(a) Point A: Low paint at low pressure (b) Point B: Full paint at full pressure

Maximum Pressure Curve

If you move point A in the previous figure to the maximum position on the Y-axis, the curve results in full paint applied all the time, no matter how much or how little pressure you use.

Soft Airbrush

If you move Point B in the previous figure to a point midway on the vertical axis, the curve gives you a soft airbrush, even at full pressure.

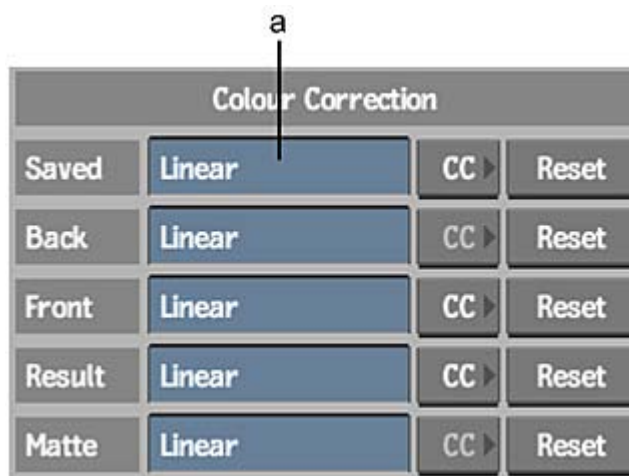

(a) Point A: Low paint at low pressure (b) Point B: Soft paint at full pressure

Using Colour Correction Setups

Use the Colour Correction Setup menu to apply colour correction setups to the clip loaded into Paint. You can bring the clip into the Colour Corrector or you can load a setup from the Colour Correction setups directory into Paint.

To load a clip into the Colour Corrector:

- 1 In the Paint menu, click Setup.
The Colour Correction menu appears.

(a) Setup Name field

- 2 Click CC next to the clip you want to load into the Colour Corrector.

The Colour Corrector appears.

- 3 Use the Colour Corrector as described in [About Colour Correcting](#) (page 947).
- 4 Save the setup to the Colour Correction setups directory.
- 5 Click Exit.

The name of the Colour Correction setup appears in the Setup Name field beside the clip label for the selected clip.

To load a setup directly from the Colour Correction setups directory:

- 1 Click the Setup Name field for the clip you want to colour correct.
The file browser appears, displaying the contents of the Colour Correction setups directory.
- 2 Select the Colour Correction setup you want to use.

To reset the colour correction for a clip:

- 1 Click Reset beside the clip you want to reset.
- 2 Click Confirm.

Text and Titling

22

Text is comprised of layers, paragraphs, and characters. You can make text spin, dance, and change colour over time. You can also create effects such as a text roll of credits, text crawls, bumpers, and text that moves on a motion path. You can use logo images in a text roll so that the logo of a sponsor appears in the credits list.

You use the Text Tool to add text and text effects to a clip. Once text effects are applied to a clip, you can then use the clip in Action or Batch or Batch FX depending on the final effect you want to achieve. Use Action to create 3D text deformation effects, including sliding, magnifying, and oscillating effects. For example, to create an effect of text rolling on a cylinder in a composite, you first render a text roll in Text and then, in Action, project it as a texture onto a cylinder. See [Diffuse Mapping](#) (page 628).

Text Workflow

The following table shows the recommended workflow for creating text in the Text tool.

Step:	Refer to:
1. Determine whether the text will appear over a clip, a black background, or a coloured frame.	Accessing the Text Tool from Tools (page 1138).
2. Set text rendering options.	Setup and Rendering Options (page 1140).
3. Determine whether you want to create a text roll, a text crawl, or text on a path or standard layer.	Creating Text Rolls and Text Crawls (page 1154).
4. Create a layer.	Adding Text to Clips (page 1144).
5. Set the position, size, and offset of the layer.	Modifying Layer and Character Properties (page 1148).
6. Enter text or load an existing text file.	Entering Text (page 1145) and Loading Text Files (page 1142).
7. Set text attributes.	Creating Text Effects (page 1148).
8. Preview the result and process the final clip.	Setup and Rendering Options (page 1140).

Accessing the Text Tool

The Text Tool can be accessed from the following locations:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.

Accessing the Text Tool from the Timeline

To access the Text tool from the timeline:

- 1 Select the Timeline tab.
- 2 Do one of the following:
 - Click the FX button.
 - Right-click on a segment in the timeline and choose Add Effect.

The Effects ribbon appears.

NOTE Effects that are enabled have already been added to the current Timeline FX pipeline.

- 3 Enable TX (Text).
- 4 You can adjust the effect's settings using the quick menu underneath the Timeline FX pipeline. Click the Editor button if you want to enter the full editor of the effect.

Accessing the Text Tool from Tools

When accessing the Text Tool, you first select whether to add text to a source clip, a coloured frame, or a black background. The first time you open the Text Tool, the frame contains a clip image, but no text. The next time you open it, the text and settings from the previous Text session appear.

To access the Text Tool from Tools:

- 1 Select **Tools ► Composite ► Text**.

If this is the first time accessing the Text Tool, the cursor changes to Pick Back.

To change to None, from the Input Mode box, select None.

NOTE You can also **Alt**-click the Text button to enable the Text button and automatically set the Input Mode box to None.

- 2 Do one of the following:
 - If you selected None, choose a resolution, width, height, pixel aspect ratio, bit depth, scan mode, and frame depth to apply to the background in the Text tool.

- If you selected Back, select the clip to which you want to add text.

TIP If you want to change the Input mode to None once in the Text Tool, you can do so from the Text Setup menu. See [Setup and Rendering Options](#) (page 1140).

The cursor changes to Render Here.

- 3 Click on any free (or a grey) area on the workspace.
You are now in Text.
- 4 If text from a previous Text session appears, click Reset All.
The Text Tool is cleared and settings are reset to their default settings.
- 5 To delete any layers from a previous session, click Delete All.

Accessing the Text Tool from Batch

To access the Text Tool from Batch:

- 1 Select Batch.
- 2 In the Batch node bin, double-click the Text node or drag the node to the Batch schematic.
Make sure you connect to other nodes or clips in the process tree.
- 3 Click the Text node.
- 4 Click the Edit button.
The Text node editor appears.

Accessing the Text Tool through Batch FX

To access Text through Batch FX:

- 1 Select Timeline.
- 2 Select the segment.
- 3 Click the FX button.
- 4 Click the Create Batch FX button.
- 5 Drag a Text node into the schematic.
The Text node is now in the schematic.
- 6 Double-click the Text node.
- 7 Click the Edit button.

You are in the Text node editor.

Setup and Rendering Options

Before rendering a text clip and rendering text effects, you must set crop settings for the text layer, blur settings, text animation, softness, and whether or not you want to use prerendering. The prerendering feature accelerates the rendering process for a text layer.

Set text rendering options in the Text Setup menu. To access the Setup menu, click Setup. The Setup controls are described as follows.

Software anti-aliasing values can range from 1 to 64. A higher value increases the sampling rate, but also increases processing time. An anti-aliasing of 1 means no anti-aliasing is performed and the result is a hard edge.

TIP A higher anti-aliasing value is usually needed with outlined text.

Softness box Defines the softness of the anti-aliasing samples.

Blur box Sets Gaussian Blur or Box Blur. Gaussian Blur uses subpixel resolution and creates a subtle effect with the Blur Shadow attribute. Gaussian has rounded, smoother edges and is better for animation; however, processing time is increased.

Box Blur has rectangular, rougher edges, but is more economical with rendering time, especially if you are working on a rough draft.

Rendering Text Clips

You can render clips in progressive or interlaced mode. Interlaced rendering produces a better result, especially if you use keyframes that are far apart, but it takes longer to render. You should preview the quality of the image and the text before you process the final clip.

To render a clip with text:

- 1 From the Rendering box, select Interlaced, Progressive, or Auto (to render using the mode of the back clip).

- 2 From the Render Mode box, select which clip gets processed.

Select:	To:
RGB	Render only the text on the back layer.
Matte	Render only the matte of the text. The text fill transparency attribute is transferred to the matte. By generating a matte, you can easily composite the text onto another clip.
Both	Render the text on the back layer and the matte of the text. The fill transparency is removed from the text and transferred to the matte.

- 3 Click Setup.
- 4 From the Setup menu Rendering section, select the sampling level from the Auto-Softness box.
- 5 Set other options as required.
- 6 Position the clip at the first frame or the specific frame where you want to start processing.
- 7 Click Preview.

TIP You can zoom (Ctrl+spacebar) or pan (Ctrl+Shift+spacebar) the image window while in Preview mode. To disable Preview, make a modification to the text or processing options, or click anywhere in the image window.

- 8 Make modifications to the text and rendering options and preview until you are satisfied with the result.
- 9 When you are ready to process the text clip, click Render.
The clip is processed from the currently displayed frame until the end of the clip.

Rendering Considerations

Rendering is contingent upon PreRender, Blur, and Animation settings. Depending on which options you choose, you can increase the rendering speed:

- When more than one non-static layer has blur shadows, Global Blur is faster, although all shadows are blurred with the same unique colour and appear under all other layers.
- When there is a combination of animated and non-animated layers, speed depends on the blur shadows. If animated text has blurred shadows, Global Blur is faster. If you want a static blurred shadow, and a non-blurred animated layer, Layer Blur is faster.
- If you have static layers only (no animation), speed depends on the number of layers and whether PreRender can be used. Global Blur is faster since it uses PreRender. The processing speed of Layer Blur is the same with one or two layers. However, it becomes progressively slower with a higher number of layers and if the layers use blur shadows.

Saving and Loading Files

You can save, load, and import text files, text setups, and images for specific use with the Text tool. You can save text, text effects, text preferences, layers and new default text settings.

You can load text files from third-party word processing packages, existing Text tool setups, and logos. Loading existing text files is particularly convenient if you are creating a long text roll of credits as it saves time that you would otherwise spend typing and spell checking.

Saving Text Files

When saving files, you can save text setups, preferences, and default settings.

To save a file:

- 1 Click Save.
- 2 In the Save menu, select an option from the Save box.

Select:	To:
Defaults	Override the default menu options in the Setup menu and replace them with your specifications.
Preferences	Save Setup menu specifications only and omit text and text attributes.
Selected Path	Save any selected text paths.
Selected Logos	Save any selected logos.
Selected Layers	Save selected layers, their text, text attributes and Setup menu options.
Text	Save text files with text attributes and Setup menu options.

- 3 Navigate and choose the directory where you want to save the file.
- 4 Type a name for the file and press `Enter` or click the Save button.
The file is saved and you return to the Text menu.

Loading Text Files

You can load text files, preferences, and ASCII files. You can also reset the Text menu settings with its factory defaults.

To load a file:

- 1 Click Load.
- 2 In the Load menu, select an option from the Load box.

Select:	To load:
Preferences	Setup menu options that you have saved.
Path	Previously saved text path setups. Setups between text paths and garbage masks are interchangeable. Therefore, you can also load a garbage mask shape as a path. NOTE Preset paths are available in the <i>user/discreet/<product home>/path/default</i> directory.
Logo	Previously saved logos.
Text File	Text files. When you select Text File, you can select the encoding of the loaded file. This applies the correct conversion from the selected file's encoding to the application's internal encoding. For example, select ISO8859-1 to import Latin-1 ASCII files, or UCS-2 to import 2-byte Unicode encoded text files. The encoding options reflect the character encodings available with your system. The load mechanism supports the same encodings as the iconv utility. Optional iconv converters are available by installing national language support options.
Multiple Text Setup	Several layers or text files at a time with preferences. Text tool preferences that were saved with the selected file are loaded as well.
Text Setup	A layer or text file created in the Text tool. Text tool preferences that were saved with the selected file are loaded as well.
Factory Defaults	The original Text tool settings that were delivered with Flame Premium.

- 3 Choose a directory in either Proxies or Titles mode.
- 4 Select the file that you want to load in the file browser. If you selected Multiple Text Setup, **Ctrl**-click the files you want to load.

NOTE If you do not select Multiple Text Setup and you use the **Ctrl** key to load multiple text files, only the last selected file is loaded.
- 5 If you are loading a text file or text setup, you can click anywhere in the user interface to abort the load before it is completed.
- 6 To discard unwanted files, enable Remove.
- 7 If necessary, click Exit Load Text to exit the file browser.

Adding Text to Clips

You add text to a clip by first creating a layer for entering the text, setting the layer attributes, and then typing the text. You can create several layers of text that overlap each other.

Creating a Layer

Text is contained in a layer called a text layer. When you create a text layer, a coloured border called the *crop border* appears in the image window indicating the region the text will occupy.

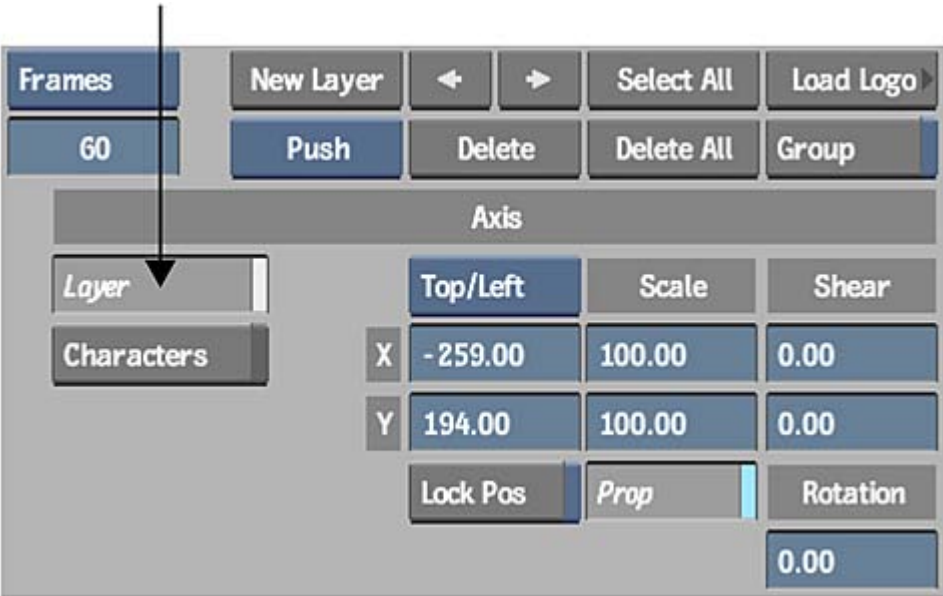

To create a layer:

- 1 Click New Layer. If this is the first layer you are creating, you can click directly in the image window.

The text layer is positioned in the upper-left corner of the safe title area by default. The text in the layer is left justified, while the width is equal to the safe title overlay. You can modify the safe title overlay using the Grid and Guide controls. You can also modify the boundary colour. See [Rendering Text Clips](#) (page 1140).

- 2 Click Axis to make sure you are in the Axis menu.
- 3 To set the text layer dimensions, enable Layer.

Each layer has its own parent axis for translating, rotating, resizing, and shearing. The axis for the layer can be in the upper-left or centre of the layer. See [Creating Text Effects](#) (page 1148).

Entering Text

The text you type may be as short as one letter or word or as long as several paragraphs. If the text is long or exists in a word processor, you can load the text file into the current layer.

You enter and edit characters much like in a word processor. You type characters using the keyboard and many known text editing conventions, such as `Shift+arrow` keys to select text lines. You can also click once to insert the cursor and select the adjacent character, double-click to select the whole word, and triple-click to select the entire line. Quadruple-click to select all characters on the layer and use the middle mouse button to paste selected text.

Use either the workstation or on-screen keyboard to enter characters in a layer. You can also paste the current text selection (from a shell or any other application) into any keyboard input field by pressing the middle mouse button or by using the pen button.

You can also input Asian characters using their corresponding ASCII codes with the numeric keypad.

To enter text in a layer:

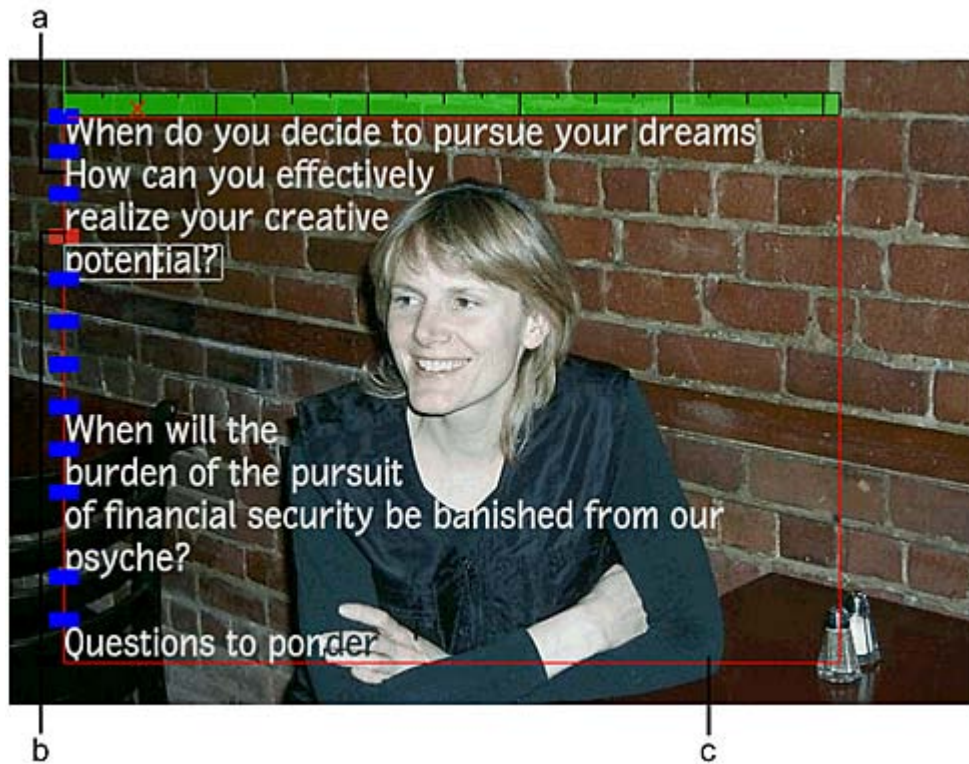

- 1 From the Text Mode box, select Edit.

TIP Use Edit mode to type text strings, select text, edit text in layers, and modify text attributes. Press `Esc` to switch between Edit and Move modes. The message bar displays the current mode.

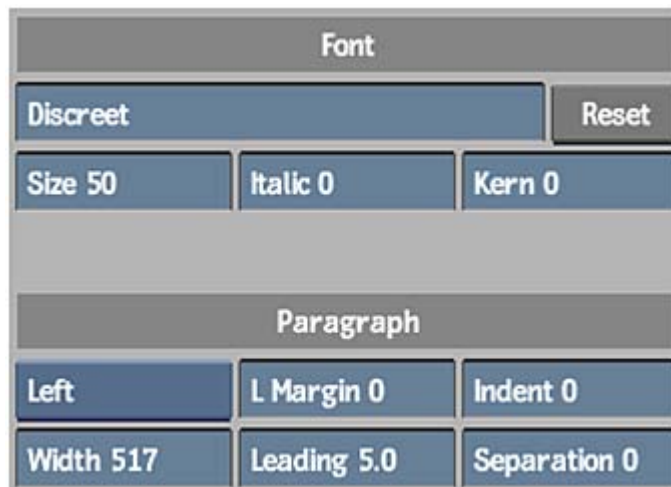

- 2 In the image window, create a new layer by doing one of the following:
 - Click New Layer.
 - Press `Alt+N`.
 - Click directly in the image window (if this is the first layer you are creating).
- 3 To begin a new paragraph within the layer, press `Enter`.

Notice that each paragraph has its own coloured boundary and a paragraph tag that is a coloured rectangle in the upper-left corner of the paragraph. In Edit mode, a selected paragraph's boundary is white.

(a) Blue indicates paragraphs in text layer (b) Red indicates currently selected paragraph, which has a paragraph boundary (c) Layer boundary is shown in red

- 4 In the Paragraph and Font menus, set properties.

Using the Text Keyboard

When you use the on-screen keyboard, consider the following:

- Special characters use the ISOLatin1 encoding vector. You specify the encoding vector in the *init.cfg* configuration file using the FontMapping keyword.
- The extended keyboard uses the Standard encoding vector.

- Asian character sets may not display all characters on the on-screen and extended keyboards. Use the numeric keypad or load an ASCII file that contains unavailable characters for the selected font. See [Loading Text Files](#) (page 1142).

To use the Text keyboard:

- 1 In the Text menu, click Keyboard.
- 2 On the on-screen keyboard that appears, enable Up ASCII to display extended characters contained in the selected font set.

NOTE Enabling Up ASCII also affects your workstation keyboard, so make sure you disable the button again before exiting the Text menu.

- 3 If the selected font has special symbol characters, enable Symbols to see them.
- 4 Type the characters in the text layer.
The keyboard characters appear in the current font.

Word Processing Keyboard Shortcuts

Typical word processing tasks include text selection, cutting, copying, and pasting. The Text tool includes several character manipulation keyboard shortcuts for these tasks.

Press:	To:
Alt+A	Select all characters in the selected text layer.
Alt+P	Select all characters in the selected paragraph within a layer.
Alt+Shift+A	Select all characters in all layers. This operation is the same as using the Select All Layers button.
Shift+up arrow	Extend the selection one line up.
Shift+down arrow	Extend the selection one line down.
Shift+left arrow	Extend the selection one character to the left.

Press:	To:
Shift+right arrow	Extend the selection one character to the right.
Shift+Home	Extend the selection to the beginning of the current line.
Shift+End	Extend the selection to the end of the current line.
Ctrl+Shift+PgUp	Extend the character selection to the beginning of the text layer.
Ctrl+Shift+PgDn	Extend the character selection to the end of the text layer.

Creating Text Effects

Use the Attributes controls to change the appearance of individual characters, paragraphs, and layers. You set similar properties for both layers and characters. You can also load a logo in a paragraph and then format it using the Attributes menu. See [Loading Logos](#) (page 1152). If you create text formats that you plan to reuse, save them using the Styles menu. See [Defining Styles](#) (page 1163).

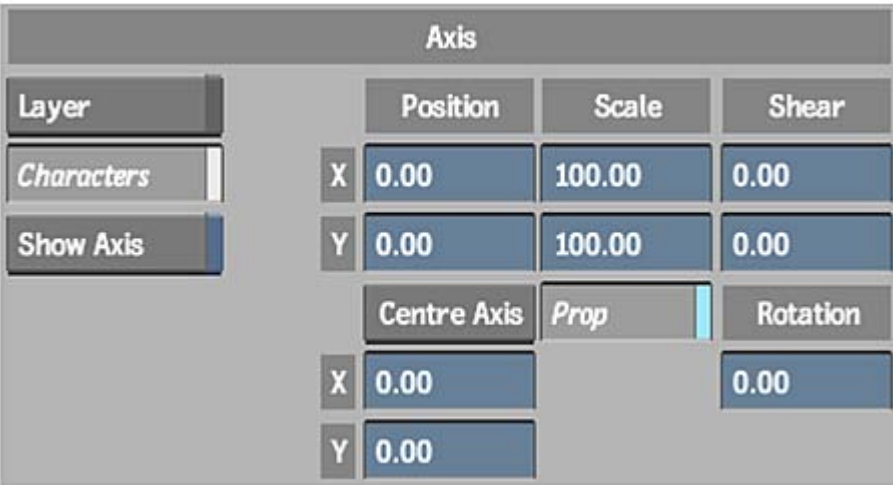

These text attributes have a cumulative effect on the selected characters. For example, if you enable the Fill and Outline buttons, the text appears as solid characters with a coloured outline.

Modifying Layer and Character Properties

Use the Layer controls in the Axis menu to rotate, translate, scale, or shear a selected layer and to apply an effect uniformly to all characters.

Use the Character controls in the Axis menu to view and position the axis of each character. You can use the position, rotation, scale, and shear settings for each character in a layer to create an effect of scrambled letters.

To edit text characters, you must be in Move or Edit mode and some text must be selected. The Layer and Character controls are described as follows.

Layer Order box (in the Layer Attributes section) Moves a layer in front of or behind another layer.

Select:	To move the layer:
Push	One position down in the stack behind another layer.
Pop	One position up in the stack in front of another layer.
Bottom	To the bottom of the stack behind all other layers.

Select:	To move the layer:
Top	To the top of the stack in front of all other layers.

Aligning Layers

Use Align Sel mode to align multiple layers and specify the direction for the alignment.

To align text layers:

- 1 In the image window, select two or more layers to be aligned. To select multiple layers, **Ctrl**-click the layers (or click the pen button).
- 2 In the Text Mode box, select Align Sel.
- 3 On the numeric keypad, press the number that corresponds with the direction in which you want to align the selected layers.

Press:	To:
4	Align left.
6	Align right.
8	Align to the top.
2	Align to the bottom.
5	Centre align.

The text mode returns to Move when the Align Sel operation is done.

Adjusting Text Leading

Use Leading mode to adjust the spacing between lines of text in a paragraph. The selected lines are adjusted in proportion to the leading values already specified. Use this mode to adjust the leading among paragraphs with various leading values.

Rekerning Text

Kerning refers to the space between characters that you can either increase or decrease. Use Rekern mode to change the kerning of all selected characters in relative proportion to the current kerning values.

Use Rekern to adjust the kerning among paragraphs with various kerning values.

To rekern text:

- 1 Select the string of characters you want to rekern.
- 2 In the Text Mode box, select Rekern.
In the Paragraph menu, the Kern field changes to the Rekern field.
- 3 Enter a new value in the Rekern field or use the up and down arrow keys to rekern the text in single increments. Press **Shift**+up arrow or **Shift**+down arrow to rekern in increments of 10 pixels.

Resizing Text

Use Resize mode to change the font size of all the characters in a selection in relative proportion to the current font sizes. Use this mode if you have several font sizes represented in a selection.

The Size field allows you to apply an absolute font size value to selected text.

To resize text:

- 1 Select the string of characters you want to resize.
- 2 In the Text Mode box, select Resize.
The Size field you used to specify the original size of the text changes to the Resize field.
- 3 Enter a new value in the Resize field or use the up and down arrow keys to resize the text in single increments. Press Shift+up arrow or Shift+down arrow to resize in increments of 10.

Offsetting Text Layers

Use Y Offset mode to shift selected layers along the vertical axis—the Y-axis. Use the up and down arrow keys to offset the selection.

Using Safe Title

Use Safe Title mode to align selected text within the safe title overlay. Use the numeric keypad (0-9) to specify the direction of alignment. Safe title is used to define the boundary for positioning text and how it appears in a rendered clip. By default, new layers appear in the upper-left corner of the safe title area.

To align to the safe title:

- 1 Select the layer you want to align with the safe title.
- 2 In the Text Mode box, select Safe Title.
- 3 Press the number on the numeric keypad that corresponds with the direction in which you want to align the selected layers. Press 1, 2, 3, 4, 6, 7, 8, or 9 to determine the direction in which to align; press 5 to align the layer in the centre of the safe title area. Press 0 to align the layer horizontally in the safe title area.

Copying and Pasting Character Channels

You can copy character attributes, transformations, or both, from one character and paste them onto a selection of others.

To copy and paste character channels:

- 1 Select the text from which you want to copy the attributes or transformations.
- 2 In the Character Channels section of the Text menu, click Copy Attributes, Copy Transformations, or Copy All.

- 3 Select the text to which you want to paste the attributes or transformations.
- 4 Click Paste.

Grouping Text Layers

You can group two or more layers together to create a montage of text and move text layers together. Grouped layers can be saved and loaded as one unit. You can add more text layers to an existing group, resulting in a new single group.

NOTE When a group of layers is selected, you cannot switch to Edit mode.

To create a text layer group:

- 1 In the Text menu, select Move from the Tools box.
- 2 **Ctrl**-click (or click the pen button) to select two or more text layers, or click Select All to select all text layers in the scene.
- 3 In the Layer Attributes section, enable Group.

Loading Logos

You can use a logo so that it appears on every frame in a clip. Also, you can use logos in text rolls to credit sponsors, contributors, and products. Place a logo directly in a paragraph and then set text formatting properties for the logo.

To insert a logo in a paragraph:

- 1 In the layer Attributes section, click Load Logo.

The Desktop appears.

- 2 Select a front clip, and optionally, a matte clip for the logo.
The logo is inserted at the cursor position in the text layer.
- 3 In the Font and Paragraph menus, increase or decrease the size of the logo in the text layer by adjusting the font size, leading, and kerning. See [Entering Text](#) (page 1145).

To save a logo:

- 1 Select the logos you want to save.

You can select and save multiple logos.

- 2 Click Save.
- 3 From the Save box, select Selected Logos.
- 4 Use the File field to name the logo.
- 5 Click Save.

The logo is saved as a *.tif* file.

Tabulating Text

You can organize text into columns by setting tabs in the Tabulation menu. In a text layer, you can also set tab stops to align text at specific locations in a paragraph.

To access the Tabulation menu:

- 1 Create a text layer.
- 2 In the Text menu, click Tabulation.

The Tabulation menu appears.

The Tabulation controls are described as follows.

To set a tab stop:

- 1 In the Tabulation menu, click Add to add the tab stop in a text layer.

(a) Tab stop shown in the ruler

- 2 Click the tab stop and drag it to its new location on the ruler. Alternatively, enter a pixel value in the Position field.

Once you set tab stops for a paragraph, press **Tab** in subsequent paragraphs to type text in the location of the next tab stop. In a text layer, each time you press **Enter**, the tab stops you set in the previous paragraph are carried to the next paragraph.

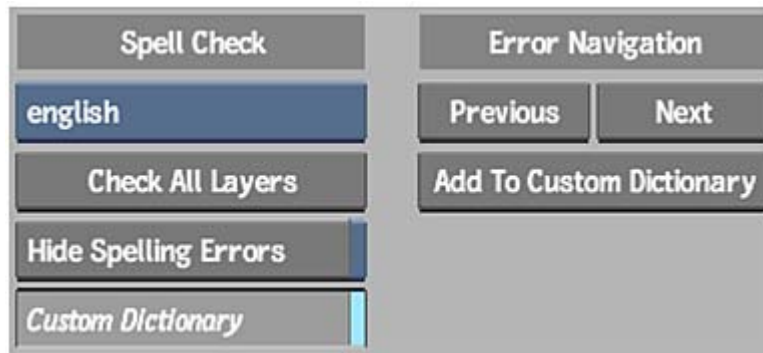

Spell Checking

In the Spell Check menu, you can check the spelling of the text in a text layer. When spelling errors are encountered, a red line is drawn through words not in its dictionary. By default, the spell checker uses the language and dictionary installed with the operating system to verify the spelling of words. You can also create your own custom dictionary.

NOTE If the spell checker is not installed on your system, the Spell Check menu controls are disabled.

To access the Spell Check menu:

- 1 In the Text menu, click Spell Check.
The Spell Check menu appears.

To spell check a text layer:

- 1 In the Text menu, click Spell Check.
- 2 Enable Check All Layers.
Lines appear through misspelled words.
- 3 To correct misspellings, in Edit mode, click Next or Previous to navigate to each misspelled word.

Creating Text Rolls and Text Crawls

You can create text rolls, which are commonly used for credit rolls. A text roll is a layer of text that rolls from the bottom to the top of a clip for a series of frames. In a text roll, you can use special fonts as well as coloured, animated, and tabulated text.

You can include logos of sponsors, contributors, and products in text rolls. For example, you can create a list of credits that uses a green, sheared font for all contributors' names and includes a single, larger capitalized letter spinning on an axis at the beginning of each title line. The contributors' names can appear in a white, semi-transparent, Courier-type font.

A text crawl scrolls text horizontally across the frame. For example, you can create a list of phone numbers that scroll from left to right across the bottom of the screen during a telethon broadcast.

To access the Roll/Crawl menu:

- 1 In the Text menu, click Roll/Crawl.
The Roll/Crawl menu appears.

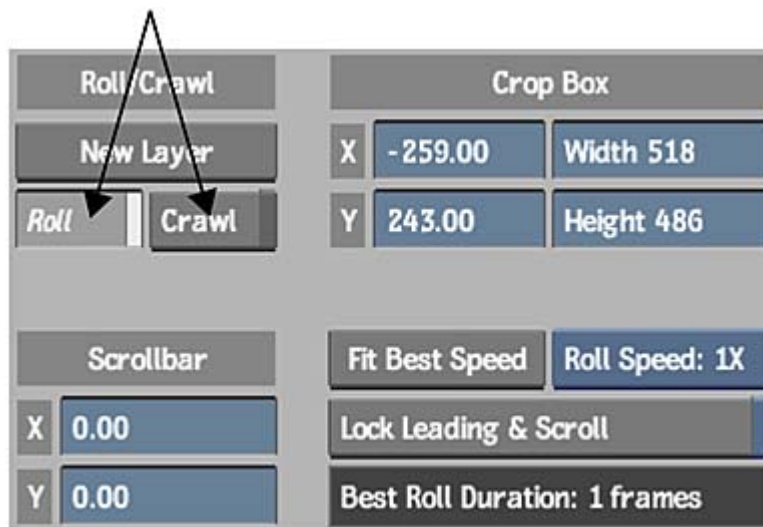

The Roll/Crawl controls are described as follows.

