Saturate trackballs several times to achieve suitable results. Continue adjusting the trackballs until you are satisfied with the result.

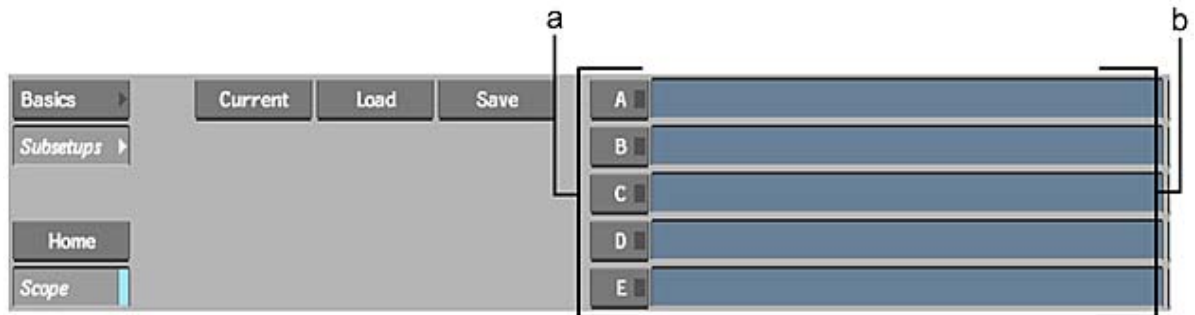

Creating Subsetups

Subsetups are Colour Warper setups selected at a specific moment at a specific frame. Subsetups are for the current frame only and do not include entire animations. You can select up to ten subsetups and compare colour corrections in other subsetups. You can save and load a group of subsetups.

NOTE The group of subsetups loaded affects all Colour Warper nodes in the current setup since subsetups are shared between Colour Warper nodes. Ten subsetups (A-J) constitute a group.

Use the Subsetups menu to:

- Selectively store intermediate setups.
- Compare any subsetup to the current setup.
- Share subsetups between Colour Warper nodes.
- Save and load a group of subsetups.

(a) Subsetup buttons (b) Subsetup fields

Storing and Retrieving Subsetups

You can store and retrieve subsetups using the Subsetup buttons.

To store and retrieve the current setup:

- 1 Press and hold one of the subsetups buttons until a message appears indicating “Storing subsetup <subsetup letter>” and release.
The LED indicator shows that the subsetup is stored. All active subsetups have a LED indicator. If you have not stored anything into a subsetup, the active light of the button will be off.
- 2 Use the setup at another frame or in another node by pressing the corresponding Subsetup button.

Naming Subsetups

You can name your subsetups. This allows you to store setups and later compare them to your current setup, or to apply the same correction to different frames in a clip.

To name a subsetup:

- 1 Click in a subsetup field, type in a name or description, and press **Enter** to store the setup.

Replacing Subsetups

You can replace or override a setup.

To replace an existing setup:

- 1 Click and hold a subsetup button to overwrite and replace an existing subsetup. A keyframe is set and the new subsetup is saved.

Comparing Subsetups

The current setup is accessed with the **Current** button and contains the most recently committed setup. Compare any of your subsetups to each other or to the contents of the current setup.

To commit the contents of the current setup:

- 1 Perform an operation such as advancing a frame or changing a value in the Basics menu. Your present settings will be displayed the next time you click **Current**.

To compare a subsetup:

- 1 Click a Subsetup button of the subsetup you want to compare.
- 2 Click **Current** to view the current result.

Saving and Loading Subsetups

Use the **Save** button in the Subsetups menu to save a group of subsetups. Then use the **Load** button in a later session to reload the same group of subsetups.

To save a group of subsetups:

- 1 In the Subsetups menu, click **Save**.
The file browser appears.
- 2 Browse to a different directory path if necessary and then type a name in the **Name** field.
- 3 Click **Save**.
The group of subsetups is saved in the specified directory.

To load a group of subsetups:

- 1 In the Subsetups menu, click **Load**.
The file browser appears.
- 2 Browse to the appropriate path and select the name of the group of subsetups.
The group of subsetups is loaded.

Painting

21

Paint Node

Paint Node is a system that provides a scalable matte painting, retouching, or restoration workflow in Batch or Batch FX.

Due to its underlying technology, Paint Node automatically scales strokes when changing the resolution, ratio, or bit depth of input clips, or when switching from Full Resolution to Proxy mode. Paint Node supports “clipless” setups, which can be applied to any image input, while accurately reproducing the sequence of painted strokes.

The Paint Node accepts a front and matte clip as input, and creates a result and output matte clip, respectively. You can paint on the result and output matte, with a selection of brushes in different paint modes.

Paint Node also allows you to connect multiple sources and use them to paint the contents of source images onto the result. This paint operation, applied with the Reveal paint tool, can be used with in-context overlay over the result image. A front and matte clip can be connected as a source by connecting the clips to a source node. The content of source front and source matte input can be used to create brush strokes on the result and output matte.

Accessing Paint Node

Paint Node can be accessed from:

- [Batch FX](#). (page 1015)
- [Batch, then select a node from the Node bin](#). (page 1016)
- [Modular Keyer](#). (page 1016)

Accessing the Paint Node from Batch FX

To access Paint Node through Batch FX:

- 1 Select Timeline.
- 2 Select the segment.
- 3 Click the FX button.

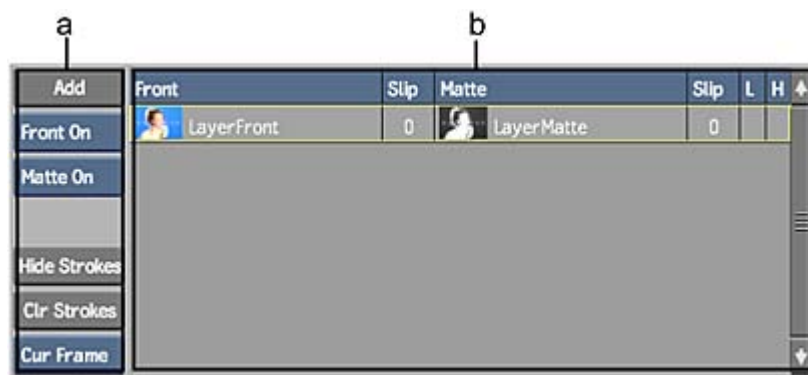

- 4 Click the Create Batch FX button.
- 5 Drag a Paint Node into the schematic.
The Paint Node is now in the schematic.
- 6 Double-click the Paint Node.
You are in the Paint Node editor.

Accessing the Paint Node from Batch

Paint Node is accessed from Batch.

To access the Paint Node from Batch:

- 1 Select Batch.
- 2 In the Batch node bin, double-click the Paint node or drag the node to the Batch schematic.
- 3 Attach a clip or node output to the front tab.
- 4 Attach a clip or node output to the matte tab. If a matte clip is not attached, the node interprets the missing input as a white clip.
- 5 In the Batch schematic, double-click the Paint Node.
The Paint Node menu appears.

(a) Source controls (b) Sources List

(a) Current Colour Pot (b) Current Brush

NOTE The Parent and Delete options in the Paint Tools box are standard Batch features and are not used in Paint Node.

Accessing the Paint Node from the Modular Keyer

To add a Paint Node in the Modular Keyer:

- 1 Double-click on, or drag, a Paint Node from the node bar and add it to the schematic.
- 2 Click the Paint Node.
You are in the Paint editor.

Using Sources

Sources are additional image data that can be used in Reveal paint operations and displayed as an overlay on the result or output matte. You can scale, rotate, and offset a source. Any transformations applied to a source will be displayed in Reveal paint strokes.

In the Paint Node menu, all sources appear in the Sources list. The Sources list allows you to select sources to be hidden, cleared, or displayed as an overlay. The first entry in the list is the front clip and matte clip.

In the schematic, source clips are connected to a Paint Node through a source node, which accepts a source front and source matte input.

A source can be a clip or the result of any process, and can include a front and/or matte clip. You can add a source node from the menu or the schematic.

If a clip with frames that are missing media is attached to a source node, the Paint Node processes incoming frames set to No Media as transparent. Strokes created with the source are stored, although they are not visible on the canvas at frames with No Media input.

When adding a source input, it is recommended that you use clips as input, or cache the node closest to the source node instead of parenting a large tree to a source node. This speeds up processing when changing frames, making for a more interactive experience.

Front		Slip	Matte		Slip	L	H
	LayerFront	0		LayerMatte	0		
	silk	0		silk	0		

(a) Front (b) Matte (c) Source front (d) Source matte

When you delete a source, it is removed from the Sources list, along with its associated strokes. When you clear a source, it remains in the Sources list, but all strokes are removed.

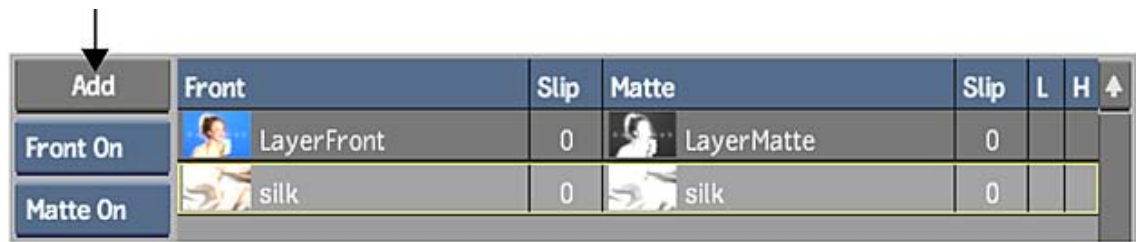

Adding a Source

When you add source, it includes both source front and source matte input. When you add a source front only, a black matte will automatically be created.

To add source node, front source and matte source:

- 1 In the Paint Node menu, click Add.
The Viewing Panel appears.
- 2 Select a source front clip, and then a source matte clip.
- 3 Click Exit Clip Select to return to the Paint Node menu.

In the Sources list, the source is added. In the schematic, the process tree is updated: a source node with the selected clips is connected to the Paint node.

	Front	Slip	Matte	Slip	L	H	
Front On	 LayerFront	0	 LayerMatte	0			
Matte On	 silk	0	 silk	0			

- 4 To help identify source nodes in the schematic, select a source in the Sources list to automatically highlight in orange the corresponding source node and link to the Paint Node. Conversely, selecting a source node also highlights the corresponding source in the Sources list.

To add a source node only:

- 1 Hold **Ctrl** and click **Add** to add a source node.
The source node is added and connected to the Paint Node.

(a) Source node (b) Paint Node

- 2 Connect clips or process tree input to the source node's front and matte inputs.

Removing a Source

You can remove a source clip from the Sources list. If you disconnected a source clip from the source node, the entry exists in the Sources list, but the clip name and proxy no longer appear. Because the stroke information is stored in the node, you can reconnect the same clip or a different clip to the source node, and the stroke information is preserved. All strokes in the canvas using the source are repainted using the new source clip.

When you delete a source node, the entry is removed from the Sources list, and the strokes stored in the node are deleted permanently.

To remove a source clip from the Sources list:

- 1 In the schematic, disconnect the source clip from the source node.

To delete a source node:

- 1 From the Tools box, select **Delete** (or use the keyboard shortcut), and click the source node in the schematic.

Clearing Strokes on a Source

You can clear strokes from the canvas that were created using a source front or source matte.

WARNING Clearing strokes for an entire sequence cannot be undone.

To clear the strokes associated with a source:

- 1 In the Sources list, select the source used to create the strokes you want to clear.
- 2 From the Selection Mode box, select Current Frame or Sequence.

- 3 Click Clear Strokes.

Hiding Strokes

You can hide a group of strokes that were created from the same source clip.

Hiding strokes is useful when you need to focus on a particular component of your image: hide strokes on the canvas that do not require attention. This feature allows you to concentrate on the current stroke. It also improves the system's interactive performance.

To hide strokes on a source:

- 1 Select the source used to create the strokes that you want to hide.
- 2 In the Sources list, click Hide Strokes (H).

A check mark appears in the H column of each source.

- 3 Click Hides Strokes again to make the strokes visible.

Restricting Strokes with the Source Matte

You can limit the sections of the source that are painted onto the canvas using the source's matte. To limit painting on the canvas using the matte. See [Restricting Brush Strokes](#) (page 1028).

To limit source brush strokes using a source matte:

- 1 In the Paint Modes box, select Reveal (E).
- 2 In the Sources list, select a source.
- 3 From the source controls, select an option in the Matte Source box.

Select:	To:
Matte Off	Paint anywhere on the canvas.
Matte On	Limit painting to areas in the source matte.
Matte Invert	Invert the source matte and limit painting to areas outside the source matte.

- 4 Draw strokes.
Brush strokes only use areas of the selected source that are delimited by its source matte.

Locking Sources

Lock a source to a specific frame. For the duration of the clip, only the source front and source matte at the selected frame is used.

To lock a source:

- 1 Select the source you want to lock.
- 2 Using the playback controls, choose the frame at which you want to lock the clip.
- 3 In the Source Front option box, select Front Lock.

A check mark appears in the L column of each selected source.

- 4 In the Source Front option box, select Front On to unlock the source.

Displaying Sources

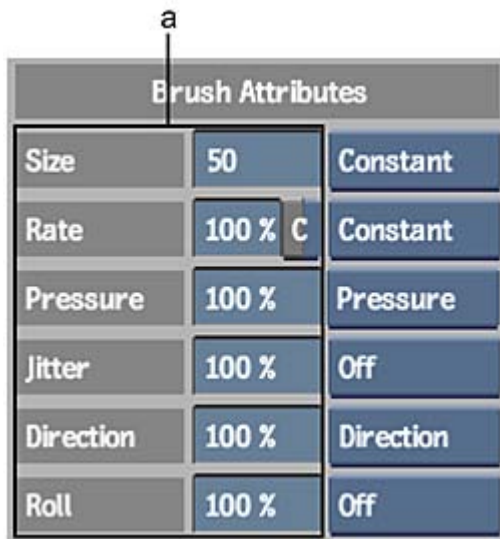

Paint Node offers an intuitive way of previewing the effects of a Reveal operation. In this view, the selected source is superimposed over the result, and the Transparency field is activated to allow for transparency adjustments. This feature allows you to see exactly what your brush strokes will reveal. See [Previewing a Reveal Operation Using a Reference Image](#) (page 1038).

Brush Attributes and Attribute Modes

You can set various brush attributes and attribute modes to determine how paint is applied to the image.

Setting Brush Attributes

The Brush Attribute fields set the size of the brush, the distribution of the paint, and the rate and direction of the paint application.

(a) Brush Attribute fields

Opacity Affects the transparency of the brush. A value of 100% applies a fully opaque colour. Use a lower value to apply a more transparent colour.

Size Determines the size of the brush, which is indicated by the diameter of the green dashed circle surrounding the cursor brush. To increase the brush size, press s and drag the brush to the right on the canvas. To decrease it, press s and drag to the left.

Rate Determines the rate at which brush strokes are applied to the canvas. Use a high value to produce a smooth continuous stroke, or a low value to produce a less continuous stroke with larger gaps between brush images. The C (Constant) button in the Rate field determines whether the consistency of the stroke is dependent on the speed at which you move the pen or mouse. For example, to create a stroke of evenly spaced dots, you could set the Rate field to 20 percent and enable Constant.

Rate attribute value = 100

Rate attribute value = 25

Pressure Affects the transparency of the paint applied to the image. To apply opaque paint, use a high percentage value. For more transparent paint, use a low value. The Pressure attribute differs from the Opacity

attribute in that you can set the Pressure attribute mode so that the paint transparency varies according to the pressure applied to the pen or the direction of the brush.

Pressure attribute value at 100%

Pressure attribute value at 50%

Jitter Randomizes the brush strokes applied to the image. A high value produces a greater dispersion of paint, while a low value produces a greater concentration.

Jitter attribute value at 100%

Jitter attribute value at 10%

Direction Causes the brush to rotate around the Z-axis and can be used to produce a calligraphy effect. The effect of the Direction attribute is most noticeable when used with one of the elliptical or star brushes. The

value of the Direction attribute causes the brush strokes to rotate by 90 degrees for each increment of 25 percent.

Direction attribute value at 100%

Direction attribute value at 75%

Direction attribute value at 50%

Direction attribute value at 25%

Roll Rolls the brush around the X-axis. The effect of the roll is most noticeable when used with one of the non-symmetrical brushes. For each increment of 25 percent, the Roll attribute value creates a rolled brush stroke of 90 degrees.

NOTE You can use any attribute mode with the Roll attribute.

Roll attribute value at 100%

Roll attribute value at 75%

Roll attribute value at 50%

Roll attribute value at 25%

Setting Brush Attribute Modes

The value of a brush attribute depends on the selected attribute.

Brush Attributes		
Size	50	Constant
Rate	100 % C	Constant
Pressure	100 %	Pressure
Jitter	100 %	Off
Direction	100 %	Direction
Roll	100 %	Off

(a) Brush Attribute Mode boxes

Off Disables the brush attribute.

Constant Keeps the brush attribute values constant.

Pressure Uses the pressure exerted on the pen as the reference value. The harder you press on the pen, the greater the brush attribute value. The softer you press, the lower the brush attribute value.

Direction Uses the direction of the brush stroke as the reference. When used with the Direction mode, the Direction attribute causes the brush strokes to follow the trajectory of the brush. Increase the value to enhance

the effect on brush direction. Drag right to use 100% of the brush attribute value, left to use 0%, up to use 25%, or down to use 75%.

Direction attribute value at 100%, Direction attribute mode

Direction attribute value at 15%, Direction attribute mode

Fade Uses the percentage value entered in the Fade field to determine the length of time that elapses before the brush stroke fades. The greater the percentage, the faster the stroke fades. A value of 100 in the Fade field causes the stroke to fade quickly, whereas a value of 1 causes the stroke to last longer. Also, strokes applied quickly will be longer than those applied more slowly.

Pressure attribute value at 100%, Fade attribute mode at 35%

Pressure attribute value at 100%, Fade attribute mode at 85%

Front, Matte, Source Front and Source Matte Allows you to use the red channel in a reference image to set brush attributes. Source Front and Source Matte mode use the red channel of the selected source in the Sources list.

Painting Brush Strokes

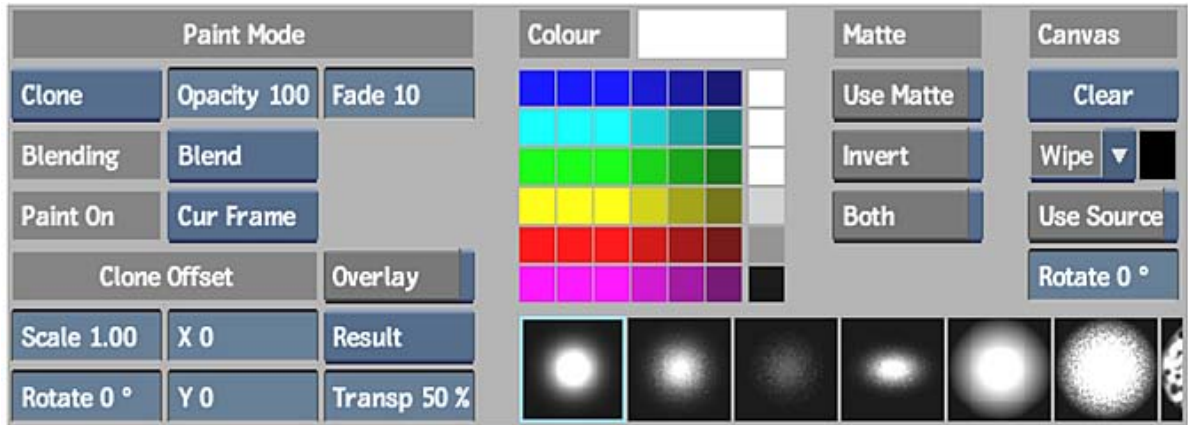

You can paint on the canvas using a variety of brush types and colours. Once you select a brush type, you can modify brush attributes to further refine your strokes. A stroke can be applied to a single frame, or simultaneously to multiple frames. You can paint on the result or output matte, or you can use matte paint mode controls to paint on the result and output matte at the same time.

You can restrict brush strokes to the area delimited by the matte. For example, assume that you have a front input that includes a person shot against a blue screen and a corresponding matte clip. If you opt to limit brush strokes to the matte, your brush strokes on the result or output matte appear only inside the matte

area and, therefore, over the person. If you then limit brush strokes to the existing strokes, new paint strokes are applied only over strokes that have already been applied.

Applying Brush Strokes

You can paint with either a pen or a mouse, and access various pressure settings.

To apply a brush stroke:

- 1 Select an option from the Paint Tools box.
- 2 Select an option from the Paint On box to apply the stroke to the current frame, all frames in the sequence, or the current frame and subsequent frames.
- 3 Select the Result (F4) or Output Matte (F4 F4) to set the view where you are painting.
- 4 If you want to paint on the result and output matte simultaneously, enable Both.
- 5 Click a brush to select it.
- 6 Set brush attributes. See [Brush Attributes and Attribute Modes](#) (page 1021).
- 7 If you will reveal a source on the image, select the source in the Sources list. See [Revealing Sources](#) (page 1033).
- 8 To change the colour, click a colour pot. If you are painting on the output matte, the brush colour is grey with an equivalent luminance value.

TIP As an alternative to using the colour pots, you can designate the colour under the pointer as the current brush colour by pressing the left **Ctrl** key and clicking on the canvas.

- 9 Click and drag on the canvas to draw a stroke.

NOTE Downstream context views are not automatically updated as you add strokes, since this would cause performance degradation. To force an update, click the Update button.

- 10 Use the eraser end of the pen if you are using the stylus to erase strokes that you have created.

Removing Brush Strokes

You can undo multiple brush strokes in Paint Node. You can use the Undo button to remove brush stroke operations, beginning with the most recent strokes. Set Undo level operations in the Preferences menu.

If you are using a stylus, remove brush strokes manually by using the back of the stylus to “erase” strokes. If the result is displayed, erasing reveals the front clip on the canvas. If the output matte is displayed, erasing reveals the matte.

Restricting Brush Strokes

You can limit the area where brush strokes are applied on the canvas. Use the matte paint mode controls to limit painting on the canvas to the matte. You can also invert the matte to limit paint to only the areas outside the original matte.

To limit which regions of a source front can be used by its source matte, use the Matte Clip option box in the source controls. See [Restricting Strokes with the Source Matte](#) (page 1020).

To limit where brush strokes are applied using the matte:

- 1 Enable Use Matte.

- 2 If you want to paint outside of your selection, enable Invert.
- 3 Draw strokes.
Brush strokes are applied only to the areas included in your selection.
- 4 Disable Use Matte to turn off matte restrictions.

Scaling Brush Strokes

You can set scaling options for brush strokes associated with the Paint Node. By specifying the previous resolution of an input clip before it was resized, the brush strokes applied to the clip can also be scaled based on these settings.

To display the stroke scaling options:

- 1 Double-click the Paint node.
- 2 Click Node Setup.

The image shows a software interface with three main sections: 'Previous Resolution', 'Stroke Resize', and 'Current Resolution'.
 - 'Previous Resolution' contains a large field '1920 x 1080 HD 1080'. Below it, a row of two fields 'W 1920' and 'H 1080' is labeled with a 'b' on the left. Below that, another row of two fields 'Set to 16:9' and 'Ratio 1.778' is labeled with an 'a' on the left.
 - 'Stroke Resize' contains a 'Fill' button.
 - 'Current Resolution' contains four fields: 'W 720', 'H 486', '8-bit', and 'Ratio: 1.333'.
 - Below the 'Previous Resolution' section, there is a 'Stroke Pan' section with two fields, 'X 0' and 'Y 0'.

(a) Aspect Ratio Presets box (b) Project Resolution Presets box

Project Resolution Presets box Provides preset aspect ratio options and an option to use a custom resolution. Set this option to indicate the previous resolution of the clip.

Width and Height fields Displays the frame width and height of the selected resolution preset. If you select Custom from the Project Resolution Presets box, use these fields to enter the values you want to use.

Aspect Ratio Presets box Provides standard frame aspect ratio options and a w:h option to use a ratio based on the values entered in the Width and Height fields. Also provides a Custom option so you can enter a frame aspect ratio in the Ratio field.

Ratio field Displays the original aspect ratio of the clip. When Ratio is set to Custom, this field becomes active so that you can enter a custom frame aspect ratio.

Stroke Resize box Select a fit method option to be applied to the clip.

Select:	To:
Centre/Crop	Center the strokes over the destination frame. If the clip at the original resolution is larger than the destination, the strokes are cropped.
Crop Edges	Fit one edge of the original clip input into the destination frame without stretching or squashing the frame. Excess parts of the original clip after resizing are cropped.
Fill	Fit the original stroke width and height into the destination frame. If the clip at its original resolution and destination frames do not have the same aspect ratio, the brush strokes can become distorted.
Letterbox	Fit the original stroke to the destination frame without squashing or stretching it, and without cropping the source.

Keep Aspect button Enable to preserve the aspect ratio of non-square pixels. This button only appears if you selected Crop Edges or Letterbox in the Fit Method box.

Stroke Pan fields Enter an X and Y value to offset existing strokes on the result. You can also reposition strokes by holding down **Ctrl+Shift** and panning the image.

Current Resolution fields Displays details of the current resolution of the clip.

Active button Enable to activate smooth filtering of pixels for enhanced display

Using Paint Modes

You can select the type of special effects you want to apply to the brush from the Paint Modes box. Strokes applied with these brushes are processed by the graphics hardware, improving interactive performance. To paint sources onto images, see [Revealing Sources](#) (page 1033).

To select a brush:

- 1 Switch to either Result (F4) or Output Matte (F4 F4) view.
- 2 From the Paint Modes box, select a brush. Refer to the sections that follow for instructions on using each brush.

TIP When a brush is selected, brush opacity and blend modes are disabled. To achieve an effect similar to modified brush opacity, use the Pressure attribute mode.

Blur

Apply a blur filter to the image with each stroke.

Original image

After using the Blur brush

To use the Blur brush:

- 1 From the Paint Modes box, select Blur (R).
- 2 Set the brush size according to the size of the area you want to blur.
- 3 Paint on the image.

Impression

Paint on colours from a reference clip. When you click on the canvas, the colour at the center of the brush is used to fill the entire brush stroke.

Original image

After using the Impression brush

Image courtesy of Buzz Image Group, Inc., and Les Films Stupefiants

Image courtesy of Buzz Image Group, Inc., and Les Films Stupefiants

To use the Impression brush:

- 1 From the Paint Modes box, select Impression.
- 2 Set the brush size.
- 3 Paint on the image.

Smear

The Smear brush smudges areas of the image, creating a fingerpainting effect.

Original image

After using the Smear brush

To use the Smear brush:

- 1 From the Paint Modes box, select Smear (T).
- 2 Set the brush size according to the size of the area you want to smear.
- 3 Paint on the image.

Clone

Use the Clone tool to paint a copy of the result image to any position on the result image. The Clone tool can also be applied to an output matte image. For example, if the result image has a tree that you would like to copy to another position on the image, you can offset a copy of it to a different position and then paint it onto the result.

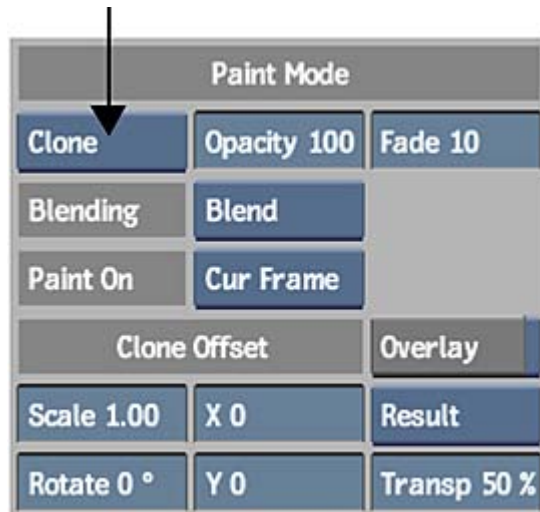

To paint a source onto the canvas, use the Reveal tool. See [Revealing Sources](#) (page 1033).

To clone an image and include cloned data in the brush strokes, use the Recursive Clone tool. See [Recursive Clone](#) (page 1033).

NOTE If changes are made upstream of the Paint Node, cloned strokes are preserved. However, the strokes will reflect the “old” input unless you force an update by clicking the Update button or by pressing U. Updates are not performed automatically because they can affect system performance.

To clone an image:

- 1 Select Clone from the Paint Modes box.

The Clone Offset parameters appear.

- 2 Set brush attributes. See [Brush Attributes and Attribute Modes](#) (page 1021).
- 3 To limit the cloned regions to the areas delimited by the matte, select an option in the Matte Source box.
- 4 To transform the reference image, do one of the following:
 - To manually offset the image, enable the Overlay button (Tab), then hold down **Ctrl+Shift** and drag the overlaid reference image.
 - To scale the image, enter a value in the Scale field.
 - To rotate the image, enter the angle of rotation in the Rotate field.

NOTE To select an area for cloning, Overlay must be turned off. If you offset an image, verify that the Overlay button is disabled after use.

- 5 To select the area you want to clone, press **Ctrl** and click the canvas.
The cursor turns red when you press **Ctrl**. When you click the canvas, the red cursor is anchored and a green cursor appears.
- 6 Position the green cursor over the destination area and click the canvas.
The green and red cursors are now locked into positions relative to each other and move in tandem.
- 7 To set precise coordinates for the clone offset, use the X and Y fields.
- 8 Click and drag on the canvas to clone to the destination area.

Recursive Clone

Use the Recursive Clone brush to paint the contents of the result image to another position on the result. Unlike the Clone tool, when brush strokes created while using the Recursive Clone tool are used as a reference when the tool is applied elsewhere, the updated image data will be used.

Original image

Image courtesy of Buzz Image Group, Inc., and Les Films Stupefiants

After using the Recursive Clone medium

Image courtesy of Buzz Image Group, Inc., and Les Films Stupefiants

To use the Recursive Clone brush:

- 1 From the Paint Modes box, select **Recur Clone** (Y).
- 2 Set the brush size according to the size of the area you want to clone.
- 3 To select the area you want to clone, press **Ctrl** and click the canvas.
The cursor turns red when you press **Ctrl**. When you click the canvas, the red cursor is anchored and a green cursor appears.
- 4 Position the green cursor over the destination area and click the canvas.
The green and red cursors are now locked into positions relative to each other and move in tandem.
- 5 To set precise coordinates for the offset, use the **X** and **Y** fields.
- 6 Paint on the image.
The image contained within the red circle brush is copied to the region defined by the green circle.

Revealing Sources

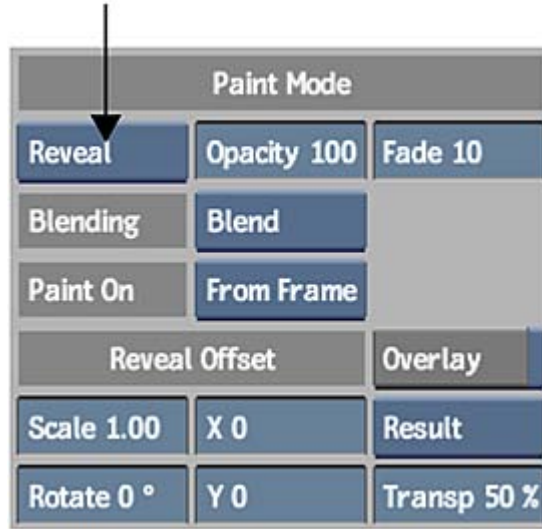

The Reveal tool allows you to paint the contents of one or more source front images directly onto the result. You can also use the Reveal tool to copy source matte images onto the output matte. For example, if one source has a tree that you would like to include on the canvas, you can select the source with the tree and then paint it onto the result.

To paint with a copy of the result or output matte image, use the Clone tool. See [Clone](#) (page 1031).

NOTE If changes are made upstream of the Paint Node, revealed strokes are preserved. However, the strokes will reflect the “old” input unless you force an update by clicking the Update button or by pressing **U**. Updates are not performed automatically because they affect system performance.

To reveal a front or matte input:

- 1 Select Reveal from the Paint Modes box.

The Reveal Offset parameters appear.

- 2 Set the brush attributes. See [Brush Attributes and Attribute Modes](#) (page 1021).
- 3 In the Sources list, select the source you want to reveal.
NOTE You can reveal sources that are marked as hidden in the Sources list. You will only be able to view the strokes created with a source when you disable Hide Strokes.
- 4 To limit the revealed sources to the areas delimited by their mattes, select an option in the Matte Source box.
- 5 To display the source as an overlay of the result image, enable Overlay (Tab). You can apply transformations to the source before you apply strokes:
 - To interactively offset a source image, press **Ctrl+Shift** and drag the source. See [Previewing a Reveal Operation Using a Reference Image](#) (page 1038).
 - To scale the source, enter a value in the Scale field.
 - To rotate the source, enter the angle of rotation in the Rotate field.
- 6 Click and drag on the canvas to apply strokes that reveal the transformed contents of the selected source.

Using Blending Modes

Blending modes are Boolean operations that can be applied to the brush's colour components. A mode is applied separately to each of the red, green, and blue components of images. You can apply blending modes to combine the RGB channels of corresponding pixels from a stroke, described as follows.

Lighten Increases the RGB channel values of each pixel of the brush stroke.

Darken Reduces the RGB channel values of each pixel of the brush stroke.

Exclusion Adds the RGB channel values of the brush stroke, then subtracts twice the product of these channels.

Hard Light Multiplies or screens the selected colour of the brush stroke onto the image, depending on the colour. The effect is similar to shining a harsh spotlight on the image, and greatly reduces the contrast levels in the image.

If the blend colour (light source) is lighter than 50% grey, the image is lightened as if it were screened—this is useful for adding highlights to an image. If the blend colour is darker than 50% grey, the image is darkened, as if it were multiplied—this is useful for adding shadows.

Multiply Multiplies the RGB channel values of corresponding pixels of the stroke and the current image and normalizes the result by dividing by 255 in 8-bit mode, or 4095 in 12-bit mode. The resulting RGB channel values are assigned to the corresponding pixels in the generated clip.

Divide Divides the RGB channel values of pixels of the stroke and the current image and normalizes the result by multiplying by 255 in 8-bit mode, or 4095 in 12-bit mode. The resulting RGB channel values are assigned to the corresponding pixels in the generated clip.

Overlay Multiplies or screens the colours, depending on the RGB channel values of the colour of the stroke and the current image. Patterns or colours overlay the existing RGB channel values while preserving the highlights and shadows of the stroke's colour. The colour of the stroke is not replaced, but is mixed with the colour of the current image to reflect the lightness or darkness of the original colour.

Screen Multiplies the inverse of the current image with the colour of the brush stroke. The resulting colour is always lighter. The colour remains unchanged when you screen with black. Screening with white produces white. The effect is similar to projecting multiple photographic slides on top of each other.

Soft Light Shines a soft, diffuse light on the image. If the blend colour (light source) is lighter than 50% grey, the image is lightened. If the blend colour is darker than 50% grey, the image is darkened.

Using this mode with a black brush stroke results in a very dark effect; with white, a very bright one.

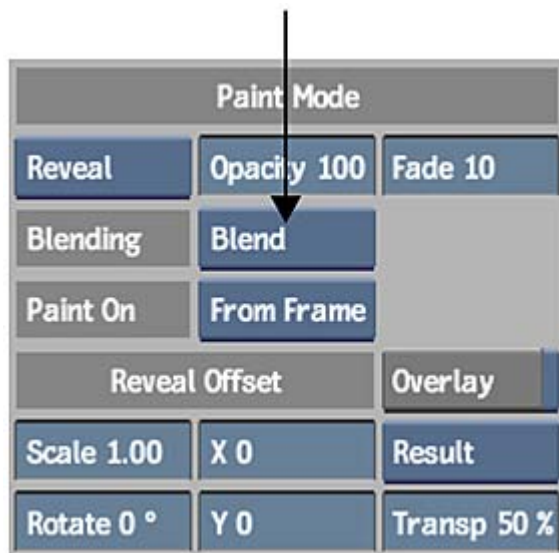

Add Adds the luma values of corresponding pixels of the brush stroke and the current image. The resulting value is assigned to the corresponding pixels in the generated clip. If the result is greater than 255 (in 8-bit mode), the pixel in the destination clip is clamped at a value of 255 (white). In 12-bit mode, the maximum colour value is 4095. The resulting clip is always brighter.

Subtract Subtracts the RGB channel values of the pixels of the current image from the RGB channel values of the pixels of the brush stroke and assigns the result to the RGB channel values of the pixel.

If an RGB channel value of the current image is larger than the corresponding channel value of the brush stroke, yielding a negative result, that result is clamped at 0 (black). The resulting clip is always darker.

To blend a stroke with the current image:

- 1 Select a Blend mode from the Blend option box.

- 2 Select a brush and colour.
- 3 Draw a stroke.

The stroke with the selected blend is applied. The current blend mode only affects new strokes. However, if you draw over existing strokes, the blend is created using the pixel values for the two different strokes.

Using the Canvas

Use the canvas controls to control clearing and wiping of the image.

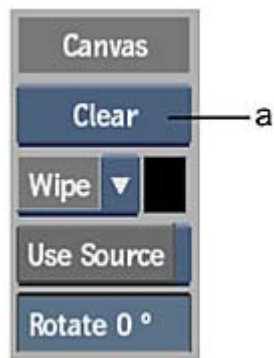

Clearing the Canvas

You can clear all strokes from the result image and output matte at the current frame or all frames. To limit the operation to a source, see [Clearing Strokes on a Source](#) (page 1019).

WARNING Any strokes that have been applied will not be maintained when you clear strokes.

To clear strokes from the canvas:

- 1 Select one of the following from the Clear Canvas option box:
 - Clear to remove strokes from the current frame.
 - Clear All to remove strokes from all frames.

(a) Clear Canvas option box

The strokes are removed from the result image.

Wiping the Canvas

You can wipe the result image when you want to apply a uniform colour at the current frame in a single brush stroke. Alternatively, you can use a source, to wipe over an image.

To wipe the result image with a colour or a source:

- 1 From the View box, select Result (F4).
- 2 Do one of the following:
 - Pick the wipe colour by clicking the colour pot to the right of the Wipe button.
 - Select the source in the Sources list and enable Use Source.

- 3 To display the source as an overlay of the result image, enable Overlay (Tab). You can apply transformations to the source before you apply the wipe:
 - To interactively offset a source image, press **Ctrl+Shift** and drag the source. See [Previewing a Reveal Operation Using a Reference Image](#) (page 1038).
 - To scale the source, enter a value in the Scale field.
 - To rotate the source, enter the angle of rotation in the Rotate field.
- 4 Do one of the following:
 - Click Wipe to wipe the front and matte.
 - Click the Wipe dropdown list and select Wipe F to wipe the front only.
 - Click Wipe dropdown list and select Wipe M to wipe the matte only.

Rotating the Canvas

During the painting process, you can rotate the canvas, making it easier to paint on any part of your image.

To rotate the canvas:

- 1 Do one of the following:
 - Set the angle of rotation in the Rotation field.
 - Press `Alt+spacebar` and drag in your image.

(a) Rotation field

Previewing a Reveal Operation Using a Reference Image

Overlaying a reference image on the result offers an intuitive way of previewing paint operations.

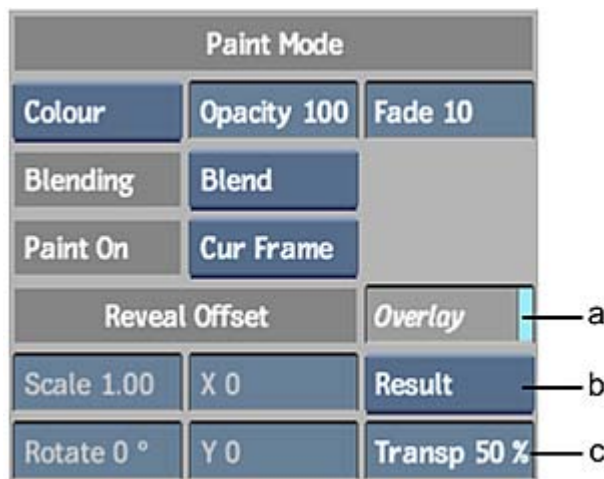

When you overlay a source onto the result, you can preview the effects of a Reveal operation. The selected image is superimposed over the result, and the transparency can be adjusted. This allows you to see exactly what your brush strokes will reveal.

When you overlay a result reference clip onto the result, you can slip the overlaid frame to display previous or next frames, creating an onion skin effect.

The overlay of the front and the matte can also be shown on the result, allowing you to rotoscope more easily, for example.

To display the reference image:

- 1 Enable the Overlay button (Tab).

(a) Overlay button (b) Reference button (c) Transparency field

The reference image appears by default at 50% transparency.

- 2 Select the reference image you want to display from the Reference box.
- 3 If you selected Source Matte or Source Front, select an image from the Sources list.
- 4 With the reference image, you can:
 - Hold down **Ctrl+Shift** and drag the source front or source matte to offset it to preview a Reveal operation.
 - Scale the image, by entering a value in the Scale field.
 - Rotate the image, by entering the angle of rotation in the Rotate field.
 - Set the Slip value in the Sources list to show a reference image at a different frame relative to the actual frame position. See [Slipping a Reference Image](#) (page 1039).
 - Set the transparency for the reference image in the Transparency field.

NOTE You can also drag the result image to offset it for a Clone operation by holding down **Ctrl+Shift**.

Slipping a Reference Image

A reference image that is offset in time can be overlaid on the canvas. You can slip a front, matte, result, output matte, source front, and source matte clips. In the Sources list, use the Slip field to indicate the offset amount.

Each slip value can be set independently. To set the same front and matte values for a source, hold down the **Alt** key and edit either value.

		a		b			
Front		Slip	Matte	Slip	L	H	
 LayerFront		0	 LayerMatte	0			
 silk		0	 silk	0			

(a) Front and Source Front Slip fields (b) Matte and Source Matte Slip fields

Saving Setups and Preferences

Paint Node setups are saved as XML files with the *.bpaint* extension. The procedures for saving and loading Paint Node setups are the same as for other setups.

Paint Tool

Use the Paint tools to create graphics, paint on images, and retouch clips. Use a matte to protect areas of the front clip during painting. Record, animate, and apply a series of brush strokes to a clip. Use the Graphic and Cut/Paste tools to create rotoscoped sequences and shape animations.

Loading Clips into Paint

When accessing the Paint Tool, you first select the clips that you want to use. Any of the following combinations of clips can be used in Paint:

- A front clip only
- A front clip and a back clip
- A front clip and a matte clip
- A front clip, a back clip, and a matte clip
- None (a blank canvas)

The front clip appears on the Paint canvas, which you can use to apply colours and effects to the clip. The matte clip delimits the area of the front clip affected by painting. The back clip can be revealed or brushed through onto the front clip. The colour of the blank canvas is defined by the wipe colour.

NOTE The image window in Paint is referred to as the *canvas* in the following sections.

To load clips into the Paint Tool:

- 1 Select **Tools ► Composite ► Paint**.
The cursor changes to Pick Front.
- 2 Select the front clip.
The cursor changes to Render Here.
- 3 Click on any free (or a grey) area on the workspace.
You are now in the Paint Tool.
The Paint menu appears.

- 4 Access one of the following Paint menus.

Click:	To:
Paint	Use the brushes or geometric shapes to paint on the canvas, record and apply strokes to the canvas, fill areas of the image with a reference colour or image, and move the image on the canvas.
Graphics	Create, edit, and animate shapes and apply them to the canvas.
CutOut	Create and add effects to cutouts and apply them to the canvas.
Setup	Set preferences, rendering options, grid guides, and colour correction options.

Accessing the Paint menu with a blank canvas

To access the Paint menu with a blank canvas:

- 1 Select **Tools ► Composite ► Paint**.
The cursor changes to Pick Front.
- 2 From the Input Mode box, select None.
The Resolution Parameters controls appear.
The cursor changes to Render Here.
- 3 Choose a resolution, width, height, pixel aspect ratio, bit depth, and scan mode to apply to the background in Paint.

NOTE The default parameters are the project resolution parameters.

- 4 Set the frames per second and drop-frame values for the clip from the Frame Code Mode box.
- 5 Click on any free (or a grey) area on the workspace.

You are now in the Paint Tool.

The Paint menu appears.

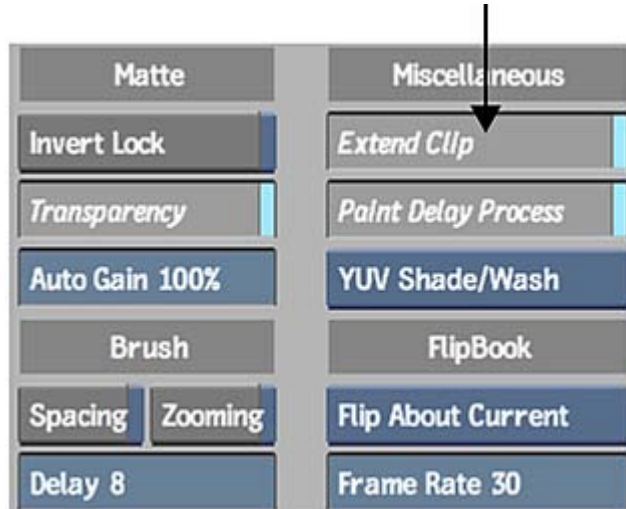

Locking and Unlocking the Duration of a Clip

You can determine whether or not frames are added to the end of a clip.

To add frames to the end of the clip:

- 1 Click Setup.

- 2 Enable Extend Clip.

- 3 Click Next Frame.

A frame is added. You can continue to add frames in the same manner with Extend Clip enabled.

TIP To maintain the length of the original clip, disable Extend Clip. No frames are added to the clip when you click Next Frame.

Using the Mouse

You can use either the mouse or the tablet and pen to paint. Press and hold the right mouse button to apply paint at 80% pressure, the middle button to paint at 40% pressure, and the left button to paint at 20% pressure.

Displaying a Reference Image

You can display a reference image in the background of the result image to use as a guide for rotoscoping.

To display the reference image:

- 1 Enable the Show button.

(a) Show button (b) Reference box (c) Transparency field (d) Slip field

The reference image appears by default at 50% transparency.

- 2 Select the reference image you want to display from the Reference box.
- 3 Set the transparency for the reference image in the Transparency field.
- 4 Set the Slip field value to show different images from the reference clip.

This option only works if the reference image you selected is from a clip with more than one frame.

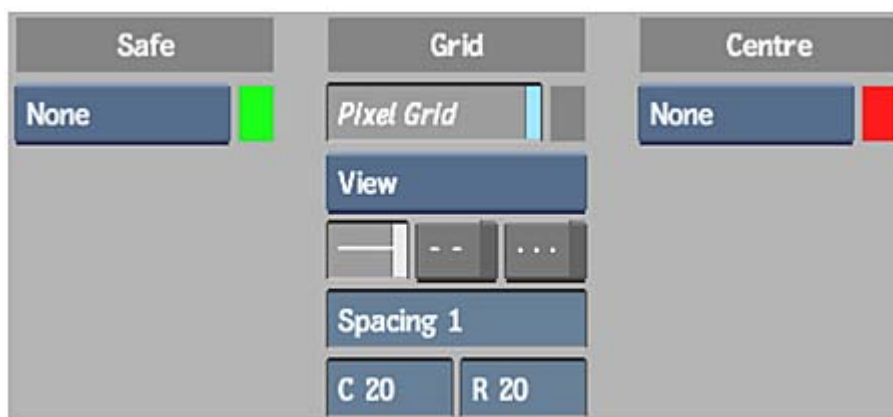

NOTE The Slip field is disabled if you select Matte or Saved from the Reference box.

Using Grids and Guides

Use the Grid/Guides button to set up reference points when painting and to accurately place strokes on the image.

Use the field guides to provide reference points when painting, and the grid to help you accurately place strokes on the image. Neither the field guides nor the grids appear on the processed clip.

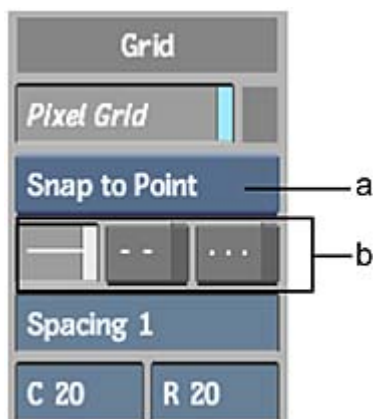

The Grid and Guides menu contains the Safe area guide controls, the Grid controls, and the Centre controls.