To create a text roll or crawl:

- 1 In the Text Setup menu Rendering section, enable PreRender, and then select Interlaced from the Render box.

- 2 In the Text menu, select Interlaced from the Render box.
- 3 Enable Auto Key.
- 4 Click Roll/Crawl to enter the Roll/Crawl menu.
- 5 Go to the first frame of the clip, and enable Roll or Crawl.

- 6 Click New Layer and add the text you want to use for the text roll or crawl.

A shaded layer appears in the image window with a vertical scrollbar for a roll or a horizontal scrollbar for a crawl. The shaded area represents the crop box area. The following is an example of a text roll.

(a) Red indicates currently selected paragraph (b) Crop box (c) Scrollbar (d) Blue indicates paragraphs in text roll layer (e) Yellow border delimits text

- 7 To set the start position of where the text appears in the text roll or crawl, use the Scrollbar X and Y fields or drag the scrollbar up or down (roll), or left or right (crawl).
- 8 Go to the frame where you want the text roll or crawl to finish and set the end position by dragging the scrollbar or using the Scrollbar X and Y fields.

- 9 If you want to calculate the ideal number of frames for the text roll, choose a roll speed: 1X, 2X, 3X, or 4X.
The suggested duration appears in the Best Roll Duration field. You can either change the number of frames in your clip to match the one in the Best Roll Duration field, or you can leave the clip as is.
 - 10 If the suggested duration is acceptable, enter it in the Duration field and then click Fit Best Speed.
The roll is created and the Scrollbar position and Leading are changed (if required) and locked.
 - 11 If the suggested duration is not acceptable, click Fit Best Speed.
The roll is created and the Scrollbar position and Leading are changed (if required) and locked.
 - 12 Click Process to render the text roll and view the results.
When you play the clip, the text rolls or crawls through the image area from the first position to the final position.
- NOTE** When processing text rolls and crawls, use PreRender in the Text Setup menu to render the roll or crawl relatively fast while bypassing the animation. Check the message bar to see whether PreRender is enabled.
- TIP** When creating credit rolls, the anti-aliasing on the text should be turned on.

Animating Text

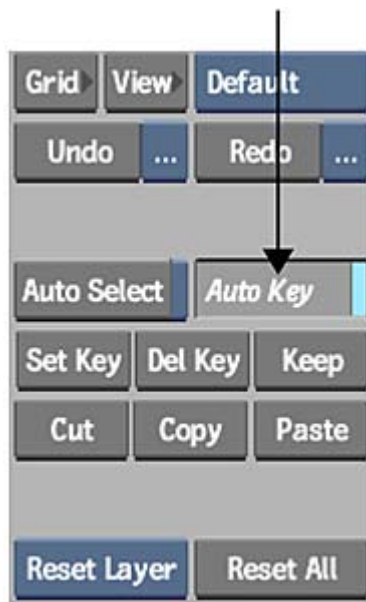

You can animate text properties including colour, softness, size, shadow, and transformation effects such as rotation, scale, and shear. For example, you can animate text channels to create an effect where the text appears gradually over time and then disappears from view.

Use Auto Key to create keyframes automatically as you make changes to text attributes. The movement between keyframes is interpolated according to the interpolation mode you set.

NOTE PreRender must be disabled when creating text animations. See [Rendering Considerations](#) (page 1141). Check the message bar to verify the PreRender status.

To animate text automatically:

- 1 In the Text Animation menu, enable Auto Key.

- 2 Go to the first frame in the clip.
- 3 With the Attribute controls, set the attributes and transformation properties.
- 4 Navigate to another frame in the clip and add more attributes and transformation properties according to the effect you want to produce.
- 5 Click Preview.
- 6 Make modifications as required and when finished, click Process.
- 7 Click Play to view the result.

When you play the clip, the animation moves from the first frame to the last.

Animating Paragraph Channels

In the Text Tool, the Animation controls include a Paragraph Channel View for viewing text channels in the Channel Editor. Use the attributes and transformation channels to animate paragraphs and characters and fine-tune animations created using the Attributes menu.

(a) Paragraph folder contains all the characters, including spaces between words (b) You can animate specific channels for each character

To animate paragraph channels:

- 1 In the Text menu, click Animation to display the Channel Editor.
- 2 From the Paragraph Channel View box, select the paragraph channels you want to view in the Channel Editor.

Select:	To view:
Current	The channels for the selected paragraph—the current cursor location.
Layer	The channels for all paragraphs in the selected layer.
All	All channels for all paragraphs in all layers.

- 3 Animate the selected channels as required.

Animating Text on a Motion Path

You can create a text layer on a spline and animate it over time. In this way, you create marquee text that twists and turns over an image or in time with other objects in the scene. The spline is fully editable; you can add control points and manipulate their tangent handles. In the Channel Editor, the Path group contains a Shape channel for the path and an Offset channel for the offset value.

You can set custom colours for the text path wireframe and vertices in the Text Setup menu. See [Setup and Rendering Options](#) (page 1140).

To animate text on a motion path:

- 1 Create a layer or select a layer in the image window.
- 2 From the Text On Path section of the Text menu, enable On Path.

By default, the text appears on a path with three vertices.

- 3 Adjust and animate the shape of the path using the Text On Path controls.

The Text On Path controls are described as follows.

Select:	To:
Move	Modify the shape of the spline by changing the position of the vertex or tangent.
Add	Add more vertices to the spline to create a more complex shape with text. Click anywhere on the path to add a vertex.
Delete	Remove a vertex from the spline.

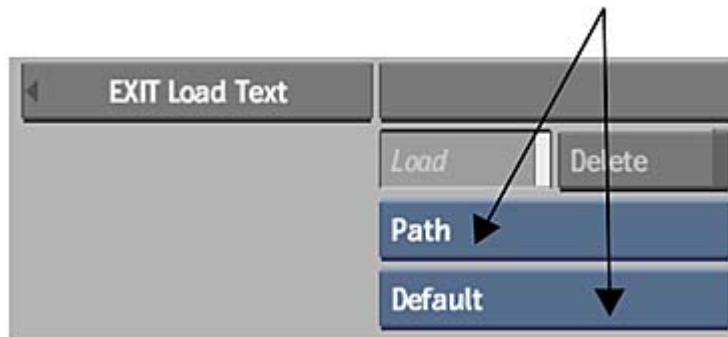

Select:	To:
Break	Separate two tangent handles and move them independently. Click a tangent; the tangent handle changes from a dashed to a solid line to indicate it is broken.
Auto	Connect broken tangents automatically. Click a tangent to reconnect it.

Saving and Loading Path Setups

You can use a garbage mask spline as a shape for the motion path of text on a path. You can save and load the Shape channel as a list in raw shape data (*.raw* file), which is compatible with garbage mask raw data. Raw setups between text paths and garbage masks are interchangeable.

To load a raw shape data file:

- 1 In the Text On Path controls, enable On Path.
- 2 Click Load.
The Text load options and file browser appear.
- 3 In the file browser, select Path and then select Default from the Text Path loading boxes.

A set of path files is visible when the Path and Default options are selected in the Load Text menu.

- 4 Browse to find the file you want to load.
TIP Gmask setup files are typically located in the `/usr/discreet/<product_name>/path/default` directory.
- 5 Click Load.
The spline appears with its new shape in the image area.

Defining Styles

Styles are sets of text attributes and specifications that can be replicated when you need to use the same format again. You create and modify styles, and save and load them from the file browser using the Styles menu. The following character attributes are saved with the style: font, colour, outline, shadow, blur, scaling, rotation and shear. In addition, the layer's background colour and opacity are saved as well.

To access the Styles menu, click the Styles button in the Text menu.

(a) Style Mode box (b) Style Option box

To define a style:

- 1 Select a character with the attributes you want to save.
You can select multiple characters, but it is the first one that defines the style.
- 2 From the Style Option box, select Define Style and then click the style button to which you want to assign the style.

- 3 Click Name and enter a name for the style. Then click the style button to which you want the name to apply.
The new name appears on the button.

NOTE You can use `Ctrl+Shift` and `F1` to `F9` to assign text attributes to Style buttons 1 through 9 from any menu.

To modify a style:

- 1 Select the character with the attributes you want to save.
- 2 From the Style Option box, select Define Style and then click the style button to which you want to assign the style.

NOTE You can use `Ctrl+Shift` and `F1` to `F9` to assign a style to Style buttons 1 through 9 from any menu.

To clear a style:

- 1 From the Style Option box, select Clear Style and then click a style button.

NOTE It is sometimes convenient to clear all styles just prior to using AutoStyle to save multiple styles automatically. AutoStyle assigns up to nine style buttons at once. See [Saving Multiple Styles Automatically](#) (page 1165).

To apply a style:

- 1 Select a paragraph or string of characters to which you want to apply a style.
- 2 Press `Ctrl+F1` to `F9`, or press the style button, to apply the style to the selected text.

Saving and Loading Styles

After you create styles, you may want to save one or all of them. You can load any of them in future sessions.

To save a style:

- 1 Do one of the following in the Styles menu:
 - Select All Styles from the Style Mode box.
 - Select One Style from the Style Mode box, and the style you want to save (Style 1 to Style 9).

- 2 Click Save Style.
The Save Styles menu and file browser appear.

- 3 Choose a directory for the style.

NOTE You can click the Create Dir button to create a new directory in which to save your styles.

- 4 Enter the filename.
The style is saved. The file browser automatically closes and the Styles menu reappears.

To load a style:

- 1 Select an option from the Style Mode box.

Select:	To:
All Styles	Load files saved with multiple styles. The file browser lists setups saved with multiple styles.
One Style	Load files saved with one style only. The file browser lists setups saved with a single style.

- 2 Click Load Style.
The Load Styles menu and file browser appear.
- 3 Navigate to the appropriate directory and select the style(s) you want to load.
- 4 If necessary, click Exit Load Text to exit the file browser.

Saving Multiple Styles Automatically

If you create a section of text with multiple sets of attributes, you can assign each set as a separate style with a shortcut and then save them. The Text Tool automatically detects the different sets of attributes used in the section and assigns each set to a Style button. You can then use shortcuts to apply them.

To assign styles from an existing layer using shortcuts:

- 1 Select the section of text.
- 2 From the Style Option box, select AutoStyle.

NOTE If you used more than nine sets of attributes in the selection, only the first nine are assigned to a Style button.

- 3 Save the styles.

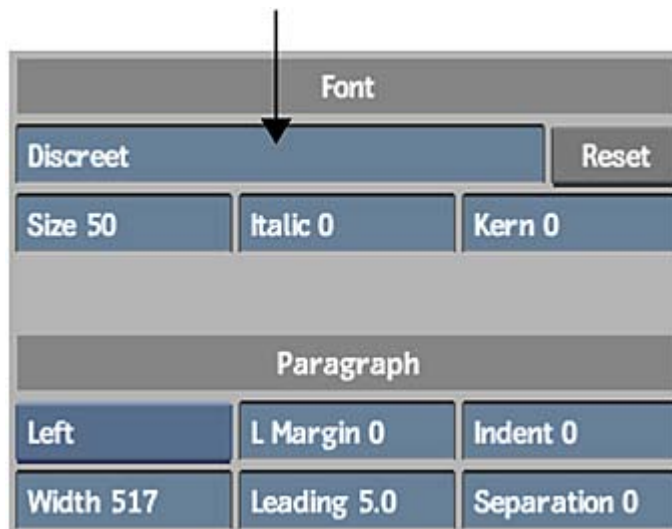

Changing Fonts

When you open the Text tool, the default font is loaded and ready to use. When you choose a different font, it becomes the current font and all text you type appears in the current font. If you edit text that has a different font, the current font is replaced by the font of the text at the cursor position. For example, if you are working with Carta font and you edit text that uses Helvetica, Helvetica becomes the current font and all subsequent text you type appears in Helvetica.

You specify the default font in the TL Effects / BFX tab of the Preferences menu. Also, you can install additional fonts for use in the Text Tool.

To change the current font:

- 1 In the Font section of the Text menu, click the Font field.

The font library appears.

(a) Font Type box (b) Font Preview window

- 2 In the Font Type box, select the font type you want to load.

Type	Description
Type 1	A single-byte font type designed for Roman language fonts. Soft-links to the Adobe® Postscript® Type 1 fonts installed with the system or supplied by Autodesk are contained in <code>/usr/discreet/font</code> directory.
CID	A multi-byte adaptation of Adobe Postscript Type 1 fonts, well-suited to representing the large character sets of Asian languages such as Japanese, Korean and Chinese.
TrueType	A widely used cross-platform font format.
OpenType®	A font developed by Adobe and Microsoft® that supports expanded character sets and layouts.
Auto	Displays all font types, detecting the type automatically.

- 3 In the file browser, navigate to the directory that contains the font you want to load.
- 4 Preview a font. Do one of the following:
 - Select a font to see it with sample text in the Font Preview window.

The sample text can be the text you selected in the text layer, or text that you enter by clicking the Font Preview window to display the on-screen keyboard.

- In the Proxies/Titles box, select Proxies to preview fonts. If no proxy appears, click Generate Proxies to generate a font proxy.

This process may take a while, but once you create the proxies, the settings are retained. Each time you return to the font library, you can toggle between viewing font titles and font proxies by selecting Proxies or Titles.

5 Select the font.

6 Click Load.

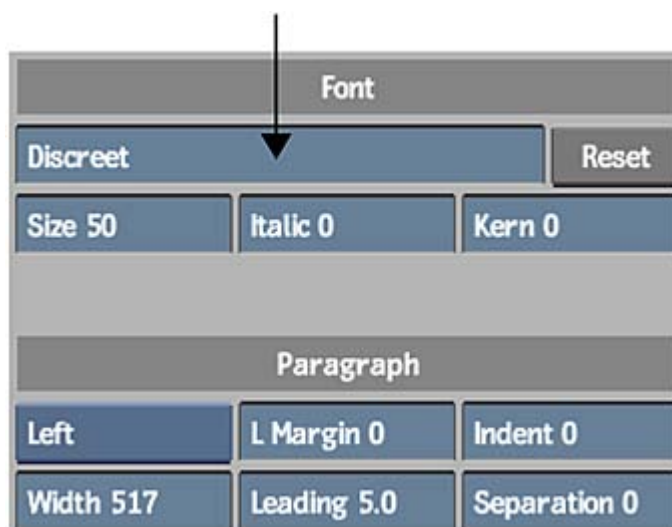

The Text menu reappears with the name of the new font in the Font field.

Pasting Text from an External Source

You can copy text from a Linux terminal or another application and paste it directly in a text layer.

To paste text from a terminal to the Text tool:

- 1 In the Text tool, create a layer for the text you want to paste.
- 2 Click the Font field and select a font.

- 3 In the terminal, copy the text.
- 4 In the Text tool, paste the text in a text layer.

Entering Non-Latin Text

When entering non-Latin text characters, consult your system documentation to make sure the required input method packages are installed. For example, to enter Chinese characters, you can use the *chinput* package.

The following example illustrates entering Japanese text in a text layer with the *kinput2*, *canna*, and *Wnn6* packages.

To enter Japanese text in a text layer:

- 1 Start the canna daemon by typing **/etc/init.d/canna start** in a Linux terminal.
- 2 Type the following commands in the terminal:
 - **kinput2 -canna &**
 - **setenv XMODIFIERS @im=kinput2**
 - **setenv LANG ja_JP.eucJP**

NOTE For detailed instructions on kinput, canna, and Wnn6, consult your system documentation.

- 3 Start your Autodesk application.
- 4 Load a clip in the Text tool.

Notice the message bar that appears at the top of the screen. This indicates you are in Latin input mode.

(a) Message bar

- 5 Create a layer and click the Font field to select a Japanese font from the file browser. From the Text Mode box, select Edit and then select the layer in the image window. When you type text, notice that you are still in Latin input mode.

- 6 Press your Input Method keyboard shortcut.
The message bar changes to indicate that you are in Japanese text mode.

(a) Message bar

- 7 Type text, as required.
- 8 Press **Enter** to accept the characters and add them to the text layer.

- 9 To revert back to Latin input mode, press the Input Method keyboard shortcut again.

Accessing OTF Fonts

In order to access symbols of the OTF font type, access the on-screen keyboard, enable the Symbols button (in the lower right of the keyboard), then use the arrow keys to browse through the pages of symbols until you find the character set you need.

Warping and Morphing

23

About Distort

Use the Distort menu to warp a clip and create morphs between two clips. Both of these effects are created using splines, which are drawn and animated in a similar way to garbage masks.

Warping using the Distort Tool

Warp is created by drawing a source spline, and then offsetting a second corresponding destination spline. When you draw a source spline, an identical destination spline is automatically created. When you move the destination spline, the offset of the destination from its source spline is what warps the clip. For example, you can draw a source spline around the eye of an actor, and then edit the points of the corresponding destination spline to make the eye bulge.

Source spline drawn around eye

Image courtesy of Behavior Communications Inc.

Offsetting destination spline creates warp

Image courtesy of Behavior Communications Inc.

Distort Warping Workflow

The general warping workflow in the Distort tool includes the following steps.

Step:	Refer to:
1. Load clips into the Distort tool.	Accessing Distort (page 1174).
2. Draw a source spline.	Drawing Splines (page 1180). TIP Use Distort's schematic as you work with splines to help organize your work. See Using Distort's Schematic (page 1186).
3. Edit the source spline.	Editing Splines (page 1184).
4. Animate the source spline.	Animating and Tracking Splines (page 1194).
5. Unlink the destination spline from the source to enable warping.	Linking and Unlinking Splines and Axes (page 1183).
6. Edit the destination spline.	Editing Splines (page 1184).
7. Animate the destination spline.	Animating and Tracking Splines (page 1194).
8. Refine the warping effect.	Refining Distortions (page 1198).
9. Set what appears at edges of clip if the distortion effect pulls the clip away from the border, revealing empty space, or the background clip.	Filling in Gaps at Edges of Distorted Clips (page 1204).

NOTE Repeat this workflow for each warped element of the clip.

Morphing in Distort

Morphs are created by creating corresponding splines on two clips and linking them together. You then set interpolation values controlling how the features contained in the first set of splines morph into the features contained in the second set of splines. This method is called source interpolation. Finally, you blend the two clips over time to complete the morph. For example, you can draw splines around the outline of an actor and each of the actor's facial features. Then duplicate these splines onto a second clip containing the actor to whom the first actor will morph into. Edit the copied splines to more accurately contour the features of the second actor, link the corresponding splines, and then blend the two clips to complete the morph.

Both sets of splines, those on the first clip, and those on the second clip, can be animated. Additionally, you can edit and animate the interpolated splines.

Source splines drawn on actor

Image courtesy of Behavior Communications Inc.

Corresponding splines on second actor are linked

Image courtesy of Behavior Communications Inc.

Distort Morphing Workflow

The general morphing workflow in the Distort tool includes the following steps.

Step:	Refer to:
1. Load clips into the Distort tool.	Accessing Distort (page 1174).
2. Draw a source spline on the Front1 clip.	Drawing Splines (page 1180). TIP Use Distort's schematic as you work with splines to help organize your work. See Using Distort's Schematic (page 1186).
3. Edit the Front1 source spline.	Editing Splines (page 1184).
4. Animate the Front1 source spline.	Animating and Tracking Splines (page 1194).
5. Display the Front2 clip.	Toggling Between Inputs (page 1178).
6. Duplicate the Front1 spline, then toggle the duplicated spline to become an Front2 spline.	Toggling Spline Nodes from One Input to Another (page 1192).
7. Edit the Front2 source spline.	Editing Splines (page 1184).
8. Animate the Front2 source spline.	Animating and Tracking Splines (page 1194).
9. In the Distort schematic, link the spline on the Front1 clip with the spline on the Front2 clip.	Linking Source Nodes (page 1193).

Step:	Refer to:
10. Set Blend and Interpolation values.	Blending Clips (page 1197) and Interpolating Features (page 1197).
11. Refine the morphing effect.	Refining Distortions (page 1198).

NOTE Repeat this workflow for each morphed feature you want to correlate from the Front1 clip to the Front2 clip.

Mesh-Based Warps and Morphs

While the Distort tool uses splines to define features of a clip you want to warp or morph, you can also use the Warper tool. Instead of splines, the Warper uses meshes to define affected features for similar warping and morphing effects.

Mesh-based warps and morphs created with the Warper can be more time-consuming since meshes have many more points to work with and usually cover the entire clip. The Warper can be useful, however, because you have more direct control over the parts of the clip being altered since you manipulate the mesh directly.

Accessing Distort

Use Distort to create warps and morphs of clips. The node uses spline-based shapes to create these effects.

To access the Distort editors, use:

- [Batch](#), then select a node from the Node bin. (page 1175)
- [Timeline](#), then use Batch FX. (page 1175)
- [Tools](#), then select the menu. (page 1175)

Distort accepts two front clips, two matte clips and one back clip as inputs, and outputs a result and an outmatte.

In Batch, you can create a more convincing morph, for example, by animating colour transitions between the first and second clips using Colour Corrector nodes.

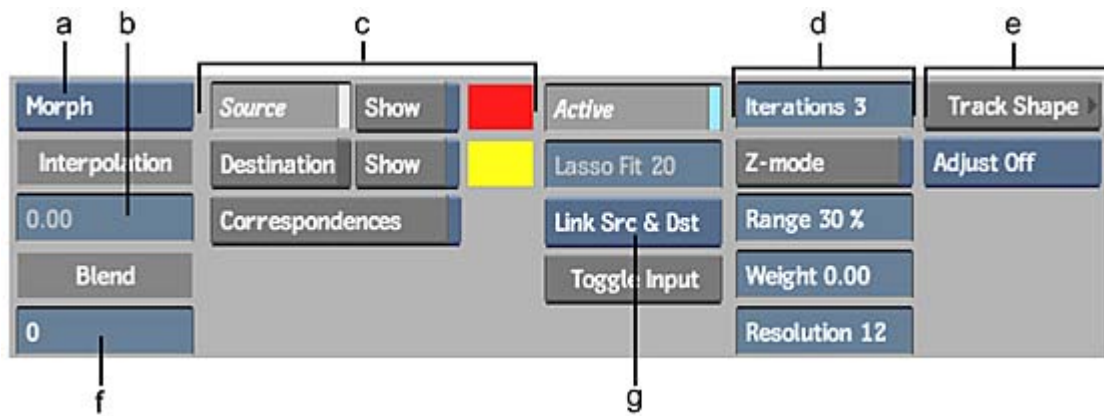

The Distort controls are described as follows.

Clip Display buttons Controls which clips, of those you load into Distort, are displayed. Use the Clip Display buttons to produce various effects, or to toggle on or off clips and mattes to facilitate your work.

Axis controls Edits the axis position, scale, and shear value of a spline.

Axis Stabilizer controls Gives access to the Stabilizer, for automatically tracking motion in the axis.

View box Sets the view in the image window. Two views available from this box, Input and Matte, each correlate with two distinct views, Front1 and Front2, or Matte1 and Matte2. You toggle between the input or matte views using the Input box.

(a) Warper button (b) Interpolation field (c) Spline Display controls (d) Refining controls (e) Shape Stabilizer controls (f) Blend field (g) Link box

TIP The distortion grid can be displayed by enabling Draw Grid in Distort's Setup menu. This can be useful when working with the Iterations and Range fields.

Accessing Distort from Batch

To access the Distort menu from Batch:

- 1 In Batch, drag and drop the Distort node from the node bin to the schematic.
- 2 Connect the node to a clip or image. You can connect up to five sockets: Front1, Front2, Matte1, Matte2, and Background. The Front2, Matte1, Matte2, and Background clips are optional.
- 3 Double-click the Distort node.
The Distort node menu appears. The Distort node outputs a warped or morphed result and a warped or morphed matte.

Accessing Distort from Batch FX

To access Distort through Batch FX:

- 1 Select Timeline.
- 2 Select the segment.
- 3 Click the FX button.
- 4 Click the Create Batch FX button.
- 5 Double-click on, or drag, a Distort node into the schematic.
The Distort node is now in the schematic.
- 6 Double-click the Distort node.
You are in the Distort node editor.

Accessing Distort from Tools

To access the Distort menu from Tools:

- 1 Select **Tools > Filter > Distort**.

The cursor changes to Pick Front.

- 2 From the Inputs box that appears, select the clips or mattes you will use.

Select:	To load:	To produce:
Front1	One input clip only	A warp of a single clip.
Front1 Matte1	An input clip with its matte	A warp of a single clip using a matte over a black background. A warped matte is also produced.
Front1 Matte1 Back	An input clip with its matte, as well as a background	A warp of a single clip using a matte over a background clip. A warped matte is also produced.
Front1 Front2	Two inputs	A morph from one clip to another over a black background.
Front1 Front2 Back	Two inputs, as well as a background	A morph from one clip to another over a background clip.
F1 F2 M1 M2	Two inputs with their respective mattes	A morph from one clip to another over a black background. A morphed matte is also produced.
F1 F2 M1 M2 Back	Two inputs with their respective mattes, as well as a background	A morph using two clips and their mattes on a background clip instead of on black. A morphed matte is also produced.

- 3 Select the clips as indicated by the cursor.

For example, if you selected Front1 Front2 Matte1 Matte2 Bkg to morph between two clips, select clips as follows:

- The clip where your morph originates is Front1.
- The clip containing the subject that will be morphed to is Front2.
- The matte for Front1 is Matte1.
- The matte for Front2 is Matte2.
- The background clip.

When the clip selection is complete, the cursor will change to Render Here.

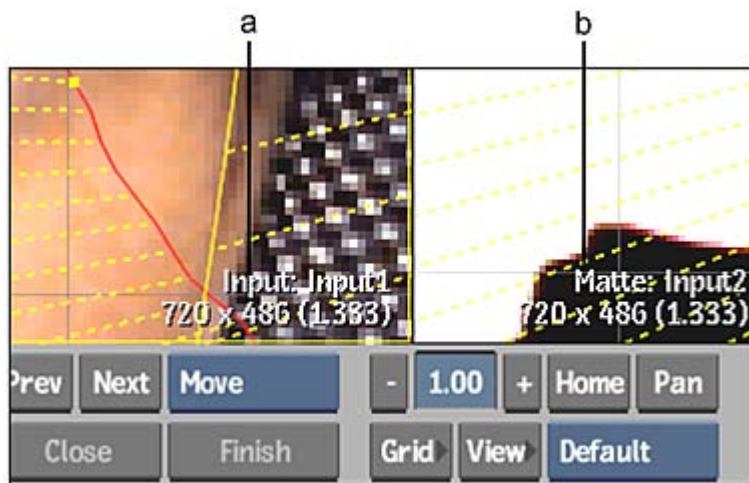

- 4 Click on any free (or a grey) area on the workspace.

You are now in the Distort Tool editor.

Using Distort's Views and Clip Display

You can change the view using the Distort menu as you create your effect.

Distort makes it easy to toggle between Front1 and Front2 clips or mattes independently in each viewport. For example, you can display Front1 in one viewport, and the matte of Front2 in another viewport.

(a) Front1 (Input1) clip displayed (b) Matte of Front2 (Input2) displayed

Within a particular view, you can also toggle on or off clips to facilitate your work or create different effects. For example, if you loaded two inputs and their mattes, as well as a background clip, you can turn on or off any of the five clips that together make up the composite.

Changing Views

Use the appropriate view, available from the Distort menu's View box, for the task you are performing.

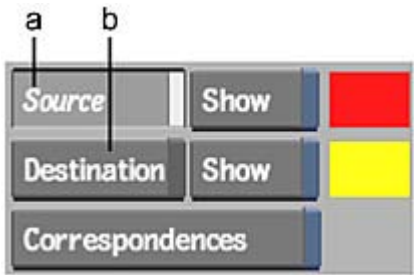

(a) View box (b) Input box

Select:	To view:
Input	The Front1 or Front2 clip. You toggle between them using the Input box.
Matte	Matte1 or Matte2. You toggle between them using the Input box.
Background	The background clip used in the warping or morphing effect.
Result	The result clip of the warping or morphing effect.
ResultMatte	The result matte that is created when you blend the IFront1 and Front2 clips when morphing.
DistortSchm	The Distort schematic.

Each of the Input and Matte views can correlate with two views if you loaded two inputs and their mattes into the Distort tool. See [Toggling Between Inputs](#) (page 1178).

While in the Input view, you can also toggle between viewing the unwarped input and the warped input by clicking between the Source and Destination buttons in the Warp and Morph menus.

(a) Source button (b) Destination button

Toggling Between Inputs

When you are morphing between clips, you can toggle between them so either Front1 or Front2 appears in the image window. The splines drawn on the clip are also displayed. For example, if you select Front1, the Front1 clip, along with its splines, is displayed in the image window. If you then select Front2, the Front2 clip appears with the splines drawn for Front2.

You can similarly toggle between Matte1 and Matte2.

To toggle between s or mattes:

- 1 From the Warp or Morph menu in the Distort tool, select an option from the Input box.

Select:	To:
Front1	Display the Front1 clip if Input is selected in the View box, or Matte1 if Matte is selected in the View box, along with the Front1 source and destination splines.
Front2	Display the Front2 clip if Input is selected in the View box, or Matte2 if Matte is selected in the View box, along with the Front2 source and destination splines.

The corresponding clip with its splines is displayed. As well, the splines that are not displayed, for example, splines added to the Front1 clip if you select Front2, are indicated as hidden in Distort's schematic.

Displaying Clips

Depending on the clips you load into Distort, you can use the Clip Display buttons to produce various effects, or to simply toggle on clips and mattes to facilitate your work. The following table shows how to set up the clips to produce various effects.

Front1	Front2	Matte1	Matte2	Back	Effect
On	Off	Off	Off	Off	Warps theFront1 clip only. This is the same as loading only one input clip.
On	On	Off	Off	Off	Morphs between two clips. This is the same as loading two input clips.

Front1	Front2	Matte1	Matte2	Back	Effect
On	Lock	Off	Off	Off	Wipes (page turns, rolls); regional warps (if the same clip is loaded as both the Front1 and Front2 clip).
On	Off	On	Off	Off	Warps the Front1 clip and Matte1 clip, composited on black.
On	On	On	Off	Off	Warps over a background with a matte clip.
On	Lock	On	Off	Off	Warps the Front1 and Matte1 clips composited on the Front2 clip.
On	On	On	On	On	Morphs between two clips and their mattes onto the selected background clip.

Creating Splines

You draw open or closed splines to match the features of a clip that you want to warp or morph. Splines are drawn in a similar way as garbage masks, by clicking to add points, or by dragging to draw freehand segments. You can also load a saved garbage mask setup to use as distort splines.

You draw a spline around a feature at the start of an effect. When you add a spline, both a source and destination spline is added to the clip. Since these splines are initially linked together and overlap, your manipulations to the source spline affect the destination spline in the same way. After you have drawn and animated the source spline, you can unlink the splines and edit the vertices and tangents of the destination spline independently.

When creating a morph between two clips, you draw splines on the Front1 clip, then optionally duplicate them to the Front2 clip. When you link the splines, those duplicated to the Front2 clip become the destination for splines drawn on the Front1 clip.

NOTE When morphing, you can also draw source spline on the Front2 clip to link to corresponding Front1 splines. Only splines with the same number of points, and drawn in the same orientation (clockwise or counter-clockwise), will create proper morphs.

You can show or hide source and destination splines, as well as change their colours.

Using Garbage Masks as Distort Splines

Garbage mask setups are created through the GMask node in Batch. You can import a saved garbage mask setup into Distort and use it as a spline. Note the following about how Distort interprets settings in the imported garbage mask setup:

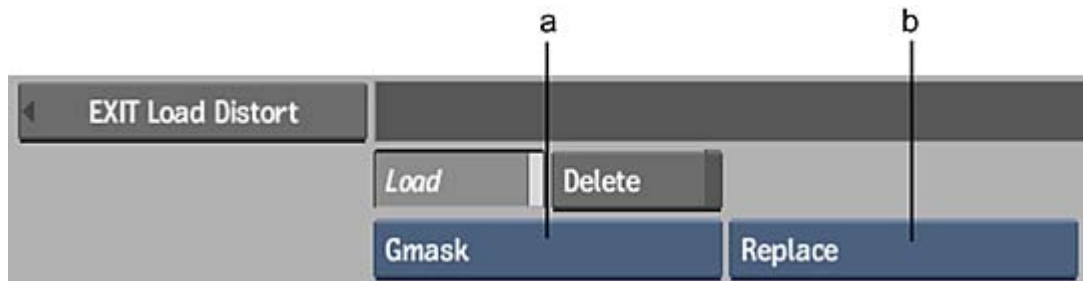

- If the imported garbage mask has animation on its axes, the animation is recreated in axes above the main axis in the Distort schematic.
- If the imported garbage mask has shape animation or explicit animation on the gmask splines, the same animation on the source and destination splines is transformed into shape animations.
- If the imported garbage mask includes tracking data, the offset parameters on the geometry are duplicated on the offset parameters of both the source and destination splines.

- Garbage mask setups that use multiples axes to manipulate instances of splines are translated to Distort instances. See [Instancing Distort Splines](#) (page 1185).

For help creating garbage masks, see [Drawing a Mask](#) (page 912).

To import a garbage mask setup into Distort:

- 1 Do one of the following:
 - In the Distort menu, click Load to open the file browser.
 - From the Distort node in Batch, click NodeSetup to display Distort's Setup menu, then click Load Node to open the file browser.
 - 2 From the Load Type box, select Gmask.
- The browser automatically points to the default Gmask folder.

(a) Load Type box (b) Load Mode box

- 3 From the Load Mode box, select whether you want the Gmask setup to append to or replace any existing Distort splines in your scene.
- 4 From the file browser, select the name of the setup to load.

TIP A library of preset garbage mask setups is available. To load a preset garbage mask, navigate to the `/usr/discreet/<product_name>/gmask/default` directory.

Drawing Splines

Draw single-point, open, or closed splines around the features you want to warp or morph at the beginning of the effect.

To draw a closed spline:

- 1 Go to the frame where you want the effect to begin.
- 2 Select Spline from the Node box.

- 3 If you are creating a morph, select the input where you want to draw the spline. To add a spline to Front1, for example, select Front1 in the Morph menu's Input box.

NOTE When creating a morph, a common strategy is to create the spline on just one input, and then duplicate it to the other. This has important advantages over creating splines on both inputs independently. See [Toggling Spline Nodes from One Input to Another](#) (page 1192).

- 4 Click Add.
- 5 Do any of the following:
 - Click to add vertices.
 - Shift-drag to add freehand segments to the spline. Vertices are added where you drag, and appear after you release *Shift*. You can then use the Lasso Fit parameter to increase or decrease the number of vertices that define the freehand segments of the spline. If you add or delete vertices on the spline, or exit, the influence of the Lasso Fit parameter on the number of vertices is lost. See [Adjusting the Number of Points in Freehand Segments](#) (page 915).
- 6 To close the spline, do one of the following:
 - Click Close.
 - Press *C*.
 - Click the first vertex.
 - While holding *Shift*, drag to the first vertex.

When the spline is closed, its vertices and tangents can then be edited.

(a) Vertex (b) Tangent

Image courtesy of Behavior Communications Inc.

To draw a single-point or open spline:

- 1 Go to the frame where you want the effect to begin.

- 2 Select Spline from the Node box.

- 3 If you are creating a morph, select the input where you want to draw the spline. To add a spline to Front1, for example, select Front1 in the Morph menu's Input box.

NOTE When creating a morph, a common strategy is to create the spline on just one input, and then duplicate it to the other. This has important advantages over creating splines on both inputs independently. See [Toggling Spline Nodes from One Input to Another](#) (page 1192).

- 4 Click Add.
- 5 Do any of the following:
 - Click to add vertices. If you are drawing a single-point spline, proceed to the next step.
 - Shift-drag to add freehand segments to the spline. Vertices are added where you drag, and appear after you release *Shift*. You can then use the Lasso Fit parameter to increase or decrease the number of vertices that define the freehand segments of the spline. If you add or delete vertices on the spline, or exit, the influence of the Lasso Fit parameter on the number of vertices is lost. See [Adjusting the Number of Points in Freehand Segments](#) (page 915).
- 6 To finish the spline, do one of the following:
 - Click Finish.
 - Press *F*.
 - Click the last vertex.

When the spline is finished, its vertices and tangents can then be edited.

If you want to view the nodes that are added with each new spline, select DistortSchm from the View box. You can use Distort's schematic to access a menu, create parent-child relationships between splines and axes, delete splines, link Front1 and Front2 splines to create morphs, as well as perform other organizational tasks. See [Using Distort's Schematic](#) (page 1186).

To show and hide splines:

- 1 From the Warp or Morph menu in the Distort tool, do one of the following:
 - To work with source splines, click Source.
 - To work with destination splines, click Destination.
 - To work with source splines while seeing the destination splines as a reference, click Destination Show.
 - To work with destination splines while seeing the source splines as a reference, click Source Show.

NOTE To toggle between splines drawn on the Front1 and Front2 clip, select Front1 or Front2 from the Input box.

To colour splines:

- 1 Click the Source colour pot or the Destination colour pot, and use the colour picker that appears.
The colour you pick is applied to all source or destination splines accordingly.

Changing the Colour of Tangents

You can change the colour of tangents on the splines you draw. This is useful to better contrast the spline's tangents from the clip so that they are easier to work with.

To change the colour of tangents on splines:

- 1 In the Distort menu, click Setup.
- 2 In the Setup menu Display section, click the Tangents colour pot.

- 3 From the colour picker that appears, select a colour.
Tangents are displayed in the colour you set.

NOTE All spline tangents are initially displayed in magenta after they are drawn until a source spline and its corresponding destination spline are offset from one another.

Linking and Unlinking Splines and Axes

Warps are created by offsetting a destination spline from its source. By default, when you draw a spline, it is linked to its corresponding source or destination. After it is drawn, you might animate it, for example, so that it follows a subject in the clip. When the splines are linked, both the source and destination splines are animated in the same way.

When you are ready to create the warp, you unlink the destination spline from its source. Manipulations then affect each spline separately, so you can alter the shape of the destination. The differences between the two corresponding splines are what creates the warp.

You can also independently unlink the axis of a source spline and the axis of a destination spline. By default, the axis nodes are linked, even if the source and destination splines themselves are unlinked. You might unlink only the axes of corresponding splines, for example, if you want their offset to create the warping effect while the actual shapes of the splines remain the same.

You use a different linking method when using source interpolation to create a morph. See [Linking Source Nodes](#) (page 1193).

To link and unlink source and destination splines or axes:

- 1 Do one of the following:
 - Select a spline by clicking it in a viewport or by clicking its spline node in the Distort schematic.

- Select an axis node in a spline node tree that is a parent to a spline node.

See [Using Distort's Schematic](#) (page 1186).

- 2 From the Warp or Morph menu in the Distort tool, click the Link box to toggle between Lnk Src & Dst and Distort.

Select:	To:
Lnk Src & Dst	Link source and corresponding destination splines, or their axes. With linked splines, if you move a spline or any of its vertices both the source and corresponding destination splines are affected in the same way. With linked axes, if you move the parent axes of a spline, the parent axes of the destination spline is affected in the same way.
Distort	Allow source and destination splines or axes to be offset from one another, which creates the warping effect.

Vertices on linked splines appear in magenta. Axes that are linked appear in magenta.

NOTE If you select Lnk Src & Dst and manipulate a vertex that has already been offset from its corresponding vertex, both the source and destination vertex snap to the same position. Similarly, if you manipulate the Axis values of a spline that has been offset from its corresponding spline with Lnk Src & Dst selected, all vertices and the splines' axes snap together.

Editing Splines

You edit splines in the same way as you edit garbage masks, working with their vertices and tangents. See [Moving Vertices and Tangents](#) (page 918).

If Lnk Src & Dst is selected from the Link box, your edits affect both the source and destination spline regardless of where you make the edits. See [Linking and Unlinking Splines and Axes](#) (page 1183).

TIP The Link box has no effect if spline nodes are linked in the Distort schematic while morphing using source interpolation. See [Linking Source Nodes](#) (page 1193).

To edit a spline:

- 1 From the Tools box, select one of the following modes to edit a spline's vertices.

Select:	To:
Select	Select one or more vertices.

Select:	To:
Move	Move vertices to a new position.
Scale	Scale vertices in relation to the axis centre of the spline.
Delete	Remove vertices from the spline.
Break	Break tangents of vertices.

Transforming Splines

You can apply transformations such as translation, rotation, scaling, and shearing to a spline. The transformation data for the spline is stored in its Axis node. See [Axis Nodes](#) (page 1190).

All transformation parameters can be animated. You can also use a motion path to animate the position of a spline.

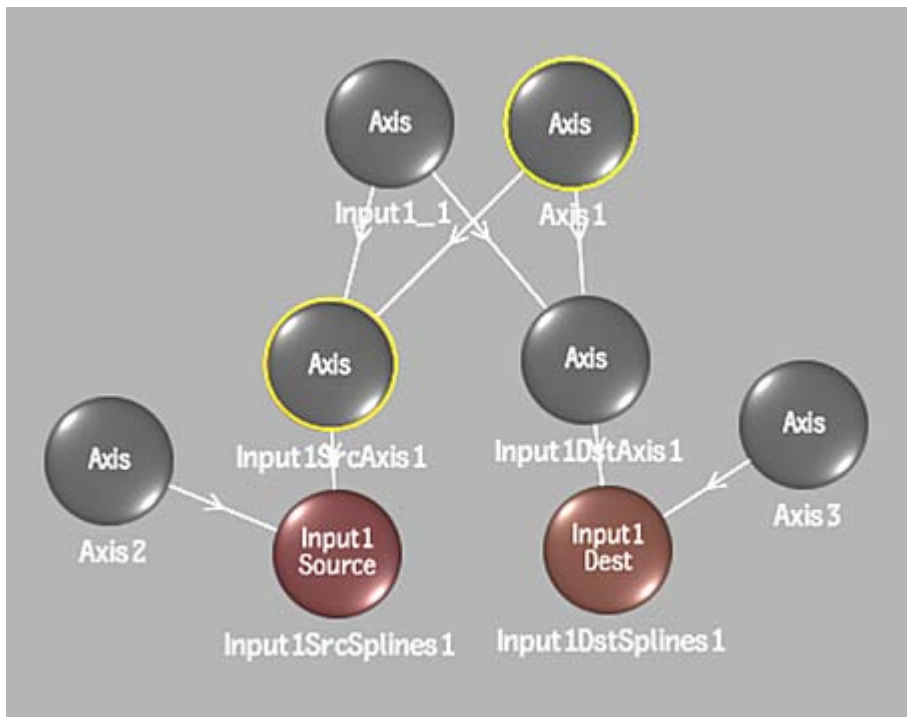

To transform a spline:

- 1 Use the Transformation fields to modify the position, shape, and size of a spline.

	Position	Rotation	Scale	Shear	Centre	Track Axis ▶
X	0.00	0.00	100.00	0.00	0.00	Rotation Off
Y	0.00	0.00	100.00	0.00	0.00	Scale Off
Z	0.00	0.00	100.00	0.00	0.00	Adjust On
Path	Prop				Input1	

Instancing Distort Splines

When you add multiple axes above a pair of source and destination splines, each axis can be used to manipulate a separate instance of the pair of splines. You can then use the Distort settings for each axis to manipulate the instance of each spline. In the following example, the Input1_1 and Axis1 axes can be used to change instances of the source and destination splines. Axis2 and Axis3 cannot be used in this manner, since they are only attached to one input spline.

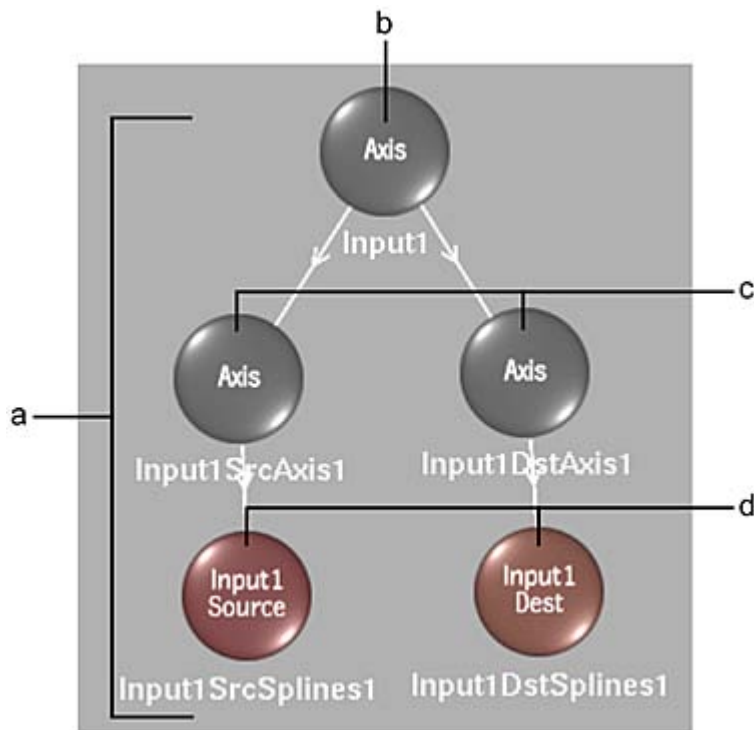

Using Distort's Schematic

The Distort schematic uses nodes to represent all the splines in the scene. The schematic shows relationships between source and destination splines, and between splines applied to the Front1 and Front2 clips.

Use the schematic to control all the splines in the scene, set parent-to-child relationships among nodes, as well as to select splines more easily.

You also use the schematic to link Front1 and Front2 source splines to create morphs using source interpolation. See [Linking Source Nodes](#) (page 1193).

When you add a spline to the Front1 clip, for example, the following spline node tree appears.

(a) Spline node tree representing corresponding splines added to Front1 (Input1) (b) Axis node for an Front1 (Input1) spline: the parent of corresponding source and destination splines (c) Axis nodes for each spline (d) Spline nodes for corresponding source and destination splines added to Front1 (Input1)

Each spline added to an input clip results in its own spline node tree in the schematic, with its own corresponding source and destination splines.

You can change an Front1 spline to an Front2 spline or an Front2 spline to an Front1 spline using the Toggle Input button. See [Toggling Spline Nodes from One Input to Another](#) (page 1192).

Visibility of the splines is controlled from the Warp or Morph menu using the Spline Display controls. When you toggle between the Front1 and Front2 clips with the Input box, splines are hidden for the inactive clip, which is also reflected in the schematic.

You can also set the transparency of the schematic. This is useful if you want to dim its display so as not to interfere with the main focus of your work.

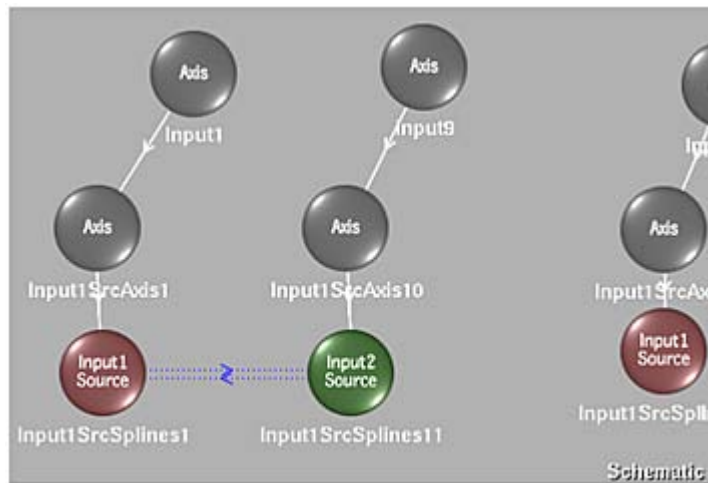

To view Distort's schematic:

- 1 Do one of the following:
 - Select DistortSchm in the View box.

- Press the ~ key. Pressing the ~ key a second time returns to the previous view.

The Distort schematic appears.

TIP Display Distort's schematic and the input clips in a multiple viewport setup. This way, you can see the splines in the clips as you select and work with them in the schematic.

To set the transparency of the Distort schematic:

- 1 In the Distort menu, click Setup.
- 2 In the Setup menu Schematic section, adjust the value in the Transparency field.

NOTE The schematic transparency has a maximum value of 90%.

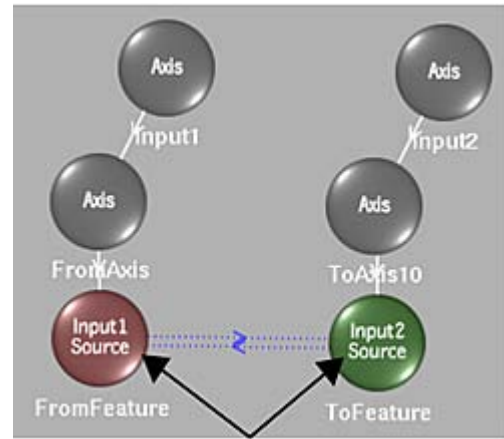

Node Types

In the Distort schematic, a node can be a spline or an axis.

Nodes help you organize warps that occur between corresponding source and destination splines in a spline node tree, and morphs that occur between linked Front1 and Front2 source nodes in different spline node trees.

Warps occur between corresponding source and destination splines that are offset from one another

Morphs occur between corresponding Front1 (Input1) and Front2 (Input2) source splines that are linked together

Spline Node Trees

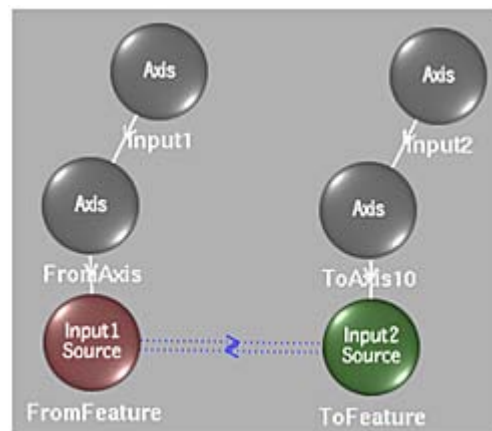

When you add a spline to the Front1 or Front2 clip, axis and spline nodes are added to the Distort schematic. These nodes represent the source spline and its corresponding destination spline, and are parented to axes in a spline node tree.

Warps are created when the source spline and destination spline in a spline node tree are offset from one another.

Morphs are created when you link a source spline from an Front1 spline node tree to a source spline from an Front2 spline node tree.

A spline node tree for a pair of corresponding splines on the Front1 (Input1) clip, and a spline node tree for a pair of corresponding splines on the Front2 (Input2) clip

When you link source splines between Front1 (Input1) and Front2 (Input2) for source interpolation, the destination splines and their respective Axis nodes are removed from the spline node trees

Axis Nodes

Use Axis nodes to control the position, rotation, scale, and shear values of splines.

Initially when you add a spline, its source and destination node is parented to its own Axis node, and these Axis nodes are in turn parented to a common Axis node. So, for example, you can control the position of a particular Front1 source spline via its Axis node. Click the Axis node, the direct parent of the Spline node, then use the Axis menu in the Distort tool to apply tracking data to the node.

If you want to affect both a source spline and its corresponding destination spline, you can use the Axis node at the top of the spline node tree.

When you add splines, they are initially parented to their own spline node tree. You can, however, add more Axis nodes to the schematic, and parent splines from different spline node trees to the same Axis node. This can be useful, for example, if you create splines for the different features of an actor's face and want them to move in tandem with the actor.

Axis nodes for corresponding splines can be unlinked from each other by selecting a spline's axis node, then selecting Enable Warping from the Link box.

Spline Nodes

Use the Spline node to select the spline itself, including all its points. Each spline added to the schematic results in a source and destination Spline node. Each Spline node is representative of a particular spline, which consists of a closed shape defined by vertices. If Link Src and Dst is selected from the Link Box, transformations applied to a source or destination spline also affect the corresponding spline. This does not apply when Front1 and Front2 source splines are linked for source interpolation. See [Linking Source Nodes](#) (page 1193).

When you add a spline, it is applied to the Front1 or Front2 clip, depending on what is selected in the Input box. You can then select it and change it from an Front1 to an Front2 spline, or from an Front2 to an Front1 spline. This changes the input for both the source and corresponding destination spline. See [Toggling Spline Nodes from One Input to Another](#) (page 1192).

You can add more Axis nodes to the schematic and link the spline nodes to them, for example, if you want to affect the children splines in the same way.

You can, for example, track all the points for the selected spline using the Stabilizer. You can also select the Spline node for a spline if you are having trouble distinguishing between splines in a complex setup.

TIP When using source interpolation, you can select either one of the linked spline nodes when you want to set the interpolation value between them.

Adding Spline Node Trees

When you add a spline, a spline node tree is added for Front1 or Front2. The spline node tree includes both Spline and Axis nodes.

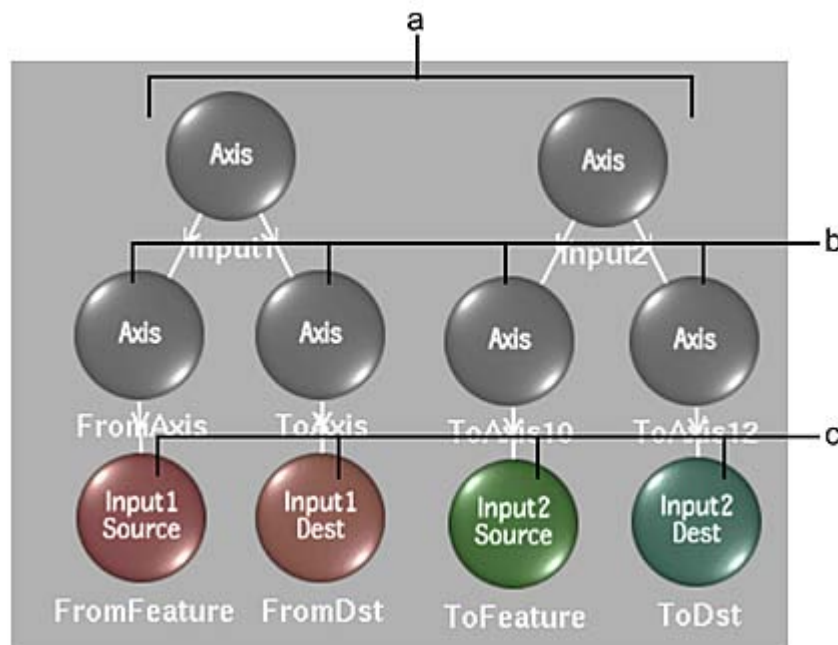

To add a spline node tree:

- 1 Select Front1 or Front2 from the Input box, depending on where you want to add splines.

NOTE Splines can be changed from Front1 to Front2, or from Front2 to Front1. See [Toggling Spline Nodes from One Input to Another](#) (page 1192).

- 2 Select Spline from the Node box.
- 3 Click Add.
- 4 Draw a spline. See [Drawing Splines](#) (page 1180).

A spline node tree is added for either Front1 or Front2 in the schematic. It includes source and destination spline nodes, each parented to their own Axis node, which are in turn parented to a common axis.

(a) Spline node trees for one Front1 (Input1), and one Front2 (Input2) spline (b) Axis nodes for individual spline wireframes (c) Spline nodes for corresponding source and destination splines

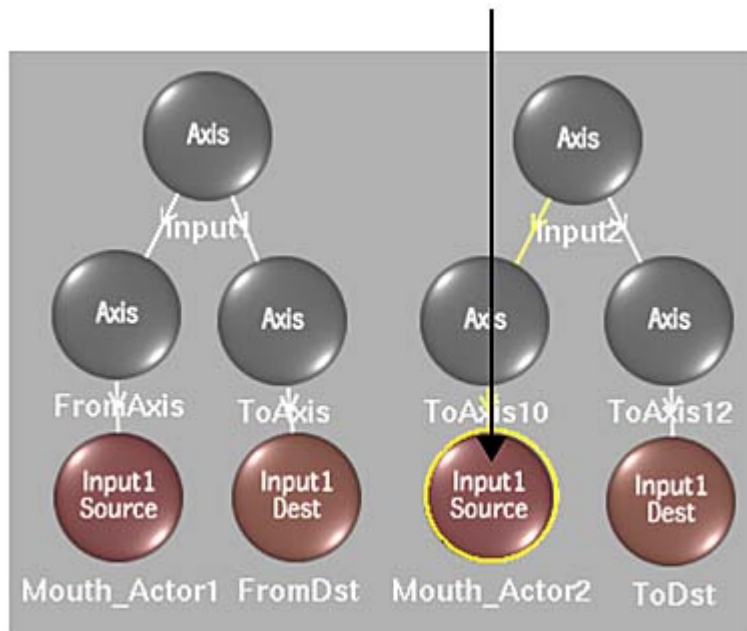

Toggling Spline Nodes from One Input to Another

Morphs work best when the source spline and destination spline have the same orientation—that is, were both drawn clockwise or counterclockwise—and the same number of vertices. You can ensure this is the case by drawing your spline on one input, then duplicating it to the other. To do this, first duplicate the spline, and then “move” the duplicate using the Morph menu's Toggle Input button. It toggles the selected spline from one input to the other.

TIP When morphing, you can duplicate splines and then toggle their input, which results in corresponding splines on the Front1 and Front2 clips that can then be linked for source interpolation.

To toggle a Spline node's input:

- 1 Select the source or corresponding destination Spline node you want to change from Front1 (Input1) to Front2 (Input2), or from Front2 (Input2) to Front1 (Input1).

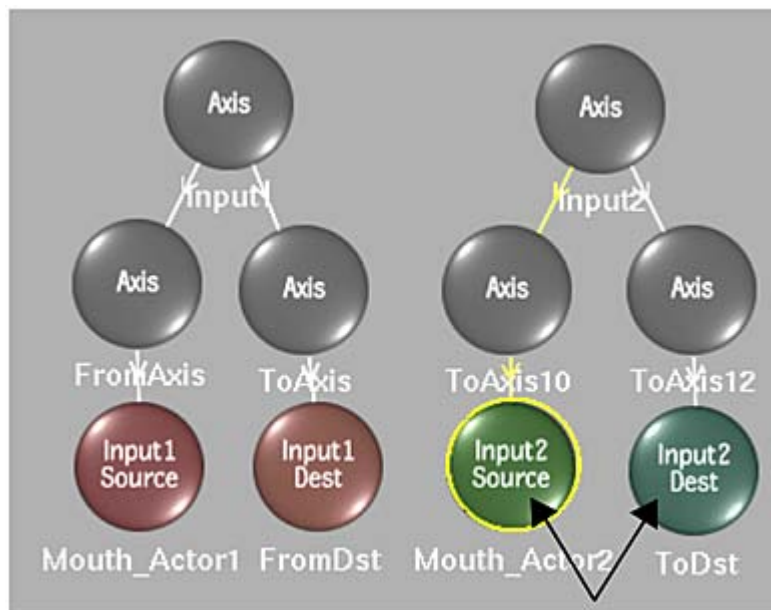

NOTE You can also select the spline directly in the clip.

- 2 Click Toggle Input.

The source and destination spline nodes change either from Front1 (Input1) to Front2 (Input2), or from Front2 (Input2) to Front1 (Input1).

Linking Source Nodes

You link a spline source node from Front1 to a spline source node from Front2 to create interpolation between them for a morph. Destination splines are no longer used and cleared from the schematic. The source of the Front2 spline node tree becomes the destination of the Front1 spline node tree.

You can create as many relationships between Front1 and Front2 spline nodes by linking them in the schematic, as there are features to correlate between the clips.

To link source nodes:

- 1 Select Link from the Tools box.
- 2 Drag from an Front1 source spline node to an Front2 source spline node.

NOTE You can only link a source spline from an Front1 to a source spline from Front2.

The splines are linked to each other, as indicated by the blue dotted connector lines. The destination splines, and their respective Axis nodes, are removed from the two spline node trees. Once Spline nodes are linked, you can set an interpolation value to determine the percentage that the feature defined by the Front1 spline mixes with the feature defined by the Front2 spline. See [Interpolating Features](#) (page 1197).

To unlink nodes:

- 1 Select Link from the Tools box.
- 2 Drag the cursor across the line that joins the two linked source spline nodes.

The spline nodes are unlinked, and the destination splines and their axes reappear for each of the affected spline node trees.

Animating and Tracking Splines

If the image you are warping or morphing is in motion, it will be necessary to animate each spline so it moves with the feature of interest. To animate a spline, set keyframes for its axes or vertices at various places in the clip. The motion between the keyframes is automatically interpolated. Alternately, use the Stabilizer to automate the process by tracking a reference point and connecting an axis or vertex to the resulting tracking data. Whichever method you choose, you can further control the shape of the spline by adding or removing vertices throughout the animation.

NOTE You can also animate correspondence points to refine the mapping of the source spline to its destination over time. See [Working with Correspondence Points](#) (page 1199).

For example, if you are creating a warp, you can load the Front1 clip into the Stabilizer and track all of the source spline's vertices. With Enable Warping selected from the Link box, you can then manually edit the points of the destination splines along the course of the clip to create the desired warp.

Similarly, if you are creating a morph, you can track the vertices of both source splines on the Front1 clip, as well as the source splines on the Front2 clip. When you then link the splines together in the Distort schematic for source interpolation, the morph animation is already set. You can refine the morph by further animating the destination spline.

At any frame, you can control the shape of the spline by adding and removing vertices. If the feature you are tracking gets larger, for example, you can add vertices to adjust the shape of the spline. Similarly, you can remove vertices that are no longer needed. Make them inactive from one keyframe to the next using the Active button, or permanently delete them. See [Manipulating Vertices and Tangents](#) (page 917).

Animating Splines

Set keyframes for spline vertices and tangents over the course of the clip.

To animate a spline:

- 1 Move to the frame where you want to begin animating the spline.
- 2 If necessary, do one of the following to display the spline you want to animate:
 - From the Warp or Morph menu, click Source to display source splines, or click Destination to display destination splines. You can also use the Show buttons to display both source and destination splines.
 - If you are working with two clips, with either Input, Matte, or Result selected in the View box, toggle the Input box to Front1 or Front2, depending on which spline you want to animate.
- 3 Select the spline in the clip or its node in the Distort schematic.
- 4 Enable Auto Key in the Animation menu.
- 5 Select Move mode in the Edit box, then select and move one or more vertices to a new location. You can also move vertex tangents.
- 6 Advance the positioner to a different frame then move some more vertices.
- 7 Continue to move vertices and tangents as you progress through the clip, so the spline follows the movement of the feature you are warping or morphing.

Loading a Clip into the Stabilizer

Use the Stabilizer controls in the Warp menu or in the Morph menu to select the clip you want to track, the spline you want to apply the tracking data to, and the tracking mode (Axis or Shape). See [How the Stabilizer Works](#) (page 870).

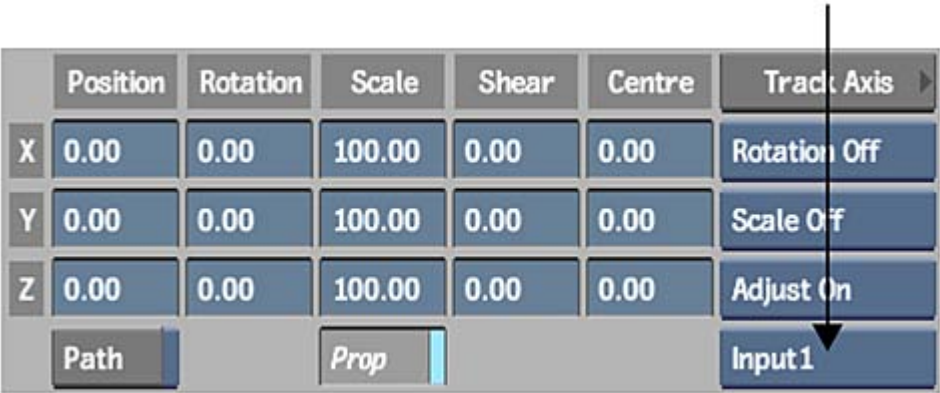

Select from the Track Clip box:	To track:
Front1	The Front1 clip.
Front2	The Front2 clip.
Matte1	The Matte1 clip.
Matte2	The Matte2 clip.
Background	The background clip.

Tracking by Axis

To make the spline follow the movement in the clip without changing shape, apply the tracking data to the spline's axis.

To track by axis:

- 1 Set the Stabilizer controls to apply the tracking data to either the source (Src) or destination (Dst) spline for either the Front1 or Front2 clip. Select the Axis node in the Distort schematic that is the parent of the spline you want to track.
- 2 Select the clip you want to track from the Track Clip box.