The Safe area guide controls and Centre controls are subsets of their corresponding controls in the Grid and Guides menu in the other tools.

Grid Controls

You can set the behaviour of the grid so that paint strokes snap or lock to points on the grid. Use the Grid controls to configure the appearance and behaviour of the grid.

(a) Grid Behaviour box **(b)** Style buttons

To toggle the grid on and off, click Pixel Grid. When Pixel Grid is on, use the following controls to configure the appearance and behaviour of the grid.

Grid Behaviour box Displays the behaviour of the grid with respect to paint strokes:

- **Snap to Point** snaps each point of a stroke to the nearest intersection of a horizontal and a vertical grid line.
- **Snap to Line** snaps the current point of a paint stroke to the nearest point on a horizontal or vertical grid line.
- **Lock to Point** locks each point of a paint stroke to the nearest intersection of a horizontal and a vertical grid line.
- **View** uses the grid without the snap to or lock to options.

Style buttons Set a style for the lines of the grid. The style is either a solid line, a dashed line, or a dotted line.

Spacing field Sets the number of pixels between the dashes in a dashed line style, or between the dots in a dotted line style.

C, R fields Set the number of columns and rows respectively in the grid.

Resetting the Grid and Guides

Use the Reset All button in the lower-right corner to reset the grid and all guides to their default values.

Using the Player in the Paint Tool

You can access the Player from the Paint Tool. To do so, click Process in the Paint Tool and then click Play once the clip is processed. Each time you access the Player, a clip is created in the Viewing Panel. This clip cannot be removed from the Paint tool. You must delete it from the Viewing Panel instead.

Selecting Colours

In Paint, you select colours using the colour picker. You store colours in the colour palette, mix or try out colours on the scratch pad, and create colour or greyscale gradients using the colour gradient.

Using the Current Colour

The current colour is used when you paint. It is also used to set the colour for the wipe function and the matte colour. Select the current colour from the colour palette, scratch pad, or colour gradient. Or, click the Current Colour pot to use the colour picker.

Using the Colour Palette

The colour palette appears in the Paint, Graphics, and CutOut menus. It contains the scratch pad and colour gradient. A series of colours are stored in the colour palette in colour pots. To select the current colour in the colour palette, click a colour pot. To set the current colour, press and hold a colour pot.

(a) Colour pot (b) Colour gradient bar

Build your own colour palette by storing the current colour in the colour pots. You can also save and load colour palettes.

To store a colour in the colour palette:

- 1 To display the colour palette, swipe the bar at the bottom of the screen.
The colour palette appears.
TIP If you do not see the palette, click the Palette button. To hide it, swipe the bar a second time.
- 2 Set the current colour.
- 3 Click a colour pot in the colour palette and hold the cursor down momentarily.
The colour is saved in the colour pots.

Using the Scratch Pad

Use the scratch pad to mix colours selected from the image or colour pots and to test the selected brush type. You can also paste cutouts into the scratch pad to use when mixing colours.

(a) Scratch pad

To mix colours on the scratch pad:

- 1 Click the Pot button.
The scratch pad appears.
- 2 Paint on the scratch pad.
- 3 Change the current colour and paint over the previous brush strokes.

The colours are mixed.

You can also use the Wash, Shade, Smear, Drag, Warp, Impressionist, Recursive Clone, Stamp, and Blur Special Effects media in the scratch pad.

To use one of the media types in the scratch pad:

- 1 Select the Special Effects medium you want to use.
- 2 Enable Medium.
- 3 Use the brush cursor to apply the medium in the scratch pad.

To set the current colour using the scratch pad:

- 1 Click the Current Colour pot.
- 2 Use the colour picker to select the mixed colour in the scratch pad.
- 3 Click the Current Colour pot to use the selected colour.

Using the Colour Gradient Bar

The colour gradient bar is used to set the gradients for graphics you create in the Graphics menu. You can also set the current colour by selecting a colour on the gradient using the colour picker.

To set the gradient:

- 1 Set the current colour.
- 2 Click either the upper or lower colour pot on the gradient bar.

NOTE You must hold the cursor down for a moment to set the Gradient colour pot.

To set the current colour using the colour gradient bar:

- 1 Click and drag the cursor across the gradient bar.
The selected colour appears in the Current Colour pot.
- 2 Select a colour.
The selected colour becomes the current colour.

Previewing an Animation

Use the Flipbook command to preview an animation by playing a sequence of either five or nine frames.

To set up the Flipbook command:

- 1 Click Setup.
The Setup menu appears.
- 2 In the Flipbook area, select an animation mode from the Flipbook box.

(a) Flipbook box (b) Frame Rate field

Select:	To:
Flip About Current	Play two (or four) frames before the current frame and two (or four) after the current frame. This is the default setting.
Flip From Current	Play five (or nine) frames beginning at the current frame.
Flip To Current	Play five (or nine) frames ending at the current frame.

- 3 Enter the frame rate in the Frame Rate field.

NOTE If the system is running at high resolution, it may not be able to achieve a flip rate of 30 frames per second.

- 4 Press **F** to play five frames, or press **Shift+F** to play nine frames.

If you selected Flip About Current, pressing **F** plays two frames before and after the current frame.

Pressing **Shift+F** plays four frames before and after the current frame.

Painting on Full-Resolution Film Images

Use the Zoom Mode box to paint on a film resolution image at full resolution from a zoomed out perspective. With this feature, you can perform complex operations like full-frame rotoscoping without having to constantly zoom in and out from the image on which you are painting.

In the Paint menu, the Zoom Mode box shows the zoom mode in which you are working. This mode is set automatically. If you zoom out from the image, the Zoom mode automatically switches from Raster to Tiled. This allows you to paint on the image from a zoomed out perspective.

(a) Zoom Mode box

NOTE If you manually switch the zoom mode to Raster while zoomed out from the image, you will not be able to paint on it.

You can also manually select either Raster or Tiled mode if you want to override the default mode. In Raster mode, if you apply paint to the edge of the image while zoomed in, the paint is applied in an abruptly sharp straight edge along the border of the canvas; the brush stroke is not completed on the image. In Tiled mode, if you attempt the same operation, the paint is applied from the full diameter of the brush you are using to the area of the image that is not visible on the canvas.

Saving and Restoring the Image

You can save the current frame on the canvas. If you want to reverse a paint application, you can restore the image without having to recreate it.

Save (Image Buffer) Saves the image that currently appears on the canvas. A single frame is stored in the Save buffer. The next time you click Save, the current frame replaces the frame stored in the Save buffer.

Restore Replaces the current image on the canvas with the contents of the Save buffer.

Preview Displays the contents of the Save buffer. Select the Saved option in the Reference box and click and hold Preview to view the contents of the Save buffer.

(a) Reference box

Exiting Paint

When exiting Paint, you may keep or discard the changes you have made to the front clip. Click Exit and select an option.

Select:	To:
Exit	Keep the changes you made to the front clip. The modified front clip appears on the destination reel.
Keep One	Keep only the current frame of the front clip. When this option is selected, a Confirm button appears to the right of the canvas. Click Confirm to keep only the current frame of the front clip. The current frame appears on the destination reel.
Cancel	Quit Paint without saving changes to the front clip. When this option is selected, a Confirm button appears to the right of the canvas. Click Confirm to quit without saving your changes, or click elsewhere to cancel.

About Canvas Mode

When you first open Paint, you are in Canvas mode. In Canvas mode, you can use brushes to modify your images. Brushes apply colour, filters, and Special Effects media to the image on the canvas. The brush cursor appears as a green cross surrounded by a circle when placed over the canvas. Canvas mode features are not available from multiple menus, such as Canvas, Geometry, Fill, and Roll.

You can also paint on the canvas using geometric shapes to define the path of the brush.

To ease the painting of canvas edges, you can roll the canvas in the image window.

To paint on the canvas:

- 1 In the Paint menu, click Canvas.

If the scratch pad is covering this button, swipe down to hide the scratch pad.

- 2 From the Paint Mode controls, click Paint.
- 3 Set a colour in the Current Colour pot. See [Selecting Colours](#) (page 1044).
- 4 Select a brush from the Brushes window. See [Selecting a Brush](#) (page 1049).
- 5 Set the brush attributes and modes in the Brush Attributes fields. See [Brush Attributes](#) (page 1054) and [Brush Attribute Modes](#) (page 1058).
- 6 Set the brush opacity in the Opacity field. Set the opacity to 100% to apply a fully opaque colour.
- 7 Stroke the brush over the canvas. To paint straight horizontal and vertical lines, press **Shift** and drag the brush up and down or left and right.
- 8 Click Undo to erase the strokes applied to the canvas since the last time you zoomed, panned, or changed a brush attribute.

Selecting a Brush

A number of predefined brush types are available in Paint including round, square, and elliptical brushes of various sizes and edge softness. The cursor has the same appearance regardless of which brush type you use. Each brush has its own icon in the Brushes window. The white portions of the brush icon indicate where the paint will be applied on the image.

See [Creating a Custom Brush](#) (page 1128).

To select a brush:

- 1 Scroll through the Brushes window.

To scroll the selections, click the Brushes window and drag left or right.

- 2 Click the brush icon you want to use.
The selected brush is highlighted by a blue outline.

NOTE Only one brush can be active at a time.

Using the Large Canvas

In Large Canvas mode, almost the entire image window is available for painting, but not all Paint options are available. You can still change the brush characteristics, medium, and show options. You can also save, restore, and wipe the canvas.

To display the large canvas:

- 1 Click Paint.
- 2 Click Canvas.
- 3 Swipe your cursor anywhere on the right edge of the screen, or press **Esc** to toggle between the large canvas and Paint menu.

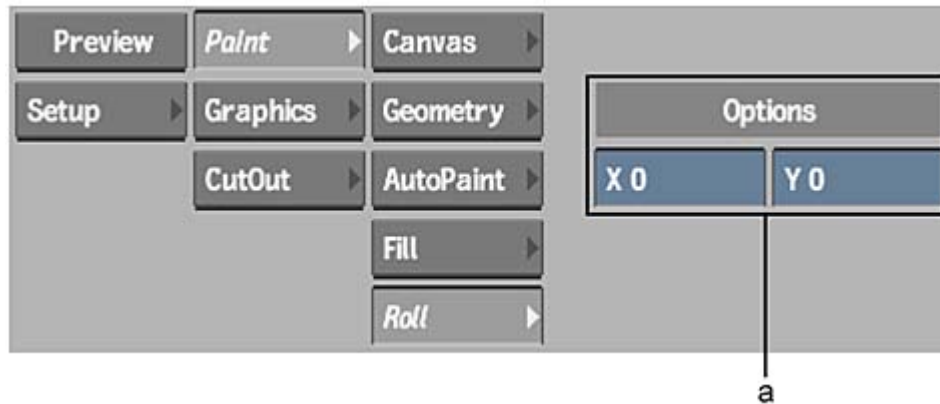

Rolling the Image

Use the Roll menu to reposition the current frame on the canvas to paint its edges.

To roll the image:

- 1 Click Paint.
- 2 Click Roll.

The Roll menu appears.

(a) Coordinate fields

- 3 Zoom in on the image if necessary.
- 4 Drag the image using the pan cursor.
You can also enter the roll values in the Coordinate fields.
- 5 To recentre the frame, click Reset.

NOTE The frame is automatically recentred when you go to another frame or exit Paint.

Painting with Geometry

Use the Geometry feature to draw lines, rectangles, circles, and triangles on the canvas.

Painting with geometry is different from drawing objects in Graphics mode. In Graphics mode, you create objects that can be edited. When you paint with geometry, you define paths for the brush to follow. Paint uses the current brush setup to apply the stroke to the canvas.

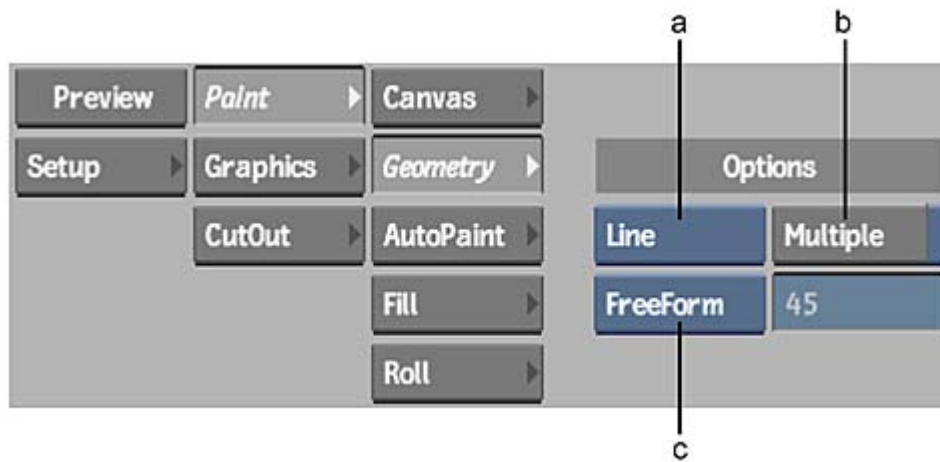

Painting Lines

Use the Line option to paint straight lines. Paint single lines one at a time, or draw connected multiple lines. You can constrain the lines to vertical or horizontal paths or specific angles.

To paint a line or multiple lines:

- 1 Click Geometry to display the Geometry menu.
- 2 Select Line from the Geometry box.

The Multiple Line button and the Line Type box appear.

(a) Geometry box (b) Multiple button (c) Line Type box

- 3 Select the type of line you want to draw from the Line Type box.

Select:	To:
Angle	Paint a line at a specific angle. This option displays a field in which you enter the angle in degrees.
Vertical	Paint vertical lines.
Horizontal	Paint horizontal lines.
FreeForm	Paint lines at any angle with no constraint.

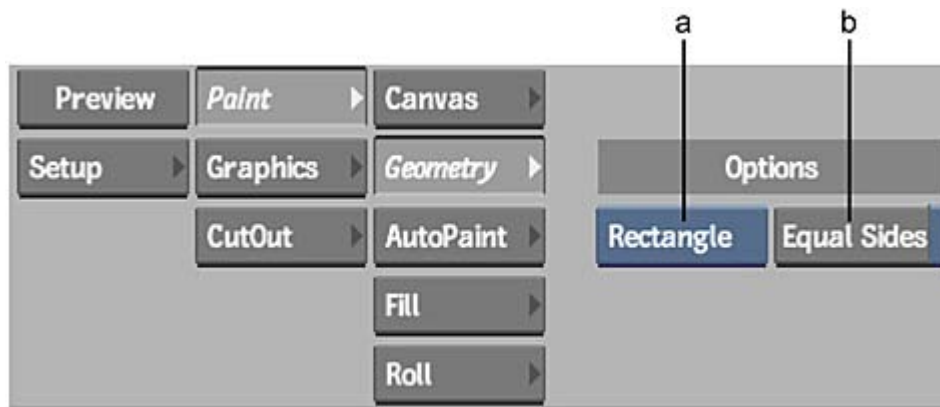

- 4 If you selected Angle, enter a degree in the field.
- 5 To draw single lines, move to the canvas and click, drag, and release.
A brush stroke is painted along the line.
- 6 To draw multiple lines, enable Multiple, move to the canvas, and click to place the start point of the first line. Click again to draw the end point. Continue clicking to place additional points and draw more lines.
- 7 To end multiple lines, click below the timebar or on the menu panel to turn the option off.
The brush strokes are painted along the lines.

Painting Rectangles

Use the Rectangle option to draw rectangles or squares.

To paint a rectangle or square:

- 1 Click Geometry to display the Geometry menu.
- 2 Select Rectangle from the Geometry box.
The Equal Sides button appears.

(a) Geometry box (b) Equal Sides button

- 3 To draw a square, enable Equal Sides or press and hold P.
- 4 Press the cursor on the canvas to anchor the first corner of the rectangle. Drag the cursor to size the rectangle.
- 5 When the rectangle is the required size, release the cursor.
A brush stroke is painted along the sides of the rectangle.

Painting Circles

Use the Circle option to draw circles of any size.

To paint a circle:

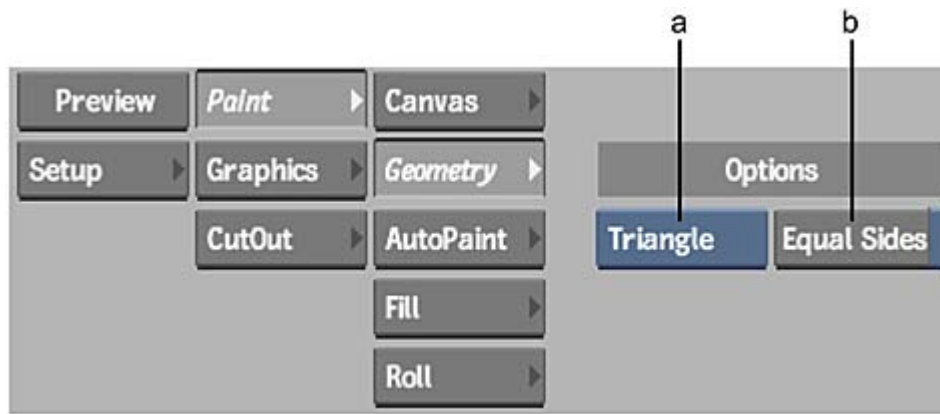

- 1 Click Geometry to display the Geometry menu.
- 2 Select Circle from the Geometry box.
- 3 Press the cursor on the canvas to anchor the centre point of the circle. Drag the cursor to size the circle.
- 4 When the circle is the required size, release the cursor.
A circular brush stroke is painted.

Painting Triangles

Use the Triangle option to draw equilateral or asymmetric triangles.

To paint a triangle:

- 1 Click Geometry to display the Geometry menu.
- 2 Select Triangle from the Geometry box.
The Equal Sides button appears.

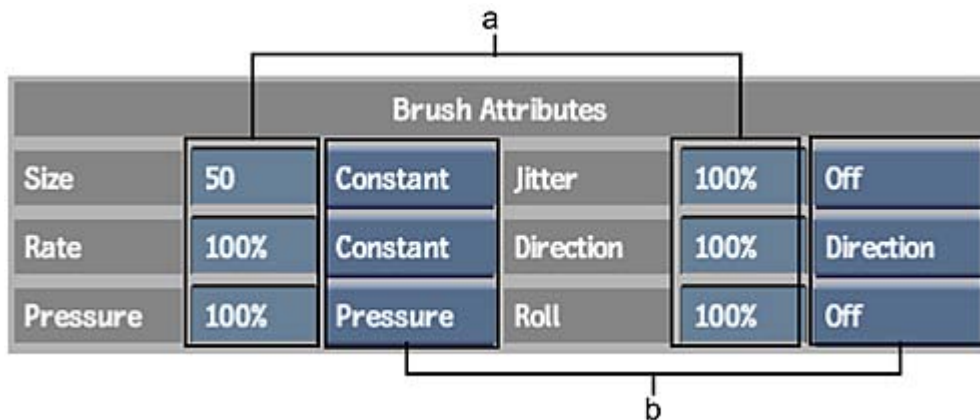

(a) Geometry box (b) Equal Sides button

- 3 To draw an equilateral triangle, enable Equal Sides or press and hold P.
- 4 Move to the canvas and click to anchor the first vertex of the triangle.
- 5 Click to place the second vertex and then again to place the third vertex. If you are drawing an equilateral triangle, drag the cursor until the triangle is the required size.
A brush stroke is painted along the sides of the triangle.

About Brush Attributes and Modes

You can set various brush attributes and attribute modes that determine how paint is applied to the image. Each brush attribute has a corresponding Attribute Mode control. You use the Preferences menu to affect the way paint is applied to the image.

(a) Brush Attribute fields (b) Attribute Mode controls

In the Paint menu, the Brush Attributes and Attribute Mode controls share the same space as the colour palette. To display the brush attributes and modes in the Paint menu, swipe the cursor at the bottom of the screen.

In the Graphics Edit menu, the Brush Attributes and Mode controls appear only when the object attribute is set to Outline or Fuzzy. To display the brush attributes and modes in the Graphics menu, swipe the cursor twice at the bottom of the screen.

NOTE The brush attribute and attribute mode values set in the Paint menu are independent from the values set in the Graphics menu.

Brush Attributes

The Brush Attribute fields set the size of the brush, the distribution of the paint, and the rate and direction of the paint application. Brush attributes are listed as follows:

- Size
- Rate
- Pressure
- Opacity
- Jitter
- Direction
- Roll

Brush Opacity

The brush opacity affects the transparency of the brush. A value of 100% applies a fully opaque colour. Use a lower value to apply a more transparent colour. Enter a value in the Opacity field.

(a) Current Colour field

NOTE You can only use the Front, Back, Result, and Saved attribute modes with the Opacity attribute.

Brush Size

The brush size is indicated by the diameter of the green dashed circle surrounding the cursor brush. To increase the brush size, set a value in the Size field and drag the brush to the right on the canvas. To decrease it, set a value in the Size field and drag to the left.

You can also use the Size buttons to increase or decrease the brush size. Click the + button to increase the brush size. Click the - button to decrease the brush size. You can also click and drag in the Size field or click and enter a value.

NOTE You can use any attribute mode with the Size attribute.

Brush Rate

The brush rate is the rate at which brush strokes are applied to the canvas. Use a high value to produce a smooth continuous stroke, or a low value to produce a less continuous stroke with larger gaps between brush images.

NOTE You can use any attribute mode with the Rate attribute.

Rate attribute value = 100

Rate attribute value = 25

Brush Pressure

The brush pressure affects the transparency of the paint applied to the image. To apply opaque paint, use a high percentage value. For more transparent paint, use a low value.

The Pressure attribute differs from the Opacity attribute in that you can set the Pressure attribute mode so that the paint transparency varies according to the pressure applied to the pen or the direction of the brush.

NOTE You can use any attribute mode with the Pressure attribute.

Pressure attribute value at 100%

Pressure attribute value at 50%

Brush Jitter

The Jitter attribute randomizes the brush strokes applied to the image. A high value produces a greater dispersion of paint, while a low value produces a greater concentration.

NOTE You can use any attribute mode with the Jitter attribute.

Jitter attribute value at 10

Jitter attribute value at 100

Brush Direction

The Direction attribute causes the brush to rotate around the Z-axis and can be used to produce a calligraphy effect. The effect of the Direction attribute is most noticeable when used with one of the elliptical or star brushes. The value of the Direction attribute causes the brush strokes to rotate by 90 degrees for each increment of 25 percent.

NOTE You can use any attribute mode with the Direction attribute.

Direction attribute at 100%

Direction attribute at 75%

Direction attribute at 50%

Direction attribute at 25%

Brush Roll

The Roll attribute rolls the brush around the X-axis. The effect of the roll is most noticeable when used with one of the non-symmetrical brushes. For each increment of 25 percent, the Roll attribute value creates a rolled brush stroke of 90 degrees.

NOTE You can use any attribute mode with the Roll attribute.

Roll attribute value at 100%

Roll attribute value at 75%

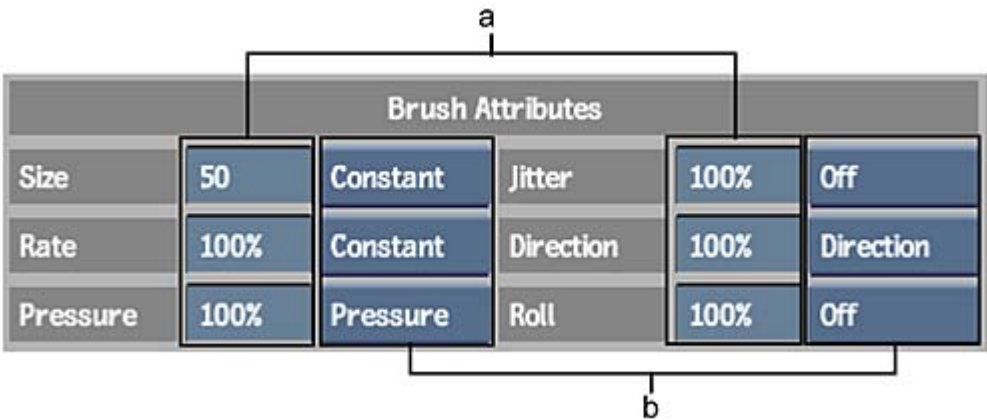

Roll attribute value at 50%

Roll attribute value at 25%

Brush Attribute Modes

The value of a brush attribute depends on the selected attribute mode. You can choose Constant, Off, Front, Back, Result, Saved, Pressure, or Direction.