- 3 Click Track Axis.
The Stabilizer menu appears.
- 4 Position the tracker on the image. Tracker 1 controls the position. Tracker 2 controls the rotation or scale. See [Working with Trackers](#) (page 872).
- 5 To use two trackers, click Tracker 2, click Active, and position the second tracker on the image.
- 6 Click Analyse to generate the tracking data.
- 7 If necessary, fine-tune the analysis.

- 8 When you are satisfied with the tracking results, click Return to apply the results to the axis and return to Distort.

Tracking by Vertices

To make the spline follow the movement and shape change in the clip, apply the tracking data to the spline's vertices.

To track by vertices:

- 1 Select the spline's vertices that you want to affect. You can first select a spline by clicking its Spline node in the Distort schematic.
- TIP** Double-clicking a Spline node displays the Warp or Morph menu.
- 2 Set the Stabilizer controls to apply the tracking data to either the source (Src) or destination (Dst) spline for either the Front1 or Front2 clip.
 - 3 Click Track Shape.

The Stabilizer menu appears. A tracker appears on each vertex that you selected. The reference frame is the frame from which you opened the Stabilizer.

- 4 If necessary, adjust the position of the trackers to ensure that each tracker has a good reference point.
- 5 Click Analyse to generate the tracking data, and if necessary, fine-tune the analysis.
For example, disable a problem tracker and re-analyse, as described in [Tracking Difficult Shots and Correcting Errors](#) (page 897).
- 6 When you are satisfied with the tracking results, click Return to apply the results and return to Distort.

Duplicating and Pasting Tracking Data

You can duplicate and paste tracking data from one mesh to another using the Channel Editor. For example, if tracking was done using Axis, you can duplicate the translation of the Front1 source spline and apply it to the Front2 source spline.

Example: To duplicate translation data:

- 1 Click Animation to display the Channel Editor.
- 2 Select the X and Y channels in the Input1 _src translate folder.
- 3 Click Duplicate.
- 4 Select the X and Y channels in the Input1_dst translate folder.
- 5 Click Paste.

The translation channels containing the tracking data from the Front1 source spline are pasted into the Front1 destination spline.

Blending Clips

When you morph features from an Front1 clip to features from an Front2 clip or a background clip, you add a blend to the Front1. By blending the clip over time, the Front1 dissolves into the Front2 or the background. Matching features, for example, the mouth of an actor on the Front1 clip, and the mouth of an actor on the Front2 clip, as defined by the corresponding source and destination splines, can correspondingly blend from one to the other as the second clip becomes visible.

To blend the Front1 clip into the Front2 clip or background:

- 1 From the Morph menu, adjust the value in the Blend box. A value of zero results in the Front1 clip being totally opaque, while a value of 100 results in the clip being completely transparent.

TIP The blend value you set can be animated over time, and is displayed in the Channel Editor by a transparency channel in the Morph folder.

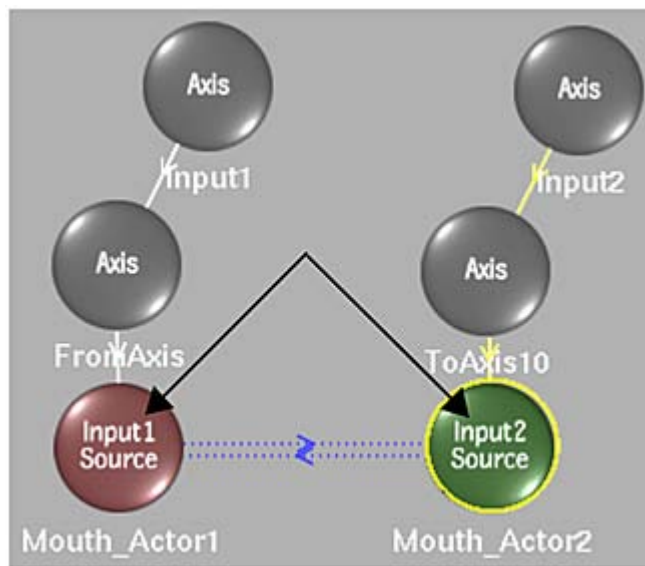

Interpolating Features

Set interpolation values for each set of Spline nodes you linked in the Distort schematic.

The interpolation value determines the percentage that the feature defined in the Front1 source spline mixes with the feature defined in the Front2 source spline.

To set the interpolation value between linked splines:

- 1 Select the Front1 (Input1) or Front2 (Input2) source Spline node of a linked pair in the Distort schematic.

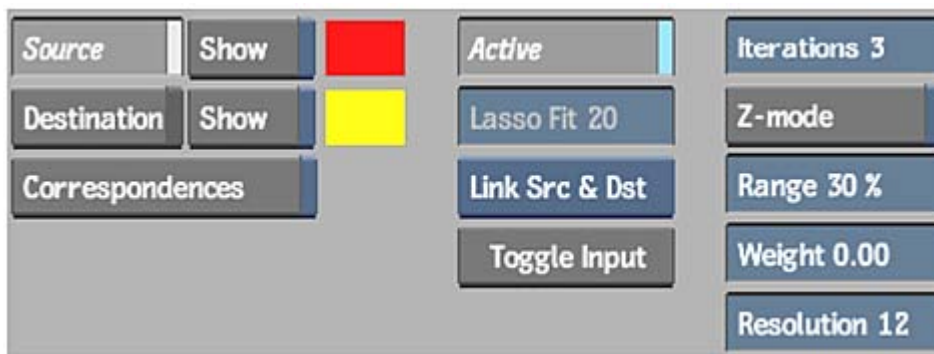

The current interpolation value for the linked splines appears in the Interpolation field.

- 2 Set the value for the interpolation. A value of 0 results in the Front1 feature remaining in its original form, while a value of 100 results in the Front1 feature distorting into the shape defined by the Front2 spline.

Refining Distortions

There are numerous methods and techniques to refine your distortions. You can adjust the correspondence between source and destination splines using correspondence points if a feature from Front1 is not mapped correctly to the corresponding Front2 feature. You can work with the number of iterations to increase the warping effect, or limit the affected region of the clip. As well, you can adjust clip resolution to affect how well clips distort.

Working with Correspondence Points

Correspondence points indicate how one frame is mapped to another in relation to source and destination splines, or Front1 and Front2 source splines when using source interpolation. If part of a clip is pulled or shifted too much during a distort, you can realign it by adjusting the correspondence points.

By default, correspondence points are added automatically. You can display the points, move them around the splines, animate them, as well as add and delete points to create a correspondence that better suits your needs. The more correspondence points a spline has, the more control you have over how the warp or morph is mapped.

To show correspondences:

- 1 Toggle on the visibility of the source splines and destination splines using the Show buttons.
- 2 In the Distort tool, click Correspondences.

Correspondence points are shown on the source and destination splines, and are connected by dotted lines. Selected splines show the connections with yellow dotted lines; unselected splines shown them in grey.

(a) Correspondences of unselected spline (grey) (b) Correspondences of selected spline (yellow) (c) Selected spline in Distort schematic

To move correspondence points:

- 1 Click Correspondences to display the correspondence points.
- 2 Select Move mode from the Edit box, then click and move a point on either the source or destination spline.

You can also select multiple points by Shift-clicking them.

Points can only be moved between the two points that surround it on the spline.

The correspondence point can only be moved between the two surrounding points

Image courtesy of Behavior Communications Inc.

The warped or morphed region is remapped according to the changes made to the correspondence points.

To add correspondence points:

- 1 Click Correspondences to display the correspondence points.
- 2 Select Add from the Tools box.
- 3 In the region of the clip where you want to improve the mapping, click the source or destination spline to add a new correspondence point.

A point is added. As well, a corresponding point is added to the corresponding spline. You can then move either of these points to improve the mapping of the clip. The more correspondence points there are, the more refined the distortion.

Adding a correspondence point to a source spline adds one to the destination spline

Image courtesy of Behavior Communications Inc.

To animate correspondence points:

- 1 Move to the frame where you want to begin animating correspondence points.
 - 2 Display a source and destination spline by clicking the Source Show and Destination Show buttons.
 - 3 Click Correspondences to display correspondence points.
- TIP** The source and destination splines should be offset from one another to best be able to animate their correspondence points.
- 4 Enable Auto Key in the Distort menu.
 - 5 Select Move mode in the Edit box, and then move one, or more, correspondence points to a new location.
 - 6 Advance the positioner to a different frame and then move a correspondence point again.
 - 7 Continue to move correspondence points as you progress through the clip to refine the warp or morph over time.

Correspondence point animation for each spline is kept in a corresPts channel in the Channel Editor. See [Distort Animation Channels](#) (page 1205).

To delete correspondence points:

- 1 Click Correspondences to display the correspondence points.
- 2 Select Delete from the Tools box.
- 3 Click a correspondence point on the source or destination spline.

The point you clicked and the corresponding point on the corresponding spline are deleted.

Adjusting Resolution

Resolution affects the sampling of the clips loaded into the Distort tool. The resolution value represents the number of pixel squares that the image is sampled at. Decrease the resolution value if you find your clips are not deforming smoothly.

NOTE Decreasing the resolution value slows down system performance.

To adjust resolution:

- 1 Use the Resolution field to increase or decrease resolution. A smaller value increases the number of samples, producing a higher quality distortion.

Adjusting the Degree of Distortion

The Distort tool includes parameters that allow you to easily control the degree of distortion in a warp or morph. You can adjust the Iterations parameter so the distorted source pixels more closely approach the destination spline. Similarly, you can adjust the Range parameter to affect all the pixels in the image, or just those in the immediate region of the warp. Displaying the distortion grid can help you evaluate the effects of your changes.

To create a warp or morph, invisible iteration points are added between the source and destination splines. These iteration points determine how many times the pixels between the splines is examined when the calculations are performed. Adjusting the number of iteration points is relevant when the distance between the splines is great; that is, when you are trying to achieve a large warp. With a small iteration number, the warp will not “follow” the destination spline closely. Increasing the number of iterations will result in a more obvious distortion. For smaller warps or morphs, there is no advantage in using a greater number of iterations; it simply increases processing time unnecessarily.

With a low number of iterations, a distortion can sometimes be too subtle

Image courtesy of Behavior Communications Inc.

Increasing the number of iterations results in a more obvious distortion

Image courtesy of Behavior Communications Inc.

By adjusting the range, you can control the region affected by the distortion. A lower value decreases the region affected by the warp, while a higher one increases it. For example, a value of 100% affects all the pixels in the image, a value of 33% affects one-third of the image, a value of 25% affects one-quarter of it. To restrict the distortion to the area immediately surrounding the vertex, choose a higher region number. To broaden the effect, choose a lower number. This parameter has a smaller effect on processing time than the number of iteration points.

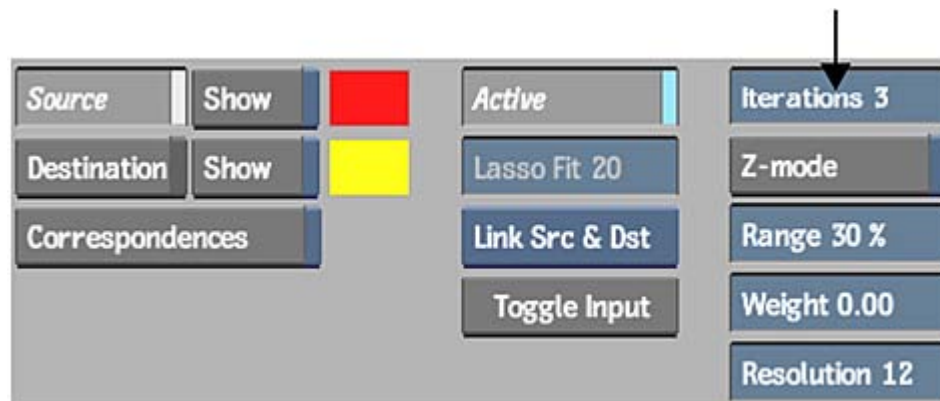

To display the distortion grid:

- 1 In Distort's Setup menu, enable Draw Grid.

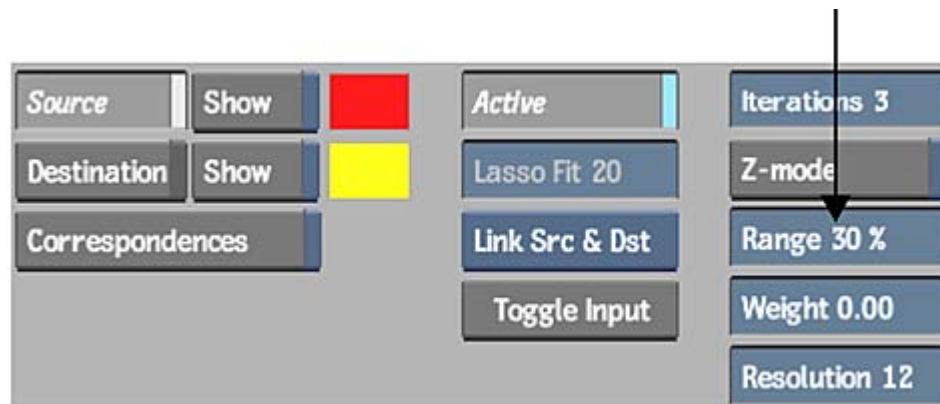

To adjust the amount the distortion “follows” the destination spline:

- 1 In the Warp or Morph menu, change the value in the Iterations field.

To change the size of the region affected:

- 1 In the Warp or Morph menu, change the value in the Range field.

Filling in Gaps at Edges of Distorted Clips

As you warp surfaces, sometimes their edges are pulled away from the absolute edge of the image, revealing either the background clip, or blank space.

You can fill this revealed area with the warped clip by repeating it.

Without Fill

Image courtesy of Das Werk and The House

With Fill, set to Part

Image courtesy of Das Werk and The House

To fill in gaps at edges of a distorted clip:

- 1 Click Setup.

(a) Repeat button (b) Repeat value (c) Amount box

- 2 In the Texture Tiling section, Enable Repeat.
- 3 Toggle the Repeat value to set the number of times the clip is repeated to fill the gaps:
 - Select 4 to repeat the clip once on each side: top, bottom, left, and right.
 - Select 8 to repeat the clip twice on each side.
- 4 Toggle the Amount button to control the portion of the clip to use to fill the gaps:
 - Select Full to squeeze the whole clip into each of the gaps.
 - Select Partial to use only a mirrored corresponding, and proportional portion of the clip to fill each of the gaps.

Warping Example

You can create many warps on a single input clip. Each destination spline offset from its source creates a warp on the clip. The following is an example of a simple warp.

To create a warp:

- 1 Once a spline shape has been made, click Warp to display the Warp menu.
- 2 From the View box, display the Result view to see the spline shape over the input clip.
- 3 Set the timebar positioner to the effect's first frame.
- 4 From the Warp menu, enable Source.
All Front1 source splines are displayed.
- 5 If necessary, adjust the vertices of the shape by moving points or curve handles.

TIP To prevent the warping of the clip as you edit a spline, make sure Link Src & Dst is selected in the Link box. Otherwise, as you edit either a source or destination spline, it will be offset from its corresponding source or destination—this is what will eventually create your warp. You can toggle between Link Src & Dst and Enable Warp by pressing the **W** keyboard shortcut.

- 6 Set the timebar positioner to the effect's final frame.
- 7 From the Link box, select Distort.

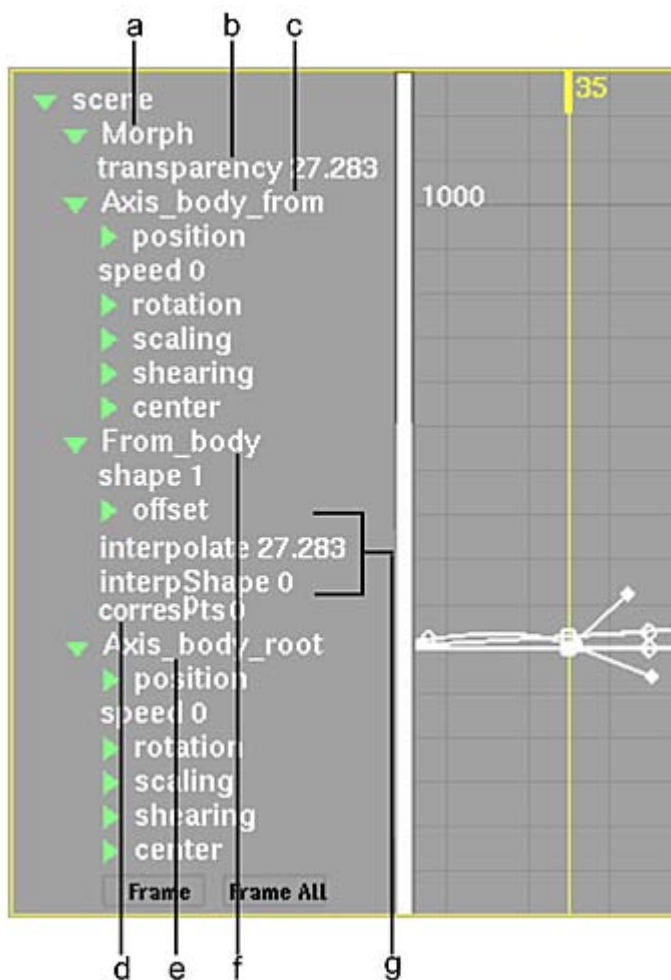

- 8 Enable Destination, and then adjust the vertices of the shape by moving points or curve handles. Edits to the destination spline-based shape will produce immediate warping.
- 9 Refine the warp as necessary. See [Refining Distortions](#) (page 1198).

Distort Animation Channels

The Distort tool includes channels for the Blend value as well as for all the Axis nodes in the schematic. Each spline in the effect contains a shape channel, with its vertex information, and an offset channel. As well, each spline contains a correspondence points channel containing point location information. All these channels are in the Morph folder in the Channel Editor.

When splines are linked, two additional channels appear under the Front1 spline's folder in the Channel Editor: an Interpolation channel corresponding to the value in the Interpolation field for the pair of linked spline nodes, and an interpShape channel. The interpShape channel contains the vertex information for the interpolated spline, which is the destination of the morph.

(a) Morph folder contains all folders and channels for both warps and morphs (b) Transparency channel corresponds to Blend parameter in Morph menu (c) Axis node folder for parent of Spline node (d) Correspondence points channel contains correspondence point information for the spline (e) Axis node folder for root of source and corresponding destination spline (f) Spline node folder for spline shape (g) Interpolation channels appear when spline nodes are linked in the schematic, under the Front1 (Input1) spline node's folder

Interpolation and InterpShape Channels

You can adjust the Interpolation and interpShape channels in the Channel Editor for each set of linked Front1 and Front2 splines to refine a morphing effect.

Each pair of linked Spline nodes produces an interpolated spline, which in turn, can be edited and animated independently.

(a) Interpolation and interpShape channels appear for linked spline nodes

The two interpolation channels, corresponding to linked spline nodes, are always in the Front1 source Spline node's folder in the Channel Editor.

(a) Corresponds to value in Interpolation field of Warp or Morph menu **(b)** Contains vertex information for interpolated spline

With Result selected in the View box, Front1 (Input1) selected in the Input box, and Source enabled, the source spline on Front1 (Input1) is displayed. It has a shape channel containing its vertex positions over time.

With Result selected in the View box, Front2 (Input2) selected in the Input box, and Source enabled, the source spline on Front2 (Input2) is displayed. It also has its own shape channel containing its vertex positions over time.

When an Front1 and Front2 spline are linked in the schematic, you select Result in the View box, Front2 in the Input box, and Destination to view the interpolated spline. The interpolated spline is the result of mixing the Front1 and Front2 source splines. Since it is the target of the morphing effect, you must click Destination to display it.

The interpolated spline's vertex information is contained in the interpShape channel in the corresponding Front1 spline's folder. Although the spline is a result of mixing the Front1 and Front2 source splines according to the Interpolation value, it can be controlled and animated independently.

(a) Morph follows contour of interpolated spline

Image courtesy of Behavior Communications Inc.

TIP Since each Interpolation channel, for every pair of linked Front1 and Front2 source splines, is independent, try using the Channel Editor's Link button on multiple Interpolation channels. This allows a common interpolation value for many sets of linked splines.

Using Distort in Batch

Use other nodes in combination with the Distort node in Batch to create more seamless warps and morphs that can be composited into media in Action.

Creating a Distortion to Feed into Action Media

You can create a morph effect in Distort, then feed the result, and the ResultMatte, into media in an Action node, to composite with additional media.

To create a distortion feeding into Action media:

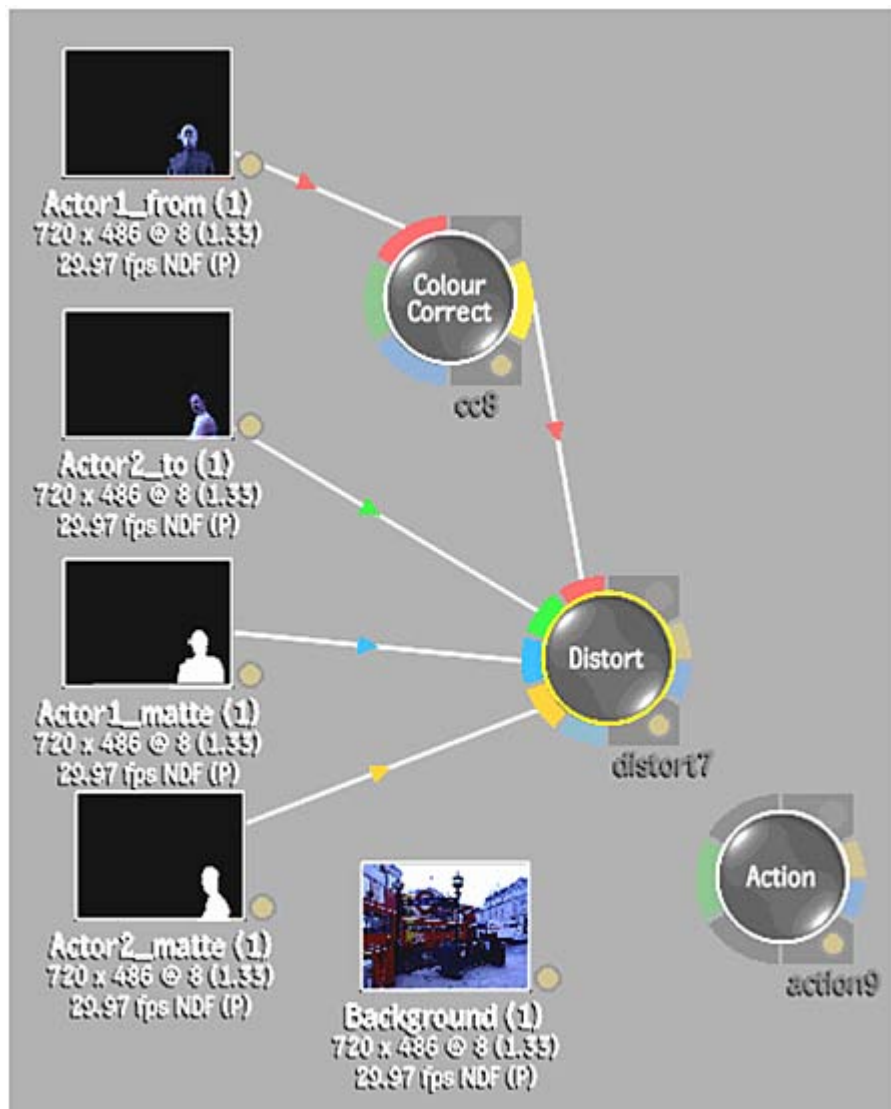

- 1 In Batch, add an Front1 clip and its corresponding matte, and an Front2 clip and its corresponding matte.
- 2 Add a background clip.

Images courtesy of Behavior Communications Inc.

NOTE The background clip will feed into the Action node, not the background socket of the Distort node.

- 3 Add a Distort node.
- 4 Add a Colour Corrector node.
- 5 Add an Action node.
- 6 Connect the Front1 clip to the Colour Corrector node.
- 7 Connect the Colour Corrector node to the Front1 socket of the Distort node.
- 8 Connect the other clips to their corresponding sockets on the Distort node: Front2, Matte1, and Matte2. There is no background connected to the background socket since Distort will feed into media of the Action node.

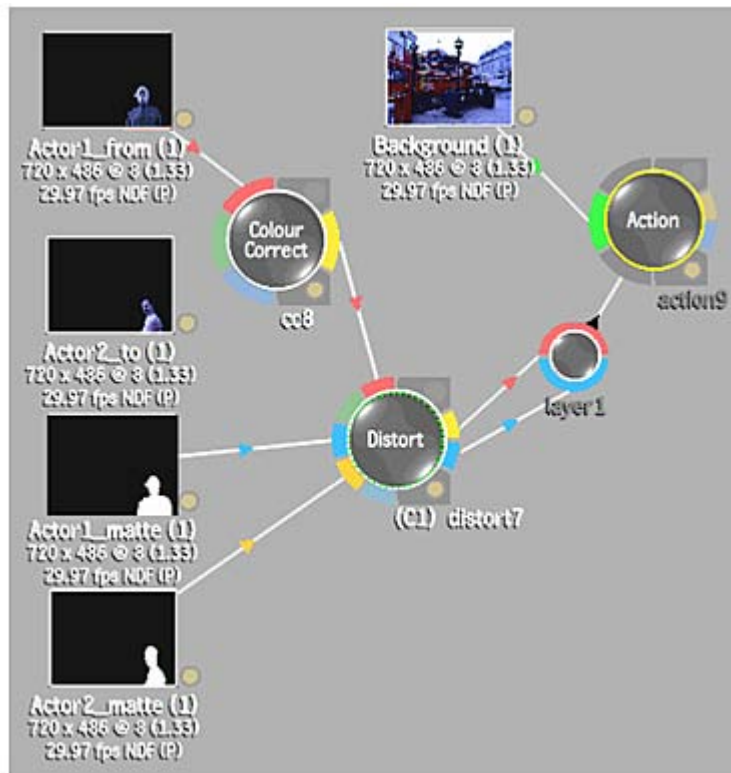

Images courtesy of Behavior Communications Inc.

- 9 Double-click the Distort node to load its controls into the work area.
- 10 Create the morph between the Front1 and Front2 clips.
- 11 Split the screen and create a context view for the Distort result and display it in a viewport.

Images courtesy of Behavior Communications Inc.

- 12 In the other viewport, access the result of the Colour Corrector. Create an animated colour correction for the Front1 clip to gradually transition to the colours in the Front2 clip.
- 13 In the Action node, connect a background clip to it.
- 14 Within the Action node, **Ctrl**-click Add to add media that feeds into the Action node in the Batch schematic.
- 15 Feed the Result and the ResultMatte of Distort into the front and matte of the media, in turn feeding into Action.

Images courtesy of Behavior Communications Inc.

- 16 In Action, add a surface for the media.
- 17 Animate the media.

Saving Preferences

You can save preferences for the Distort tool and node.

The state of the following parameters are saved as preferences:

- Autokey
- Icons
- Icon Transparency
- Fill
- Source/Destination
- Show Destination
- Axis Motion Path
- Axis Scale Proportional

You can save preferences as a file you can reload, or as the tool's or node's defaults which are loaded when you reset all, or create new Distort nodes in Batch.

For more information on saving and loading preferences, and managing default preferences, see [Setting Preferences](#) (page 1717).

Saving and Loading Distort Setups

Distort setups can be saved and loaded as setup files, with spline and other information preserved. You can also exchange Distort setups between the Distort tool and the Distort node in Batch.

To save a Distort setup:

- 1 Do one of the following:
 - In the Distort menu, click Save to open the file browser.
 - From the Distort node in Batch, click NodeSetup to display Distort's Setup menu, then click Save Node to open the file browser.
- 2 Select Setup as the type of file to save.
- 3 Type the name of the setup, and click Save.

To load a Distort setup:

- 1 Do one of the following:
 - In the Distort menu, click Load to open the file browser.
 - From the Distort node in Batch, click NodeSetup to display Distort's Setup menu, then click Load Node to open the file browser.
- 2 From the Load Type box, select the type of files to load.

(a) Load Type box (b) Load Mode box

- 3 From the Load Mode box, select whether to want the setup to append to or replace any existing Distort splines in your scene.
- 4 From the file browser, select the name of the setup to load.

NOTE If the Distort setup you are loading was created in a different resolution than the current project, click Scale Setup to scale the setup's splines.

About the Warper

Use the Warper to warp a clip or morph from a source clip to a result clip. Warping is free-form distortion of an image; it is a transition effect that matches the morphology of one clip gradually to that of another clip, such as when a human is morphing into an alien.

Accessing the Warper

You must select the required clips to access the Warper. You can enter the Warper with one to five clips. The number of clips that you load depends on the effect that you want to produce.

To access the Warper:

- 1 Select **Tools > Filter > Warper**.

The cursor changes to Pick Front.

- 2 Select the types of clips you want to load into the Warper from the Input Mode box.

Select:	To load:	To produce:
Front1	Front clip only	A warp of a single image.
Front1/Front2	Front and back clips	A morph, a wipe, or a regional warp.
Front1/Matte1	Front and matte clips	A warp of a single image using a matte.
Front1/Front2/Matte1	Front, back, and matte clips	A warp over a background using a matte.
F1/F2/M1/M2/Back	Front, matte, back, back matte, and background clips	A morph using two clips and their mattes on a background clip instead of on black.

- 3 Select the front clip.

The cursor changes to Render Here.

- 4 Click on any free (or a grey) area on the workspace.

You are now in the Warper Tool.

NOTE Regardless of which clips you load into the Warper, there are always two compositing layers available: a front layer and a back layer. If you do not load a back clip, black is used for the back layer.

To reset the Warper:

- 1 Click Reset All, and click Confirm when prompted.
Warper options are restored to their default settings.

Setting Up the Clips

Use the Clip Setup boxes to specify how each clip loaded into the Warper will be used.

Front	On
Back	Off
Matte	Off
Back Matte	Off
Background	Off

For Front and Back clips, the Clip Setup box contains On, Off, and Lock options. For Matte and Back Matte clips, the Clip Setup box contains On, Off, and Invert options. Background clips contain On and Off options.

Select:	To:
On	Warp the clip.
Off	Disable the clip. When a clip is disabled, it is not displayed and is not used in the processed result.
Lock	For Front and Back only, process the front or back clip in the final composite without warping it.
Invert	For Matte and Back Matte only, invert the front or back matte.

Activating Clips

The following table shows how to set up the clips to produce various effects.

Front1	Front2	Matte1	Matte2	Back	Effect
On	Off	Off	Off	Off	Warps the front clip only. This is the same as loading a front clip only.
On	On	Off	Off	Off	Morphs between two clips. This is the same as loading a front clip and a back clip.
On	Lock	Off	Off	Off	Wipes (page turns, rolls); regional warps (if the same clip is loaded as the front clip and the back clip).
On	Off	On	Off	Off	Warps the front clip and matte clip, composited on black.
On	On	On	Off	Off	Warps over a background with a matte clip.
On	Lock	On	Off	Off	Warps the front and matte clips composited on the back clip.
On	On	On	On	On	Morphs between two clips and their mattes onto the selected background clip.

Creating Meshes

After you load and set up your clips in the Warper, you create meshes to define the shape and position of the input image—the original image before the warp or morph—and the output image—the result of the warp or morph. The meshes use control points to determine the change, in shape and position, and create a convincing transition from the input image to the output image.

You use two meshes, a source mesh and a destination mesh, to generate the warp effect. For instance, if you want to morph a square into a circle, the source mesh defines the input image, which is a square, and the destination mesh defines the output image, which is a circle.

Defining a Mesh

When creating a mesh, you anchor the mesh to the surrounding area. To ensure this, create the mesh over a slightly larger area of the image than the part you want to affect. For example, to warp a person's mouth, extend the mesh to cover the lower half of the person's face. This “anchors” the area surrounding the warp so that it is not affected by the warp. You begin by defining the number of patches in the mesh and then placing it over the required area in the image.

To define a mesh:

- 1 Go to the frame where you want the effect to begin.
- 2 Specify which mesh will be created.

Meshes			Mapped To
Front Source	Show	<input type="checkbox"/>	Front Source
Front Destination	Show	<input type="checkbox"/>	Source Interp
Back Source	Show	<input type="checkbox"/>	Back Source
Back Destination	Show	<input type="checkbox"/>	Source Interp
Source Interp	Show		

Click:	To create:
Front Source	The front source mesh.
Front Destination	The front destination mesh.
Back Source	The back source mesh in a morph.
Back Destination	The back destination mesh in a morph.

For information on when to create each type of mesh, see [Warping](#) (page 1228) and [Morphing](#) (page 1230).

- 3 Click Add Mesh.

- 4 In the Xcells and Ycells fields, set the number of patches for the mesh. For example, to create a mesh that is 10 patches wide by 5 patches high, enter 10 in the Xcells field and 5 in the Ycells field. Enable the Proportional button to automatically set the X and Y cells fields to the same value.
- 5 Click the image and drag the cursor to draw the mesh.

TIP If you cannot see the mesh properly against the colours in the image, you can customize the colours of the various meshes using the colour pots beside each mesh name.

Adding Patches

As you build the mesh, you may need to add patches to cover more of the image.

To add patches:

- 1 In the Warper menu, click Add Mesh.
- 2 To add only one patch, click the edge of the patch that is closest to where you want to add a patch. The new patch is approximately the size of the adjacent patch.
- 3 To add several patches, drag from the edge of an existing patch over the area in which to add patches. Each new patch added is approximately the size of its adjacent patch.

Deleting Patches

You can delete patches if you make a mistake while creating the mesh.

To delete patches:

- 1 In the Warper menu, click Delete.

- 2 To delete a patch that lies along the boundary of the mesh, click the middle of the patch.
- 3 To delete a line that connects two patches that are not along the boundary, click both sides of the line.

Modifying a Mesh

Use the modelling controls in the Warper menu to modify the meshes to define the original and the final shape of the image. You can modify the shape and size of the patches or the location and orientation of the mesh, divide the patches into smaller subpatches, and split the edges into smaller segments.

NOTE The more detail you add to the mesh, the more control you have when warping or morphing a clip. However, if you have too much detail, the meshes may be difficult to modify.

If you cannot see the mesh properly against the colours in the image, you can customize the colours of the various meshes, as well as those of the splines, tangents, and vertices. See [Display Settings](#) (page 1236).

Moving Control Points, Edges, and Tangent Handles

You can manipulate control points and tangent handles on the mesh to add precision to your warp effect. Click the control points to access their tangent handles, then click the tangent handles to change the shape of a patch.

Click the Move button to move a vertex, an edge, or a tangent handle.

To:	Click:
Move a control point	The control point and drag. Note that the X, Y, and Z coordinates of the selected vertex appear in the corresponding fields in the menu.
Move an edge	Near the centre of the edge and drag.
Move a tangent handle	The corresponding vertex to display its tangents, then click the tangent handle and drag.

Selecting Multiple Control Points

Select multiple control points to translate, scale, or rotate all or part of the mesh while maintaining the spatial relationship between the selected control points.

To select multiple control points:

- 1 In Warper menu, click Select.

- 2 Hold down the `Ctrl` key and drag a selection box over the control points that you want to select.

NOTE To deselect individual points, click the points. To deselect all, click outside the area of selected control points.

Translating, Scaling, and Rotating the Mesh

Use the Translate, Scale, and Rotate options to change the position, size, and orientation of part or all of the mesh.

To translate, scale, or rotate the mesh:

- 1 Select the appropriate area of the mesh. See [Selecting Multiple Control Points](#) (page 1218).
- 2 In the Warper menu, select Translate, Scale, or Rotate.

- 3 Click Move.
- 4 Click one of the selected control points and drag.
The selected area of the mesh is translated, scaled, or rotated.

NOTE You can also translate, scale, and rotate the entire mesh using the Translate, Scale, and Rotate channels in the Channel Editor. However, you cannot use the Channel Editor to affect only part of the mesh.

Breaking Tangents

By default, a vertex's tangents work together. Moving one tangent has the inverse effect on the opposite one to maintain a smooth curve at the vertex. In certain cases, you may want the tangents to move independently of each other.

Consider the mesh in the following example.

Suppose that you want to move tangent A to change the shape of edge A. Moving tangent handle A also causes tangent B to move in the opposite direction (as shown above); tangent A and tangent B are locked. You can use the Break command to break the tangents and move them independently (as shown here).

After using Break to break two tangents, you can use the Auto command to rejoin them. Note that resetting the tangents also resets the corresponding edges to their default positions.

To break tangent handles:

- 1 In the Warper menu, click Move.
- 2 Click a vertex to display its tangents.
- 3 Click Break, then click a tangent handle.

The tangent and the opposite one can now be moved independently. The tangent handles are solid indicating they are broken.

NOTE If the vertex has four tangents, click one handle of each pair to make all four tangents move independently.

To reset broken tangent handles:

- 1 In the Warper menu, click Move.
- 2 Click a vertex to display its tangents.
- 3 Click Auto, then click a tangent handle.
The tangents and edges are reset.

Subdividing a Patch

You can divide patches in a mesh into smaller subpatches and split the edges into smaller segments using the Subdivide button.

To subdivide a patch:

- 1 In the Warper menu, click Subdivide.

- 2 Click the edge of a patch and drag the cursor to the opposite edge.

NOTE To delete an edge created with Subdivide, enable Delete and click the edge.

Adding a Vertex

For more control when manipulating an edge, add a vertex to the edge.

To add a vertex:

- 1 In the Warper menu, click Split.

- 2 Click the edge of a patch where you want to add a vertex.

NOTE To delete a vertex created using the Split button, click Delete, then click the vertex.

Using the Freehand Mesh Tool

Use the Freehand Mesh tool to perform intricate mesh modelling.

To create a freehand mesh:

- 1 In the Warper menu, click Freehand.

- 2 Click the edge of a patch, and continue clicking until you complete the mesh.
- 3 **Ctrl**-click the final vertex.

To delete a freehand mesh:

- 1 Click Delete.
- 2 Click the spline or vertex you want to delete, or click Undo.

Warping with the Magnet Tool

Use the Magnet tool to define the shape of the warped image. The Magnet tool warps the area of the mesh under the Magnet. You can set the size of the Magnet and define its effect on the selected area.

Note that the Magnet's effect is most noticeable when the selected area includes many control points (that is, when the grid has many patches, when you are using a large Magnet, or both).

To use the Magnet tool:

- 1 In the Warper menu, click Magnet.
- 2 Place the cursor over the mesh and adjust the Magnet size by pressing `Ctrl+S` and dragging.
- 3 Place the Magnet over the control points you want to warp and click.
The affected control points turn red.
- 4 Drag the Magnet to produce the effect you want.

NOTE By default, the Magnet translates the mesh. To scale or rotate the mesh, select the Scale or the Rotate option in the selection box beside the Magnet button.

Customizing the Magnet's Effect

You can customize the Magnet's effect by changing the shape of the curve in the Magnet Curve Editor. Note that, by default, the Magnet has the greatest effect on the pixels at the centre of the Magnet and the least effect on the pixels at its perimeter.

To customize the Magnet's effect:

- 1 In the Warper menu, click MEditor.
The Magnet Curve Editor appears.

(a) Tools box

2 Adjust the shape of the Magnet curve.

You can also use the Edit Mode options to modify the curve.

NOTE You can save and load custom Magnet settings using the Save and Load buttons in the Magnet Curve Editor.

Tips and Tricks

You can experiment with the Magnet curve to achieve different effects.

(a) Point representing effect at the Magnet's centre (b) Point representing effect at the Magnet's perimeter

- Invert the curve to affect the pixels at the perimeter of the Magnet more than those at the centre.
- Flatten the curve along the horizontal axis to have the same effect on all pixels under the Magnet.
- Add extra control points and create a sine or wave curve to make the control points move in opposite directions.
- Move the curve into the negative horizontal axis to create a magnet with an opposing magnetic effect.

Modifying the Meshes for Live-Action Clips

If you are warping or morphing a live-action or moving clip, you must define the source mesh at several frames in the clip. The Warper interpolates the location and shape of the mesh between frames.

Creating a mesh over the length of a live-action or moving clip can be time-consuming. To simplify the mesh-building process, create the mesh for the first frame of the required clip, then use the Stabilizer to generate the successive meshes.

NOTE You can track the source or destination mesh for either the front or the back clip.

With the Stabilizer, you can track the movement in the clip, and then apply the tracking data to the mesh (tracking by Axis). This translates the mesh so that it follows the movement in the clip without changing shape. Alternatively, you can track the movement of selected points in the image, and apply the tracking data to the mesh (tracking by Vertices). This translates and changes the shape of the mesh so that it matches the position and shape of the image over the length of the clip.

Loading a Clip into the Stabilizer

Use the Stabilizer controls in the Warp menu (if you are warping) or in the Morph menu (if you are morphing) to select the clip you want to track, the mesh you want to apply the tracking data to, and the tracking mode.

Select:	To:
Front	Track the front clip.
Back	Track the back clip.
Axis	Apply the tracking data to the axis of the mesh. You can use one or two trackers in the Stabilizer.
Vertices	Apply the tracking data to the mesh control points (vertices). You must select the control points you want to track before entering the Stabilizer. You can track up to 1000 control points. Note that tracking by vertices sets a shape keyframe at every frame of the clip.
Source	Apply the tracking data to the source mesh of the selected clip.
Destination	Apply the tracking data to the destination mesh of the selected clip. This option can be useful if front and back destination meshes are different.

Tracking by Axis

To make the mesh follow the movement in the clip without changing shape, apply the tracking data to the mesh axis.

To track by axis:

- 1 Set the Stabilizer controls to apply the tracking data to either the Source or Destination mesh for either the Front or Back clip.
- 2 Select Axis.
- 3 Click the Stabilizer button.
The Stabilizer menu appears.
- 4 Position the tracker on the image. See [Working with Trackers](#) (page 872).
- 5 To use two trackers, click Tracker 2, click Active, and position the second tracker on the image.
- 6 Click Analyse to generate the tracking data.
- 7 If necessary, fine-tune the analysis.
- 8 When you are satisfied with the tracking results, click Return to apply the results and return to the Warper.

Tracking by Vertices

To make the mesh follow the movement and shape change in the clip, apply the tracking data to the mesh vertices.

To track by vertices:

- 1 Select the mesh control points that you want to affect. See [Selecting Multiple Control Points](#) (page 1218).
- 2 Set the Stabilizer controls to apply the tracking data to either the Source or Destination mesh for either the Front or Back clip.
- 3 Select Vertices.
- 4 Click the Stabilizer button.
The Stabilizer menu appears. A tracker appears on each vertex that you selected. The reference frame is the frame from which you opened the Stabilizer.
- 5 If necessary, adjust the position of the trackers to ensure that each tracker has a good reference point.
- 6 Click Analyse to generate the tracking data, and if necessary, fine-tune the analysis.
For example, disable a problem tracker and re-analyse, as described in [Tracking Difficult Shots and Correcting Errors](#) (page 897).
- 7 When you are satisfied with the tracking results, click Return to apply the results and return to the Warper.

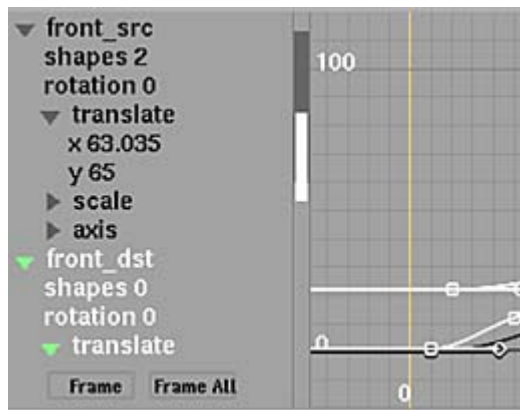

Copying and Pasting Tracking Data

You can copy and paste tracking data from one mesh to another using the Channel Editor. For example, if tracking was done using Axis, you can copy the translation of the front source mesh and apply it to the back source mesh.

To copy translation data:

- 1 Click Animation to view the Channel Editor.
- 2 Select the X and Y channels in the front_src translate folder.
- 3 Click Copy.
- 4 Select the X and Y channels in the front_dst translate folder.
- 5 Click Paste.

The translation channels containing the tracking data from the front source mesh are pasted into the front destination mesh.

If tracking was done using Vertices, you can copy the shape animation of the front source mesh and apply it to the front destination mesh.

Example: To copy shape animation data:

- 1 Select the front_src shapes channel.
- 2 Click Copy.
- 3 Select the front_dst shapes channel.
- 4 Click Paste.

The shapes channel containing the tracking data from the front source mesh is pasted into the front destination mesh.

Copying and Pasting Meshes for a Live-Action Clip

For a live-action clip, use the Channel Editor to copy the shapes curve of one mesh and paste it into another mesh. The shape and translation of the mesh at each frame are copied.

To copy and paste meshes for a live-action clip:

- 1 Create the mesh at the first frame of a clip and modify it over several frames to define the movement in the clip.
- 2 Click Animation to view the Channel Editor.
- 3 Select the shapes channel for the mesh you are copying (front_src, front_dst, back_src, or back_dst).
- 4 Click Copy.
- 5 Select the shapes channel for the mesh that you want to be the same as the copied mesh (front_src, front_dst, back_src, or back_dst).
- 6 Click Paste.

NOTE If Auto Key in the Setup menu is enabled, a keyframe is created in the associated animation channel at the current frame every time the mesh is copied to a new frame and modified. When you copy the shapes curve to a new mesh, you copy the mesh and all its keyframes.

Copying and Pasting Meshes for a Still Clip

For a still clip, use the Copy and Paste buttons in the Warper menu to copy a mesh and paste it into another mesh.

To copy and paste meshes for a still clip:

- 1 Create the mesh at the first frame of the clip.
- 2 Click Copy in the Warper menu to copy the mesh—including its translation, scale, and rotation values.
- 3 Go to the required frame and display the mesh (source or destination) where you want to paste the copy.
- 4 Click Paste.

Warping

Warping changes the shape of the image in a clip. When you warp an image, you start by drawing a mesh over the region of the image you want to warp. You then modify the mesh over the image at specific keyframes to distort the image.

To create the warp, define a source mesh and a destination mesh for the front clip. The source mesh defines the area of the image that you want to warp; it outlines the shape of the non-distorted image in each frame of the clip. The destination mesh defines what the warped image looks like; it outlines the shape of the distorted image in each frame of the clip. Typically, you set the destination mesh at several frames of the clip. The Warper generates a smooth transition between frames.

The general steps for warping:

- 1 Load the appropriate clips into the Warper. If you are warping just a region of the clip, load the same clip as the Front and the Back clip. See [Warping a Region of a Clip](#) (page 1230).
- 2 In the Warper menu, click Warp.
- 3 Set up the clips. See [Setting Up the Clips](#) (page 1214). In general:
 - Set Front to On.
 - If you are warping just a region of the clip, set Back to Lock.
- 4 Click Front to view the front clip.
- 5 Define the source mesh for the original image.
- 6 Define the destination mesh for the warped image.
- 7 Process the clip.

Defining the Source Mesh

Use the modelling tools to define the source mesh so that it outlines the original shape of the image in the front clip.

To define the source mesh for the original image:

- 1 Go to the first frame of the clip.
- 2 Click Front Source to define the source mesh for the front clip.
- 3 Add a mesh over the area to warp and modify its shape to match the original image.

- 4 If you are using a live-action or moving clip, the source mesh must follow the movement of the image. You can either modify the mesh manually throughout the clip, or use the Stabilizer to track the movement in the clip. See [Modifying the Meshes for Live-Action Clips](#) (page 1224).

Defining the Destination Mesh

Set the destination mesh to be the same as the source mesh at the first frame, then change the shape of the destination mesh at different frames of the front clip to outline the required shape of the distorted image.

To define the destination mesh for the warped image:

- 1 Click Front Source.
- 2 Go to the first frame in the clip.
- 3 Click Copy to copy the source mesh.
- 4 Click Front Destination to select the destination mesh for the front clip.
- 5 Click Paste to paste the copied mesh into the destination mesh.
- 6 At several frames in the clip, modify the destination mesh to outline the required shape of the warped image.

TIP In the view box, select Result to see the pixels move as you move the mesh points.

- 7 When you finish modifying the meshes, go to frame 1 and click Process to process the clip.

Warping a Still Clip

To warp a still clip, you define the source mesh only for the first frame of the clip since the object to warp has the same shape and location in each frame of the clip. Typically, you have to define the destination mesh only for the first and the last frames of the clip. The Warper generates a smooth transition between the two frames.

The following illustration shows the source and destination meshes used to warp a square into an oval.

Source Mesh:

First Frame

Last Frame

Destination Mesh:

First Frame

Last Frame

Warping a Region of a Clip

When a clip is processed, only the area defined by the mesh is processed. If you want to warp only a region in an image (known as regional warping), but you want to see the entire image in the result, you must load the same clip as the front and the back clip, and then lock the back clip.

Morphing

Morphing gradually transforms an image in a front clip into an image in a back clip. The effect is achieved by warping the two images and dissolving between the front and back clips. Unlike warping, which requires only a front source mesh and a front destination mesh, morphing requires a source mesh and a destination mesh for both the front clip and the back clip.

The front source mesh defines the original shape of the image in each frame of the front clip. Similarly, the back source mesh defines the original shape of the image in each frame of the back clip.

NOTE You should create the mesh over a slightly larger area of the image than just the part you want to affect. See [Defining a Mesh](#) (page 1216).

Both the front and the back destination meshes correspond to the warped image. Since the front clip transforms into the back clip:

- At the first frame, the front and back destination meshes correspond to the shape of the front clip.
- At the last frame, the front and back destination meshes correspond to the shape of the back clip.

The general steps for morphing:

- 1 Load the appropriate clips into the Warper. You need to load at least a front clip and a back clip.
- 2 In the Warper menu, click Morph.
- 3 Set up the clips (see [Setting Up the Clips](#) (page 1214)). In general:
 - Set Front to On.
 - Set Back to On.
- 4 Click Front to view the front clip.
- 5 Define the front source mesh to match the shape of the front clip at each frame.
- 6 Define the back source mesh to match the shape of the back clip at each frame.
- 7 Define the front and back destination meshes. You can either use Source interpolation to automatically modify the destination meshes or copy and paste the meshes and set the keyframes manually.

- 8 When you finish modifying the meshes, go to frame 1 and click Process to process the clip.

Defining the Front Source Mesh

The front source mesh defines the original shape of the image in each frame of the front clip.

To define the source mesh for the front clip:

- 1 Go to the first frame of the clip.
- 2 In the Morph menu, click Front Source.
- 3 Add a mesh over the area to be morphed and modify its shape to match the image.
- 4 Make the front source mesh match the image at each frame of the front clip. You can either modify the mesh manually or use the Stabilizer to track the movement in the front clip.

Defining the Back Source Mesh

The back source mesh always contains the same number of control points and patches as the front source mesh. Copy the front source mesh to use as a starting point, then adapt the mesh shape to the image at each frame of the back clip.

If you are using the Stabilizer and you need more detail for the back source mesh, add subdivisions to the mesh. Be sure to add the same subdivisions to the front source mesh.

NOTE Enable the Fixed button in the Stabilizer menu.

To define the source mesh for the back clip:

- 1 Go to the first frame of the clip.
- 2 Click Front Source, then click Copy to copy the front source mesh.
- 3 In the Morph menu, click Back Source to select the back source mesh.
- 4 Click Paste to paste the copied mesh into the back source mesh.
- 5 Click Back to view the back clip.
- 6 Modify the back source mesh to match the image in the back clip at each frame. You can either modify the mesh manually or use the Stabilizer to track the movement in the back clip.

Using Source Interpolation

Use source interpolation to automatically define the destination meshes. Source interpolation automatically creates the transition from the front source mesh at the first frame to the back source mesh at the last frame of the clip.

NOTE If you want to add another effect, such as scaling, during the morph, do not use source interpolation. You must define the front and back destination meshes manually at several frames. See [Setting Keyframes Manually](#) (page 1232).

Dissolve and Interpolation Curves

Source interpolation uses two predefined animation curves—dissolve and interpolation—to calculate the percentage change from the front source mesh to the back source mesh over the length of the clip. These values are set in the Dissolve and Interpolate fields:

- The Dissolve field defines the percentage change in the colour of the pixels at the current frame.
- The Interpolate field defines the percentage change in the position of the pixels at the current frame.

The default values in these fields are 0% at the first frame and 100% at the last frame. Using the default values results in a smooth dissolve from the pixels in the front image to those in the back image, as well as a smooth transition from the shape of the front image to that of the back image. You can change the rate of the morph by changing the interpolation and dissolve values.

To use source interpolation:

- 1 Click Morph to display the Morph menu.
- 2 Under Mapped To, select Source Interp to use source interpolation for the Front Destination mesh and Back Destination mesh.
- 3 Enable Curves to activate the interpolation and dissolve curves.

- 4 In the View box, select Result to view the result, and play the clip.

To change the rate of the morph:

- 1 In the Warper menu, click Animation to display the Channel Editor.
- 2 Select the dissolve or the interpolate channel.
- 3 Modify the curve.

Setting Keyframes Manually

If you are not satisfied with the source interpolation result, you can set the keyframes manually. However, you will have to set the keyframes throughout the clip—you cannot use source interpolation in conjunction with manual keyframes.

To set a keyframe manually:

- 1 Go to the frame corresponding to the keyframe you want to set.
- 2 Click Front Destination to display the front destination mesh.
- 3 Modify the mesh.
- 4 Copy the front destination mesh and paste it into the back destination mesh for that frame.
Alternatively, if you want the back destination mesh to always match the front destination mesh, select the Front Destination under Mapped To adjacent to the Back Destination Meshes button.

Morphing Between Two Still Clips

To morph between two still clips, you define the source meshes only for the first frame of the front and back clips (since the objects have the same shape and location in each frame of the clips). You can use source interpolation to create a smooth morph.

The following illustration shows the source and destination meshes needed to morph a square into a circle.

Front Source Mesh:

First Frame

Last Frame

Back Source Mesh:

First Frame

Last Frame

Front and Back Destination Meshes:

First Frame

Last Frame

Morphing Between Two Live-Action Clips

To morph between two live-action clips, you have to define the source and destination meshes for the front and back clips for the duration of the clips—since the objects change shape and location in each frame of the clips. You can use the Stabilizer to track the movement of the objects and source interpolation to create a smooth morph.

The following illustration shows the source and destination meshes needed to morph a square into a circle, both moving from the upper-left to the lower-right corner of the image window.

Setup Options

From the Setup menu, you can customize display colours and set processing options.

Rendering Settings

Use the Rendering settings to improve the final output quality of your image.

Texture Settings

Use the following controls to choose between hardware texture-mapping or polygons for processing.

Repeat Specifies how pixels are handled when a source mesh goes outside of the borders of an image. When this button is disabled, anything outside of the image is considered black. When the button is enabled, the image is repeated. TexRepeat is disabled by default.

Warper Settings

Use these settings to define general warper properties.

Slip Settings

Slips a clip by a specified number of frames. Click in the field for the clip you want to slip and enter the number of frames. The first frame of the clip will be repeated by the number specified to result in a delayed start.

Select:	To slip:
Front	The front clip.
Back	The back clip.
Matte	The front matte.
BMatte	The back matte.

Display Settings

Enable the Icons button to display splines, tangents, and vertices in the image. You can also customize the colours of splines, tangents, and vertices using the colour pot next to each button.

Effects and Tools Reference

24

This section provides information about the effects and tools that you can use on your media.

2D Histogram

Use the 2D Histogram to display the luminance distribution of the matte.

To access the 2D Histogram menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

2D Histogram Menu Settings

Lift field Displays the value added to the resulting pixels to create the final matte. Editable.

Gain field Displays the value that the resulting pixel values are multiplied by to create the final matte. Editable.

Histogram Displays a bar graph that is used to adjust the luminance values of the image. In the Ranges menu, the curves for the three luma ranges are also displayed.

Minimum Input field Displays the lower limit of the luminance values. Pixels with lower values are mapped to black.

Minimum Output field Displays the lower limit of the luminance values for black pixels.

Maximum Input field Displays the upper limit of the luminance values. Pixels with higher values are mapped to white.

Maximum Output field Displays the upper limit of the luminance values for white pixels.

Out Range box Select a curve that is constant (Clamp) or linear (No Clamp) before the first point of the curve and after the last point of the curve.

When using 16-bit floating point images, you can select Clamp to clamp colour and luminance values, or No Clamp to allow pixel floating point values to be less than 0 or more than 1.

Frame Selection box Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Destination button Enable to show a histogram of the colour values in the result or destination clip.

The destination colour values are obtained from the current frame. If you input both front and matte clips, the colour values in the front clip that are defined by the white part of the matte are displayed.

Reset button Resets to default histogram settings.

Zoom field Displays the vertical zoom value of the histogram.

You can also zoom horizontally by pressing `Ctrl+spacebar` and dragging left or right in the histogram. To pan horizontally, click `spacebar` and drag left or right in the histogram.

2D Transform

Use 2D Transform to apply basic axis transformations and camera shake effects to clips.

To access the 2D Transform menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and a matte clip, and outputs a result and an outmatte.

2D Transform Menu Settings

Timeline FX Quick Menu Settings

To see the full 2D Transform menu, click the Editor button.

2D Transform Tab selector Select the tab settings you want to modify.

General Settings

Transform Type box Select Perspective to modify all available settings, or Pan & Scan to modify only Position and Scale. In Pan & Scan mode, some Axis and Camera Shake settings are unavailable.

Camera Shake button Enable to simulate camera shake in the image.

Show Icons button Enable to display the vertex editing tool in the image window.

Scan Mode box Select the scan mode of rendered clips.

Axis Settings

Position X field Displays the X-axis offset applied to the clip. Editable.

Position Y field Displays the Y-axis offset applied to the clip. Editable.

Position Z field Displays the depth offset of the clip. Available when Transform Type is set to Perspective. Editable.

Rotation X field Displays the degree of rotation on the X axis. Available when Transform Type is set to Perspective. Editable.

Rotation Y field Displays the degree of rotation on the Y axis. Available when Transform Type is set to Perspective. Editable.

Rotation Z field Displays the degree of rotation along the Z axis. Available when Transform Type is set to Perspective. Editable.

Scale X field Displays the X-axis scaling offsets applied to the clip. Editable.

Scale Y field Displays the Y-axis scaling offsets applied to the clip. Editable.

Scale Z field Displays the Z-axis scaling offset. Available when Transform Type is set to Perspective. Editable.

Proportional button Enable to affect the Scale fields proportionally.

Shear X field Displays the offset value for the horizontal edges of the clip. Available when Transform Type is set to Perspective. Editable.

Shear Y field Displays the offset value for the vertical edges of the clip. Available when Transform Type is set to Perspective. Editable.

Shear Z field Displays the depth value of the horizontal edges of the clip. Available when Transform Type is set to Perspective. Editable.

Centre X field Displays the centre point value of the clip along the horizontal axis. Available when Transform Type is set to Perspective. Editable.

Centre Y field Displays the centre point value of the clip along the vertical axis. Available when Transform Type is set to Perspective. Editable.

Centre Z field Displays the centre point value of the clip along the Z axis. Available when Transform Type is set to Perspective. Editable.

Matte Offset Settings

Axis

☒ Matte Offset

☐ Camera Shake

☐ Stabilization

	Position	Rotation	Scale	Shear	Centre
X	0.00	N/A	100.00	N/A	N/A
Y	0.00	N/A	100.00	N/A	N/A
Z	N/A	0.00°	N/A	N/A	N/A

Prop

Position X field Displays the X-axis offset applied to the matte. Editable.

Position Y field Displays the Y-axis offset applied to the matte. Editable.

Rotation Z field Displays the degree of rotation along the Z axis. Editable.

Scale X field Displays the X-axis scaling offset applied to the matte. Editable.

Scale Y field Displays the Y-axis scaling offset applied to the matte. Editable.

Proportional button Enable to affect the Scale fields proportionally.

Camera Shake Settings

Axis	<input type="checkbox"/> Matte Offset	<input type="checkbox"/> Camera Shake	<input type="checkbox"/> Stabilization	
	Amount	Frequency	Phase	Centre
Translate X	N/A	N/A	N/A	X N/A
Translate Y	N/A	N/A	N/A	Y N/A
Rotate Z	N/A	N/A	N/A	
Scale	N/A	N/A	N/A	

Translate X Amount field Displays the amount of horizontal movement applied to the clip. Editable.

Translate Y Amount field Displays the amount of vertical movement applied to the clip. Editable.

Rotation Z Amount field Displays the degree of rotation on the Z axis. Available when Transform Type is set to Perspective. Editable.

Scale Amount field Displays the amount of scaling applied to the clip. Editable.

Translate X Frequency field Displays the frequency of horizontal movement applied to the clip. Editable.

Translate Y Frequency field Displays the frequency of vertical movement applied to the clip. Editable.

Scale Frequency field Displays the frequency of scaling applied to the clip. Editable.

Rotation Z Frequency field Displays the frequency of rotation on the Z axis. Available when Transform Type is set to Perspective. Editable.

Translate X Phase field Displays the phase of horizontal movement applied to the clip. Editable.

Translate Y Phase field Displays the phase of vertical movement applied to the clip. Editable.

Rotation Z Phase field Displays the phase of rotation on the Z axis. Editable.

Scale Phase field Displays the phase of scaling applied to the clip. Editable.

X Centre field Displays the centre point value of the clip along the horizontal axis. Available when Transform Type is set to Perspective. Editable.

Y Centre field Displays the centre point value of the clip along the vertical axis. Available when Transform Type is set to Perspective. Editable.

Stabilization Settings

Axis	Matte Offset	Camera Shake	Stabilization
Enter Stabilizer ▶		Stabilize	Reference
Invert Stabilization	Position X	0.00	Set Frame
Framing	Position Y	0.00	Frame 1
Shift	Scaling	100.00	
	Rotation	0.00°	

Enter Stabilizer button Enable to enter the Stabilizer editor.

Invert Stabilization button Enable to apply an inverse of the stabilization data to recreate the original camera shake.

Framing Mode box Select a method to fill or remove the area where the image has been shifted after stabilization.

Position X button Enable to include the X-axis position in the stabilization.

Position X field Displays the amount of stabilization data found in the animation channel for the X position.

Position Y button Enable to include the Y-axis position in the stabilization.

Position Y field Displays the amount of stabilization data found in the animation channel for the Y position.

Scaling button Enable to include scaling in the stabilization.

Scaling field Displays the amount of stabilization data found in the animation channel for scaling.

Rotation button Enable to include the rotation in the stabilization.

Rotation field Displays the amount of stabilization data found in the animation channel for rotation.

Set Frame button Enable to set the current frame as a reference frame that has no transformation data.

Reference Frame field Displays the frame number of the reference frame that has no transformation data. Non-editable.

Perspective and Random Seed Settings

Perspective
FOV 40.00
Random Seed
0

Perspective field Displays the field of view. Available when Transform Type is set to Perspective. Editable.

Random Seed field Displays the random seed value of the camera shake. Editable.

Texture Settings

Texture	
Filter	Lanczos
Precision	5.25
Crisp/Soft	0.83
Repeat Mode	Repeat Off

Filter box Displays available filters to control the quality of resize operations. The list of filters changes when you switch between Perspective and Pan & Scan Transform Types.

Precision field Displays the frequency cut-off point used during resize. Editable only when doing a pan and scan with Shannon or Lanczos filters.

Crisp/Soft field Displays the amount of blurring used during resize. Editable only when doing a pan and scan with Mitchell, Shannon or Lanczos filters.

Repeat Mode box Select an option to fill the empty portions of the frame.

Select:	To:
Repeat Last	Repeats last pixel color.
Tile Repeat	Wrap the image around to fill the area.
Mirror Repeat	Repeats the source pixels both vertically and horizontally.
Repeat Off	Use a colour to fill the area. Use the adjacent colour pot to pick the colour. You will lose texture and will fill the rest of the image with a black border.

Anti-Aliasing Settings

Anti-Aliasing button Enable to activate sampling and softness.

Sampling box Select the number of samples to use in the anti-aliasing process.

Softness field Displays the level of softness of the samples. Editable.

Motion Blur Settings

Motion Blur button Enable to apply a motion blur to a selected clip.

Samples field Displays the number of frames to sample when creating the blur. The samples include the current frame, and an equal distribution of past and future frames. Editable.

Phase field Displays the level of softness of the samples. Editable.

Shutter field Displays the number of frames for which the shutter stays open. For example, when the shutter value is set to 3, every third frame is a sample. Editable.

Lock Transform button Enable to lock the transformation of the motion blur effect.

Result Output Settings

Result Output box Select an output option. Select Premultiplied to output alpha values in the colour channels of the result.

Canvas Resolution Settings

Resize Fit Mode box Select whether to resize the clip with width and height values.

Same as Input

The output resolution remains the same as the input resolution.