(a) Brush Attribute fields (b) Attribute Mode controls

In Constant mode, the brush attribute values remain constant. In Off mode, the attribute is disabled.

The Front, Back, Result, and Saved modes use the colour values in a reference image to vary the brush attribute value. Pressure and Direction modes affect how paint is applied by causing the brush attribute value to vary in relation to the pressure exerted on the pen and the direction of the brush, respectively.

NOTE Do not set the Size, Rate, or Pressure attributes to Off mode.

Using Reference Images

The Front, Back, Result, and Saved modes use the red channel in reference images to set the brush attribute values. Front mode uses the front clip as the reference, Back mode uses the back clip, Result mode uses the result clip, and Saved mode uses the image in the Save buffer.

Direction of the Brush

The Direction mode uses the direction of the brush stroke as the reference.

When used with the Direction mode, the Direction attribute causes the brush strokes to follow the trajectory of the brush. Increase the percentage value to enhance the effect on brush direction.

Drag:	To:
Right	Use 100% of the attribute value.
Left	Use 0% of the attribute value.
Up	Use 25% of the attribute value.
Down	Use 75% of the attribute value.

Direction attribute value at 100%, Direction mode

Direction attribute value at 15%, Direction mode

Pressure Exerted on the Pen

The Pressure mode uses the pressure exerted on the pen as the reference value. The harder you press on the pen, the greater the brush attribute value. The softer you press, the lower the brush attribute value.

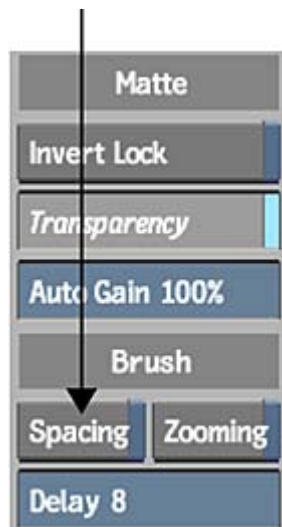

NOTE The Pressure attribute mode cannot be used in the Graphics menu.

Preferences Affecting Brushes

The Spacing setup preference affects how paint strokes are applied to the canvas.

To enable Brush Spacing:

- 1 Click Setup in the Paint menu.
- 2 Enable Spacing.

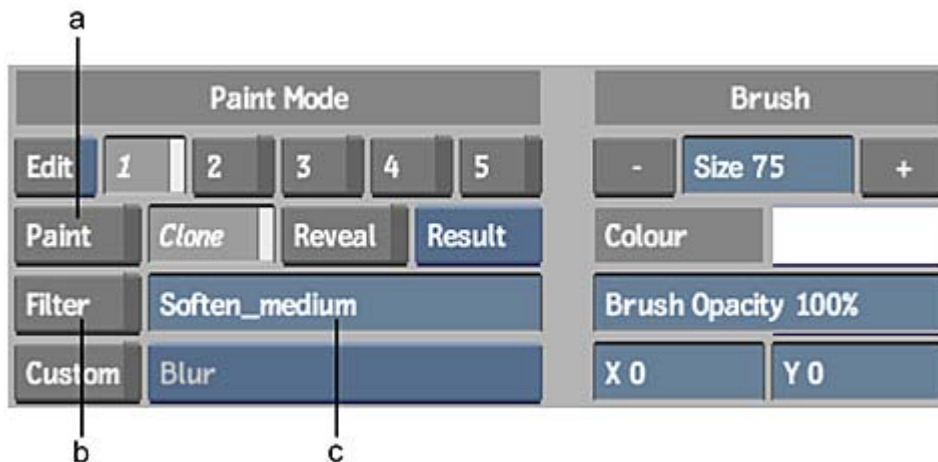

This option sets a uniform distance between paint strokes. No matter how fast you move the brush, the brush spreads the paint evenly.

TIP Use a high brush rate when using stamps with the Spacing option enabled. See [Using the Stamp Medium](#) (page 1068).

Applying Filters

When applying filters, it is important to try different brush types and change the brush attributes to create different effects.

Apply filters to the canvas using the brush, Wipe command, or Wash and Shade media. Paint uses the same filter library as the Filter command in the Processing menu.

(a) Paint Media button (b) Filter button (c) Filter field

To brush a filter onto the image:

- 1 In the Paint menu, click the Filter field.
The filter library appears.
- 2 Select the filter you want to use.

You are returned to the Paint menu and the filter name appears in the Filter field.

- 3 Click Filter to enable the selected filter.
- 4 Set the brush opacity. The opacity determines the level of filtering. Reduce the opacity value to reduce the level of filtering.
- 5 Paint on the image.

Original image

After using the emboss filter

Using Special Effects Media

Special Effects media can be brushed onto the image in Canvas mode. You can also apply the Wash, Shade, and Reveal media to the entire image using the Wipe command. See [Wiping Using Special Effects Media and Filters](#) (page 1072). Only one media type can be used at a time.

Use the media buttons to enable some Special Effects media, for example, the Clone and Reveal media. Other media types, such as Drag and Smear, are enabled using the Custom Media box.

(a) Special Effects Media buttons (b) Reference box (c) Custom Media box

The following Special Effects media are available.

Use:	To:
Blur	Apply a blur filter to portions of the image. See Blurring the Image (page 1062).

Use:	To:
Clone	Copy a portion of the image to a new location. See Cloning the Image (page 1063).
Drag	Create an image trail from a selected region of the screen. See Dragging the Image (page 1064).
Impressionist	Paint on colours from a reference clip. See Using the Impressionist Medium (page 1065).
Recursive Clone	Make a number of copies of a selected area of the image. See Using the Recursive Clone Medium (page 1066).
Reveal	Brush a reference image onto the current image. See Revealing a Reference Image (page 1066).
Shade	Darken or lighten the image depending on the luminance value of the current colour. See Washing and Shading the Image (page 1070).
Smear	Smudge areas of the image. See Smearing the Image (page 1067).
Stamp	Apply a captured image to the image. See Using the Stamp Medium (page 1068).
Warp	Stretch and distort a region of the image. See Warping the Image (page 1069).
Wash	Apply a transparent wash of the current colour to the image. See Washing and Shading the Image (page 1070).

Blurring the Image

Use the Blur medium to blur portions of the image.

To blur the image:

- 1 Click Custom and select Blur from the Custom Media box.
The Blur option boxes appear.

(a) Filter Type box (b) Blur Strength box

- 2 Click Canvas.

- 3 Set the brush size according to the size of the area you want to blur.
- 4 Select either a Box or Gaussian filter from the Filter Type box.
- 5 Set the density of the Blur brush from the Blur Strength box.
You can choose Light, Medium, or Heavy.
- 6 Drag the brush on the image.

Original image

After using the Blur medium

Cloning the Image

Use the Clone medium to copy a region of the image and paint it on a destination point. The result image is used as the source for the Clone medium. The offset between the origin point and the destination point is set in the Offset fields.

To paint using the Clone medium:

- 1 Click Clone.
The Clone controls appear.

(a) Offset fields

- 2 Click Canvas.
- 3 Set the brush opacity. The brush opacity determines the transparency of the clone. When the opacity value is set to 100%, the clone is completely opaque.
- 4 Set the brush size.
- 5 Set the offset between the origin point and the destination point in the Offset fields.

A tracking circle appears at the offset co-ordinates you specified; this is the destination point for the cloned image.

TIP Press `Ctrl` and drag the cursor to set the destination point.

6 Paint on the image.

The image contained within the red circle brush is copied to the region defined by the green circle.

Original image

After using the Clone medium

Dragging the Image

Use the Drag medium to drag a selected area of the image across the canvas. The selected area is painted on the canvas as you drag the brush, creating an image trail.

NOTE The Direction brush attribute cannot be used with the Drag medium.

To use the Drag medium:

- 1 Click Custom and then select Drag from the Custom Media box.
- 2 Click Canvas.
- 3 Set the brush size.
- 4 Position the brush over the region of the image that you want to use. Hold down the cursor to select that region.
- 5 Drag the brush.

The selected region is painted onto the image as you drag. The pressure of the brush determines the density of the image trail. See [Brush Pressure](#) (page 1055).

Original image

After using the Drag medium

Using the Impressionist Medium

Use the Impressionist medium to brush on colours from a reference clip. The brush opacity determines how much colour is taken from the reference clip. When the opacity value is set to 100%, all the colour is taken from the reference image. At 50%, the colour applied is a 50/50 blend of the reference colour and the result image.

To use the Impressionist medium:

- 1 Click Custom and then select Impressionist from the Custom Media box.
- 2 Click Canvas.
- 3 Set the brush opacity.
- 4 Select a reference image from the Reference box.
- 5 Paint on the image.

Original image

After using the Impressionist medium

Revealing a Reference Image

Use the Reveal medium to reveal portions of an image or an entire reference image. You can reveal specific areas using the brush or the entire image using the Wipe command. The opacity of the brush determines how much of the reference image is revealed on the image. When the opacity is set to 100%, the reference image applied is completely opaque. At 50%, the reference image applied is a 50/50 blend of the reference image and the result clip.

To reveal a reference image on the canvas:

- 1 Click Reveal.
- 2 Click Canvas.
- 3 Set the brush opacity.
- 4 Select a reference image from the Reference box.
- 5 Paint on the image.

Back image

Result image

The Back image revealed on the Result image

Using the Recursive Clone Medium

Use the Recursive Clone medium to make multiple copies of an area of an image. The result image and the paint applied to it is used as the source. Each copy is a degraded version of its predecessor. The offset between the origin point and the destination point is set in the Offset fields.

To paint using the Recursive Clone medium:

- 1 Click Custom and select Recursive Clone from the Custom Media box.
The Recursive Clone options appear.

(a) Offset fields

- 2 Click Canvas.
- 3 Set the offset between the origin point and the destination point in the Offset fields.
A red tracking circle appears around the destination point.
- 4 Paint on the image.
The image contained within the green circle brush is copied to the region defined by the red circle.

Original image

After using the Recursive Clone medium

Smearing the Image

Use the Smear medium to smudge portions of the image.

To smear the image:

- 1 Click Custom and select Smear from the Custom Media box.
- 2 Click Canvas.

- 3 Drag the brush over the area you want to smear.

Original image

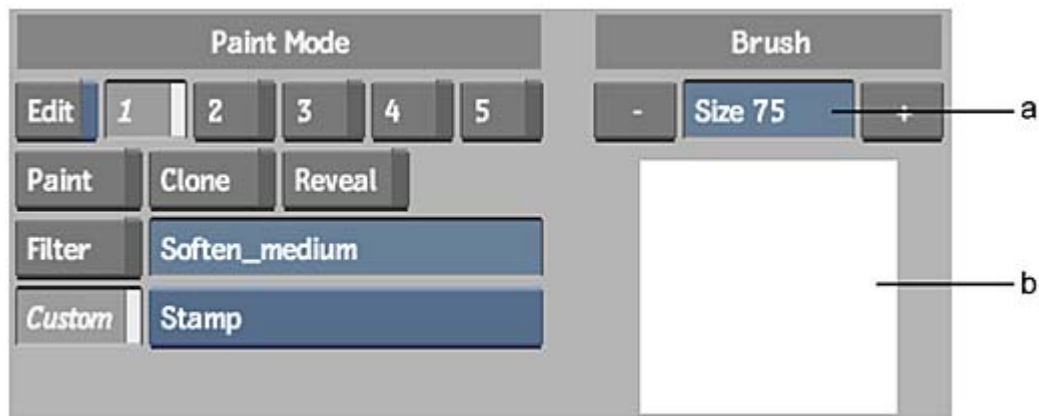

After using the Smear medium

Using the Stamp Medium

Use the Stamp medium to capture a portion of the image and apply it to the canvas.

To capture and apply a stamp:

- 1 Click Custom and select Stamp from the Custom Media box.
The Stamp window appears beneath the Brush Size field.

(a) Brush Size field (b) Stamp window

- 2 Click Canvas.
- 3 Set the brush size. Use a small brush to isolate a specific detail of the image. Use a large brush to capture a bigger sample.
- 4 Click and hold the cursor on the Stamp window.
- 5 Without releasing the cursor, move it over the image.
The Stamp window is updated as you move the cursor across the image.
- 6 Release the cursor when the Stamp window contains the part of the image you want to capture.
The brush cursor appears.
- 7 Paint on the image.

(a) The captured stamp

(a) Stamp applied using a circular brush (b) Stamp applied using an air brush (c) Stamp applied using a chalk brush

Saving and Loading Stamps

You can save a stamp and load it in another session to use with a different clip. See [Saving Setups](#) (page 1125).

Warping the Image

Use the Warp medium to stretch and distort regions of the image.

To warp the image:

- 1 Click Custom and select Warp from the Custom Media box.
- 2 Click Canvas.
- 3 Set the brush size.

The area that can be warped is determined by the brush size.

- 4 Select a portion of the image and hold down and drag the cursor to warp the selection.

Original image

After using the Warp medium

Washing and Shading the Image

Use the Wash medium to apply a transparent wash of the current colour to the image. Use the Shade medium to darken or lighten the image. You can wash or shade specific areas using the brush or the entire image using the Wipe command.

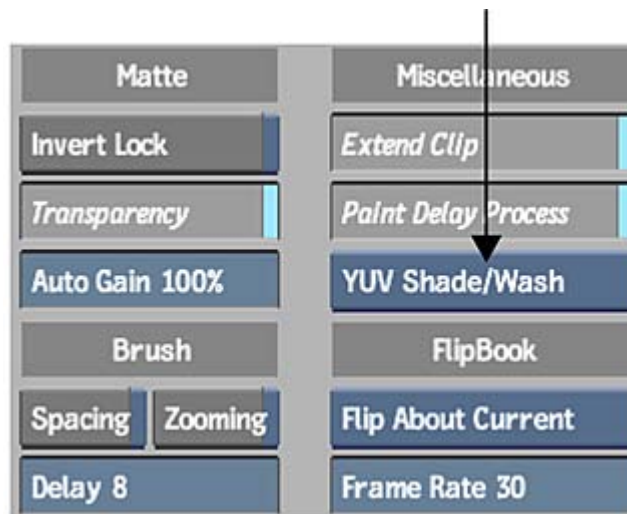

With the Shade medium, you darken images using a colour with a low luminance value, and lighten them using a colour with a high luminance value. The opacity of the brush affects the transparency of the paint applied to the image. When the opacity value is set to 100%, the paint applied is completely opaque. As you decrease the opacity, the paint becomes more transparent.

Selecting a Colour Model

You can apply the colour using either the YUV or HLS.

To select a colour model:

- 1 Click Setup.
- 2 Select either YUV Shade/Wash or HLS Shade/Wash.

To use Wash or Shade:

- 1 Click Custom, and select Wash or Shade from the Custom Media box.
- 2 Click Canvas.
- 3 Set the current colour.
- 4 Set the brush opacity.
- 5 Paint on the image.

A paint stroke using the Paint medium, current colour red.

A paint stroke using the Wash medium, current colour red.

A paint stroke using the Shade medium, current colour red.

Wiping an Image

Use the Wipe command to apply colours, filters, and Special Effects media to the entire result image in a single stroke.

(a) Wipe colour pot

NOTE You can also wipe an image with the AutoPaint Wipe mode. See [Wiping the Canvas in AutoPaint](#) (page 1078).

Wiping Using a Colour

Use the Paint medium to wipe the image with a selected colour. The colour used is set in the Wipe colour pot.

To wipe the image using a colour:

- 1 Set the current colour you want to use for the wipe. See [Selecting Colours](#) (page 1044).
- 2 Click the Wipe colour pot.
The current colour is transferred to the wipe colour.
- 3 Set the brush opacity.
A value of 100% wipes the image with a completely opaque colour.
- 4 Click Wipe.

Wiping Using Special Effects Media and Filters

You can use a filter, or the Reveal, Clone, Wash, and Shade Special Effects media.

To wipe with Special Effects media and filters:

- 1 Set the wipe colour.
- 2 From the Paint Mode controls, select the Special Effects medium to be applied. See [Using Special Effects Media](#) (page 1061).

NOTE If you are using a filter for the wipe, you must enable the Filter button.

- 3 Set the brush opacity.
A value of 100% wipes the image with the full effect of the Special Effects Media or filter.
- 4 Enable the Wipe Using Paint Mode button.
- 5 Click Wipe.

Using the Wipe Command in Graphics

You can also use the Wipe command in the Graphics menu. The Wipe command wipes over any objects tacked down on the image. Objects not tacked down are not part of the image and are not wiped over.

Filling an Image

Use the Fill command to fill areas of an image with similar colour values or areas delimited by a colour. These areas can be filled with either a solid colour or a reference image. You can choose how far the filled area extends by specifying how similar the pixels must be in order to be filled. This enables you to fill only the dark areas of an image, or include slightly lighter areas.

Use the Fill controls to set the colour model, range, and softness of the fill.

To display the Fill controls:

- 1 Click Fill in the Paint menu. If the Fill button is hidden by the colour palette, swipe the bottom of the screen.

Defining the Range for the Fill

When you use the Fill command, you specify a range for the colour comparison. The Fill command compares the colour values of adjacent pixels to determine if the values are within the specified colour range. Adjacent pixels within the range are filled.

The range is determined using two values: the colour value of the pixel you select to begin the fill, called the *selection point*, and the value you set in the Range field.

Selecting Colour Channels

You can use either the RGB or YUV model. Within each colour space, you can work with any combination of colour channels. For example, if you select the R, G, and B channels in the RGB colour model, the Fill command considers the red, green, and blue values. Adjacent pixels with red, green, and blue values within the specified range are filled.

Adjusting the Softness

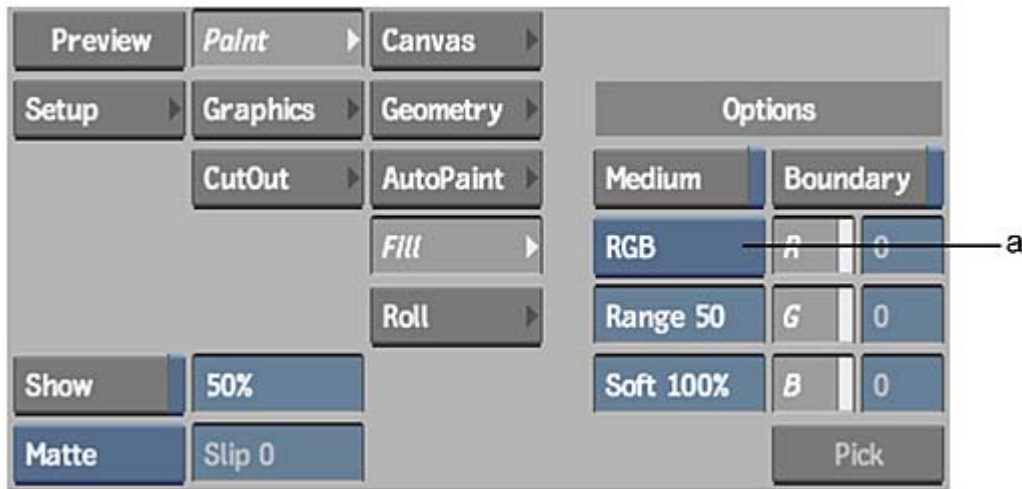

The softness value for the fill determines the amount of colour diffusion applied at the edges of the fill. This value can be adjusted to modify the transition between the filled and unfilled areas. A softness value of 100% produces the greatest amount of diffusion. A softness value of 0% produces a filled area with well-defined edges.

Filling a Region with a Colour

You can choose to fill an image with the current colour.

To fill a region of the image with a colour:

- 1 Click Fill.
The Fill controls appear.

(a) Colour Model box

NOTE To fill a matte, click From Matte. When this button is enabled, the pixels in the matte are used for the colour comparison. If this button does not appear at first, click Matte on the right side of the menu panel.

- 2 Select a colour model from the Colour Model box.

Select:	To:
RGB	Display the R, G, and B channel buttons. Enable each channel you want to use.
YUV	Display the Y, U, and V channel buttons. Enable each channel you want to use.

- 3 Set the colour range in the Range field.
You can also set a tolerance by enabling the Boundary button and selecting a distinct boundary colour from the image.
- 4 Set the softness in the Soft field.
- 5 Set the current colour.
- 6 Select a point in the area you want to fill. This is the selection point.

The pixels that fall within the specified range are filled with the current colour.

Original image

Fill with range 75 and softness 100

Fill with range 75 and softness 50

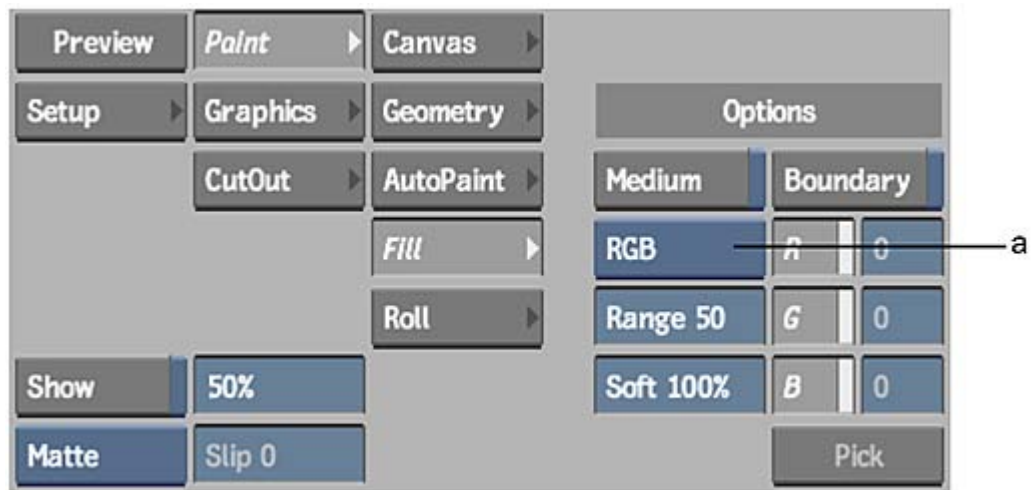

Fill with range 50 and softness 100

Filling a Region with an Image

You can fill a region of an image with a reference image instead of a colour. The front, back, or result image can be used as the reference image. The Wash, Shade, Clone, or Reveal media can also be used to perform the fill.

To fill a region with a reference image:

- 1 Click Fill.
The Fill controls appear.

(a) Colour Model box

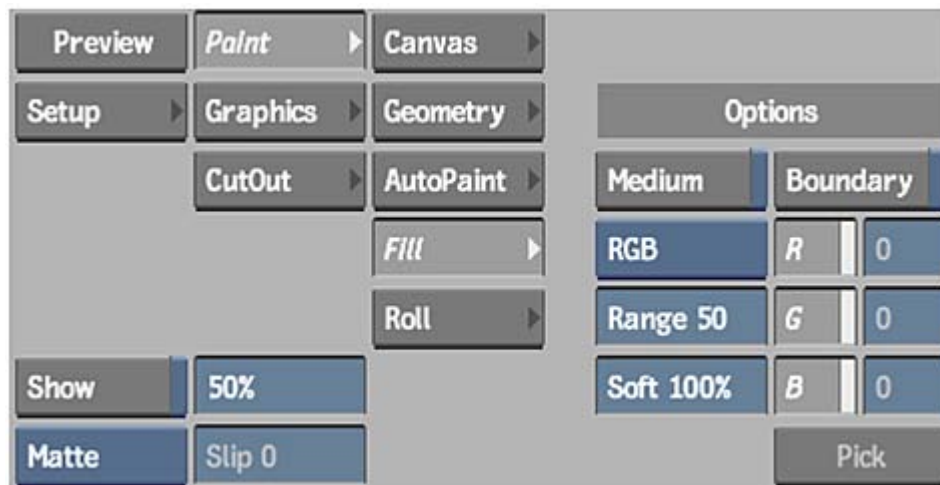

- 2 Select the colour model and channels you want to work with.
- 3 Set the range and softness in the Range and Softness fields.
- 4 Select the Special Effects medium you want to use (Clone, Reveal, Wash, or Shade). See [Using Special Effects Media](#) (page 1061).
- 5 Set the Reference box to Front, Back, Result, or Saved, and set the brush opacity.
A value of 100% fills the area completely with the reference image.
- 6 Enable Medium.
- 7 Select a point in the area you want to fill.