Custom

You define the output resolution.

Auto Scale

The output resolution changes dynamically, which insures that any transformation applied will not crop the image across the whole length of the clip.

Width field Displays the width of the image. Editable.

Height field Displays the height of the image. Editable.

3D Blur

Use the 3D Blur to create a plausible blur effect using Z-depth map information.

(a) Z-depth input tab (b) Forward Flow input tab (c) Kernel input tab

to access the 3D Blur menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).

This node accepts a front, back, and matte as input. Additional inputs are available for the Z-depth map, forward vector, and kernel media. It outputs a result and an outmatte.

The 3D Blur can be used in the following ways:

- As a defocus node that can be modulated by a Z-depth map.
- As an artistic blur node, by modifying the pattern of the highlights. This can be done by editing the pattern profile curve or attaching an external clip to the appropriate node input.
- As a motion blur node, by including forward motion data.
- As a node using a combination of these scenarios.

3D Blur Menu Settings

Creating a Lens Blur

Lens blur simulates the blur created by a camera lens, such as a rack defocus.

The primary input of the 3D blur node is the front clip and the matte clip. A blur effect can be created with a front clip only. However a matte clip allows you to determine how the matte is used. The Blending settings also determine how the input is composited in the Result view.

Divide Front button Enable to unpremultiply the front clip using the matte clip. This button is active when a matte is in use.

Output box Select an option to determine how to composite the output in the Result view. The output can be a blurred premultiplied or unpremultiplied result using the front clip and the matte clips, or a composite of the blurred front clip over a background clip. Premultiplied output is equivalent to compositing the resulting front on a black background using the resulting matte. This button is active when a matte is in use.

Use the 3D Blur type settings to refine and constrain the amount of blur to apply to the image and to constrain the amount of blur. Higher blur values increase rendering time. You can increase rendering

performance by decreasing the blur quality. When you are ready to create a result clip and an output matte, you can select the highest quality blur.

Blur Type box Select the type of 3D Blur to apply. Some of the settings differ based on the blur type you choose.

Blur Width field Displays the horizontal blur amount in pixels. Editable.

Blur Height field Displays the vertical blur amount in pixels. Editable.

Blur Proportional button Enable to constrain blur amount proportions.

Sides field Displays the number of sides in a Gaussian blur shape. Available when Gaussian is chosen as the blur type. Editable.

Rotation field Displays the angle of rotation of a Gaussian blur shape. Available when Gaussian is chosen as the blur type. Editable.

Kernel Precision box Select the quality and speed of the defocus blur. For example, a 1x1 Kernel results in a fast, but coarse defocus blur. Available when Defocus is chosen as the blur type.

Z Slicing field Displays the amount of slices to blend to determine the Z-Depth interpolation of a defocus blur. Available when Defocus is chosen as the blur type. Editable.

You can offset the light and colour values in the source image. Highlights are applied to the image before the blur is applied.

Adjust button Enable to activate highlight controls.

Gain field Displays the light values of the image. Editable.

Offset field Displays each colour value adjusted by this increment. Editable.

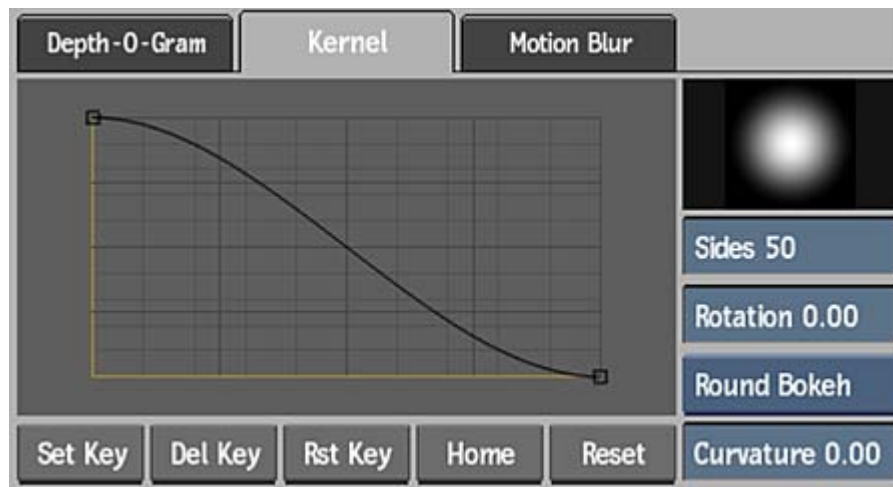

Threshold field Displays the minimum colour value included in highlights. Editable.

Ramp Range field Displays the difference between the Threshold value and the value at which the highlights take full effect. Editable.

Max Effect At field Displays the value at which the highlights take full effect. Non-editable.

Changing the Blur Pattern

Use the Kernal tab to edit the blur kernel pattern.

The kernel is the basic blur shape. The shape of the kernel is determined by its number of sides, its rotation, and the shape of its S-curve. This curve represents the shape of the pattern, from its centre to the outside. The default S-curve defines the softness of the blur. You can change the curve by manipulating the two points that define the curve, or you can add points to the curve. Use the Tools box to add and delete points on the curve.

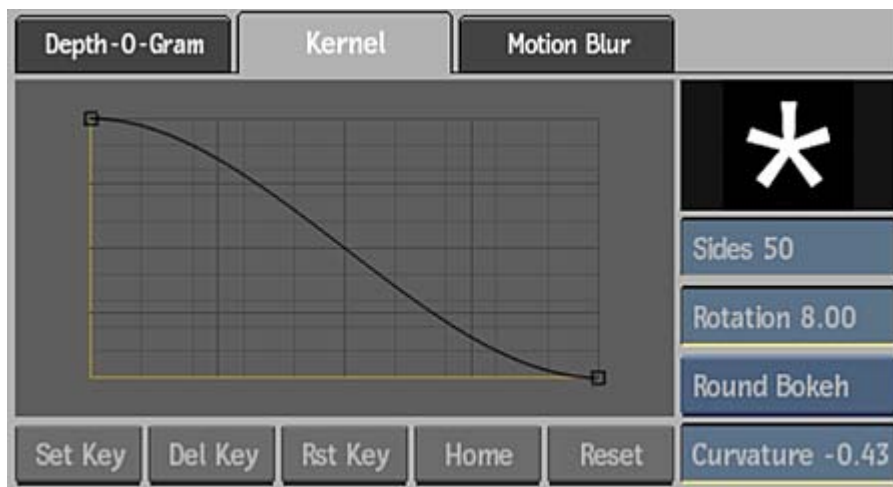

Sides field Displays the number of sides in the kernel shape. Editable, if kernel information is not attached to the node.

Rotation field Displays the angle of rotation of the kernel shape. Editable, if kernel information is not attached to the node.

Bokeh Type box Select whether to use a round or angle bokeh curve to define the kernel shape.

Curvature field Displays the amount of curvature applied to a round bokeh kernel shape. Editable.

You can define the blur shape using external kernel information by attaching an input to the Kernel tab. The input can be a different resolution than the other node inputs.

External blur information is not editable. Like the default blur shape selections, the shape determines the influence of the kernel's pixels on each pixel in the front input.

Simulating a Depth of Field Effect

Depth blur effects control the amount of blur based on a depth of field matte. Depth blur settings are displayed in the Depth-O-Gram tab.

A depth of field map (Z-depth map) can be connected to the node. Black portions of the map are in focus. White portions display the highest level of blur. Note that a Z-depth map imported from another application may use the opposite convention and may need to be inverted.

(a) Z-depth map (b) Front View (c) Blurred portion in Result View

Image courtesy of Jean-Marc Belloncik

Depth Map settings can be used to invert colour values in the Z-depth map for reuse with the 3D Blur node.

Z-Depth button Enable to activate depth-of-field controls and apply the effect to the image.

White Value box Select whether white pixels represent the furthest point or nearest point on the Z-axis.

Slopes field Displays the gamma value. Applies a gamma curve to the Z-depth map before it is used. Editable.

Gain field Displays the white balance value. Applies a gain curve to the Z-depth map before it is used. Editable.

Max Blur Field Displays the maximum total horizontal and vertical blur amount to clamp the value and avoid unnecessary rendering. The cumulative effect of the high blur amount (Basic tab), and gamma and gain correction applied to the Depth map (Depth tab) may result in very large values, which greatly increases the rendering time. Editable.

Blur Z-Depth button Enable to allow pre-blurring of the Z-Buffer. Disable to increase performance time.

Edge Blur field Displays the minimum blur value of "in focus" pixels. In some instances, an out-of-focus object that appears closer to the camera (that is, in front of the focus plane) can have hard edges. In this case, increase the value in the field to add a blur to these edges. Editable.

Use the Depth-O-Gram settings to refine focus values.

Focus Plane field Displays the distance of your focus point, which is the point at which there is no blur on the image. Editable.

Focus Offset field Displays the distance between the focus plane and the near offset represented as a percentage of the total offset range. Select 50% to make the near and far offsets equidistant from the focus point. Editable.

Focus Range field Displays the distance the near and far offset. Editable.

Frame option box Select how you want to frame the histogram.

Zoom field Displays a vertical zoom value for the histogram to display. You can zoom horizontally by pressing Ctrl+spacebar and dragging left or right in the histogram. To pan horizontally, click spacebar and drag left or right in the histogram. Editable.

Z Plot button Click to activate the pick cursor. Use to select a pixel in the image to display its depth.

Z Plot Colour pot Displays the colour that indicates the plane on which the plotted value is located.

Use On-Screen Widgets section in the NodeSetup menu to define display settings.

Near/Far button Enable to display the focus offset plane in the image window.

Near and Far colour pots Select the colours that indicate the nearest and furthest points of focus.

Focus Plane button Enable to display the plane on which the focus point lies in the image window.

Focus Plane colour pot Select the colour that indicates the plane on which the focus point is located.

Modifying Depth of Field Gesturally

Depth blur effects can be modified gesturally by dragging the focus, near offset, and far offset planes in the graphic representation of the depth of field. As you drag these elements, the planes are also displayed in the Result view as a preview of the areas that will be in focus. Use the depth control fields to change the gamma and gain, and to change the focus range while keeping the focus plane constant. These parameters are updated in the depth of field display automatically.

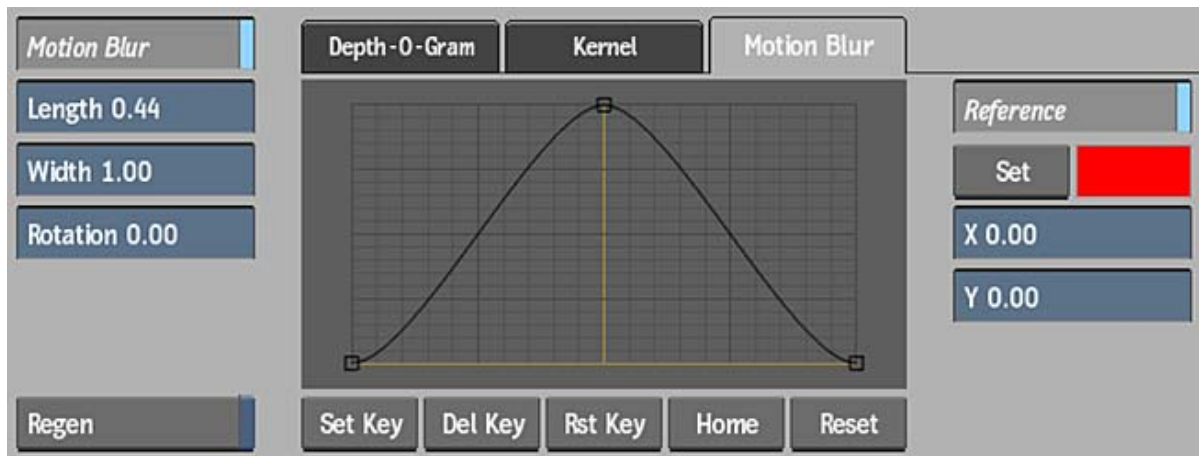

(a) Plot Value Plane (b) Near Focus Offset Plane (c) Focus Offset (d) Focus Plane (e) Far Focus Offset Plane (f) Focus Range

Simulating a Motion Blur Effect

The motion blur simulates the blur created by a fast-moving object or camera. A blur effect can be created with front clip input and a clip with forward motion data input into the Forward Flow tab.

Use the Motion Blur Profile to define the opacity of the blur. The opacity increases at the top of the curve. By default, the blur is more transparent further away from the pixel. The midpoint represents the opacity of the blur at the position of the pixel.

Motion Blur button Enable to activate the motion blur controls and apply the effect to the image.

Length field Displays the amplitude of the motion blur. Editable.

Width field Displays the width of the blur. Editable.

Rotation field Displays the angle of rotation to apply to motion vectors. Motion is rotated counterclockwise. Editable.

Reference button Enable to activate the reference controls and apply the effect to motion blur.

Set button Enable to apply the motion blur to objects that do not have the same relative motion as the selected pixel. Enabled if the X or Y field is edited.

Set Reference colour pot Displays the colour of the crosshair that marks the reference point in the image window.

X field Displays the horizontal position of the pixel to use as a reference point at the selected frame. A reference point can be selected directly in the frame using the cursor. Editable.

Y field Displays the vertical position of the pixel to use as a reference point at the selected frame. A reference point can be selected directly in the frame using the cursor. Editable.

Auto Matte

Use the Auto Matte to generate a high-contrast matte from a clip.

Image courtesy of Optimus

To access the Auto Matte menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip as input, and outputs a result.

Auto Matte Menu Settings

General Settings

Minimum field Displays the minimum luma value considered to be part of the opaque area of the matte. Editable.

Maximum field Displays the maximum luma value considered to be part of the transparent area of the matte. Editable.

Gain field Displays a value, in percentage, that is multiplied to the pixel values in the resulting matte to reduce or increase the grey levels.

Auto Stabilize

Use the Auto Stabilize to analyse the movement in a clip and remove camera instability. For example, you can remove camera jitter or lock an object's position over a sequence of frames to make it appear motionless.

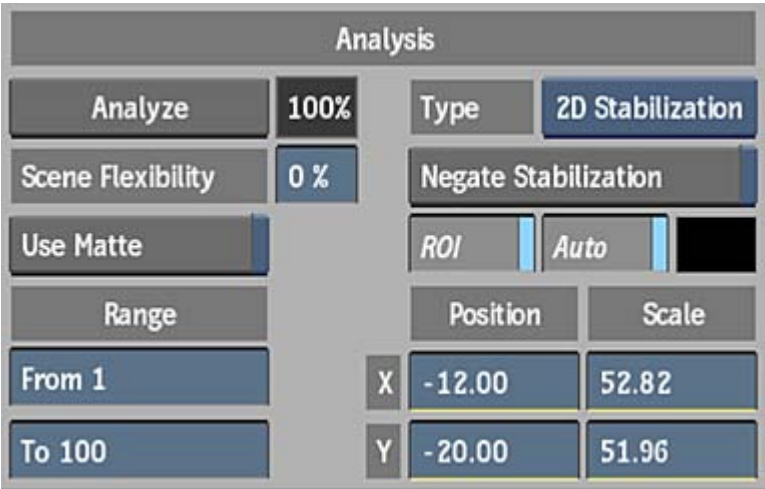

To access the Auto Stabilize menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts front and matte clips, and outputs a result and an outmatte.

Auto Stabilize Menu Settings

Analysis Settings

Analyze button Click to run the stabilization analysis. During analysis, the viewport defaults to the Front view, and the frame advances as the stabilization is calculated. Progress can be monitored by the keyframes that have been created during analysis and the percentage of completion displayed next to the Analyze button. Track points are displayed on the clip to indicate how the stabilization was tracked.

Progress field Displays the percentage of the analysis that is complete. Non-editable.

Scene Flexibility field Displays the level of focus on rigid objects that move in the clip. Enter 0% to focus on a single rigid object as it moves or 100% to analyse all visible motion paths. If the analysis has no scene flexibility, the stabilization will focus on a single rigid object as it moves in the clip. Use the following values as a general guideline:

Select:	To:
0%-20%	Stabilize a pan, tilt, zoom, or the motion of a single rigid object that is visible during the entire analysis.
30%-70%	Stabilize objects that change their shape or depth, and exclude objects that are smaller or moving rapidly.
80%-100%	Stabilize all visible movements.

Use Matte button Enable to exclude black areas on the matte from analysis on the front clip, and constrain the Analysis region.

Range From field Displays the value of the first frame to include in the analysis. Editable.

Range To field Displays the value of the last frame to include in the analysis. Editable.

Stabilization Method box Select whether to perform a two-dimensional or perspective analysis.

Negate Stabilization button Enable to apply the inverted parameter values.

Region of Interest button Enable to display a rectangle that can be resized to indicate the region you want to analyse on the front clip. Select Front from the View box.

Auto button Enable to automatically track motion within the region of interest. At each frame, the position of the region of interest is updated based on the motion within the area. If this button is disabled, and the region of interest was not previously tracked, the region of interest remains static.

Stabilization Settings

Position X button Enable to include the X-axis position in the stabilization.

Position X Option box Select whether to lock the X-axis position at the reference frame to all frames in the analysis (Fixed), or to apply smoothness to the stabilization curve on the X-axis.

Position Y button Enable to include the Y-axis position in the stabilization.

Position Y Option box Select whether to lock the Y-axis position at the reference frame to all frames in the analysis (Fixed), or to apply smoothness to the stabilization curve on the Y-axis.

Rotation button Enable to include the rotation in the stabilization.

Rotation Option box Select whether to lock the rotation at the reference frame to all frames in the analysis (Fixed), or to apply smoothness to the stabilization curve on the rotation.

Scaling button Enable to include scaling in the stabilization.

Scaling Lock Option box Select whether to lock the scaling at the reference frame to all frames in the analysis (Fixed), or to apply smoothness to the stabilization curve on the scaling.

NOTE You can change the centre of rotation and scaling for the image. By default, the centre of rotation and scaling is the centre of the image, represented by a yellow crosshair. Switch to Front view, then hold down C and click the new centre point.

Perspective button Enable to include perspective in the stabilization.

Perspective Option box Select whether to lock the perspective at the reference frame to all frames in the analysis (Fixed), or to apply smoothness to the stabilization curve on the perspective.

Smoothness field Displays the level of smoothness of the stabilization curves generated by the analysis and determines the mix between the original motion and the completely stabilized transformation. Editable.

Mix field Displays the percentage of smoothness used in the final stabilization output and determines how smooth the stabilization curves are. Editable.

Reference and Tracker Settings

Set Reference Frame button Click to set the current frame as the reference frame for the stabilization.

Reference Frame field Displays the current reference frame. Non-editable.

Display Size field Displays the pixel width and height of track points. Editable.

Show Cloud button Enable to display the track point cloud.

Delete and Update button Click to delete selected track points and update stabilization curves. Selected points are displayed in red in the image.

Offset Settings

Offsets	
2D Transform	Perspective
Position X 0.00	Project X 0.000
Position Y 0.00	Project Y 0.000
Rotation 0.00	Anamorphic 0.000
Scaling 0.00	Shear 0.000

Position X field Displays the X-axis offset applied to the clip. Editable.

Position Y field Displays the Y-axis offset applied to the clip. Editable.

Rotation field Displays the rotation offset applied to the clip. Editable.

Scaling field Displays the scaling offsets applied to the clip. Editable.

Project X field Displays the X-axis projection offsets applied to the clip. Editable.

Project Y field Displays the Y-axis projection offsets applied to the clip. Editable.

Anamorphic field Displays the anamorphic offsets applied to the clip. Editable.

Shear field Displays the shearing offsets applied to the clip. Editable.

Rendering Settings

Rendering	
Repeat Mode	Hardware Filtering
Repeat Off	Active
Canvas Resolution	AA 8 Samples
Custom	Softness 1.00
W 720	H 486

Repeat Mode box Select an option to fill the empty portions of the frame.

Select:	To:
Repeat Last	Repeats last pixel color.

Select:	To:
Tile Repeat	Wrap the image around to fill the area.
Mirror Repeat	Repeats the source pixels both vertically and horizontally.
Repeat Off	Use a colour to fill the area. Use the adjacent colour pot to pick the colour. You will lose texture and will fill the rest of the image with a black border.

Resize Fit Mode box Select whether to resize the clip with width and height values.

Select:	To:
Same as Input	The output resolution remains the same as the input resolution.
Custom	You define the output resolution.

Width field Displays the width of the image. Editable.

Height field Displays the height of the image. Editable.

Hardware Filtering button Enable to filter subpixel information.

Anti-Aliasing button Enable to activate sampling and softness.

Sampling box Select the number of samples to use in the anti-aliasing process.

Softness field Displays the level of softness of the samples. Editable.

Common

Clear Buffer button Clears the Undo/Redo list of performed actions.

Use Proxies button Enable to use proxy-sized clips instead of the resolution clip. Increases interactivity performance.

Backup button Enable to automatically save backups of Tools data.

Tools Save field Displays the time delay for an automatic save when you are using a tool that you have accessed from the Tool tab. Non-editable.

Append Type button Appends the output type (Result or OutMatte) to the filenames of rendered clips.

Average

Use Average to simulate the motion blur of a moving object in a clip. An image averaging function is applied to the frames to create the motion blur.

To access the Average menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Average Menu Settings

The Average Node processes frames based on data from preceding and subsequent sample frames. A frame set to No Media with missing media may include a sample.

General Settings

Average Over field Displays the number of frames used to calculate the average and create the transparency for the motion blur effect. Editable.

Weighted/Uniform box Select whether to uniformly average surrounding frames or give frames closest to the current frame a greater weight when calculating the transparency for the motion blur effect.

Frames box Select whether the blur is calculated from previous frames only or future frames as well.

Blend & Comp

Use Blend & Comp to apply basic blending and compositing between two inputs, and their mattes, over a background.

To access the Blend & Comp menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts up to two front and matte clips, as well as a back clip, and outputs a result and outmatte.

Blend & Comp Menu Settings

General Settings

Blend Type box Select the set of blend mode operations available in the Blend Mode box.

Blend Mode box Select a blend operation. Options determined by Blend Type box.

Swap Inputs button Enable to switch the rendering order of the inputs.

Input Settings

NOTE Input 1 and 2 settings are identical. Activate and use based on inputs selected for Blend & Comp.

Active button Enable to activate the input.

Clamping box Select a clamping option.

Matte box Select how the matte is used when blending.

Pre-multiplication box Select whether the colour values in the input are pre-multiplied or divided from the alpha, or left as-is when blending.

Transparency field Displays the transparency value. Editable.

Gain Trackball Adjusts the gain of the input.

Saturation field Displays level of colour purity in the image. Editable.

Gamma field Displays the gamma level. Editable.

Offset field Displays a value that modifies all of the colour parameters. Editable.

Red Gain field Set the percentage of colour values in the red channel. Editable.

Green Gain field Set the percentage of colour values in the green channel. Editable.

Blue Gain field Set the percentage of colour values in the blue channel. Editable.

Luma Gain field Set the percentage of luma gain value to display. Editable.

Proportional button Enable to adjust the gain of the colour values proportionally.

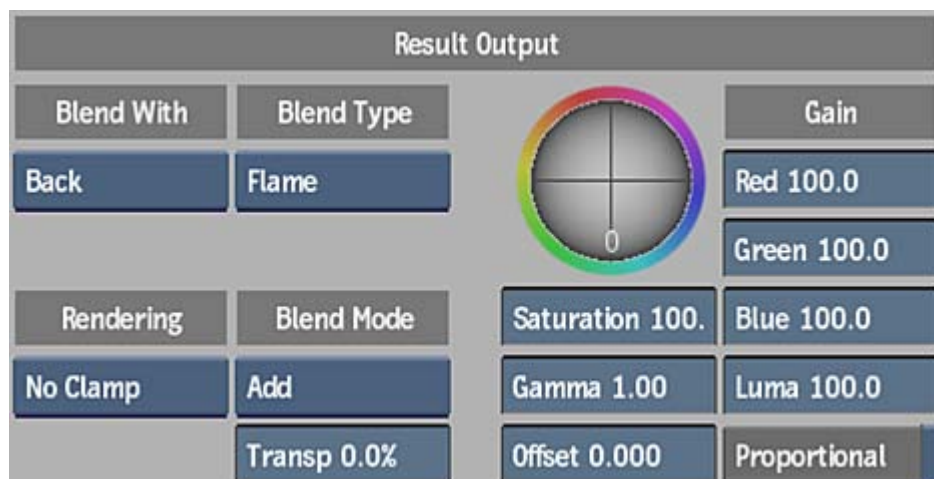

Matte Blending Settings

Composition box Select how the input mattes are combined.

Correlation box Select whether the mattes are related to each other. For example, select Correlated if the mattes are from different, but continuous parts on the same object.

Result Output Settings

Blend With box Select whether you want to blend the inputs with the second input clip, the background clip or a colour.

Blend Type box Select the set of blend mode operations available in the Blend Mode box.

Clamping box Select a clamping option.

Blend Mode box Select a blend operation. Options determined by Blend Type box.

Transparency field Displays the transparency value. Editable.

Gain Trackball Adjusts the gain of the input.

Saturation field Displays level of colour purity in the image. Editable.

Gamma field Displays the gamma level. Editable.

Offset field Displays a value that modifies all of the colour parameters. Editable.

Red Gain field Set the percentage of colour values in the red channel. Editable.

Green Gain field Set the percentage of colour values in the green channel. Editable.

Blue Gain field Set the percentage of colour values in the blue channel. Editable.

Luma Gain field Set the percentage of luma gain value to display. Editable.

Proportional button Enable to adjust the gain of the colour values proportionally.

Blur

Use Blur to apply and customize a blur filter to a clip.

To access the Blur menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and a matte clip, and outputs a result and outmatte. The outmatte clip can have a different level of blur than the result clip.

Blur Menu Settings

Quick Menu Settings

The following selector is unique to the quick menu when Defocus is selected in the Blur Type box. To see the full Blur menu, click the Editor button.

Blooming and Bokeh Menu selector Select whether to display Blooming settings or Bokeh blur settings.

General Settings

Regen button Enable to get dynamic updating of the image as you make changes.

Setup Settings

Clamp Input button Enable to clamp colour and luminance values on input in the 16-bit floating point rendering pipeline.

Clamp Render box Select a clamping option for colour and luminance values on output in the 16-bit floating point rendering pipeline.

Blur Type Settings

Blur Type for Gaussian

Blur Type for Radial

Blur Type box Select the type or shape of blur filter to apply to the clip. Depending on the blur type, some of the other blur settings may vary.

Bokeh Blur field Displays the amount of smoothness applied to sharp bokeh edges. This creates the blur that is applied to out-of-focus points of light to simulate a shallow focus. Editable.

Bias field Displays the direction of a blur. Enter a positive value for forward, a negative value for backward, or 0 for a blur that moves in both directions. Available when Directional or Radial Stamp is chosen as the blur type.

Radial Mode box Select whether a radial blur or glow moves in one circular direction (Spin) or two rotating directions (Twist). Available when Radial is chosen as the blur type.

Samples field Displays the quality of a Radial Stamp blur or glow. Editable. Available when Radial Stamp is chosen as the blur type.

Color Space Settings

Colour Space box Select whether to blur in RGB or YUV space. The Channels settings change to reflect this setting.

Centre Settings (Radial Only)

Stabilizer button Opens the Stabilizer menu to track the centre of the blur from the source clip.

Centre X field Displays the X position of the centre of the radial blur (or gesturally move the red circle in the image). Editable.

Centre Y field Displays the Y position of the centre of the radial blur (or gesturally move the red circle in the image). Editable.

NOTE You can also move the red circle on the image to set the position of the centre of the blur. The Centre X and Y fields update accordingly.

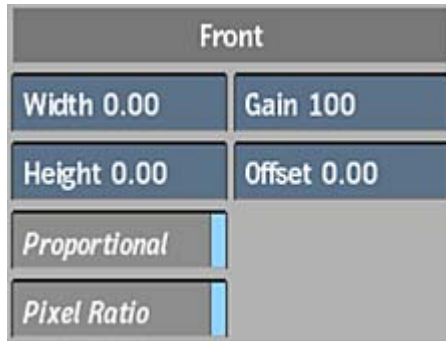

Absolute/Relative box Select whether to position and offset the centre of the radial blur in a relative mode (expressed as a percentage) or absolute mode (expressed in pixels).

Offset X field Offsets the centre along the X axis (or press Ctrl and gesturally move the red circle in the image). This field is useful to apply changes to the centre after tracking has been performed. Editable.

Offset Y field Offsets the centre along the Y axis (or press Ctrl and gesturally move the red circle in the image). This field is useful to apply changes to the centre after tracking has been performed. Editable.

NOTE You can also press **Ctrl** and move the red circle on the image to set the offset of the centre blur.

Front Settings

Width field Displays the width of the blur. Increasing the blur increases the render time. Editable.

Height field Displays the height of the blur. Increasing the blur increases the render time. Editable.

Proportional button Enable to affect the width and height proportionally.

Pixel Ratio button Enable to blur the image using the same proportion as its aspect ratio.

Gain field Displays a value by which pixel colour values are multiplied. The offset value is added to this value to determine the final colour. Editable.

Offset field Displays the value to add to current pixel colour values. The resulting colour value is clipped at 0. Editable.

Length field (Directional) Displays the radius amount of a directional blur. Editable.

Angle field (Directional) Displays the angle of a directional blur. Editable.

Amount field (Radial, Radial Stamp) Displays the amount of radial blur. Editable.

Rotation field (Radial, Radial Stamp) Displays the angle of rotation for a radial blur. Editable.

Blooming Settings (Defocus Only)

Basic/Additive Blooming button Switch between basic blooming and additive blooming bokeh effects. The basic blooming mode displays the gain applied to highlights in non-HDR images, to allow the creation of bokeh patterns without affecting colour integrity. The additive blooming mode allows you to create higher intensity bokeh patterns from any source image, using minimum and maximum thresholds for highlight segregation.

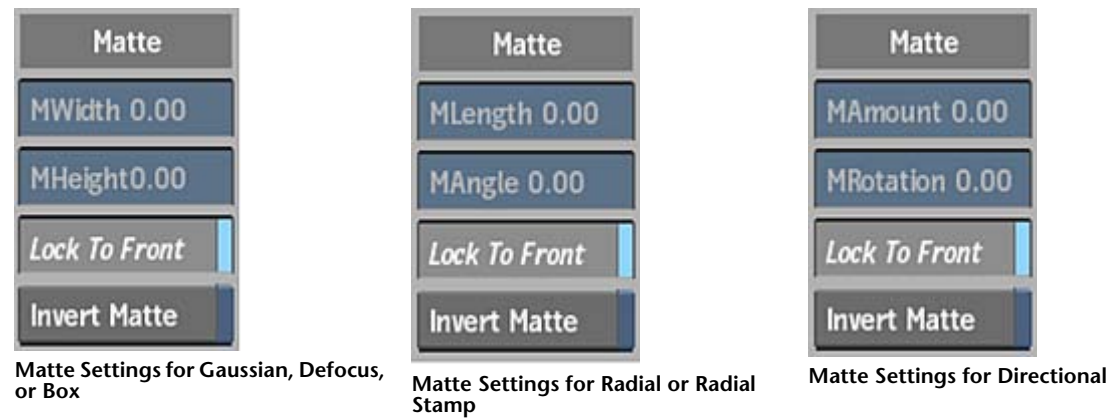

Basic Blooming field Displays the gain applied to highlights in non-HDR images, to allow the creation of bokeh patterns without affecting colour integrity. This creates the glow effect that is applied to the bright spots of the image to simulate light bleeding, or blooming, over the edges. Editable.

Additive Blooming field Displays the amount of high intensity bokeh patterns that can be created from any source image generating extreme highlight content . Editable.

Additive Blooming minimum field Displays the minimum threshold for highlight segregation. Editable.

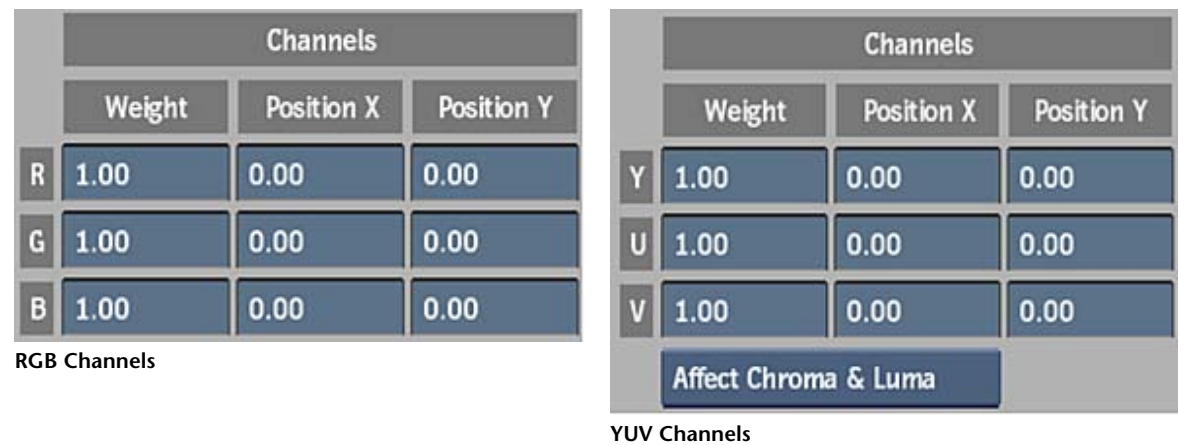

Additive Blooming maximum field Displays the maximum threshold for highlight segregation. Editable.

Matte Settings

- Matte Width field** Displays the width of the blur for the matte. Editable.
- Matte Height field** Displays the height of the blur for the matte. Editable.
- Matte Length field** Displays the radius amount of a directional blur for the matte. Editable.
- Matte Angle field** Displays the angle of a direction blur of the matte. Editable.
- Matte Amount field** Displays the amount of radial blur for the matte. Editable.
- Matte Rotation field** Displays the angle of rotation for a radial blur for the matte. Editable.
- Lock To Front button** Enable to keep the matte values the same as their corresponding values for the front clip.
- Invert Matte button** Enable to blur the region outside the area defined by the matte.

Channel Settings

- Weight field** Displays the weighted value of the channel.
- Position X field** Displays the horizontal offset of the channel.
- Position Y field** Displays the vertical offset of the channel.

YUV Colour box Select whether to affect Luma or Chroma only, or include both when blurring in YUV colour space.

Blending Settings

Screen option box Select a logical operation that can be used to blend the front clip and the result clip.

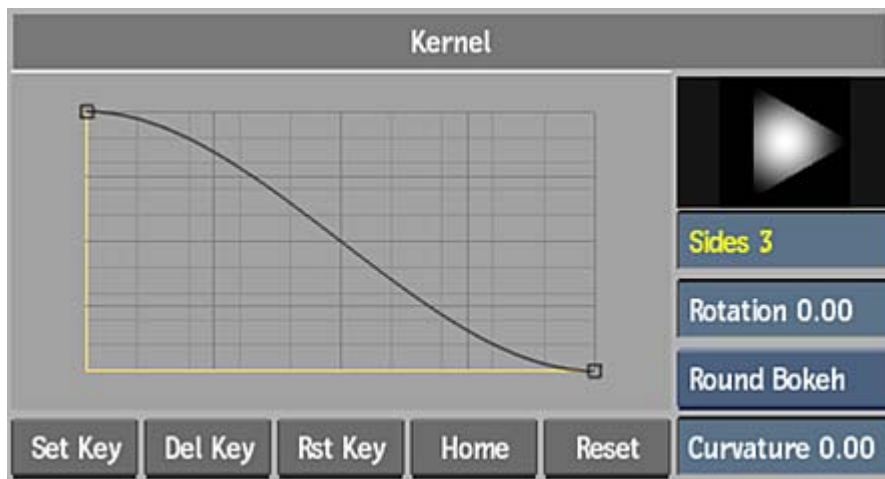

Transparency field Displays the percentage of blending when the result is composited on the front clip. Editable.

Use Matte button Enable to apply the blur with the areas defined by the matte.

Rendering Settings

Rendering Mode box Select whether to render in Automatic, Progressive or Interlaced mode.

Kernel Settings (Defocus Only)

The kernel is the defocus blur shape. The shape of the kernel is determined by its number of sides, its rotation, and the shape of its S-curve. This curve represents the shape of the pattern, from its centre to the outside. The default S-curve defines the softness of the blur. You can change the curve by manipulating the two points that define the curve, or you can add points to the curve. Use the Tools box to add and delete points on the curve.

Sides field Displays the number of sides in the kernel shape. Editable, if kernel information is not attached to the node.

Rotation field Displays the angle of rotation of the kernel shape. Editable, if kernel information is not attached to the node.

Bokeh Type box Select whether to use a round or angle bokeh curve to define the kernel shape.

Curvature field Displays the amount of curvature applied to a round bokeh kernel shape. Editable.

Bump Displace

Use the Bump Displace effect to create displacement-like emboss effects using light and surface bumps. You can select Front or Front/ZDepth or Front/ZDepth/Matte from the Input Mode box.

To access the Bump Displace menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip and a displacement clip (usually a matte), and outputs a result.

Bump Displace Menu Settings

Bump Settings

Bumps	
Channel Select	Luminance
Min 0.00%	Max 100.00%
Height 2.00	Softness 1.00

Minimum Bumps field Displays the lower limit of the bump depth. Editable.

Maximum Bumps field Displays the upper limit of the bump depth. Editable.

Bump Height field Displays the height value for the effect. Positive numbers create an embossed look. Negative numbers create an engraved look. Editable.

Bump Softness field Displays a blurring value for the effect. Editable.

Light Settings

Light X Position field Displays the horizontal position of the light. Editable. You can also use the light icon in the image window to change the position of the light.

Light Y Position field Displays vertical position of the light. Editable. You can also use the light icon in the image window to change the position of the light.

Light Z Position field Displays the depth of the light. Editable. You can also use the light icon in the image window to change the position of the light.

TIP You can also use the light icon in the image window to gesturally position the light.

Light Scale field Displays a value that you can modify to see the results of moving your light when using extreme X, Y or Z values. Editable.

Shaded field Displays the level of intensity for the image. Editable.

Ambient field Displays the percentage of overall lighting for the image. Editable.

Threshold field Displays the percentage of bumps filtered out by using light exposure. Editable.

Red Light field Displays the red value of the light. Editable.

Green Light field Displays the green value of the light. Editable.

Blue Light field Displays the blue value of the light. Editable.

Light Colour Pot Displays the colour of the light. Click to open the Colour Picker and specify a value.

Texture Settings

Diffuse Gain field Displays a value for the contrast in the image. Use to increase or decrease the intensity of highlights and shadows in surface features. Editable.

Shininess field Displays a value for the amount of shine in the image. Editable.

Specular field Displays a value for the reflectiveness of the image. Editable.

RGB Distortion Settings

Red Distortion field Displays the amount of distortion in the red channel. Editable.

Green Distortion field Displays the amount of distortion in the green channel. Editable.

Blue Distortion field Displays the amount of distortion in the blue channel. Editable.

Repeat Mode Settings

Repeat Mode Settings Select an option to fill the empty portions of the frame.

Anti-Aliasing Settings

Anti-aliasing button Enable to activate sampling and softness.

Sampling box Select the number of samples to use in the anti-aliasing process.

Softness field Displays the level of softness of the samples. Editable.

Burn-In Letterbox

Use Burn-In Letterbox to burn a letterbox into a clip.

To access the Burn-In Letterbox menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Burn-In Letterbox Menu Settings

General Settings

Aspect Ratio box Select a preset or custom aspect ratio.

Offset field Displays the vertical offset. Drag left or right to apply the letterbox to a lower or higher portion of the image. Editable.

Border colour pot View the current border colour. Editable.

Ratio field Displays the custom aspect ratio. Editable.

NOTE The Ratio field is only available when Custom is selected from the Aspect Ratio box.

Burn-In Timecode

Use Burn-In Timecode to burn-in clip information.

To access the Burn-In Timecode menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Burn-In Timecode Menu Settings

General Settings

Text Colour	<input type="color"/>	As Front	Safe Title
Shadow	<input type="checkbox"/>	Horizontal Centre	X 0
Background	<input type="checkbox"/>	Bottom	Y 0
Font	Discreet	Size	50
<name>			

Text colour pot Select the current colour of burned-in text. Select to open the colour picker.

Shadow button Enable to add a drop shadow to burned-in information.

Shadow colour pot Displays the current shadow colour. Select to open the colour picker.

Background button Enable to display a rectangular background to burned-in text.

Background colour pot Displays the current background colour. Select to open the colour picker.

Font box Displays the font used for burned-in text.

Name field Displays the name of the clip. Click to enter new name or comment. Editable.

Scan Format box Select to scan a frame-based clip with or without interlacing, or use the scan format of the front clip.

Offset box Select to display the burned in information within the full frame, or a safe area. This box is only active when position is set using the Horizontal Position and Vertical Position boxes.

Horizontal Position box Select the horizontal placement of the burned-in text.

Horizontal Position field Set the position on the Y-axis. Drag left or right to move the text in the same direction. Editable.

Vertical Position box Select the vertical placement of burned-in text.

Vertical Position field Set the position on the X-axis. Drag left or right to move the text up or down. Editable.

Size field Displays the font size of burned-in text. Drag left or right to decrease or increase the point size. Editable.

Comments	Frame Number	Total	100
Date/Time	Keycode	No KC	
Source Timecode	00:00:00:00	29.97 fps NDF	
Record Timecode	00:00:00:00	29.97 fps NDF	

Comments button Enable to include the current clip name or comment in burned-in text.

Frame Number button Enable to include the current frame number in burned-in text.

Frame Total button Enable to include the total number of frames in burned-in text.

Total Frames field Click to enter a value for the total number of frames in the clip. Editable.

Date/Time button Enable to include the current date and time in burned-in text.

Keycode button Enable to include the keycode in burned-in text.

Keycode field Click to enter a keycode. Editable.

Source TC button Enable to include the source timecode in burned-in text.

Source TC field Click to enter a new source timecode. Editable.

Source TC Frame Mode box Select the style of source frame code notation.

Record TC button Enable to include the record timecode in burned-in text.

Record TC field Click to enter a new record timecode. Editable.

Record TC Frame Mode box Select the style of record frame code notation.

Clamp

Use the Clamp node to clamp 16-bit floating point OpenExr clips.

To access the Clamp menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

Clamp Menu Settings

General Settings

Out of Range box Select a curve that is constant (clamp) or clamps negative values below 0.

Colour Corrector

About Colour Corrector

The Colour Corrector includes tools that provide precise control over colour values. You can modify luma ranges in a clip (shadows, midtones, and highlights), sample colours, and adjust the colour balance. You can rewire colour channels and suppress colours, as well as animate a colour correction by manipulating the animation curve in the Channel Editor.

When working with large images, you can free up additional screen space with the Overlay user interface. This feature is exclusive to the Colour Corrector and the Colour Warper. The Colour Warper's Overlay user interface is not available when accessing the Colour Warper as a Batch or Batch FX node.

For details on using the Overlay user interface, see [Overlay User Interface](#) (page 949).

Accessing the Colour Corrector

To access the Colour Corrector, you must load clips of the same resolution. If the clips you want to load have different resolutions, resize them so that they have the same resolution.

You can load a front clip, a front and back clip, or a front, back, and matte clip for colour correction. Changes in colour are applied to the front clip.

To access the Colour Corrector menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- Modular Keyer, Action or Paint tool.

Colour Correct Menu Settings

Timeline FX Quick Menu Settings

To see the full Colour Correct menu, click the Editor button.

Luma Range Quick Menu selector Select the quick menu for the luma range you want to modify.

Colour Channel Quick Menu selector Select the quick menu for the colour channel you want to modify.

Use Mask button Enable to use the matte to delimit the Colour Correct or Colour Warper effect.

Main Menu

Crop button Displays a crop box to view colour changes on a limited region of the clip.

Setup button Opens the Setup menu where you setup either Colour Correct or Colour Warper options.

Animation button Opens the Animation menu where you display the animation channel.

Master button Modifies the luma range for the entire image after individual range modifications.

Shadows button Modifies the luma range for the dark areas in the image.

Midtones button Modifies the luma range for the midlevel areas in the image.

Highlights button Modifies the luma range for the light areas in the image.

Regen button Enable to get dynamic updating of your colour corrections.

Rewire box Select an option to rewire the RGB channels of an image, or create a monochrome or negative image.

Red Rewiring box Select a color or luma channel to replace the red values with the selected channel values. Select 1-R to replace red values with its inverse values. Active when Master range is selected.

Green Rewiring box Select a color or luma channel to replace the green values of an image with its inverse (1-R), red, blue, or luma values. Active when Master range is selected.

Blue Rewiring box Select a color or luma channel to replace the blue values of an image with its inverse (1-R), red, green, or luma values. Active when Master range is selected.

Reset Basics Resets colour correction controls.

Hue field Displays the colour range. Editable.

Saturation field Displays level of colour purity in the image. Editable.

Pivot field Displays the percentage value of the colour range around which the contrast pivots. The default value is 50% for integer input and 18% for floating point input. Editable.

Hue field Displays the colour range. Editable.

Gain field Drag left or right to increase or decrease light greys from the white area of the image.

RGB Gamma field Adjust the grey values. Editable.

Red Gamma field Adjust the grey values in the red channel. Editable.

Green Gamma field Adjust the grey values in the green channel. Editable.

Blue Gamma field Adjust the grey values in the blue channel. Editable.

RGB Gain field Set the percentage of original colour values to use in the image. Editable.

Red Gain field Set the percentage of colour values in the red channel to display in the image. Editable.

Green Gain field Set the percentage of colour values in the green channel to display in the image. Editable.

Blue Gain field Set the percentage of colour values in the blue channel to display in the image. Editable.

RGB Offset field Adjust the colour values by adding an offset value. Editable.

Red Offset field Adjust the colour values in the red channel by adding an offset value. Editable.

Green Offset field Adjust the colour values in the green channel by adding an offset value. Editable.

Blue Offset field Adjust the colour values in the blue channel by adding an offset value. Editable.

Contrast field Adjust the gradations between the light and dark areas in the image. Editable.

Red Contrast field Adjust the gradations between the light and dark areas in the red channel of image. Editable.

Green Contrast field Adjust the gradations between the light and dark areas in the green channel of image. Editable.

Blue Contrast field Adjust the gradations between the light and dark areas in the blue channel of image. Editable.

Red Suppression button Enable to suppress red colour values in the image.

Green Suppression button Enable to suppress green colour values in the image.

Blue Suppression button Enable to suppress blue colour values in the image.

Cyan Suppression button Enable to suppress cyan colour values in the image.

Magenta Suppression button Enable to suppress magenta colour values in the image.

Yellow Suppression button Enable to suppress yellow colour values in the image.

Front colour patch Displays colour sampled from the front clip.

Result colour patch Displays the result of front clip colour correction.

Back colour patch Displays colour sampled from the back clip.

Sampling box Select the type of colour values to display for sampled colours.

Sample Data Type box Select the type of measurement to use for RGB values of sampled colours.

Histogram Menu

Histogram tab Displays the Histogram menu where you adjust the red, green, blue, and luminance channels of the image.

Histogram Displays a bar graph that is used to adjust the luminance values of the image. In the Ranges menu, the curves for the three luma ranges are also displayed.

Minimum Input field Displays the lower limit of the luminance values. Pixels with lower values are mapped to black.

Minimum Output field Displays the lower limit of the luminance values for black pixels.

Maximum Input field Displays the upper limit of the luminance values. Pixels with higher values are mapped to white.

Maximum Output field Displays the upper limit of the luminance values for white pixels.

Channel Selection box Select the luminance or an RGB channel to extract its values for the key.

Out Range box Select a curve that is constant (Clamp) or linear (No Clamp) before the first point of the curve and after the last point of the curve.

When using 16-bit floating point images, you can select Clamp to clamp colour and luminance values, or No Clamp to allow pixel floating point values to be less than 0 or more than 1.

Frame Selection box Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Source button Enable to show a histogram of the source colour values.

The source colour values are obtained from the current frame. If you input both front and matte clips, the colour values in the front clip that are defined by the white part of the matte are displayed.

Source View box Select whether to display all RGB Source histograms or only the histogram you are working on (Mono).

Destination button Enable to show a histogram of the colour values in the result or destination clip.

The destination colour values are obtained from the current frame. If you input both front and matte clips, the colour values in the front clip that are defined by the white part of the matte are displayed.

Destination View box Select whether to display all RGB Destination histograms or only the histogram you are working on (Mono).

When viewing the Source and Destination histograms at the same time in Mono mode, the Destination histograms are lighter; in RGB mode, the Destination histograms are displayed with a white outline.

Reset button Resets to default histogram settings.

Zoom field Displays the vertical zoom value of the histogram.

You can also zoom horizontally by pressing `Ctrl+spacebar` and dragging left or right in the histogram. To pan horizontally, click `spacebar` and drag left or right in the histogram.

Curves Menu

Curves tab Displays the Curves menu to display luminance and RGB curves.

Curves Display the curves for the luminance and each RGB channel.

Home button Restores the position of panned or zoomed curves to the default setting.

Move button This setting is available when you access the Colour Corrector via the Timeline. Select an option to work directly in the image window or schematic.

Match button Matches colours in the front and back colour patches, and assigns a number to the current match.

Match field Displays which match is currently displayed.

ReMatch button Overrides the selected match operation with current settings.

Out Range box Select a curve that is constant (Clamp) or linear (No Clamp) before the first point of the curve and after the last point of the curve.

Reset button Resets to default curve settings.

Ranges Menu

Ranges tab Displays the HLS Ranges menu where you can adjust highlight, midtone, and shadow ranges.

Reset button Resets to default histogram and curve settings.

Setup

Border button Enable to display a crop box border.

Border colour pot Displays the border colour. Editable.

Top field Displays the position for the top of the crop box. Editable.

Bottom field Displays the position for the bottom of the crop box. Editable.

Left field Displays the position for the left side of the crop box. Editable.

Right field Displays the position for the right side of the crop box. Editable.

Invert Matte button Enable to colour correct the region outside the area defined by the matte.

Background field Displays the background brightness value. Editable

Colour Curves

Use Colour Curves to access a clip's colour menu, remove colour spill from a front clip, and perform a hue shift.

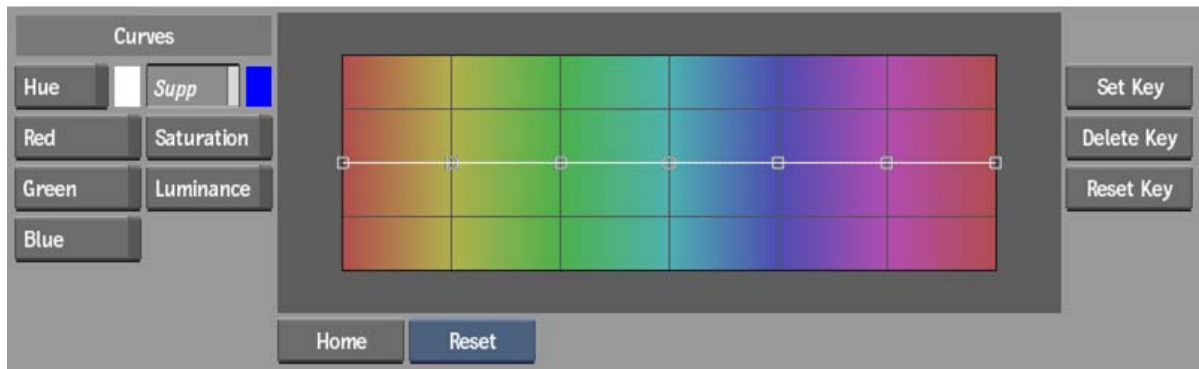

To access the Colour Curves menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Colour Curves Menu Settings

General Settings

Curve Channel button Enable this button to select the colour curve for a specific channel. Only one Curves button can be enabled at a time. Each Curves button is active when you modify its curve in the graph.

Hue colour pot Displays the colour to shift toward when the curve is modified. Editable.

Suppression colour pot Displays the colour to suppress in the clip. Editable.

Home button Reverts to the original view.

Reset box Resets the curve view.

Set Key button Sets a keyframe at the selected frame.

Delete Key button Deletes the selected keyframe.

Reset Key button Resets the curve at the selected keyframe.

Color Warper

About the Colour Warper

When you colour correct an image or clip, use the Colour Warper to perform advanced colour corrections and create artistic colour effects. The way in which you approach these tasks depends on your goal, the number of clips you are using, and the type of clips being used.

Clips created from source material shot with the same camera equipment under the same lighting conditions may be colour corrected quickly and easily to correct lighting and colour imbalances. Clips created from source material shot at different times of the day, in different seasons, at different locations, or using different equipment require more work. With the Colour Warper, you can manipulate colours with precision and ease, working on the entire clip as you would with traditional tools or working with a matte to adjust a range of colour in the clip.

Use the Colour Warper to gesturally set black and white levels, adjust specific colours and colour ranges, and accurately match colours in one clip to another. You can also perform hue shifts and suppress colour to remove colour spill or create visual effects such as a colour cast. While you manipulate the colour content of a clip, you can monitor reference clips as well as changes in the colour distribution to ensure that you achieve the result you want. Original data is always preserved, so you can adjust colours without the risk of permanently losing colour information.

When working with 16-bit floating point images in the Colour Warper, you can plot colours outside of the 0 to 1 range. Even when working with integer images, clamped colour information (colours that go beyond the RGB range) can be retrieved using the Colour Warper controls.

(a) Clamped colour

(a) Colour information restored

When working with large images, you can free up additional screen space with the Overlay user interface. This feature is exclusive to the Colour Corrector and the Colour Warper. The Colour Warper's Overlay user interface is not available when accessing the Colour Warper as a Batch or Batch FX node.

For details on using the Overlay user interface, see [Overlay User Interface](#) (page 949).

Accessing the Colour Warper

Use the Colour Warper to modify the colour content in your clips. You can manipulate colour content with intuitive controls that provide precise colour correction, and view histograms that help you visualize your image's colours. You can also output a matte corresponding to selected colours.

You can access the Colour Warper as a Batch or Batch FX node that you drag and drop into the process tree or the Modular Keyer's processing pipeline. Access the Colour Warper from the Modular Keyer to remove colour spill, or access it from Batch or Batch FX to modify the colour content of your clips.

To access the Colour Warper menu, use:

- Batch, then select a node from the Node bin.

- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- Modular Keyer, Action or Paint tool.

Color Warper Menu Settings

Timeline FX Quick Menu Settings

To see the full Colour Warper menu, click the Editor button.

Use **Mask button** Enable to use the matte to delimit the Colour Correct or Colour Warper effect.

Colour Warper Menu Settings

Basics button Opens the Basics menu where you perform basic colour correction, warping, suppression and saturation of your clips.

Subsetups button Opens the menu where you store, compare, and share Colour Warper subsetups.

Basics Menu

Colour correct your clips. You can adjust shadows, midtones, and highlights, and control black and white levels, hue, and saturation. You can also perform colour warping, colour suppression, and colour saturation on a limited range of colour as well as adjust gamma and luminance curves.

Home button Positions a vectorscope at its default location and size.

Scope button Enable to display a 2D or 3D vectorscope in the Result view.

Work On box Select an option to apply colour corrections to all or part of an image. Select Master to apply colour corrections to the entire image or select a selective to generate a matte and perform selective colour correction.

Clear /Reset box Select whether to clear the value at the current frame or reset the value for the entire animation curve.

Selective View box Select whether to view the matte, selective, or result image.

Clear /Reset box Select whether to clear the value at the current frame or reset the value for the entire animation curve.

Black field Displays the luminance value in the image shadows without affecting the chrominance values. Editable.

White field Displays the luminance value in the image highlights without affecting the chrominance values. Editable.

Hue field Displays the luminance value in the image shadows without affecting the chrominance values. Editable.

Saturation field Displays the global saturation value. Editable.

Red Gamma field Displays the gamma level in the red channel.

Clear /Reset box Select whether to clear the value at the current frame or reset the value for the entire animation curve.

Green Gamma field Displays the gamma level in the green channel.

Clear /Reset box Select whether to clear the value at the current frame or reset the value for the entire animation curve.

Blue Gamma field Displays the gamma level in the blue channel.

Clear /Reset box Select whether to clear the value at the current frame or reset the value for the entire animation curve.

Select button Activates the pick cursor. Use to sample an area to adjust. Activate the cursor again and select the area to match.

Plot button Activates the pick cursor. Use to sample an area to display its result clip colour value.

Ref button Activates the pick cursor. Use to sample an area to display its reference clip colour value.

Trackball option box Select a method of adjustment for a range of colour.

Luma field Displays the luminance of the destination colour. Editable.

Tools box Select a tool to work with.

Home button Restore the histogram to its default zoom and pan settings.

Clear /Reset box Select whether to clear the value at the current frame or reset the value for the entire animation curve.

Source button Enable to show a histogram of the colour values in the front, or source clip.

Destination button Enable to show a histogram of the colour values in the result clip.

Zoom field Displays the zoom ratio of the histogram. Editable.

Selective menu

Define colour ranges using softness and tolerance to create a matte and apply colour correction to a selected region.

1 Enable to apply the matte for Selective 1 to the result.

2 Enable to apply the matte for Selective 2 to the result.

3 Enable to apply the matte for Selective 3 to the result.

Invert button Enable to invert the matte or selective.

Gaussian button Enable to apply a Gaussian blur to the matte. Disable to apply a box blur.

X field Displays the width of the blur. Editable.

Y field Displays the height of the blur. Editable.

Pick Custom button Define the tolerance range based on a sample from the image. Drag the cursor over the image to define initial tolerance.

Red button Define the tolerance range based on the red channel.

Green button Define the tolerance range based on the green channel.

Blue button Define the tolerance range based on the blue channel.

Cyan button Define the tolerance range based on the cyan channel.

Magenta button Define the tolerance range based on the magenta channel.

Yellow button Define the tolerance range based on the yellow channel.

Shadows button Define the tolerance range based on the dark areas in the image.

Midtones Define the tolerance range based on the midlevel areas in the image.

Highlights button Define the tolerance range based on the light areas in the image.

Adjusting box Select Tolerance to add tolerance to the matte, +Softness to add softness to the matte, or -Softness to remove softness from the matte.

Sharpness field Displays the percentage of sharpness of the matte. Editable.

Tolerance button Enable to apply the grey tolerance indicator on the hue cube.

Softness button Enable to apply the black softness indicator on the hue cube.

Move/Zoom box Select Move to adjust the softness and tolerance by moving the handles on the hue cube or Zoom to zoom in by dragging on the cube.

Low Softness field Displays the minimum value for the softness range. Editable.

Low Tolerance field Displays the minimum value for the tolerance range. Editable.

High Tolerance field Displays the maximum value for the tolerance range. Editable.

High Softness field Displays the maximum value for the softness range. Editable.

Frame Options box Select Home to return the hue cube to its default position, Plot Colour to enlarge the gradient to include the plot and reference colours, or Autoframe to view the complete gradient range.

Auto Key button Set keyframes automatically when changes are made to a frame.

Gamma Options

RGB button Enable to display the RGB gamma curve.

Red button Enable to display the red gamma curve.

Green button Enable to display the green gamma curve.

Blue button Enable to display the blue gamma curve.

Luminance button Enable to display the luminance curve.

Warp Options

Source colour pot Displays the colour you want to modify. Editable.

Destination colour pot Displays the corrected colour.

Subsetup Menu

Store, compare, and share Colour Warper subsetup.

Current button Access the most recently committed setup.

Load button Open the file browser to load a group of subsetup within a directory.

Save button Open the file browser to save active subsetup in a specific directory.

Subsetup A LED button Indicates the subsetup is stored.

Subsetup A button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup B LED button Indicates the subsetup is stored.

Subsetup B button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup C LED button Indicates the subsetup is stored.

Subsetup C button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup D LED button Indicates the subsetup is stored.

Subsetup D button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup E LED button Indicates the subsetup is stored.

Subsetup E button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup F LED button Indicates the subsetup is stored.

Subsetup F button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup G LED button Indicates the subsetup is stored.

Subsetup Gbutton Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup H LED button Indicates the subsetup is stored.

Subsetup H button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup I LED button Indicates the subsetup is stored.

Subsetup I button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Subsetup J LED button Indicates the subsetup is stored.

Subsetup J button Apply an active subsetup to the current frame. Hold down to replace an existing subsetup.

Name field Displays the name of the subsetup. Editable.

Setup Menu

Customize your work environment by adjusting vectorscope and hue cube settings, updating colour information, cropping the area you want to colour correct, and inverting a matte.

Scope box Displays the vectorscope you want to use to view the clip.

Canvas button Enable to show the vectorscope canvas. When the canvas is off, the vectorscope is transparent, but can be outlined.

Lines button Enable to show the vectorscope outline.

Bars box Select the SMPTE bars setting for the 2D vectorscope.

Size box Select the size of the coloured squares or cubes that make up the histogram.

Clear Buffer button Clears the Undo buffer of all previous undo operations.

Levels field An upper limit for the number of undo or redo operations. Editable.

Coloured Frame

Use Coloured Frame to generate a colour bar, noise, gradient, or colour clip that can be used as the clip for other nodes.

To access the Coloured Frame menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node outputs a result.

The Coloured Frame node includes eight colour pots for storing and selecting customized colours for creating frames. You can specify a frame's resolution and bit depth.

Coloured Frame Menu Settings

General Settings

Source Type box Select whether to generate frames of solid colour, noise, or colour bars.

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution.

Width field Displays the custom width resolution of the clip. Editable.

Height field Displays the custom width resolution of the clip. Editable.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the custom render/output aspect ratio. Editable

Bit Depth box Select the render/output bit depth of clips.

Scan Mode box Select the scan mode of clips.

Current Colour bar Displays the pattern applied to the colour source.

Luminance box Select whether to apply 75% or 100% luminance to the colour frames.

Combine

Use Combine to combine the individual color space channels of three different source clips (RGB, YUV, or HSL).

To access the Combine menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front, back and matte clip, and outputs a result.

Combine Menu Settings

General Settings

Colour Space Type box Select which type of colour space to combine.

Comp

Use Comp to blend two inputs and their mattes. The type of composition is determined by the selected blending mode.

To access the Comp menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.

The Timeline FX pipeline uses:

- The upper track as the primary clip and matte (optional) that comprise the foreground of the composition.
- The lower tracks as the secondary clip and matte (optional) that comprises the background.

This node accepts:

- In the upper tabs, the primary clip and matte that comprise the foreground of the composition.
- In the lower tabs, the secondary clip and matte (optional) that comprise the background.

TIP The default inputs for the foreground and background can be switched using the Swap Inputs button in the Comp menu.

This node outputs a result and an output matte.

Comp Menu Settings

Input Controls		Blending		Output Controls
Input 1	Input 2	Blend Type	Matte	No Clamp
Matte On	Matte On	Flame	Composition	Premultiplied
No Clamp	No Clamp	Blend Mode	1 Over 2 (Over)	
Premultiplied	Premultiplied	Blend	Correlation	
Transp 0.0%	Transp 0.0%	Swap Inputs	Uncorrelated	

Timeline FX Quick Menu Settings

To see the full Comp menu, click the Editor button.

Input Settings

NOTE Input Front and Input Back settings are identical.

Matte box Select how the matte is used when blending.

Clamping box Select a clamping option for colour and luminance values on input in the 16-bit floating point rendering pipeline.

Premultiplication box Select whether the colour values in the input are premultiplied by the matte or not.

Transparency field Displays the transparency value. Editable.

Blending Settings

Blend Type box Select whether to use Flame or Photoshop blend modes.

Blend Mode box Select how the front and back inputs are composited. The available list of modes depends on the selection in the Blend Type box.

Swap Inputs button Enable to switch the rendering order of the inputs.

Blend Matte Settings

Composition box Select how the input mattes are combined.

Correlation box Select whether the mattes are related to each other. For example, select Correlated if the mattes are from different, but continuous parts on the same object.

Output Controls Settings

Clamp Render box Select a clamping option for colour and luminance values on output in the 16-bit floating point rendering pipeline.

Pre-multiplication box Select whether the colour values in the output are pre-multiplied or not.

Compound

Use Compound to combine the contents of several frames into a single frame.

To access the Compound menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Compound Menu Settings

General Settings

First Rendered Frame field Displays the first frame at which output is rendered from the node. Unrendered output does not display any media. Editable.

Compound Over field Displays the number of frames that are combined into one frame. Editable.

Damage

Use Damage to apply a large variety of film or video degradation effects to a clip.

To access the Damage menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Damage Menu Settings

General Settings

Damage Type

Film

Random Seed

0

Timing Offset

0

Damage Type box Select an option for the media type of damage effects to use. Selecting one of the effects groups from the Damage Type box will display a menu of options for this effect.

Random Seed field Displays the number used to generate random variations in the damage effects. Editable.

Timing Offset field Displays the number used for timing offset in the damage effects. Editable.

Damage Effect buttons Enable to display options for an effect. Click LED to switch between On (blue) and Off (grey).