Filling a Boundary

Use the Boundary option to fill an area of the canvas delimited by another colour.

To use boundary fill:

- 1 Click Fill.
The Fill controls appear.

- 2 Select the colour model and channels you want to work with.
- 3 Set the range for the fill in the Range field.
- 4 Enable Boundary.
The Pick button is no longer greyed out.
- 5 Click Pick.
The cursor changes to a colour picker when dragged over the image.
- 6 Drag the colour picker over the canvas without clicking.
The various colour channel values in areas of the image are displayed as you move the colour picker around the canvas.
- 7 Click a point to select the colour for the boundary. You can also select a colour by entering the RGB values directly in the colour channel fields.
The cursor changes to a paint bucket.
- 8 Click the area inside the boundary to fill that region.

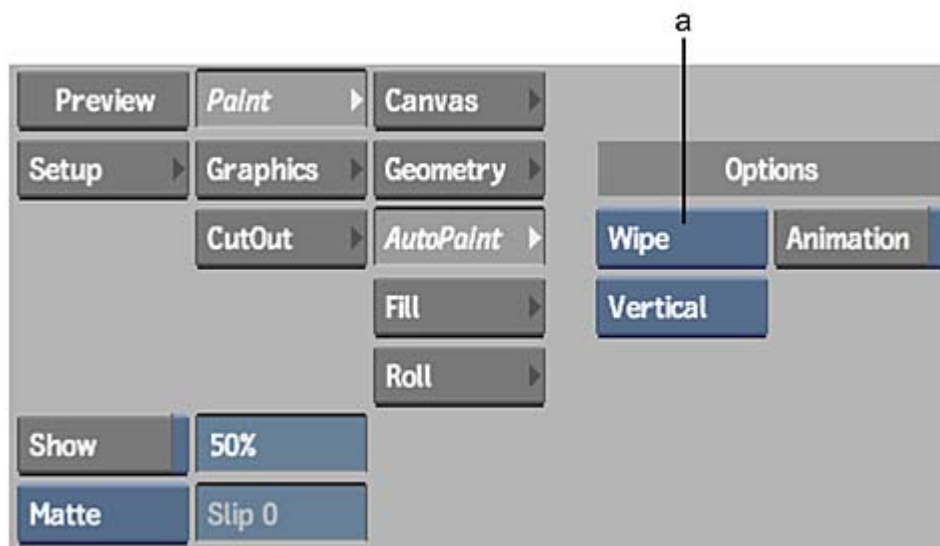

NOTE To fill a boundary with a reference image, set the Reference box to Front, Back, or Saved, and enable Medium.

Using AutoPaint

Use the AutoPaint controls to apply paint strokes to each frame in the result clip, a range of frames, or the current frame.

To display the AutoPaint controls:

- 1 Click AutoPaint in the Paint menu. If the controls are hidden by the colour palette, swipe the bottom of the screen.

(a) Autopaint Mode box

The AutoPaint Mode options are described as follows.

User Records and plays back a series of manual paint strokes.

Random Applies a number of random strokes to the image.

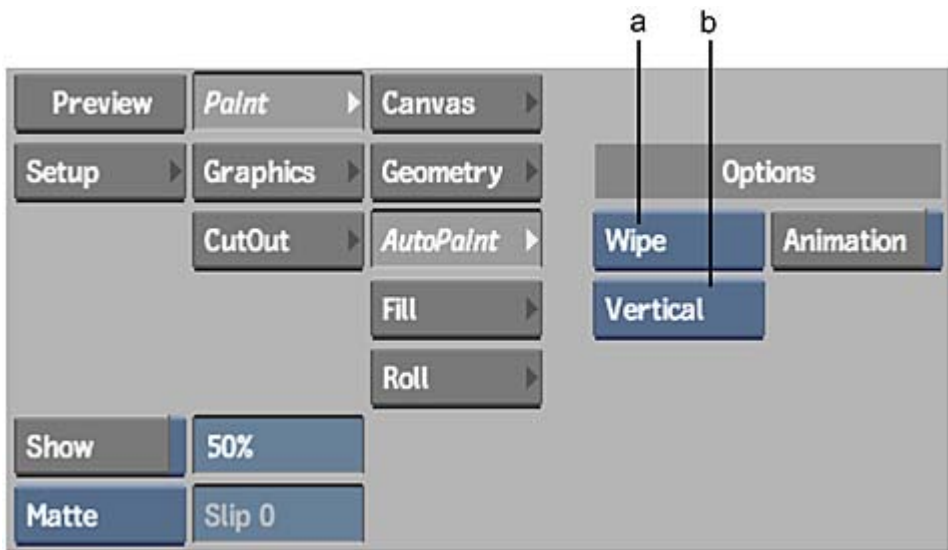

Wipe Wipes the entire canvas with the current colour or medium.

Wiping the Canvas in AutoPaint

Use Wipe mode to automatically apply paint strokes from left to right, top to bottom, or diagonally across the entire canvas. You can use a filter or any of the Special Effects media except Warp, Drag, and Smear. The size of the brush determines the number of strokes applied. Use a small brush to apply several strokes or a large brush to apply fewer strokes.

To wipe the canvas in AutoPaint:

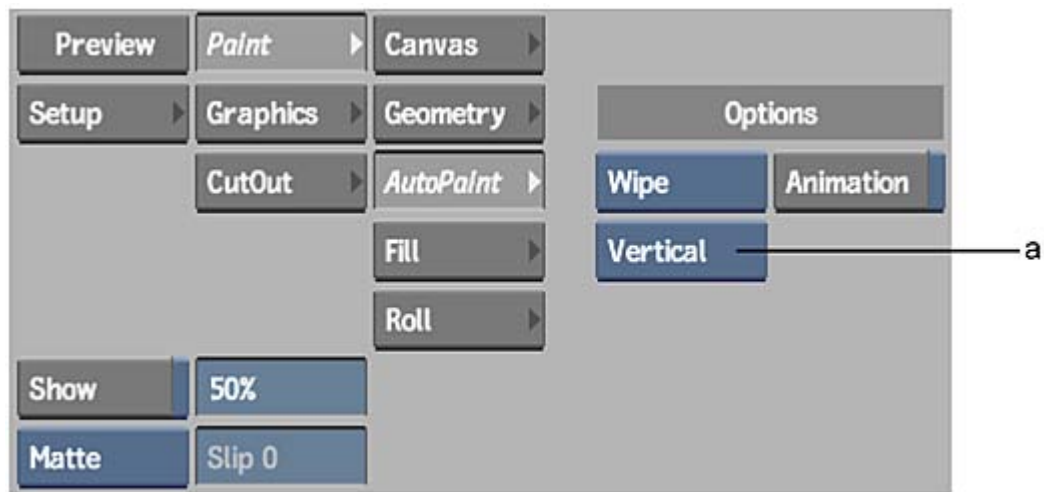

- 1 Click AutoPaint, and select Wipe from the AutoPaint Mode box.
The Wipe menu appears.

(a) AutoPaint Mode box (b) Wipe Mode box

- 2 Set the current colour.
- 3 Select the Special Effects medium or filter, and set the brush attributes. See [Using Special Effects Media](#) (page 1061), and [Brush Attributes](#) (page 1054).
- 4 Select the Wipe mode in the Wipe Mode box. If this box is not visible, make sure that the attribute mode for the Direction attribute is set to Direction.

Select:	To:
Diagonal	Apply diagonal strokes.
Vertical	Apply strokes from top to bottom.
Horizontal	Apply strokes from left to right.

(a) Wipe Mode box

- 5 Enable Animation to display the Channel Editor.
If the Channel Editor is not visible, swipe the bar below the menu.
You can animate all brush attributes as well as the current colour.
- 6 Enable Wipe if you are using a filter or colour.
- 7 Click the image to apply the paint strokes only to the current frame. Click Process to apply the paint strokes to each frame in the front clip.

Original image

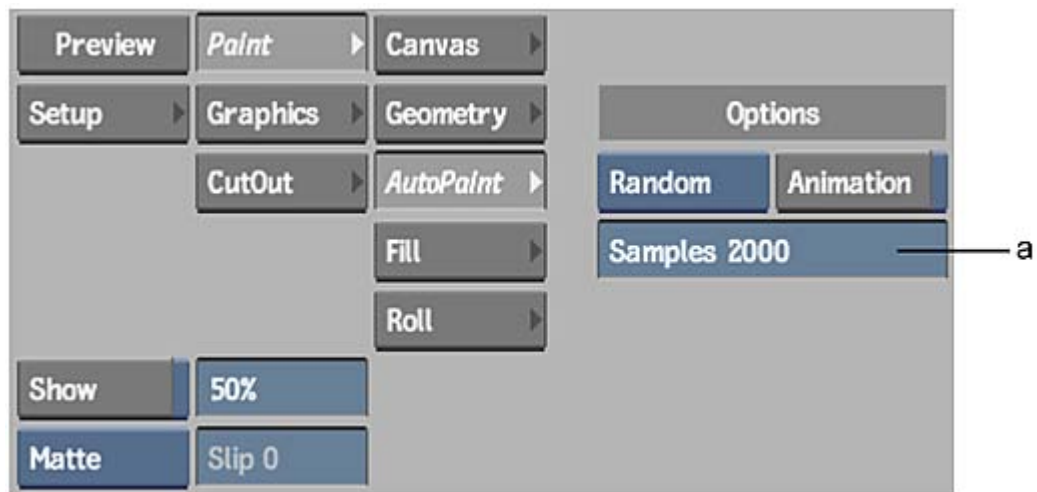

After using the Wipe command with Jitter attribute at 35% and Colour attribute mode set to Front

Applying Random Strokes

Use Random mode to automatically generate a number of paint strokes with random orientation on the image. Use the Samples field to specify the number of random strokes you want to generate. You can use any Special Effects media in Random mode except Warp and Drag.

To apply random paint strokes to the image:

- 1 Click AutoPaint and select Random from the AutoPaint Mode box.
The Samples field appears.

(a) Samples field

- 2 Enter the number of strokes you want to apply in the Samples field.
- 3 Set the current colour.
- 4 Select the Special Effects medium, and set the brush attributes. See [Using Special Effects Media](#) (page 1061), and [Brush Attributes](#) (page 1054).
- 5 Enable Animation to display the Channel Editor. If the Channel Editor is not visible, swipe the bar below the menu.
You can animate the following parameters:
 - Number of strokes
 - All the brush attributes
 - Colour
- 6 Click the image to apply the paint strokes to the current frame only. Click Process to apply the paint strokes to each frame in the front clip.

Original image

After using the Random command with Jitter attribute at 30% and Colour attribute mode set to Front

Recording Brush Strokes

Use User mode to record and play back a series of paint strokes. Only the positions of the brush strokes are recorded. This means that you cannot change the brush type, current colour, or brush attributes while

recording the strokes. You can, however, change or animate these parameters after you finish recording and before you play back the strokes.

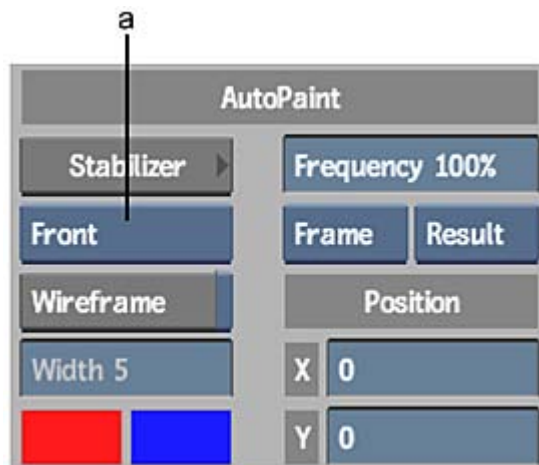

TIP You can also play paint strokes created by converting objects (write-ons).

To record a series of brush strokes:

- 1 Click AutoPaint and select User from the AutoPaint Mode box.
- 2 Set the brush characteristics so that you can see the recorded brush strokes on your image.
NOTE The strokes you paint are recorded as a series of points or stamps of the brush. The number of strokes is determined by dividing the number of points by the number of frames. The quality of the rendered strokes depends on the number of recorded points. To record a larger number of points, select a small brush size.
- 3 Enable Record.
- 4 Begin painting on the image.
The position of each brush stroke is recorded, and the stroke count appears in the message bar.
- 5 To stop recording, click below the timebar.
All paint strokes applied to the image while recording are removed from the image and the number of strokes is recorded.
NOTE AutoPaint stores only one set of recorded paint strokes at a time. If you record another set of paint strokes, you lose your previously recorded strokes.

Tracking with AutoPaint

You can apply tracking data to the painted strokes.

(a) Tracking box

To apply tracking data to recorded strokes:

- 1 Enable Animation.
- 2 Select Front, Back, or Result from the Tracking box and click Stabilizer to track a point and apply the offset information to the recorded strokes.
NOTE You can only track after you record paint strokes.
- 3 Use the X and Y field to offset the painted strokes.

Playing Recorded Brush Strokes

After recording brush strokes, you can apply them to the front clip using the Play option, which is activated automatically when you finish recording the paint strokes.

To play recorded strokes:

- 1 Enable Play.
The Play options appear.

- 2 Define the brush characteristics using the Brush Attribute fields.
- 3 Define the duration of the stroke sequence using the second timebar. Drag the indicator to modify the duration.

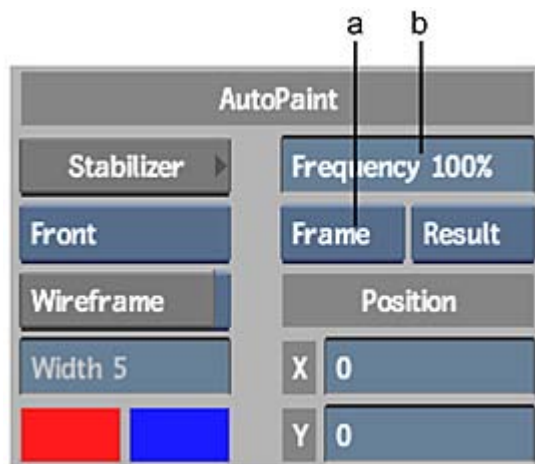

(a) Indicator

The number of strokes is divided by the length of the stroke, defined by the second timebar. The indicator in the second timebar is identical to a track in the Channel Editor.

- 4 Enable the Play options.

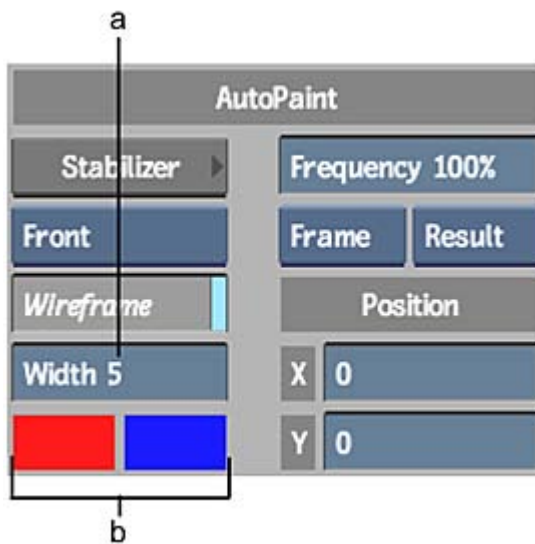

Enable:	To:
Part	Play only a part of the recorded strokes. AutoPaint applies the strokes to a frame, erases those strokes, and moves to the next frame. This has the effect of creating streaks on your rendered clip.
Backward	Play the paint strokes backward.
Distance	Play paint strokes based on distance. AutoPaint divides the length of paint strokes by the number of frames to determine what to render in each frame.
Stroke	Play the paint strokes simultaneously.

- 5 Enable Animation.
The Animation menu appears.

(a) Animation Type box (b) Frequency field

- 6 Enable Wireframe to preview the path(s) of the painted strokes.

(a) Width field (b) Wireframe colour pots

The wireframe preview shows the complete path(s) of the painted strokes. It also shows what will be painted in each frame as set using the second timebar.

You can set the width of the wireframe using the Width field. You can also change the colour of the path and progression wireframes using the colour pots beneath the Width field.

For Path animation, you define how often AutoPaint reads the Channel Editor values when rendering the points or stamps that make up a given stroke. At a frequency of 100%, AutoPaint reads the Channel Editor values the most frequently.

For example, assume you set your AutoPaint sequence of 100 stamps to run over 10 frames using Path animation. If you set the Frequency field to 100%, AutoPaint reads the Channel Editor values 10 times every frame. If you set the Frequency field to 50%, AutoPaint reads the Channel Editor values 5 times every frame.

TIP Use the Frequency field to lower the processing time for your AutoPaint sequence. Use a low frequency to render a quick preview of the result.

- 7 Swipe the bar at the bottom of the menu to display the Channel Editor.

You can animate the following parameters:

- Sampling amount
- X and Y values
- Brush size, rate, pressure, jitter, direction, roll, opacity, and colour
- Tracker translation

NOTE The Channel Editor only appears if Animation is enabled. Also, animation data in the Channel Editor is not erased when you record new strokes.

- 8 To apply the paint strokes, click Process.

NOTE If you are zoomed in on the image and are in the Raster zoom mode, only the visible portion of the image will be processed. This is much faster than using Tiled mode, but will not apply your modifications to the entire frame. For more information on zoom modes, see [Painting on Full-Resolution Film Images](#) (page 1047).

About Mattes

Mattes protect specific areas of the image when you apply paint, filters, or Special Effects media to the canvas. You can also use mattes to limit the area of a cutout.

For instructions on loading mattes into Paint, see [Loading Clips into Paint](#) (page 1040), and [Loading Setups](#) (page 1126).

To use the matte:

- 1 Click Use to enable the matte.

- 2 Paint on the image.
- 3 Click Use again to disable the matte.

Using Mattes with Cutouts

If you enable your matte when creating a cutout, the cutout is limited by the matte. Only objects outside the matte will show up in the cutout. See [Creating a Cutout](#) (page 1116).

Viewing Mattes

You can view the matte as you use it.

To view the matte:

- 1 Load the matte into Paint.
- 2 Enable Show.
- 3 Select Matte in the Reference box.

The matte appears.

Changing the Matte Colour

If the colour used to display the matte blends with the image, you can change its colour.

NOTE The matte is always created using shades of grey.

To change the matte display colour:

- 1 Set the current colour.
- 2 Click the Matte colour pot.

The matte colour display changes to the current colour.

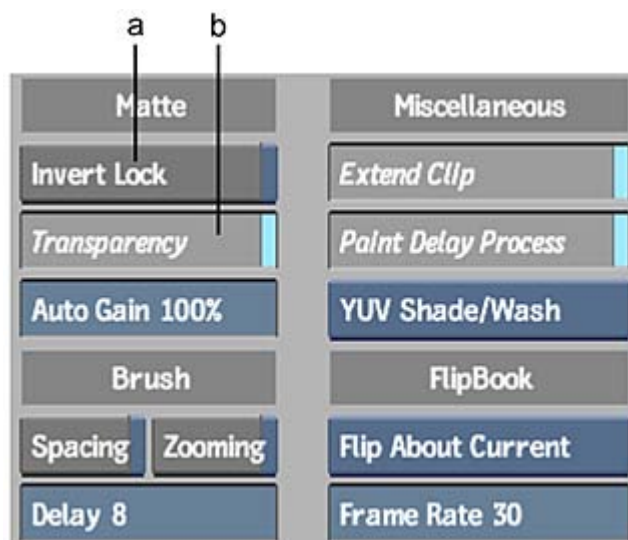

Changing the Matte Display Transparency

When viewing the matte, use the Transparency field to vary the matte display transparency from 0% (completely transparent) to 100% (fully opaque). Press **Alt+T** or click Transparency in the Setup menu to toggle between the last set value and 100%.

(a) Transparency field

NOTE The transparency value only affects the display of the matte. It does not affect how the matte is used.

(a) Invert Lock button (b) Transparency button

Inverting the Matte Clip

Click Invert to invert the matte in the current frame. Enable Invert Lock in the Setup menu to invert the matte in every frame of the clip.

Creating or Modifying Mattes

You can create or modify a matte by painting directly on the matte using any brush, Special Effects media, or graphic tool. For information on using graphic and cutout tools to create mattes, see [Using the Cutout Commands](#) (page 1117).

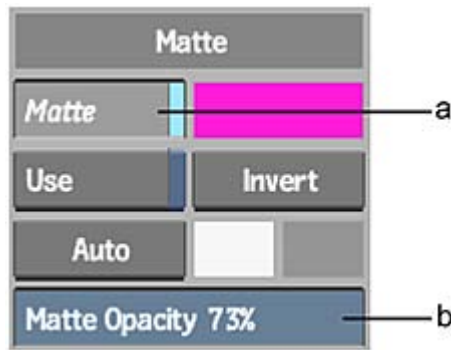

To create or modify a matte:

- 1 Load the matte into Paint.

NOTE You must load a matte clip in order to process a matte in Paint. If you want to create a matte from scratch, load a black source as the matte clip.

- 2 Click Matte.

The Matte menu appears.

(a) Matte button (b) Matte Opacity field

- 3 Set the paint transparency in the Matte Opacity field.
The value in the Matte Opacity field determines the transparency of the paint applied to the matte. Use a value of 100 to apply fully opaque paint or objects to the matte. Reduce the Matte Opacity value to increase the transparency of the paint.
- 4 Paint or place graphics or cutouts on the matte.
The paint and graphics are applied to the matte. If you use graphic tools, use Tack to tack the graphic to the matte. See [Tacking Down Selected Objects](#) (page 1115).
- 5 You can save the matte in the matte library. See [Saving Setups](#) (page 1125).
- 6 To process the matte clip, click Exit.
The new matte clip is saved to the rendered destination.

Painting on the Matte and Image

When applying paint strokes or graphics to the image, enable Both to paint the image and the matte simultaneously.

Resetting the Matte

If you do not load a matte, Paint displays the last matte that was loaded.

To erase the matte:

- 1 Click Matte.
- 2 Set the Matte Opacity to 0%.
- 3 Click Wipe.
The matte is erased.

Creating a Gradient Matte

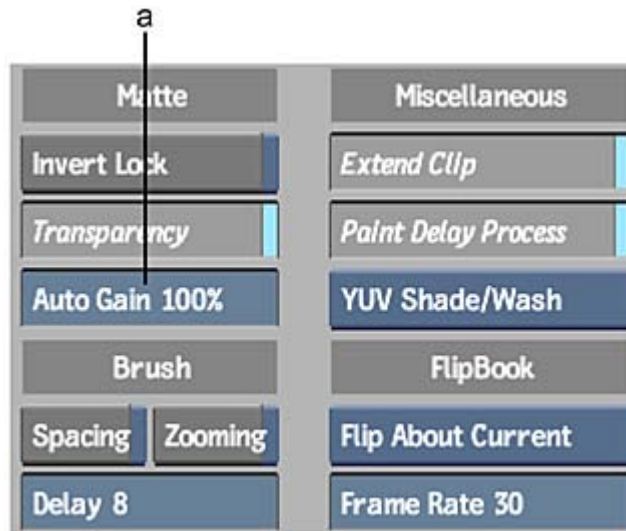

You can use graphics that contain gradients to create a matte that blends from one level of the matte colour to another level. A gradient matte is useful for blending paint strokes or creating soft edges.

To create a gradient matte, draw a graphic with a gradient on the matte, and then use the Channel Editor to change the “a” channel of the start or end colour of the gradient. See [Creating Graphics](#) (page 1089), and [Changing the Object Gradient](#) (page 1103).

Creating High-Contrast Mattes

Use the Auto command to create a high-contrast matte. This command works like the Auto Matte command in the Processing menu. The minimum and maximum luminance values for the matte are set using the two colour pots in the AutoMatte menu. Any pixel with a luminance value below the minimum is set to black, and any pixel with a luminance value above the maximum is set to white.

Unwanted grey areas can be removed from the matte by increasing the percentage in the Auto Gain field in the Setup menu.

(a) Auto Gain field

Pixel values between the minimum and maximum values are multiplied by the Gain value. The resulting values are clipped at the specified maximum luminance value. The Gain is expressed as a percentage value. The default value of 100% has no effect on the image since the luminance values are multiplied by 1.

To use the AutoMatte command:

- 1 In the Paint menu, click Matte.
The AutoMatte menu appears.

(a) Minimum luminance (b) Maximum luminance

- 2 Set the minimum luminance value for the matte in the colour pot on the left. To set the value, click the field and use the colour picker to select the lightest colour from the image.
- 3 Set the maximum luminance value for the matte in the colour pot on the right.

- 4 Set the Auto Gain for the matte. The Auto Gain field is in the Setup menu.
- 5 Click Auto to generate the matte.
- 6 Click Use to enable the generated matte.

Using Graphics in Paint

Accessing the Graphics Menu

To access the Graphics menu, click the Graphics button in the Paint menu. Some options may be hidden if the colour palette is open. Swipe the cursor across the bars at the bottom of the screen to hide the colour palette.

Creating Graphics

Graphics can be used to create cutouts or mattes, or to apply geometrical shapes, text, and fills to the result clip.

To create a graphics object:

- 1 In the Paint menu, click Graphics.
- 2 Click Add.
- 3 Select the type of object to add by selecting an icon in the Object Tools window.

- 4 Draw the object on the image. See [Using the Object Tools](#) (page 1090).
- 5 Set the resolution to be used when adding or editing objects. See [Setting the Object Resolution and Display](#) (page 1100). Objects appear at full resolution when they are drawn.
- 6 Set the object's attributes and gradient. See [Setting the Object Attribute](#) (page 1102), and [Changing the Object Gradient](#) (page 1103).
- 7 Set the object's colour in the Current Colour pot. See [Selecting Colours](#) (page 1044).
- 8 Resize and move the object. See [Changing the Size or Position of an Object](#) (page 1105).
- 9 Use the Transformation box or controls to move, rotate, or scale the object. See [Changing the Shape of an Object](#) (page 1106).
- 10 Use the Animation controls to animate the object. See [Animating Graphics](#) (page 1110).

- 11 Click the Tack button to permanently place the object on the result clip.
Once the object has been tacked down, it cannot be moved, rotated, deleted, resized, or copied. See [Tacking Down Objects](#) (page 1114).

Auto Edit After Add

After you add an object to the image, Paint automatically switches from Add mode to Edit mode. You can turn off this default setting by disabling the Auto Edit After Add button in the Setup menu. You can then add objects one after another without interruption.

(a) Auto Edit After Add button

Using the Object Tools

A number of predefined graphic tools are available in Paint. The cursor looks the same for all graphic types. When you move the cursor onto an image, it appears as a small green cross with crosshairs that extend the width and height of the canvas. The crosshairs help align objects on the image.

Each tool has its own icon in the Object Tools window.

To select an object tool:

- 1 Scroll through the Object Tools window.

Click the Object Tools window and drag left or right. Use the left mouse button to scroll slowly, the middle button to scroll faster, and the right button to scroll the fastest.

- 2 Click the object tool icon you want to use.
The selected object tool is highlighted by a blue outline.

NOTE Only one object tool can be active at a time.

Drawing a Line

Use the Line object tool to draw a single straight line or a multi-line object (a series of lines joined end-to-end).

To draw a line or a series of lines:

- 1 In the Graphics menu, click Add.
- 2 Select the Line tool in the Object Tools window.
The Create Multiple Lines button appears.
- 3 Click Create Multiple Lines.
- 4 To draw multiple lines, move to the canvas and click to place the start point of the first line. Click again to draw the end point. Continue clicking to draw more lines.
- 5 To end a multiple line object, click Create Multiple Lines.
- 6 To draw single lines, move to the canvas and click, drag, and release.
Paint draws the line as you drag.

Drawing a Rectangle

Use the Rectangle object tool to draw a rectangle or square in one of two ways:

- Corner-to-corner, with the two vertices located at diagonally opposite corners of the rectangle
- Centre-to-corner, with the first vertex at the centre of the rectangle and the second at one corner

To draw a rectangle from corner-to-corner:

- 1 In the Graphics menu, click Add.
- 2 Select the Rectangle tool in the Object Tools window.
- 3 Press the cursor to anchor one corner of the rectangle. Do not release the cursor.
- 4 Drag the cursor diagonally. You can adjust the width and height of the rectangle as long as you hold down the cursor.
- 5 Release the cursor to anchor the second vertex.
The rectangle is drawn on the image.

To draw a rectangle from centre-to-corner:

- 1 In the Graphics menu, click Add.
- 2 Select the Rectangle tool in the Object Tools window.
- 3 Press **Alt**.
- 4 Position the cursor where you want to place the centre of the rectangle and press down.
- 5 Drag diagonally, and release the cursor when the rectangle is the correct size.

Drawing a Square

Press **P** while you draw and repeat the procedure for drawing a rectangle from corner-to-corner.

Drawing a Triangle

Use the Triangle object tool to draw a triangle or equilateral triangle. The vertices are located at the three corners of the triangle.

To draw a triangle:

- 1 In the Graphics menu, click Add.
 - 2 Select the Triangle tool in the Object Tools window.
 - 3 Position the cursor and press to anchor the first vertex on the image. Do not release the cursor.
 - 4 Drag the cursor horizontally to draw the base of the triangle. You can continue to adjust the length of the base as long as you press down on the cursor.
 - 5 Release the cursor to anchor the second vertex.
 - 6 Move the cursor to where you want to place the third vertex. You can continue to adjust the position of the third vertex until you press down on the cursor. Press to anchor the third vertex.
- The triangle is drawn on the image.

Drawing an Equilateral Triangle

An equilateral triangle has three sides of equal length. To draw an equilateral triangle, repeat the procedure for drawing a triangle and press **P** while drawing the base of the triangle. This also establishes the height of the triangle. Release the cursor to anchor the second and third vertices on the image.

Drawing an Ellipse

Use the Ellipse object tool to draw an ellipse defined by three vertices. The first vertex determines the centre of the ellipse. The second vertex determines the horizontal radius of the ellipse. The third vertex determines the vertical radius.

To draw an ellipse:

- 1 In the Graphics menu, click Add.
 - 2 Select the Ellipse tool in the Object Tools window.
 - 3 Position the cursor at the centre of the ellipse and press to anchor the point on the image. Do not release the cursor.
 - 4 Drag the cursor horizontally to establish the width of the ellipse. You can continue to adjust the width as long as you press down on the cursor.
 - 5 Release the cursor to anchor the second vertex.
 - 6 Move the cursor along the vertical axis to position the third vertex. You can continue to adjust the height of the ellipse until you press down on the cursor. Press to anchor the third vertex.
- The ellipse is drawn on the image.

To draw a circle with the Ellipse tool:

- 1 In the Graphics menu, click Add and select the Ellipse tool.
- 2 Press **P**.
- 3 Position the cursor at the centre of the circle and press to anchor the point on the image. Do not release the cursor.

- 4 Drag the cursor horizontally to establish the radius of the circle. Notice that there are two vertices at the edge of the circle, as there are for an ellipse.
- 5 Release the cursor and the **P** key to anchor the second and third vertices.
The circle is drawn on the image.

Drawing a Circle

Use the Circle object tool to draw a circle in one of two ways:

- Centre-to-edge, with one vertex at the centre of the circle and a second on the circumference
- Edge-to-edge, with two vertices at opposite points on the circumference

To draw a circle from edge-to-edge:

- 1 In the Graphics menu, click Add.
- 2 Select the Circle tool in the Object Tools window.
- 3 Position the cursor at the centre of the circle and press to anchor that point on the image. Do not release the cursor.
- 4 Drag the cursor to establish the radius of the circle. You can continue to adjust the size of the circle as long as you press down on the cursor.
- 5 Release the cursor to anchor the second vertex.
The circle is drawn on the image.

To draw a circle from centre-to-edge:

- 1 In the Graphics menu, click Add and then select the Circle tool.
- 2 Press and hold **Alt**.
- 3 Drag the cursor to establish the radius of the circle.
When the circle is the required size, release the cursor.

Drawing a Polygon

Use the Polygon object tool to create a series of connected lines that form a closed or open object. You can specify how the vertices of the polygon should be connected by selecting one of the options from the Polygon Mode box.

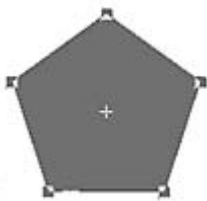

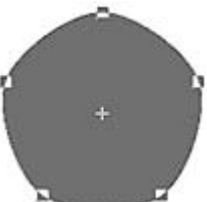

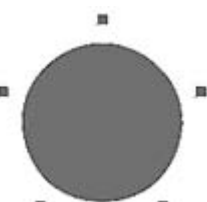

To draw a polygon:

- 1 In the Graphics menu, click Add.
- 2 Select the Polygon tool in the Object Tools window.
The Polygon menu appears.

(a) Polygon Mode box (b) Sides field

- 3 Select an option from the Polygon Mode box to set the type of curve used to join the vertices of the polygon.

Select:		To:
Linear		Use straight lines to join the vertices of the polygon.
Cardinal		Use a smooth curve that passes through the vertices of the polygon.
Bspline		Use a very smooth curve that passes on the inner side of the vertices of the polygon.
Bezier		Use Bezier curves. Each vertex of the polygon has a tangent with two tangent handles. In Edit mode, you can move the tangent handles to adjust the slope of the polygon. See Editing a Bezier Curve (page 1107).

The minimum number of vertices for a polygon depends on the type of interpolation used. A polygon should have at least three vertices when using Linear interpolation, or four when using Cardinal or B-spline interpolation. The maximum number of vertices is 255. A polygon can be concave.

- 4 To create an open-ended polygon, click Opened Shape.
- 5 Position the cursor at one vertex of the polygon, and click to anchor that point on the image.
- 6 Release the cursor and move it to where you want the next vertex of the polygon. You can continue to adjust the positioning of the next vertex until you press down on the cursor. Press to anchor the point on the image.
- 7 Repeat steps 4 and 5 for each vertex.
- 8 To close the polygon, press anywhere outside the canvas.
The polygon is drawn on the image.

Rubber Banding

Rubber banding is the default setting for drawing polygons and lines. This means that a vertex is added to the polygon only when you press and release the cursor.

To draw a polygon with multiple vertices, disable the Rubber Banding button in the Setup menu. When you drag the cursor while drawing a polygon or line, vertices are drawn on the image.

(a) Rubber Banding button

Drawing Regular Polygons

Draw regular polygons using the Sides field and the **P** key. A polygon can have three or more sides. This enables you to draw a triangle or a square based on the centre point of the object.

To draw a regular polygon:

- 1 In the Graphics menu, click Add.
- 2 Select the Polygon tool in the Object Tools window.
- 3 Enter the number of sides for the polygon in the Sides field.
- 4 Press **P**.
- 5 Position the cursor over the image and press down.
This is the centre of the polygon.
- 6 Drag the cursor away from the centre point. The polygon is drawn on the image. You can continue to adjust the size of the polygon as long as you press down on the cursor.
- 7 When the polygon is the correct size, release the cursor.
The polygon is drawn on the image.

Drawing a Fill Object

Use the Fill object tool to fill areas of an image with colour. While this is similar to using the Fill command in the Paint menu, you can only use this tool with colour, Shade, and Wash, and not to fill areas with a reference image. However, you can edit fill objects after you draw them.

NOTE A fill object cannot have a gradient.

To draw a fill object:

- 1 In the Graphics menu, click Add.
- 2 Select the Fill object in the Object Tools window.
The Fill object controls appear.

- 3 Select a colour model from the Colour Model box (RGB or YUV).
- 4 Select the colour channels you want to use (R, G, and B, or Y, U, and V).
The choice of colour channels determines how Paint evaluates the area you want to fill. For example, if you select R, G, and B, Paint fills areas whose adjacent pixels have red, green, and blue values in the specified range. If you select only R, Paint fills only areas whose adjacent pixels have red values in the specified range.
- 5 Enter the Range and Softness values for the fill.
The range determines how far the fill spreads from the point you click on the image; if you increase the range, you increase the fill area. The softness determines how much diffusion occurs at the edges of the fill; if you increase the softness, you increase the diffusion at the edges of the fill.
- 6 Move the cursor to the canvas and click inside the area to fill.
Paint fills the area with the current colour starting at the point you click.

NOTE The colour of the image and the channel, range, and softness settings determine the extent of the fill. As you move the fill object, it changes size and shape in response to the different colours in the image.

Drawing a Text Object

Use the Text object tool to add text to the image. You can change the size, kerning, and inclination of the text string.

To add a text object:

- 1 In the Graphics menu, click Add.
- 2 Select the Text tool in the Object Tools window.
The Text object controls appear.

(a) Text field (b) Font field

- 3 Click the Font field and select a new font from the font library.
- 4 Click the Text field, type the text string, and click Enter.
- 5 Click the image to place the text object.

You can adjust the size, kerning, and italics of the text in Edit mode.

Use:	To:
Size	Adjust the size (in pixels) of the text.
Italic	Incline the text. Enter a positive value to slant the text to the right, and a negative value to slant it to the left.
Kern	Adjust the space (in pixels) between all letters in the text.

Selecting Objects

You must select an object before you can edit it. In Edit mode, you can select objects in three ways:

- Click an object to select it.
- Use the Selected field to select individual objects.
- Use the All command to select all objects at once.

Using the Selected Field

As you add objects to the image, they are numbered sequentially, starting at 1. You can select an object by specifying the number of the object in the Selected field.

As you change the number in the Selected field, the corresponding object is highlighted by a selection box.

To select a single object using the Selected field:

- 1 Set the number in the Selected field to the number of the object you want to edit.

You can also click the < and > buttons beside the Selected field to move through the sequence.

- 2 When the selection box outlines the object, release the cursor. You can now edit it.

Selecting More than One Object

To select an additional object, hold down **Shift** and click another object. Repeat this step for each object you want to select.

Deselecting Objects

To deselect an object or objects, select a different object or click the Add button.

Selecting All Objects

To select all the objects, click the All button. All is shown in the Selected field. Click it again to deselect them.

Editing Objects

Use the object controls to copy, delete, hide, or layer objects.

Copying Objects

Use the Copy command to create multiple copies of an object. Once a copy is created, it can be selected and edited like any other object.

To copy an object:

- 1 In the Graphics menu, click Copy.
- 2 Click the object you want to copy. Do not release the cursor.
A copy of the object is superimposed on the original image. You cannot see the copy until you drag it to a new location.
- 3 Drag the copy to a new location.
- 4 When the copy is positioned correctly on the image, release the cursor.

Deleting Objects

Use the Delete command to remove one or more objects from the image.

To delete one or more objects:

- 1 Select the objects you want to delete. Click an individual object or use the Selected box to select an object. To select multiple objects, click an object, press **Shift**, and click any other objects you want to delete.
- 2 Click Delete.
All selected objects are removed from the image.

To delete all objects from the image:

- 1 Enable All.
- 2 Click Delete.
All objects are deleted from the image.

Hiding Objects

Use the Hide/Unhide commands to hide or unhide objects before they are tacked onto the image.

To hide or unhide one or more objects:

- 1 Select the objects you want to hide. Click an individual object or use the Selected box to select an object. To select multiple objects, click an object, press **Shift**, and click any other objects you want to hide.
- 2 In the Graphics menu, click Edit and then click Hiding.
The Hide options appear.

Select:	To:
Hide Selected	Hide all selected objects.
Hide Unselected	Hide all objects that are not selected.
Unhide All	Show all hidden objects.

Changing the Order of Overlapping Objects

Objects can be drawn so they overlap other objects to produce a stack of objects.

To send an object to the bottom of the stack:

- 1 Select the object.
- 2 In the Graphics menu, click Push and then click the object until it is at the bottom of the stack.

NOTE To bring the object back to the front, click the object until it moves to the front.

Setting the Object Resolution and Display

Use the Object Resolution box to set the resolution while drawing or editing objects. The objects are regenerated at high resolution once you release the cursor at the end of each editing operation. Use the options in the Setup menu to affect the display of the graphics before they are tacked down onto the image.

To set the object resolution:

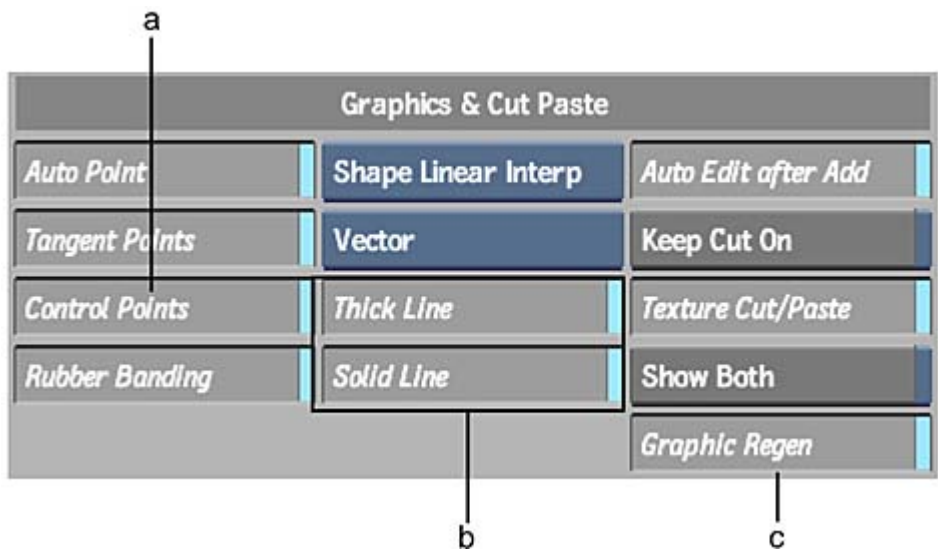

- 1 Select an option from the Object Resolution box.

Select:	To:
Full Res	Display the object at full resolution when updating. This is helpful for displaying gradients, but slows down the rate at which image display is refreshed.
Low Res	Display the object at low resolution when updating.
Wireframe	Display the object as a wireframe when updating.

Wireframe Display Options

The Thick Line and Solid Line buttons in the Setup menu determine the thickness and continuity of the wireframe.

(a) Control Points button (b) Thick Line and Solid Line buttons (c) Graphic Regen button

Enabling and disabling the Thick Line and Solid Line buttons affects the wireframe as follows:

- When Thick Line is enabled, the wireframe has a thickness of 2 pixels.
- When Thick Line is disabled, the wireframe has a thickness of 1 pixel.
- When Solid Line is enabled, the wireframe is unbroken.
- When Solid Line is disabled, the wireframe is dashed.

Increasing Editing Speed

To speed up editing, disable the Graphic Regen button in the Setup menu. Instead of waiting for the graphics objects to be regenerated at the end of an editing operation, the objects appear at the display resolution. This can be a useful time-saving feature.

Hiding the Object Vertices

Each object is defined by two or more vertices. These vertices, or tangent handles, appear while you are drawing or editing the object.

Disable the Control Points button in the Setup menu to turn off the display of the vertices while you are drawing or editing the object. This feature is useful if you want to trace the outline of a figure.

Displaying Anamorphic Geometry

Select Use Aspect Ratio in the Rendering area of the Setup menu to draw and display anamorphic geometry. For normal display, click Use Aspect Ratio and switch to Use Square Pixels.

(a) Anti-alias field (b) Use Aspect Ratio option

Anti-Aliasing for Objects

The jagged edges that can occur along diagonal and curved lines in geometry are caused by aliasing, or insufficient spatial sampling of the image. The process of minimizing jagged edges by increasing the sampling rate is called *anti-aliasing*.

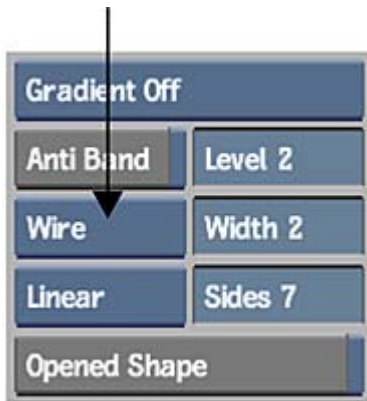

Use the Anti-alias field in the Rendering Setup menu to specify an anti-aliasing factor for geometry. When the value is set to 1, no anti-aliasing occurs. Best results are obtained with a value of 4.

Setting the Object Attribute

Use the Object Attribute box to set the display mode for the object you add to the image.

To change the object attribute:

- 1 In the Graphics menu, click Edit.
- 2 Select the object you want to edit.
- 3 Click Attributes.
- 4 Select an option from the Object Attribute box.

Select:	To:
Solid	Draw a filled object with a well-defined edge. Use the Brush Opacity field to set the object's transparency. No other brush attributes or types are available. Line objects cannot be set to Solid.
Outline	Draw an outline of the object. Use the Brush Attribute buttons to set the appearance of the outline. See Changing the Object's Appearance (page 1102).
Fuzzy	Draw a solid object with a soft edge. Use the Brush Attribute fields to set the appearance of the outline.
Wire	Draw a wireframe object. Use the Brush Opacity field to set the object's transparency. No other brush attributes or types are available.

Changing the Object's Appearance

You can change the appearance of an object by changing any of the following display attributes:

- Current colour
- Brush attribute values or modes
- Special Effects media or filters
- Colour gradient

Changing display attributes affects all currently selected objects. See [Selecting Objects](#) (page 1097).

Setting Brush Attributes and Modes

In the Graphics menu, you can only change brush attributes and modes when using the Outline or Fuzzy attribute. See [Brush Attributes](#) (page 1054).

If the Brush Attribute controls are not visible, swipe the bar at the bottom of the menu. Use the Current Colour pot to set the graphic's colour, and the Opacity field to set the opacity of the object, or the effect a graphic has on the image.

Using Filters and Special Effects Media with Graphics

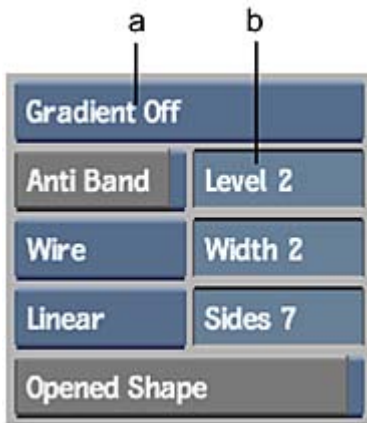

Any filter can be used with objects. Only the Paint, Clone, Reveal, Wash, and Shade Special Effects media can be used. See [Using Special Effects Media](#) (page 1061).

Changing the Object Gradient

All objects, except the fill object, can have a gradient. You can edit a gradient or apply a gradient to an object that does not have one. A selected object with a gradient displays a gradient control bar that you can use to edit the orientation of the gradient.

To edit a colour gradient:

- 1 In the Graphics menu, click Edit.
- 2 Select the object you want to edit.
- 3 Click Attributes.
- 4 Select an option from the Gradient box.

(a) Gradient box (b) Noise Level field

Select:	To:
Rectangular Gradient	Use a rectangular gradient in which colour changes from top to bottom.
Circular Gradient	Use a circular gradient in which colour changes from centre to edge.
Gradient Off	Turn off the gradient and use a solid colour.

- 5 Set the colours for the gradient. See [Using the Colour Gradient Bar](#) (page 1046).
 - 6 To eliminate banding, enable Anti Band.
Banding normally appears only if you are working at 8-bit colour depth and if the gradient that you apply is stretched.
- TIP** You can also set a noise level to the anti-band function. Noise may help when colour bands are very large. Set the value in the Noise Level field to 7 to apply the maximum noise, or lower it to apply less dither/noise. If you set the value to 0, no noise is applied.
- 7 Use the gradient control bar to change the object's gradient.

Using the Gradient Control Bar

When you select an object with a gradient, Paint displays a gradient control bar in addition to the object transformation box. The gradient control bar has two handles at each end that show the colours of the gradient. In a rectangular gradient, the bar also indicates the direction of the gradient.

(a) Gradient control bar (b) Centre point of gradient

(a) Start point of the gradient (b) Gradient control bar (c) End point of the gradient

NOTE If you want to move the transformation box, press **M** and click the location where you want to move the box.

To use the gradient control bar:

- 1 Select an object with a gradient, or add a gradient to an object.
Paint displays the transformation box and the gradient bar.
- 2 Move the handles of the gradient control bar to change the orientation and location of the gradient.

In a rectangular gradient, this affects the gradient orientation. For example, the default orientation for a rectangular gradient is top to bottom. If you drag one of the handles left or right, you change the orientation to diagonal. If you drag the handles so the gradient bar is horizontal, you get a rectangular gradient with the colours blended from side to side.

If you select the centre colour handle in a circular gradient, you can move the gradient's centre inside the object or even outside it.

- 3 To decrease the amount of one colour visible in an object, move the handle to the edge or outside the object.

Changing the Size or Position of an Object

Use the transformation box, or the transformation controls in the Axis Transformation menu, to change the size or position of an object. You can use the transformation box and controls to modify the object in the following ways:

- Move the object in any direction on the image.
- Rotate the object about its centre point.
- Change the size of the object.

You can translate, resize, or rotate more than one object at the same time by selecting all the objects you want to edit.

Using the Transformation Box

To display the transformation box, click the Edit button in the Graphics menu and click the object you want to edit.

(a) Reset handle (b) Centre point (c) Resize handle (d) Rotation handle (e) Translation handle

The position of the transformation box is saved for each object. To move the transformation box, press **M** and click the destination.

Resize handle To change the size of an object, drag the resize handle in any direction. To maintain an object's proportions, press **PE** as you drag the resize handle.

Centre point To change the point around which the object rotates, move the centre point.

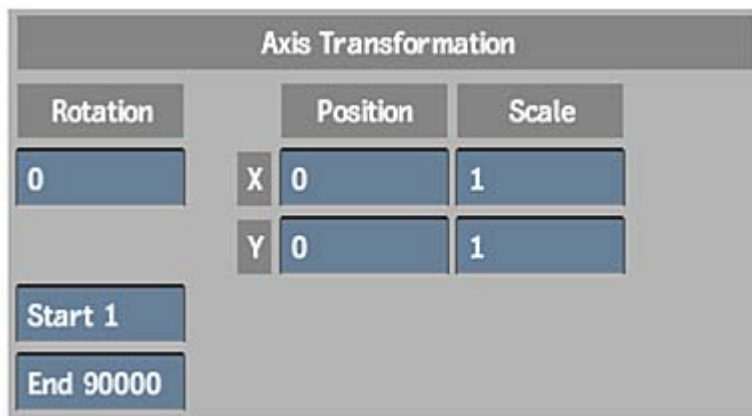

Rotation handle To rotate the object about its centre point, drag the rotation handle.

Translation handle To move the object in any direction on the image, drag the translation handle. The transformation box moves with the object.

Reset handle To restore the object to its initial size and position on the image, click the reset handle.

Using the Transformation Controls

Use the transformation controls to translate, rotate, and resize a selected object. To display the transformation controls, select an object and click the Transform button.

The image shows a dialog box titled "Axis Transformation". It contains three main sections: "Rotation", "Position", and "Scale". The "Rotation" section has a single input field with the value "0". The "Position" section has two input fields, one for "X" and one for "Y", both with the value "0". The "Scale" section has two input fields, one for "X" and one for "Y", both with the value "1". Below these sections are two buttons: "Start 1" and "End 90000".

Axis Transformation			
Rotation		Position	Scale
0	X	0	1
	Y	0	1
Start 1			
End 90000			

X (Position) Move the object along the horizontal axis (X-axis).

Y (Position) Move the object along the vertical axis (Y-axis).

X (Scale) Change the size of the object along the horizontal axis.

Y (Scale) Change the size of the object along the vertical axis.

Rotation Set the object's angle of rotation along the Z-axis. The object is always rotated around its centre point.

Reset Use the Reset button to reset the object to its initial size and position.

Start and End Numeric Fields Use these fields to set when the object appears in the clip.

Changing the Shape of an Object

To change the shape of an object, such as a polygon or a line, you must add, delete, or move a vertex on the object.

To change the shape of an object:

- 1 In the Graphics menu, click Edit.
- 2 Select the object you want to edit.
The object vertices and the transformation box appear on the selected object.
- 3 Press the vertex you want to edit and drag it to a new location. When you are satisfied with the new position, release the cursor.

Adding and Deleting Vertices on a Polygon or Line

Change the shape of a polygon or line by changing its number of vertices.

To add a vertex to a polygon or line:

- 1 In the Graphics menu, click Edit.

- 2 Select the polygon or line you want to edit.
The vertices for that object are selected.
- 3 Press **A**.
- 4 Press on one of the existing vertices and drag outward. A vertex is added counterclockwise to the selected point.
To add a point clockwise to the selected point, press **Ctrl+A**.
- 5 Repeat steps 3 and 4 for each vertex you want to add to the object.

To delete a vertex from a polygon or line:

- 1 In the Graphics menu, click Edit.
- 2 Select the polygon or line you want to edit.
The vertices for that object are selected.
- 3 Press **D**.
- 4 Click the vertex you want to delete.
The selected vertex is deleted from the object.
- 5 Repeat steps 3 and 4 for each vertex you want to delete on the object.

The Auto Point Command

When you add or delete a vertex on a polygon or line, the same point is added or deleted on all shapes for that object. You can disable this option in the Setup menu. When the Auto Point button is disabled, any point you add or delete on a shape is added/deleted in the current shape key only.

(a) Auto Point button

Editing a Bezier Curve

When you use the Bezier option to draw a polygon, each vertex of the polygon has two tangents. Each tangent ends with a handle.

(a) Tangent (b) Vertex (c) Handle

Use Edit mode to move a tangent handle and adjust the slope of the adjacent side of the polygon. When you move one tangent handle, the tangent's reciprocal handle moves in the opposite direction because handles A and B are joined to keep the joint at the intersection of the two edges smooth.

(a) Edge A (b) Tangent A (c) Handle B (d) Edge B

(a) Edge A (b) Handle B (c) Edge B

To adjust the slope on one side of the vertex only, press B and click the vertex. This breaks the tangent so that you can move its handles independently. To reset the tangent, press B and click the vertex again.

(a) Edge A (b) Handle A (c) Handle B (d) Edge B

Converting Graphics to AutoPaint Strokes

Use the Convert command to convert objects to AutoPaint strokes.

(a) Convert button

You can play the paint strokes using the AutoPaint controls in the Paint menu. See [Using AutoPaint](#) (page 1077).

The following shows how a hexagon is drawn over six frames. One edge is drawn in each frame. After the object is converted to AutoPaint strokes, it is always drawn as an outline regardless of its attributes in the Graphics menu.

To determine how much of an object to draw in each frame, the number of edges in the object is divided by the number of frames in the clip. The polygons are drawn one after the other in the order in which they were drawn in the Graphics menu.

To convert an object to AutoPaint strokes:

- 1 Select the object.
- 2 Click Convert and Confirm.

Animating Graphics

Use the Channel Editor and Shape Animation controls to animate Paint graphics. You can animate the position, display, and shape of a graphic. To display the Channel Editor, click the Animation button and swipe the cursor across the bottom of the screen.

Animation Parameters

The following parameters can be animated for every object:

- Position, rotation, and size
- Brush attributes
- Gradient orientation, transparency, and colour
- Colour (red, green, and blue channels)
- Wireframe width
- Range and Softness of a fill object
- Transparency
- Size, Kerning and Italics for a text object

NOTE In Paint, the commands in the Tools box can be performed on animation curves only. To modify a keyframe by editing the object in the image window, you must use the editing commands in the Graphics menu.

Shape Animation

To animate the shape of an object, you must create keyframes with the Shape Animation controls. Each shape you define becomes a keyframe in the Shape channel of the Channel Editor. The difference between the keyframes is interpolated and the shape animation is created.

The Shape channel is used to identify the number and location of shape keyframes in a clip. Use the shape curve to control the rate at which an object changes to a new shape. The following figure shows the Shape channel for an object that changes from shape 1 in frame 1, to shape 2 in frame 8, and shape 1 in frame 15.

To animate the shape of an object:

- 1 Create an object.

This original shape becomes shape keyframe 1 in the Channel Editor.

- 2 Advance to another frame in the clip.
- 3 Select the object, and change its shape.

To change its shape, you must move, add, or delete a vertex on the object. This new shape is shape keyframe 2 in the Channel Editor.

Shape Interpolation

Use the Shape Interpolation box in the Setup menu to specify the interpolation between shapes in the animation.

(a) Shape Interpolation box

Select:	To:
Shape Linear Interp	Produce sudden transitions between shapes.
Shape Cardinal Interp	Produce smooth transitions between shapes.

NOTE The type of shape interpolation you use is independent of the type of polygon interpolation you use.

Moving between Shape Keyframes

Use Previous and Next to move between shape keyframes in an animation.

To move between keyframes:

- 1 Select the object you want to modify.
- 2 Click Edit and then Shapes.
The Shapes menu appears.

- 3 Click Next to advance to the next shape keyframe.
- 4 Click Previous to go to the previous shape keyframe.

Deleting Keyframes

Use Delete to delete a shape keyframe from the animation.

To delete a shape keyframe:

- 1 Select the object.
- 2 Click Shapes.
The Shapes menu appears.
- 3 Select the keyframe you want to delete.
- 4 Click Delete.
The selected shape is deleted.

Adding Keyframes

Use Add to create a shape keyframe. This can be useful for creating animations that start and end with the same shape.

To add a shape key using Add:

- 1 Select the object you want to animate.
- 2 Go to the frame where you want to add the shape keyframe.
- 3 Click Shapes.
The Shapes menu appears.
- 4 Click Add.
A new keyframe is added to the Shape channel in the Channel Editor.

Gradient Animation

Use the Channel Editor to animate the colours, orientation, and direction of a colour gradient. The Gradient folder includes Start and End folders for the two colours in the gradient. The Start and End folders each contain channels for the X and Y position of the colour, as well as the R, G, B, and alpha values.

Although you can animate the gradient independently, by default, the gradient will follow any transformations of the object.

To animate a gradient:

- 1 Select the object with the gradient you want to animate.
- 2 Click Animation. If necessary, swipe the cursor across the bottom of the screen to display the Channel Editor.
- 3 Click the Geometry and Stroke folders to expand them.
If you selected more than one object, a Stroke folder appears for each selected object. Click the Stroke folder for the object you want to animate.
- 4 Click the Gradient folder to expand it, and click the Start and End folders:
 - The Start folder contains the X and Y channels and a Colour folder for the gradient's colour.
 - The End folder contains the X and Y channels and a Colour folder for the gradient's colour.

- 5 Click to expand each Colour folder.

Use:	To:
x	Move colour origin left or right. This is the same as moving the gradient bar handle.
y	Move colour origin up or down. This is the same as moving the gradient bar handle.
r	Change percentage of red in the colour.
g	Change percentage of green in the colour.
b	Change percentage of blue in the colour.
a	Change percentage of the colour's alpha channel. Use this channel to create a gradient matte or to change the opacity of the colour.

- 6 Change the values for the channels in different frames to create a gradient animation.

Rendering the Animation

To render the animation, click Render in the Graphics menu. Make sure you are at the first frame of the animation since the clip will be processed from the currently displayed frame until the end of the clip.

Saving and Restoring Objects

Use the Store and Recall commands to save and restore objects to the image. Use the Library menu to save or load graphics from the graphics library.

To save or load a graphic:

- 1 In the Paint menu, click Load or Save.
- 2 Select Geometry from the Load or Save option box.

(a) Save option box

- 3 Select a file or type in a name for the graphic.

NOTE If you are using Save and have typed in a name for the file, you must press **Enter** to finish saving the file.

The Store and Recall Commands

To save the selected graphic in the buffer, click Store in the Graphics menu. The current object replaces the graphic saved in the buffer.

The Store command does not save the result image. This means that if you tacked the objects onto the image, they are not saved using the Store command. To restore the geometry to the image, click Recall.

(a) Store button (b) Recall button

TIP Use Store and Recall to add graphics to clips loaded at a later time.

Tacking Down Objects

An object can be selected, deleted, edited, and transformed until it is tacked down on the image. As soon as it is tacked down, the object becomes part of the image and can no longer be manipulated.

There are several ways to tack down an object:

- Select a Tack mode so that an object is either tacked down as soon as it is drawn or as soon as the next object is drawn.
- Tack down selected objects only.
- Tack down all objects simultaneously using the Tack All command.

Tack Modes

The Tack mode is selected with the Tack Mode box in the Rendering Setup menu.

To set the Tack mode:

- 1 In the Paint tool, click Setup.
The Setup menu appears.

(a) Tack Mode box

- 2 In the Rendering area, select an option from the Tack Mode box.

Select:	To:
Vector	Explicitly tack down the objects using the Tack command.
Edit Last	Edit the last object drawn until the next object is added to the image. As soon as the next object is added, the last object is tacked down.
Raster	Tack down an object as soon as it is added to the image.

Tacking Down Selected Objects

When the Tack mode is set to Vector, objects must be explicitly tacked down on the image using the Tack button.

(a) Tack button

To tack down one or more objects:

- 1 Select the objects you want to tack down.
- 2 Click Tack.
All selected objects are tacked down on the image.

To tack down all objects on the image:

- 1 In the Graphics menu, Enable All.
- 2 Click Tack.
All objects are tacked down on the image.

Cutting and Pasting in Paint

Accessing the CutOut Menu

To access the CutOut menu, click the CutOut button in the Paint menu. Some options may be hidden if the colour palette is open. Swipe the cursor across the bar at the bottom of the screen to hide the colour palette.

Creating a Cutout

Creating a cutout is similar to creating a graphic. In the CutOut menu, you use the same controls as you would in the Graphics menu to select, copy, hide, move, rotate, resize, delete, store, recall, push, and tack cutouts.

To create a cutout:

- 1 Click CutOut.
- 2 Click Add.
The CutOut Shadow options appear.

(a) Shadow Type box (b) Blending Mode box

- 3 To limit the area of the cutout with a matte, enable Use in the Matte controls.
- 4 Select an option from the Shadow Type box.

The Shadow Type box determines how the cutout will be pasted onto the result clip. See [Pasting Cutouts](#) (page 1120).

- 5 Click Attributes.
- 6 To create a cutout that spans the entire clip, enable Sequence.
- 7 Click one of the four Cutout commands. See [Using the Cutout Commands](#) (page 1117).

NOTE To use the GeoCut option, select all the objects you want to use in the cutout in the Graphics menu before clicking the GeoCut button.

- 8 Draw the cutout on the image.
- 9 Set the resolution to be used when updating the object.
The object appears at full resolution when it is drawn. See [Setting the Object Resolution and Display](#) (page 1100).
- 10 Set the cutout's position using the transformation box or controls.
- 11 Set the cutout's colour using the Current Colour pot.
- 12 Click Tack to permanently place the object on the result clip.
Once the object is tacked down, it cannot be moved, rotated, deleted, resized, or copied.

Keep Cut On

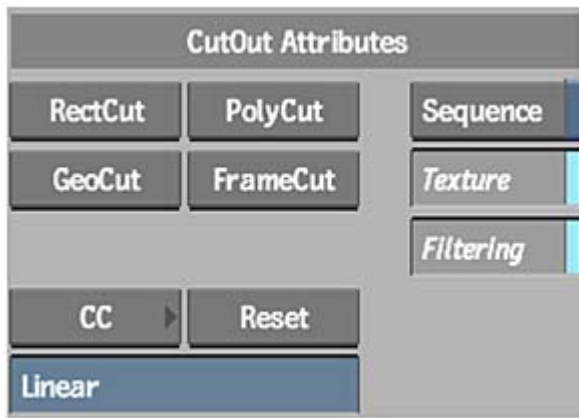

Once you add a cutout to the image, the default setting automatically switches from Cut mode to Edit mode. To prevent the switch to Edit mode, enable Keep Cut On in the Setup menu.

(a) Keep Cut On button

Using the Cutout Commands

Four commands are used to create cutouts: FrameCut, RectCut, PolyCut, and GeoCut. FrameCut, RectCut, and PolyCut create cutouts using shapes you define in the CutOut menu. Geocut creates cutouts using objects you select in the Graphics menu.

The FrameCut Command

Use the FrameCut command to make a cutout of the entire frame.

To create a cutout of an entire frame:

- 1 Click Add in the CutOut menu.
- 2 Click FrameCut.

The entire frame is cut out and pasted onto the image.

The RectCut Command

Use the RectCut command to cut and paste a single rectangular area of the image.

To use the RectCut command:

- 1 Click Add in the CutOut menu.
- 2 Click RectCut.
- 3 Draw a rectangle over the area of the image that you want to cut out.

The image area defined by the rectangle is copied and pasted onto the image.

The PolyCut Command

Use the PolyCut command to cut and paste a single polygonal area of the image.

To use the PolyCut command:

- 1 Click Add in the CutOut menu.
- 2 Click PolyCut.
- 3 Draw a polygon over the area of the image that you want to cut out.

The image area defined by the polygon is copied and pasted onto the image.

The GeoCut Command

Use the GeoCut command to create a cutout with objects you selected in the Graphics menu.

To create a cutout using GeoCut:

- 1 Click Graphics in the Paint menu.
- 2 Create any number of objects.
- 3 Select all the objects you want to use to make the cutout.
- 4 Set the opacity of the object(s) using the Brush Opacity field.
The opacity of the object(s) used in the cutout determines the transparency of the cutout. Use objects with a low opacity value to create an opaque cutout. Use objects with a high opacity value to create a transparent cutout.
- 5 Click CutOut in the Paint menu.
- 6 Click GeoCut.
The image area defined by the selected objects is copied and pasted onto the image.

Displaying Graphics and Cutouts

To display both the cutouts and the graphics objects in the CutOut menu, enable Show Both in the Setup menu. Although the graphics objects appear, they cannot be edited. Enabling Show Both also displays both the graphics objects and the cutouts in the Graphics menu. Although the cutouts appear, they cannot be edited.

(a) Show Both button

Increasing Editing Speed

To streamline cut and paste functionality, use Graphic Regen and Texture Cut/Paste in the Setup menu, and Texture in the CutOut menu.

The Graphic Regen Button

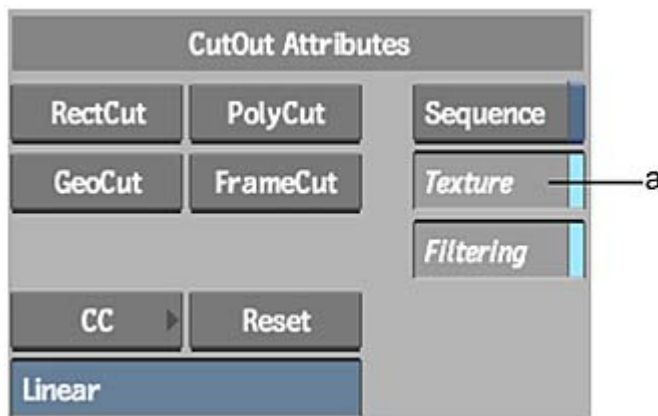

Disable Graphic Regen (regeneration) in the Setup menu to ensure the cutout always appears at the display resolution.

(a) Texture Cut/Paste button (b) Graphic Regen button

Texture Cut/Paste and Texture Button

Enable Texture Cut/Paste in the Setup menu or Texture in the CutOut menu to speed up cut and paste operations. These preferences are designed for platforms that support fast texture mapping.

(a) Texture button in CutOut menu

The Filtering button can be used when Texture is enabled. Use Filtering to avoid image degradation as a result of recursive cutting and pasting. When Filtering is enabled, the image should not degrade.

Pasting Cutouts

Four options in the Shadow Type box are available for pasting a cutout onto the image.

Select:	To:
Emboss	Create an embossed cutout. See The Emboss Option (page 1121).
Extrude	Create cutout extrusions. See The Extrude Option (page 1122).
None	Use the blend functions available for pasting cutouts. See The Blend Options (page 1122).

Select:	To:
Shadow	Add a drop shadow to the cutout. See The Drop Shadow Option (page 1123).

The Emboss Option

The Emboss option makes the cutout appear etched into the image. Shadows and highlights are added to simulate the effect of light shining on a raised object. Three layers are used to produce this effect:

- The top layer is a copy of the cutout in which the luminance values are increased by 50%. The top layer adds the highlights to the cutout.
- The middle layer is the cutout.
- The bottom layer is a copy of the cutout in which the luminance values are decreased by 50%. The bottom layer adds the shadow to the cutout.

Offset Field

Use the Offset field to specify the offset value in pixels for the three layers. The best results are obtained with values of 1 or 2.

(a) Paste Mode box (b) Offset field (c) Direction field

Direction Field

Use the Direction field to specify the angle of the simulated incident light. The values range from 0 to 7 and specify the following angles of incident light.

The Extrude Option

The Extrude option makes the cutout appear to pop out of the image by redrawing the cutout one layer on top of another. Each layer in the stack is offset slightly from the one below so only the edges of the layer are visible.

Editing the Layers

When you create a cutout using the Extrude option, two layers are created to produce the effect. There are vertices at the centre of each layer for manipulating the layer. You can change the depth and direction of the extrusion by moving either layer.

Changing the Colour of the Layers

Enable Use Colour to apply the current colour to the extrusion layers. The cutout image is used for the top layer only. When Use Colour is enabled, use the Brush Opacity field to set the transparency of the extrusion layers.

The Blend Options

The Blend options are similar to the commands in the Processing menu. They use the RGB values of the cutout and those of the result image. Select a blend option from the Blend Mode box.

(a) Blend Mode box

Blend Pastes the cutout onto the result image.

Add Adds the RGB values of the corresponding pixels in the cutout and the result image. Values greater than 255 are clipped.

Subtract Subtracts the RGB values of pixels in the image from those of the cutout. Values less than 0 are clipped.

Black Pastes a black object in the shape of the cutout on the result image.

White Pastes a white object in the shape of the cutout on the result image.

Colour Pastes a coloured object in the shape of the cutout on the result image. The current colour is used for the object.

NAdd Min Compares the brightness values of corresponding pixels in the cutout and the result image, and uses the pixel with the smaller value in the tacked down cutout.

NAdd Max Compares the brightness values of corresponding pixels in the cutout and the result image, and uses the pixel with the greater value in the tacked down cutout.

Multiply Multiplies the RGB values of corresponding pixels in the cutout and the result image. The value is normalized by dividing the result by 255.

The Drop Shadow Option

You can add a drop shadow to a cutout by selecting the Drop option from the Paste Mode box. The drop shadow's colour is taken from the Current Colour pot.

(a) Paste Mode box (b) Scale and Shear fields (c) Softness field (d) Shadow Opacity field

Shadow Opacity field Adjusts the transparency of the drop shadow. Decrease the value to increase the transparency.

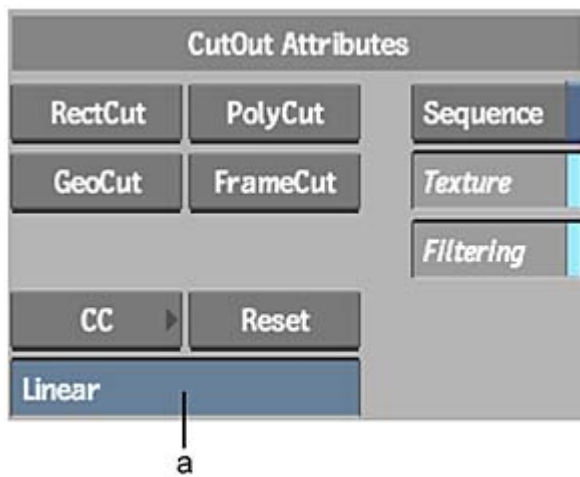

Softness field Adjusts the edge softness of the drop shadow. Increase the value to increase the softness of the shadow.

Scale and Shear fields Shears and scales the drop shadow along the X- or Y-axis. These fields can be used to add lighting perspective to the image.

Colour Correcting Cutouts

Apply colour correction to cutouts using the Colour Correction field and CC in the CutOut menu. Click the Colour Correction field to load a setup directly from the colour correction library. Click CC to load the cutout into the Colour Corrector.

The default colour correction setup is Linear. When you load a different setup, the name of the setup appears in the Colour Correction field. To reset the colour correction setup, click Reset.

(a) Colour Correction field

Animating Cutouts

Use the Channel Editor to animate cutouts. To display the Channel Editor, click Animation and swipe the cursor across the bottom of the screen.

The following parameters can be animated for every cutout:

- Position, rotation, and shearing
- Brush attributes
- Colour (red, green, and blue channels)
- Emboss options
- Shadow options

Loading and Saving Cutouts

Use the Cutout Library to load and save cutouts.

To save or load a cutout:

- 1 In the Paint menu, click Save or Load.
- 2 Select CutOut from the Save or Load option box.
- 3 Select a file or type in a name for the cutout.

NOTE If you are using Save and have typed in a name for the file, you must press **Enter** to finish saving the file.

Preserving Paint Cutouts

Paint cutouts are saved in the Lost+_Found library on the Paint reel rather than in memory in order to conserve memory. During a session, you must not delete the Paint reel or its cutouts because they will be used when you return to Paint. However, you can safely delete the cutouts once you exit and restart the application because the Paint reel in the Lost+_Found library is not searched in subsequent sessions.

About Paint Setups

A setup is a file that contains a record of all changes you make to a clip in a particular tool. This record includes references to clips used. Setups let you save your work separately from the clips, so you can load and work on them any time, or apply the setup to other clips. Both the procedure and the interface involved in saving Paint setups and preferences differ slightly from those involved in saving setups in most other tools

NOTE Custom brushes, brush sets, colour pots, and palette setups that you create in Paint are stored in your user directory. These resources are loaded when you specify a user in the Project Management menu.

Saving Setups

You can save pictures, preferences, mattes, palettes, brush groups, brushes, and stamps. You can also save cutouts, cut sequences, recorded strokes in AutoPaint, as well as geometry created in the Graphics menu.

To save a setup:

- 1 In the Paint menu, click Save.
- 2 Select the item you want to save from the option box.

Select:	To:
Picture	Save an image created in Paint.
Matte	Save the matte.
Palette	Save the current colour palette.
BrushSet	Save the current set of brushes.
Brush	Save the brush that is currently active.
Stamp	Save the Stamp currently in the Stamp window.
Geometry	Save the geometry created in the Graphics menu. This also includes all cutouts.
CutOut	Save the cutouts created in the CutOut menu.
CutSequence	Save the cutout sequence created in the CutOut menu.
AutoPaint	Save the last series of recorded strokes.
Preferences	Save current preferences.
Defaults	Save current default values.

The file browser appears, listing any existing setups for that item.

- 3 Type the name of the setup in the Save field.

- 4 Press Save (Enter) to save the setup.

Cropping a Setup

Use the crop box to limit the area of the picture, matte, cutout, or paint graphics to be saved in the setups directory.

To save a cropped matte, image, or cutout:

- 1 In the Paint menu, click Save.

- 2 Click Picture, Matte, or CutOut to specify the element from the image you want to save.
- 3 Draw the crop box on the canvas by pressing and dragging the cursor diagonally across the screen. Alternatively, use the left, right, top, and bottom Crop fields to set the boundaries of the crop box.

NOTE Click Reset to reset the crop box values.

- 4 Click Save.
- 5 Select the item you are saving from the option box and name the setup in the keyboard display. If you want to overwrite an existing setup, select the filename from the file browser.
- 6 Press Save (Enter) to save the setup.

Loading Setups

Use the Load button to load any type of Paint setup.

To load a setup:

- 1 Click Load.
The Load Paint menu appears.
- 2 Select the type of setup you want to load from the Load option box.
A list of existing setups appears in the file browser.
- 3 Click the title or proxy of the setup you want to load.

Deleting Setups

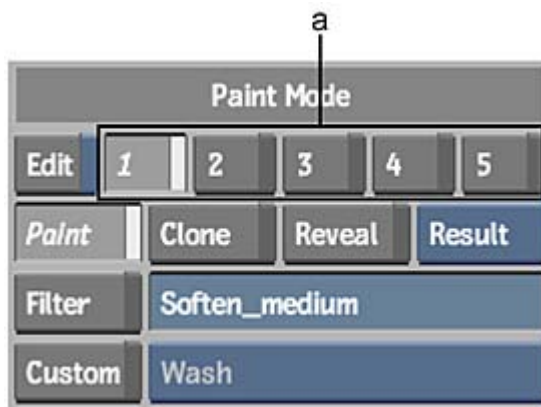

Use the Delete button to remove setups from the setup directory.

To delete a setup:

- 1 Click Load.
The Load Paint menu appears.
- 2 Enable Delete.
- 3 Select the type of item you want to remove from the Load option box.
A list of existing setups appears in the file browser.
- 4 Click the title or proxy of the setup you want to remove and click Confirm.

Creating and Saving Brush Setups

Within a given brush set, there are five individual brushes. You can create and save five brush setups using the buttons numbered 1 to 5 in the Paint menu. Each brush setup saves the brush type, attribute values and modes, Special Effects medium, filter, fill parameters, and colour correction setups.

(a) Brush Setup buttons

To create and save a brush setup:

- 1 In the Paint menu, click one of the five Brush Setup buttons.
- 2 Enable Edit next to the Brush Setup buttons.
- 3 Set the brush attributes. See [Brush Attributes](#) (page 1054).
- 4 Disable Edit to save the changes to the selected brush setup.

NOTE To save a set of five brush setups, use BrushSet in the Save menu.

Copying Brush Setups

You can copy brush setups using the setup buttons.

To copy brush setups:

- 1 Select a setup using the Brush Setup buttons and enable Edit.
- 2 Press **Ctrl** and click another Brush Setup button to copy the setup.
- 3 Disable Edit to save the setup.

Creating a Custom Brush

With Paint, you can create your own custom brushes for specialized applications. You can modify an existing brush, draw your own brush shape, or grab a part of the image to use as a custom brush.

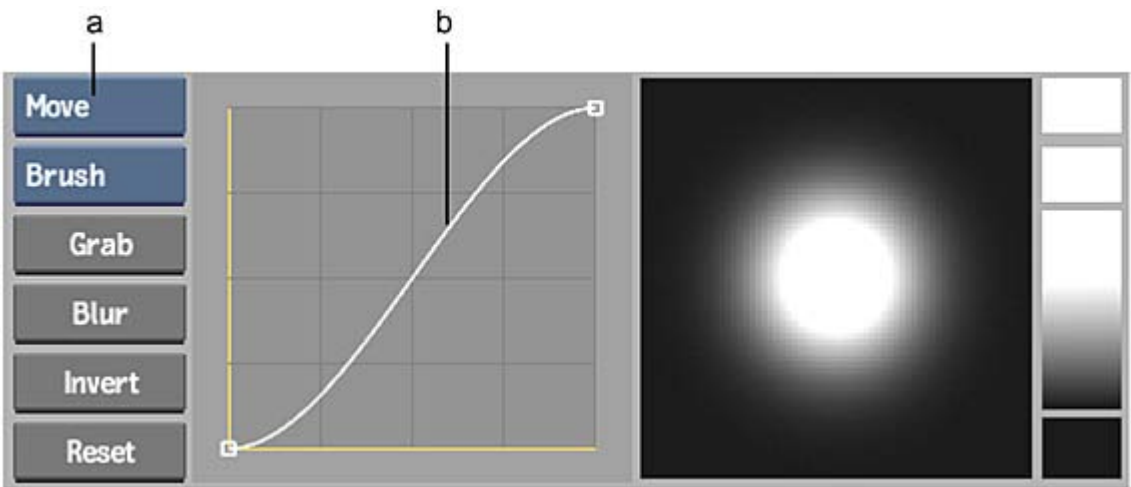

Use the Custom Brush menu to create your own brush. To display the Custom Brush menu, double-click one of the brush icons in the Brushes window. An enlarged view of the selected brush appears in the editing panel.

There are three ways to create a custom brush:

- Using the brush profile
- Drawing a brush shape in the editing panel
- Grabbing an area of the image

Changing the Brush Profile

The brush profile describes the size and edge softness of the custom brush. The default S-curve defines a circular airbrush. You can change the curve by manipulating the two points that define the curve, or you can add points to the curve.

(a) Profile box (b) Brush profile

The profile does not affect the brush in the editing panel until you modify the curve or click the Update button.

Changing the Curve

By default, there are two points that define the brush profile. For the following table and examples, these points will be named A and B as shown in the preceding illustration. To move the points that define the curve, select the Move option from the Profile box.

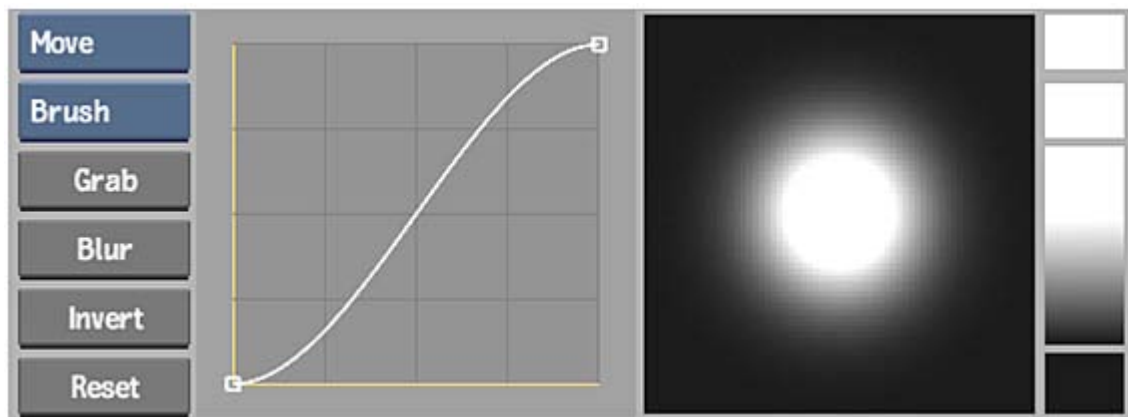

Move:	To:
Point A up	Lighten the brush.
Point B down	Darken the brush.

Move:	To:
Point A right	Harden the outer edge of the brush.
Point B left	Soften the middle of the brush.

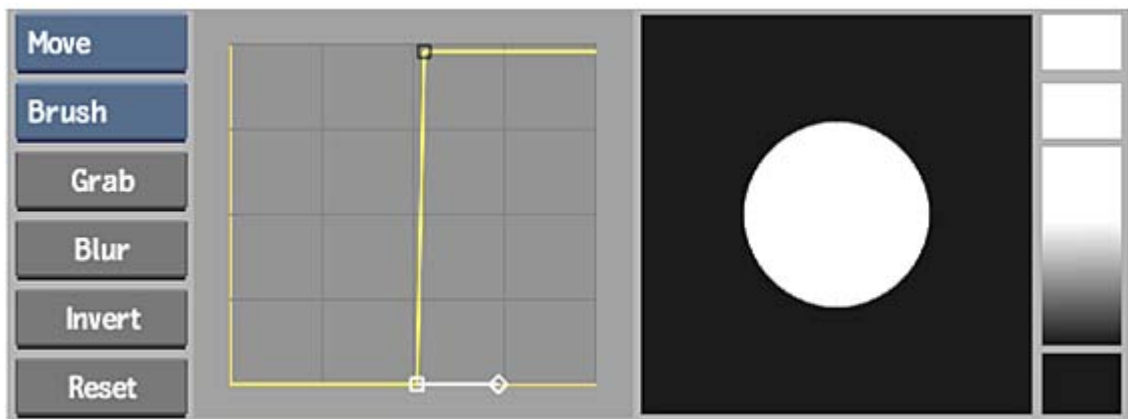

To move the points only on the X-axis, select the Xscale option from the Profile box. To move the points only on the Y-axis, select the Yscale option. To break a point and manipulate its tangent, select the Break option and click on a point.

Adding Points to the Curve

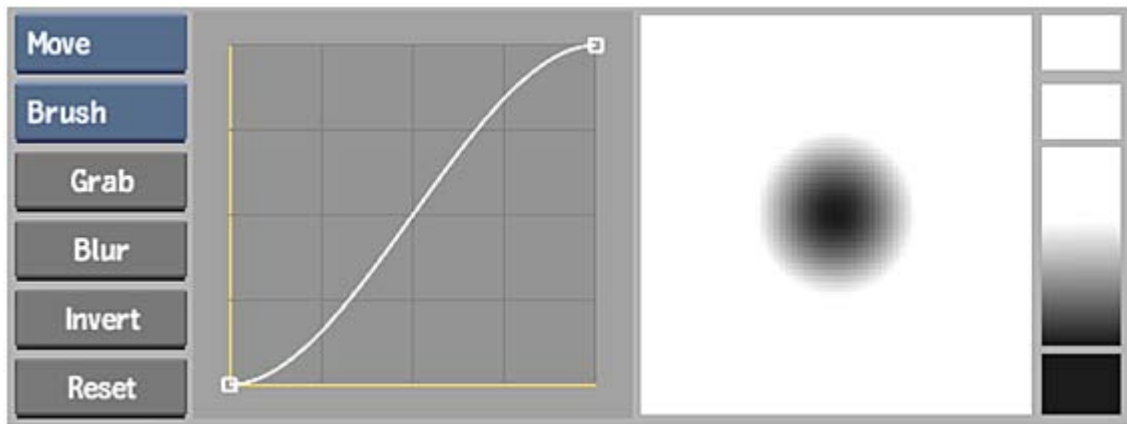

To add points to the curve, select the Add option from the Profile box and click on the curve. To delete points from the curve, select the Delete option and click on one of the points on the curve.

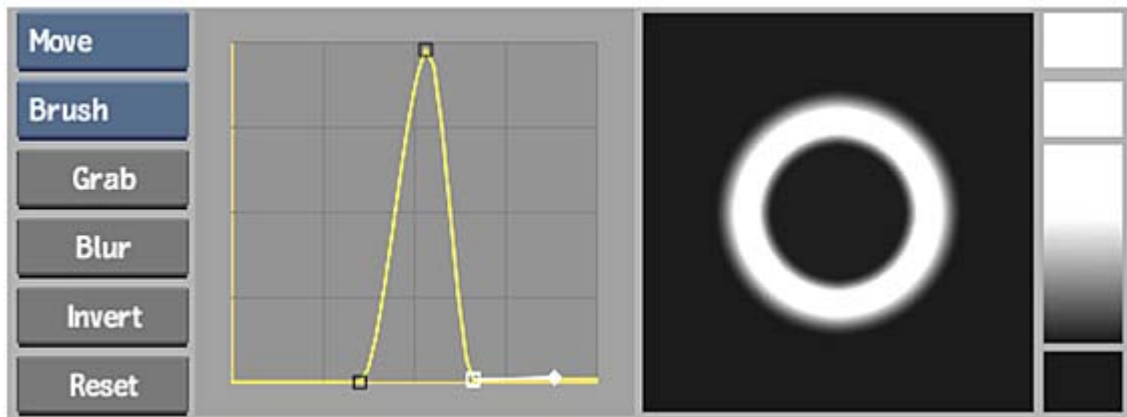

Default S-shaped curve

Hard edge curve

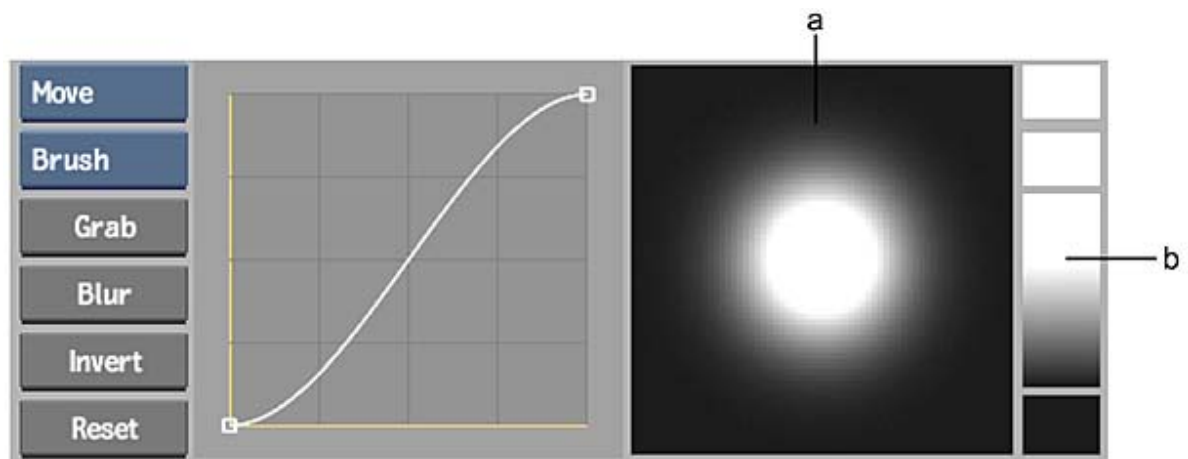

Invert brush curve

Ring-shaped brush curve

Drawing and Updating a Brush Shape

You can draw a new brush shape or update the current brush shape in the editing panel. The new shape is drawn using the brush that you selected to open the Custom Brush menu.

(a) Editing panel (b) Gradient bar

NOTE You cannot use the Undo command when drawing or updating a custom brush.

To draw a brush shape:

- 1 To create a new shape, erase the existing brush shape by painting over the editing panel.
- 2 Draw the new shape.
- 3 To invert the brush shape, click Invert.
- 4 To blur the brush shape, click Blur. Each time you click Blur, a 3 x 3 filter is applied to the brush image.

Selecting an Area of the Image

You can select an area of the image to use as the custom brush. The brush created from the selected area will be a square monochrome brush.

To grab an area of the image:

- 1 Click Grab in the Custom Brush menu.
- 2 Click on the image and drag across the screen to define the selection box.
To select a square area, press **P** as you sweep out the selection box.
The selected area appears as a monochrome image in the editing panel. If the area that you select is not square, then the selected area is resized to fit in the editing panel.

Updating an Existing Brush

To update an existing brush, click the Update button. The changes are applied to the brush icon that you selected to open the Custom Brush menu.

Creating a New Brush

To create a new brush, click the New button. This creates an icon for the new brush shape and adds it to the Brushes window.

Saving the Custom Brush

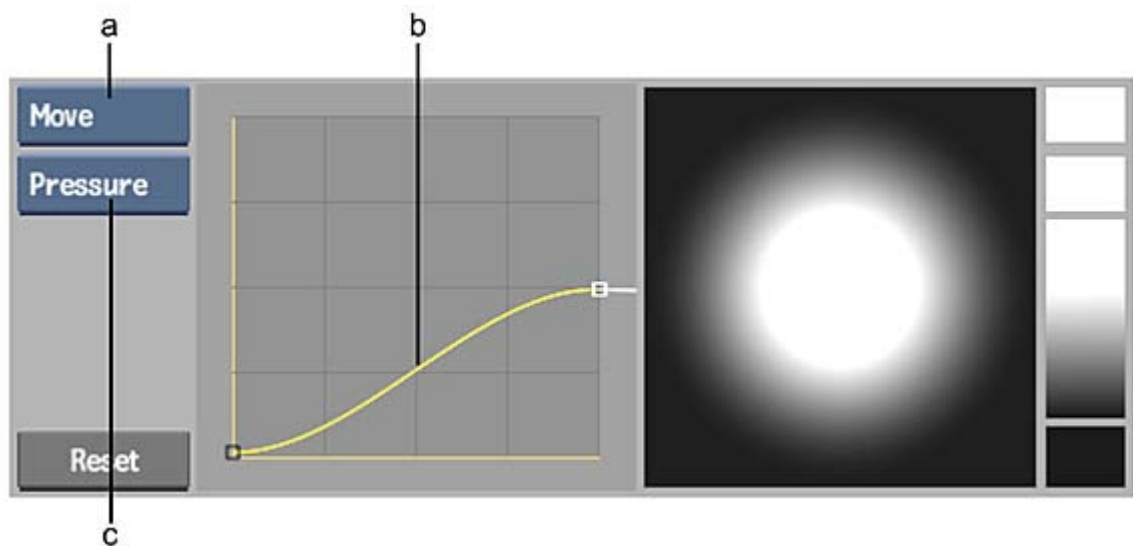

Custom brushes are not saved automatically when you exit Paint. To save the updated or new brush for use in another work session, click the Save button. This opens the Brush setups directory. Use the keyboard to enter the name of the brush, and click the Enter button. The new brush is saved in the Brush setups directory.

Loading a Custom Brush

Click the Load button to load a custom brush from the Brush setups directory.

Customizing the Pressure Profile

Adjust the pressure profile to change the amount of pressure needed to paint with a given brush. The slope of the curve indicates how quickly paint is applied as you press on the tablet. If the curve is steep, a small amount of pressure applies full paint to the canvas. If the curve is soft and rounded, you must press harder and longer to apply full paint.

(a) Profile box (b) Pressure curve (c) Brush/Pressure box

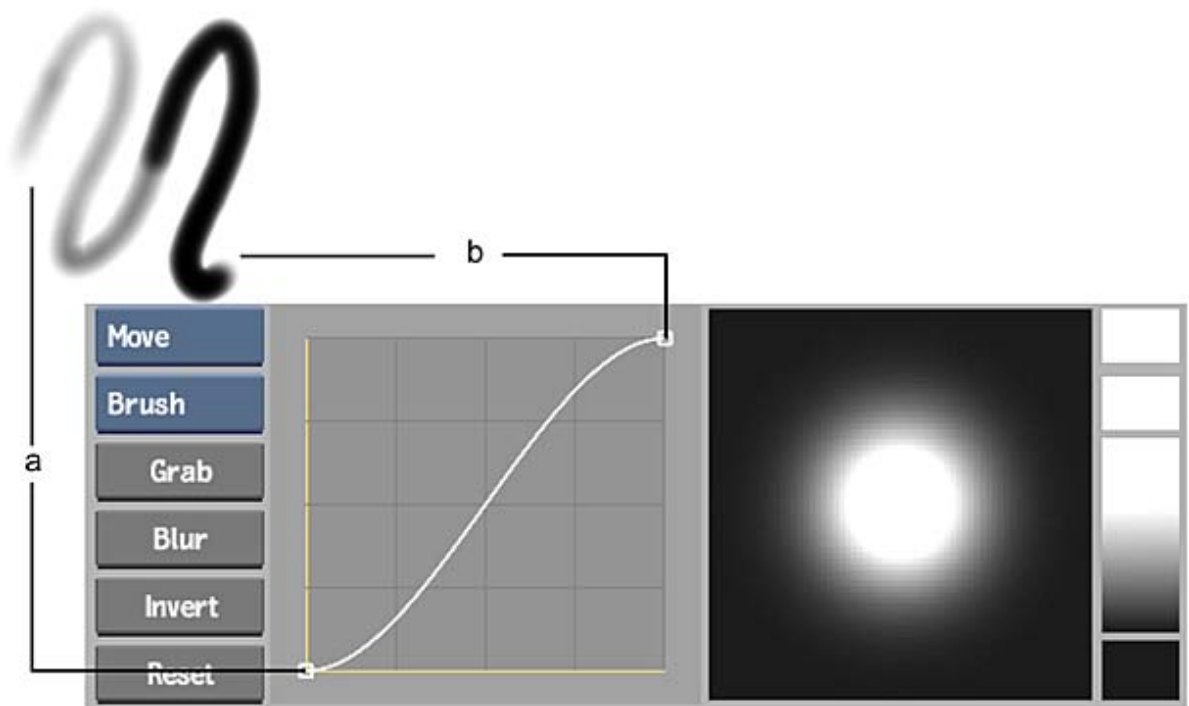

You use the options in the Profile box to change and add points to the pressure curve. Click Load to load a Pressure profile. Click Save to save a custom pressure profile.

To edit the pressure profile:

- 1 Toggle the Brush/Pressure box to Pressure.
- 2 Double-click a brush icon in the Brushes window to display the Custom Brush menu.
- 3 Click the Brush/Pressure box to display the pressure profile.
- 4 Select Move from the Tools box.
- 5 Press the left point (A) and drag it to its new position.
This changes the amount of paint the brush applies when you press lightly on the tablet.
- 6 Press the right point (B) and drag it to its new position.
This changes the amount of paint the brush applies when you press down firmly on the tablet.
- 7 Click Update to update the pressure profile for the brush.
The pressure settings will be used when you paint with the brush during the current work session.

Default Pressure Profile

Pressure is mapped along the horizontal axis (X-axis) of the curve, and the amount of paint applied is mapped along the vertical axis (Y-axis). If you are using the default S-shaped curve and you press lightly on the pen, very little paint is applied. As you press harder, more paint is applied.