Film Settings

Use the Film Damage effects to apply a large variety of film degradation effects to a clip.

When you select Film from the Damage type box, the Film Damage Effects are displayed, along with the most useful adjustment box to the right of each.

Film Defects		Projection Defects	
<input type="checkbox"/> Blotches	Amount 1.00	<input type="checkbox"/> Defocus	Spacing 80.00
<input type="checkbox"/> Colour	Saturation 100	<input type="checkbox"/> Flicker	Spacing 60
<input type="checkbox"/> Dust	Amount 10.00	<input type="checkbox"/> Hairs	Amount 3.00
<input type="checkbox"/> Grain	Transp 80.0%	<input type="checkbox"/> Jitter	Spacing 30.00
<input type="checkbox"/> Scratches	Amount 10.00	<input type="checkbox"/> Vignette	Scale 1.00
<input type="checkbox"/> Splices	Spacing 120.00		

Blotches Settings

Blotches button Use this effect to simulate blotches on old film.

Blotch Amount field Displays the amount of blotches applied to the image. Editable.

Blotch Transparency field Displays the percentage of transparency applied to the blotches. Editable.

Blotch Transparency Variation field Displays the percentage of variation for the transparency applied to the blotches. Editable.

Blotch Size field Displays the average size of the blotches. Editable.

Blotch Size Variation field Displays the percentage of variation in the size of the blotches. Editable.

Blotch Softness field Displays the percentage by which the blotches are out of focus. Editable.

Blotch Negative Mix field Displays the amount of negative blotches in the mix. Editable.

Blotch colour pot Displays the tint applied to the blotches in the image. Editable.

Colour Settings

Colour button Use this effect to simulate colour fading and variation in old film.

Colour Gain trackball Drag to adjust the colour gain. This is an alternate control combining the Red Gain, Green Gain, Blue Gain, and Luma fields.

Colour Saturation field Displays the level of colour purity in the image. Editable.

Colour Gamma field Displays the amount of gamma correction applied to the image. Editable.

Colour Offset field Displays the amount by which all the colour parameters are modified. Editable.

Red Gain field Displays the amount of gain applied to the red channel. Editable.

Green Gain field Displays the amount of gain applied to the green channel. Editable.

Blue Gain field Displays the amount of gain applied to the blue channel. Editable.

Luma field Displays the amount of gain applied to the luminance channel. Editable.

Proportional button Enable to synchronize changes in red, green, blue, and luma channels.

Hue field Displays the colour range. Editable.

Shadows colour pot Displays the tint applied to shadows in the image. Editable.

Highlights colour pot Displays the tint applied to highlights in the image. Editable.

Minimum Colour Value field Displays the luminance value in the image shadows. Editable.

Maximum Colour Value field Displays the luminance value in the image highlights. Editable.

Dust Settings

Dust button Use this effect to simulate dust particles on old film.

Dust Amount field Displays the amount of dust particles applied to the image. Editable.

Dust Transparency field Displays the percentage of transparency applied to the dust particles. Editable.

Dust Transparency Variation field Displays the percentage of variation in transparency applied to the dust particles. Editable.

Dust Size field Displays the average size of the dust particles. Editable.

Dust Size Variation field Displays the percentage of variation applied to the size of the dust particles. Editable.

Dust Softness field Displays the percentage by which the dust is out of focus. Editable.

Dust Negative Mix field Displays the amount of negative dust particles in the mix. Editable.

Dust colour pot Displays the tint applied to the dust particles in the image. Editable.

Grain Settings

Grain button Use this effect to simulate grain on old film.

Grain Coloured button Enable for the grain to be coloured. Disable for the grain to be monochrome.

Grain Transparency field Displays the percentage of transparency applied to the grain. Editable.

Grain Blur field Displays the amount of blur applied to the grain. Editable.

Grain Width field Displays the width of the grain in pixels. Editable.

Grain Height field Displays the height of the grain in pixels. Editable.

Grain Proportional button Enable to effect the width and height proportionally. Editable.

Scratches Settings

Scratches button Use this effect to simulate scratches in old film.

Scratch Amount field Displays the amount of scratches applied to the image. Editable.

Scratch Width field Displays the average width of the scratches. Editable.

Scratch Width Variation field Displays the percentage of variation in the width of the scratches. Editable.

Scratch Length field Displays the average length of the scratches. Editable.

Scratch Length Variation field Displays the percentage of variation in the length of the scratches. Editable.

Scratch Transparency field Displays the transparency of the scratches. Editable.

Scratch Discontinuity field Displays the percentage of gaps that occur in the scratches. Editable.

Scratch Roughness field Displays the amount of irregularities and changes in alignment of the scratches. Editable.

Scratch Negative Mix field Displays the amount of negative scratches in the mix. Editable.

Scratch colour pot Displays the tint applied to the scratches. Editable.

Scratch Travel field Displays the amount in pixels that the scratches move along. Editable.

Scratch Travel Variation field Displays a percentage of variation that the scratches travel. Editable.

Scratch Angle Variation field Displays the angle at which the scratches occur. Editable.

Scratch Spread field Displays the area of the frame over which the scratches are spread. Editable.

Scratch Horizontal Offset field Displays the horizontal offset of the scratches. Editable.

Scratch Duration field Displays the duration in frames of the scratch effect. Editable.

Scratch Duration Variation field Displays the variation in duration for the scratch effects. Editable.

Splices Settings

Splices button Use this effect to simulate splices on old film.

Splice Auto box Select whether the splice occurs automatically or is manually inserted. Select Manual to display the Create Splice and Delete Splice buttons.

Splice Type box Select what kind of splice to be applied to the image.

Splice Border Width field Displays the width of the splice border. Editable.

Splice colour pot Displays the colour used for the splice effects. Editable.

Splice Projector Roll field Displays the amount of space that the frame will travel as a percentage. Editable.

Splice Motion Blur field Displays the amount of motion blur applied to the splice effects. Editable.

Splice Jitter field Displays the amount of jitter applied to the splice effects. Editable.

Splice Defocus field Displays the amount of defocus applied to the splice effects. Editable.

Splice Spacing field Displays the spacing in frames between splice effects. Editable.

Splice Spacing Variation field Displays the percentage of variation in spacing between splice effects. Editable.

Splice Duration field Displays the duration in frames of the splice effects. Editable.

Splice Duration Variation field Displays the percentage of variation in duration for the splice effects. Editable.

Temporal	
Create Splice	Duration 10.00
Delete Splice	Variation 50.00%

Create Splice button Creates a splice at the current frame. Available when Splice Auto is set to Manual.

Delete Splice button Deletes the splice at the current frame. Available when Splice Auto is set to Manual.

Defocus Settings

Defocus button Use this effect to simulate projection defocus on old film.

Defocus
Amount 20.00
Variation 50.00%

Defocus Amount field Displays the amount of defocus applied to the image. Editable.

Defocus Amount Variation field Displays the percentage of variation in the amount of defocus applied to the image. Editable.

Temporal	
Spacing 80.00	Duration 5.00
Variation 20.00%	Variation 0.00%

Defocus Spacing field Displays the spacing in frames between defocus effects. Editable.

Defocus Spacing Variation field Displays the percentage of variation in the spacing between defocus effects. Editable.

Defocus Duration field Displays the duration in frames of the defocus effects. Editable.

Defocus Duration Variation field Displays the percentage of variation in duration for the defocus effects. Editable.

Flicker Settings

Flicker button Use this effect to simulate frame flicker on old film.

Flicker
Amount 20.00
Variation 20.00%
Balance 0.00

Flicker Amount field Displays the amount of flicker added to the image. Editable.

Flicker Amount Variation field Displays the percentage of variation in the amount of flicker added to the image. Editable.

Flicker Balance field Displays the ratio of dark and bright flickers used for the effect. Editable.

Temporal	
Spacing 60.00	Duration 3.00
Variation 10.00%	Variation 50.00%

Flicker Spacing field Displays the spacing in frames between flicker effects. Editable.

Flicker Spacing Variation field Displays the percentage of variation in the spacing between flicker effects. Editable.

Flicker Duration field Displays the duration in frames of the flicker effects. Editable.

Flicker Duration Variation field Displays the percentage of variation in duration for the flicker effects. Editable.

Hairs Settings

Hairs button Use this effect to simulate hairs on old film.

Hairs	
Amount 3.00	Jitter 5.00
Transp 20.0%	Softness 0.00%
Variation 10.00%	
Size 1.00	
Variation 50.00%	

Hair Amount field Displays the amount of hairs applied to the image. Editable.

Hair Transparency field Displays the transparency applied to the hairs. Editable.

Hair Transparency Variation field Displays the percentage of variation in transparency applied to the hairs. Editable.

Hair Size field Displays the average size of the hairs. Editable.

Hair Size Variation field Displays the percentage of variation in size of the hairs. Editable.

Hair Jitter field Displays the amount of jitter applied to the hairs. Editable.

Hair Softness field Displays the percentage by which the hair is out of focus. Editable.

Temporal
Duration 2.00
Variation 50.00%

Hair Duration field Displays the duration in frames of the hair effects. Editable.

Hair Duration Variation field Displays the percentage of variation in duration for the hair effects. Editable.

Jitter Settings

Jitter button Use this effect to simulate projection jitter on old film.

Jitter
X Amount 0.02%
Y Amount 0.80%
Variation 50.00%

Jitter X Amount field Displays the amount of horizontal movement applied to the jitter effect. Editable.

Jitter Y Amount field Displays the amount of vertical movement applied to the jitter effect. Editable.

Jitter Amount Variation field Displays the percentage of variation applied to the movement of the jitter effect. Editable.

Temporal	
Spacing 30.00	Duration 2.00
Variation 10.00%	Variation 50.00%

Jitter Spacing field Displays the spacing in frames between jitter effects. Editable.

Jitter Spacing Variation field Displays the percentage of variation in the spacing between jitter effects. Editable.

Jitter Duration field Displays the duration in frames of the jitter effects. Editable.

Jitter Duration Variation field Displays the percentage of variation in duration for the jitter effects. Editable.

Vignette Settings

Vignette button Use this effect to simulate vignetting on old film.

Vignette Scale field Displays the size of the vignette effect compared to the size of the frame. Editable.

Vignette Ratio field Displays the ratio of width to height of the vignette effect. Editable.

Vignette Transparency field Displays the amount of transparency applied to the vignette effect. Editable.

Vignette Softness field Displays the amount of softness added to the edge of the vignette effect. Editable.

Analog Video Settings

Use the Analog Video Damage effects to apply a large variety of analog video degradation effects to a clip.

When you select Analog Video from the Damage type box, the Analog Video Damage Effects are displayed, along with the most useful adjustment box to the right of each.

VTR Defects		Broadcast Defects

Analog Colour Green Channel Gain field Displays the amount of gain applied to the green channel. Editable.

Analog Colour Blue Channel Gain field Displays the amount of gain applied to the blue channel. Editable.

Analog Colour Red Channel X Shift field Displays the amount of horizontal offset applied to the red channel. Editable.

Analog Colour Green Channel X Shift field Displays the amount of horizontal offset applied to the green channel. Editable.

Analog Colour Blue Channel X Shift field Displays the amount of horizontal offset applied to the blue channel. Editable.

Analog Colour Red Channel Y Shift field Displays the amount of vertical offset applied to the red channel. Editable.

Analog Colour Green Channel Y Shift field Displays the amount of vertical offset applied to the green channel. Editable.

Analog Colour Blue Channel Y Shift field Displays the amount of vertical offset applied to the blue channel. Editable.

Ghosting Settings

Ghosting button Enable to simulate ghosting from poor signal reception.

Ghosting	
Amount 5.00	Distortion 10.00
Variation 50.00%	Scale 100.00
Transp 20.0%	Angle 0.00
Variation 50.00%	Colour 10.00

Ghosting Amount field Displays the number of repeated ghost images applied to the original image. Editable.

Ghosting Amount Variation field Displays the percentage of variation in the number of ghost images. Editable.

Ghosting Transparency field Displays the percentage of the transparency applied to the ghosted images. Editable.

Ghosting Transparency Variation field Displays the percentage of variation in the transparency of the ghosted images. Editable.

Ghosting Distortion field Displays the amount of distortion applied to the ghosted images. Editable.

Ghosting Scale field Displays the amount of scaling applied to the ghosted images. Editable.

Ghosting Angle field Displays the angle applied to the ghosted images. Editable.

Ghosting Colour Degradation field Displays the amount of colour degradation applied to the ghosted images. Editable.

Temporal	
Spacing 80.00	Duration 10.00
Variation 40.00%	Variation 80.00%

Ghosting Spacing field Displays the spacing in frames between ghosting errors. Editable.

Ghosting Spacing Variation field Displays the percentage of variation in spacing between ghosting errors. Editable.

Ghosting Duration field Displays the duration in frames of the ghosting errors. Editable.

Ghosting Duration Variation field Displays the percentage of variation in the duration of ghosting errors. Editable.

Scanlines Settings

Scanlines button Use this effect to simulate scanlines from poor signal reception.

Scanlines	
Scale 2.00	Offset 0.00
Variation 20.00%	Softness 100.00
Speed 2.00	Angle 0.00
Transp 10.0%	

Scanlines Scale field Displays the size of the scanlines applied to the image. Editable.

Scanlines Variation field Displays the percentage of variation in the size of the scanlines. Editable.

Scanlines Variation Speed field Displays the speed at which the scanline variation occurs. Editable.

Scanlines Transparency field Displays the percentage of transparency applied to the scanlines.

Scanlines Vertical Offset field Displays the vertical offset for the scanline effect. Editable.

Scanlines Softness field Displays the amount of softness applied to the scanlines. Editable.

Scanlines Angle field Displays the angle at which the scanlines occur. Editable.

Snow Settings

Snow button Enable to simulate snow from poor signal reception.

Snow	
Amount 20.00	Size
Variation 40.00%	Width 5.00
Transp 95.0%	Height 3.00
Variation 10.00%	Proportional
Sparseness 8.00	

Snow Amount field Displays the amount of snow applied to the image. Editable.

Snow Amount Variation field Displays the percentage of variation in the amount of snow applied to the image.

Snow Transparency field Displays the percentage of transparency or softness, applied to the snow. Editable.

Snow Transparency Variation field Displays the percentage of variation in the transparency or softness, applied to the snow. Editable.

Snow Sparseness field Displays the density of the snow. Editable.

Snow Width field Displays the width in pixels of the snow particles. Editable.

Snow Height field Displays the height in pixels of the snow particles. Editable.

Snow Proportional button Enable to effect the width and height proportionally. Editable.

TV Distort Settings

TV Distort button Use this effect to simulate TV lens distortion from a poor video camera.

TV Distort
Amount 15.00
Variation 0.00%
Radius 0.70
Ratio 0.60

TV Distort Amount field Displays the amount of TV lens distortion applied to the image. Editable.

TV Distort Amount Variation field Displays the percentage of variation in the amount of TV lens distortion applied to the image.

TV Distort Radius field Displays the size of the image to which the TV lens distortion is applied. A value of 1 includes the entire image. Editable.

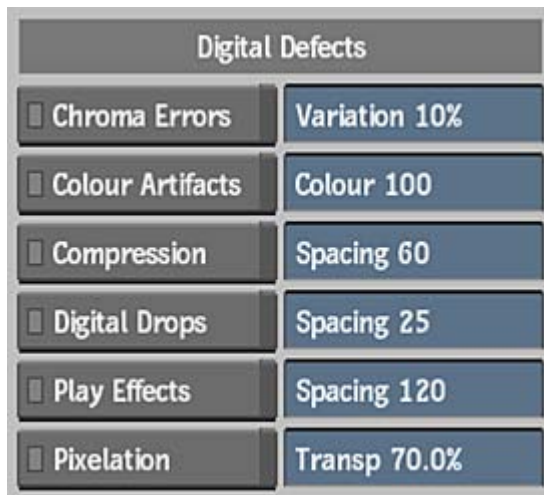

TV Distort Ratio field Displays the ratio of height to width that is affected by the TV lens distortion effect. Editable.

Digital Video Settings

Use the Digital Video Damage effects to apply a large variety of digital video degradation effects to a clip.

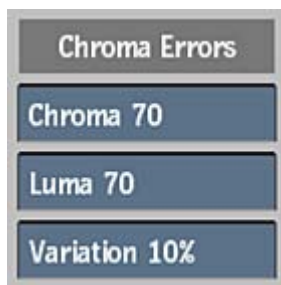

When you select Digital Video from the Damage type box, the Digital Video Damage Effects are displayed, along with the most useful adjustment box to the right of each.

Chroma Errors Settings

Chroma Errors button Use this effect to simulate chroma errors in badly encoded digital video transmissions.

Chroma Amount box Displays the value representing the change to the chroma channel. Editable.

Luma Amount box Displays the value representing the change to the luminance channel. Editable.

Variation Amount box Displays the percentage of variation applied to the Chroma and Luma channels.

Colour Artifacts Settings

Colour Artifacts button Use this effect to simulate digital colour artifacts and degradation appearing in badly encoded digital video transmissions.

Colour Degradation Amount box Displays the amount of digital colour degradation applied to the image. Editable.

Colour Degradation Variation box Displays the percentage of variation in the amount of colour degradation applied to the image. Editable.

Contrast box Displays the amount of contrast applied to the image. Editable.

Brightness box Displays the amount of brightness applied to the image. Editable.

Tint Colour box Displays the tint value applied to the colour in the image. Editable.

Shadows colour pot Displays the tint applied to shadows in the image. Editable.

Highlights colour pot Displays the tint applied to highlights in the image. Editable.

Compression Settings

Compression button Use this effect to simulate digital compression errors in badly encoded digital video transmissions.

Compression Amount field Displays the amount of the digital compression effect applied to the image. Editable.

Compression Amount Variation field Displays the percentage of variation in the amount of digital compression applied to the image. Editable.

Compression Edges Active button Enable to activate edge detection errors in compression.

Compression Edges Minimum field Displays the minimum threshold value used to detect edges. Available when Active button is enabled. Editable.

Compression Edges Maximum field Displays the maximum threshold value used to detect edges. Available when Active button is enabled. Editable.

Compression Edges Width field Displays the width of the edge in pixels. Available when Active button is enabled. Editable.

Compression Edges Softness field Displays the softness of the edge. Available when Active button is enabled. Editable.

Temporal	
Spacing 60	Duration 20
Variation 10%	Variation 0%

Compression Spacing field Displays the spacing in frames between digital compression errors. Editable.

Compression Spacing Variation field Displays the percentage of variation in spacing between compression errors. Editable.

Compression Duration field Displays the duration in frames of the compression errors. Editable.

Compression Duration Variation field Displays the percentage of variation in duration of the compression errors. Editable.

Digital Drops Settings

Digital Drops button Use this effect to simulate digital drop errors in badly encoded digital video transmissions.

Digital Drops
Amount 5
Coherence 60
Variation 100%

Digital Drops Amount field Displays the amount of digital drop errors applied to the image. Editable.

Digital Drops Coherence field Displays the amount of coherence to digital drop errors in the image. Editable.

Digital Drops Amount Variation field Displays the percentage of variation in the amount of digital drop errors applied to the image. Editable.

Temporal	
Spacing 25	Duration 20
Variation 10%	Variation 50%
Freeze Frame	

Digital Drops Spacing field Displays the spacing in frames between digital drop errors. Editable.

Digital Drops Spacing Variation field Displays the percentage of variation in spacing between digital drop errors. Editable.

Digital Drops Freeze Frame button Displays the number of repeat frames added to create a jerky digital drop effect. Editable.

Digital Drops Duration field Displays the duration in frames of the digital drop errors. Editable.

Digital Drops Duration Variation field Displays the percentage of variation in duration for the digital drop errors. Editable.

Play Effect Settings

Play Effects button Use this effect to simulate digital play effects in badly encoded digital video transmissions.

Play Effects Speed field Displays the amount of change to the speed of playback applied to the image. Editable.

Play Effects Shuttering field Displays the amount of shuttering during playback that is applied to the image. Editable.

Play Effects Spacing field Displays the spacing in frames between play effects errors. Editable.

Play Effects Spacing Variation field Displays the percentage of variation in spacing between play effects errors. Editable.

Play Effects Duration field Displays the duration in frames of the play effects errors. Editable.

Play Effects Duration Variation field Displays the percentage of variation in the duration for play effects errors. Editable.

Pixelation Settings

Pixelation button Use this effect to simulate reduced resolution and digital pixelation errors in badly encoded digital video transmissions.

Pixelation Width Amount field Displays the width in pixels of the new pixelation block. Editable.

Pixelation Height Amount field Displays the height in pixels of the new pixelation block. Editable.

Pixelation Proportional button Enable to effect the width and height proportionally. Editable.

Pixelation Average button Displays the amount of averaging applied between the pixel block and its surroundings. Editable.

Pixelation Transparency field Displays the percentage of transparency, or softness, applied to the pixel blocks. Editable.

Pixelation X Offset field Displays the horizontal offset for the pixelation effect. Editable.

Pixelation Y Offset field Displays the vertical offset for the pixelation effect. Editable.

Pixelation Size Variation field Displays the percentage of variation in the size of pixels during playback. Editable.

Deal

Use Deal to deal out the frames of a single clip evenly to any number of destination clips.

To access the Deal menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

The Clip field defines the number of times the clip is split; the Frame determines which of the dealt clips is output. The First Processed Frame field set the value at which output is processed from the node. Unprocessed output does not display any media.

Deal Menu Settings

General Settings

First Rendered Frame field Displays the first frame at which output is rendered from the node. Unrendered output does not display any media. Editable.

Clips field Displays the number of times the clip is split. Editable.

Start Frame field Displays which frame of the input clip used to determine which dealt clip is output. Editable.

Deform

Use Deform to apply various types of deformation effects to clips.

To access the Deform menu, use:

- Batch, then select a node from the Node bin.

- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front and a matte clip, and outputs a result and an outmatte.

Deform Menu Settings

General Settings

Deform Type button Select the type of deformation you want to create. The available effect parameters change based on the selection.

Deform Ripple box (not shown) Select how you want the ripples created. Pond Ripples create ripples with a 45 degree offset. Out from Center pushes the ripples away from the center, extending the first half, and compressing the second half of each ripple. Around Center rotates the crest of each ripple in a clockwise direction around the center.

Repeat Mode box Select an option to fill the empty portions of the frame.

Effect Parameters

NOTE The following settings are available when Crumple is selected from the Deform Type button.

Effect Parameters	
Amplitude	40.00
Time Offset	50.00
Octaves	1.00

Amplitude field Displays the amount of deformation. Increase the value to increase the effect. Editable.

Time Offset field Displays the time offset interval of the crumpling. Editable.

Octaves field Displays a value for the number of layers summed in the operation, from zero to 10. Increase the value to increase the fractal effect. Editable.

NOTE The following settings are available when Magnify is selected from the Deform Type button.

Effect Parameters	
Radius	50.00
Amount	5.00
Direction	Both
Damping	Linear

Radius field Displays the size of the affected area. You can also drag the circle in the image window to change the size of the radius. Editable.

Amount field Displays the amount of the deformation. Editable.

Direction box Select Horizontal, Vertical, or Both to indicate the direction of the magnification.

Damping box Select how the effect is applied within the radius. Select None to apply no damping, Linear to decrease the effect linearly to 0, or Quadratic to decrease the effect quadratically to 0.

NOTE The following settings are available when Pinch is selected from the Deform Type button.

Effect Parameters	
Radius	50.00
Amount	0.2500
Damping	Linear

Radius field Displays the size of the affected area. You can also drag the circle in the image window to change the size of the radius. Editable.

Amount field Displays the amount of the deformation. Editable.

Damping box Select how the effect is applied within the radius. Select None to apply no damping, Linear to decrease the effect linearly to 0, or Quadratic to decrease the effect quadratically to 0.

NOTE The following settings are available when Ripple is selected from the Deform Type button.

Effect Parameters	
Amplitude	181.33
Ripples	5.00
Radius	50.00
Phase	0.00
Max Ridges	200
Damping	None

Amplitude field Displays the amount of deformation. Increase the value to increase the effect. Editable.

Ripples field Displays the frequency of the ripples (from zero to 60). Editable.

Radius field Displays the size of the affected area. You can also drag the circle in the image window to change the size of the radius. Editable.

Phase field Displays the spread of the ripples to the centre. Use this value to animate the ripple effect. Editable.

Max Ridges field Displays the total number of ripples that can be generated. For example, set to 5 to create 5 rings of distortion. Editable.

Damping box Select how the effect is applied within the radius. Select None to apply no damping, Linear to decrease the effect linearly to 0, or Quadratic to decrease the effect quadratically to 0.

NOTE The following settings are available when Twirl is selected from the Deform Type button.

Effect Parameters	
Radius	50.00
Angle	360.00
Damping	Linear

Radius field Displays the size of the affected area. You can also drag the circle in the image window to change the size of the radius. Editable.

Twirl Angle field Displays the direction of the twirl. Editable.

Damping box Select how the effect is applied within the radius. Select None to apply no damping, Linear to decrease the effect linearly to 0, or Quadratic to decrease the effect quadratically to 0.

NOTE The following settings are available when Wave is selected from the Deform Type button.

Effect Parameters	
Amplitude	90.67
Frequency	30.00
Phase	0.00
Compression	0.00

Amplitude field Displays the amount of deformation. Increase the value to increase the effect. Editable.

Wave Frequency field Displays the number of waves. Editable.

Phase field Displays the spread of the ripples to the centre. Use this value to animate the ripple effect. Editable.

Compression field Displays a pixel flattening value (negative values flatten to the left, and positive values flatten to the right). Editable.

Transform Settings

Input Transform			
	Position	Centre	Scale
X	0.00	0.00	100.00
Y	0.00	0.00	100.00
	Rotation		Prop
	0.00		Icons

NOTE Transform settings for Input, Deform and Output are identical.

Transform X Position field Displays the horizontal position of the transformation. Enable the Icons button to change the position by dragging the vertex tool in the image window. Editable.

Transform Y Position field Displays the vertical position of the transformation. Editable. Enable the Icons button to change the position by dragging the vertex tool in the image window. Editable.

Transform Rotation field Displays the rotation of the transformation. Editable. Enable the Icons button to change the rotation by dragging the vertex tool in the image window. Editable.

Transform Centre X field Displays the centre point value of the transform along the horizontal axis. Editable.

Transform Centre Y field Displays the centre point value of the transform along the vertical axis. Editable.

Transform X Scale field Displays the horizontal scale factor. Editable.

Transform Y Scale field Displays the vertical scale factor. Editable.

Proportional button Enable to scale X and Y values proportionally.

Icons button Enable to display the vertex editing tool in the image window.

Anti-Aliasing Settings

Active button Enable to activate software anti-aliasing.

Anti-Aliasing Sampling box Select the number of samples to use in the anti-aliasing process.

Anti-Aliasing Softness field Displays the softness value for software anti-aliasing. Editable.

Degrain

Use Degrain to remove grain from the RGB channels of a selected colour in an image.

To access the Degrain menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Degrain Menu Settings

General Settings

Render Method box Select whether you are removing grain from progressive or interlaced media.

Crop box Applies the Degrain to a specific region in the clip.

Red Average slider Displays the amount of blur applied to the red channel.

Red Average field Displays the amount of blur applied to the red channel. Editable.

Green Average slider Displays the amount of blur applied to the green channel.

Green Average field Displays the amount of blur applied to the green channel. Editable.

Blue Average slider Displays the amount of blur applied to the blue channel.

Blue Average field Displays the amount of blur applied to the blue channel. Editable.

Proportional RGB Average button Enable to blur RGB channels proportionally.

Red Sharpen slider Displays the amount of sharpness applied to the red channel.

Red Sharpen field Displays the amount of sharpness applied to the red channel. Editable.

Green Sharpen slider Displays the amount of sharpness applied to the green channel.

Green Sharpen field Displays the amount of sharpness applied to the green channel. Editable.

Blue Sharpen slider Displays the amount of sharpness applied to the blue channel.

Blue Sharpen field Displays the amount of sharpness applied to the blue channel. Editable.

Proportional RGB Sharpen button Enable to sharpen RGB channels proportionally.

Deinterlace

Use Deinterlace to separate the odd and even scanlines of a clip.

To access the Deinterlace menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip as input, and outputs a result.

For each frame of the clip, the result clip contains one frame with odd scanlines (Field 1) and one frame with even scanlines (Field 2).

Deinterlace Menu Settings

General Settings

First Rendered Frame field Displays the first frame at which output is rendered from the node. Unrendered output does not display any media. Editable.

Field Dominance box Select Field 1 or Field 2 dominance, or Auto to have the application detect automatically the field dominance.

Interpolation box Enable to interpolate a blend between adjacent lines and fill in the isolated scan lines. This also reduces interlacing artifacts.

Denoise

Use the Denoise effect to reduce or remove noise and grain from your source media.

To access the Denoise menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result clip.

Denoise Menu Settings

Setup Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Export button Click to export a Denoise setup to be used as a Lustre Degrain preset.

Import button Click to open the browser to select a Lustre Degrain preset to import.

Grain Analysis Settings

Add Bounding Box button Adds a new sub-region. Click and drag the bounding box in the image window to set the location.

Remove Bounding Box button Select an option to remove the currently selected bounding box or all the bounding boxes.

Analyze button Click to determine the grain structure.

Reference frame field Displays the frame number that is analysed. You can use this frame analysis as a reference that can be edited and applied to the clip.

Show Icons button Enable to display all the defined bounding boxes.

Bounding Box colour pot Displays the colour used for the border of the bounding boxes. Click to change the colour.Editable.

Denoise Settings

Denoise button Enable to use noise removal on the clip.

Red Gain field Displays the gain for red channel colour values. Editable.

Green Gain field Displays the gain for green channel colour values. Editable.

Blue Gain field Displays the gain for blue channel colour values. For film scans, the grain is often greater in this channel. Editable.

Proportional button Enable to change gain values proportionally for all three colour channels.

Grain Size field Displays a value in pixels that is proportional to the size of the grain. The default value is 3, but may be higher for 4K images. Editable.

Smoothing Radius field Displays the blur radius. For smoother results, a higher value will add more pixels to the blur, but increase rendering time. Editable.

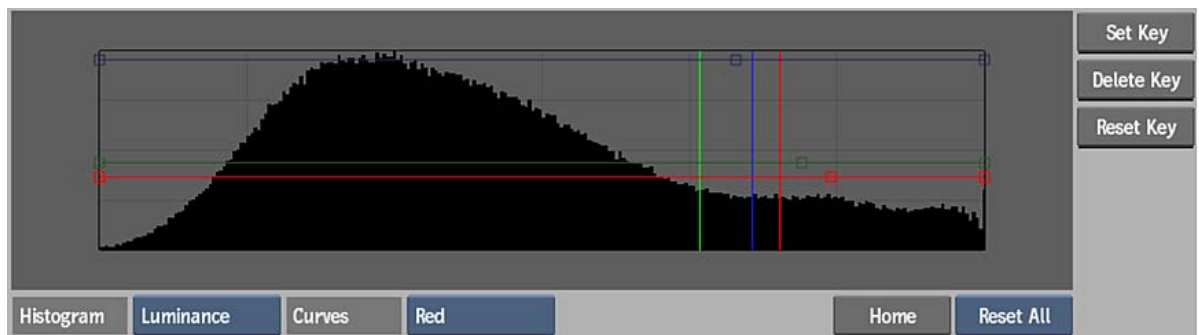

Detail field Displays the amount of detail to preserve when the Smoothing Radius is set to a high value. It is recommended you enter 0.05 to 0.15 as an initial value. Editable.

Opacity field Displays a percentage of the level of opacity between the source image and the output with the applied grain filter. Editable.

Use Past button Enable to compare with pixel data from previous frames.

Use Future button Enable to compare with pixel data from subsequent frames.

Histogram Settings

Histogram box Select to display the red, green, blue, or luminance histogram in the graph. Select Current Curve to display the histogram for the currently selected Curves Channel.

Curves Channel box Select to highlight the red, green, or blue channel curve in the graph.

Home button Reverts to the original view.

Reset box Resets the curve view.

Set Key button Sets the current values for the selected channels in the current frame.

Delete Key button Deletes the selected keyframe or curve.

Reset Key button Select to reset the current curve or all the curves to default.

Median Filtering Settings

Median Filtering	
Type	Standard
Criteria	RGB Component
Radius	1
Iterations	1
Opacity	100%

The Median Filter removes noise by calculating the median value for each pixel (the most probable pixel value) and applies an edge-preserving smoothing filter.

Median Filtering button Enable to use the median filter.

Type box Select the filtering mode. Options are:

- Standard: Applies the standard filtering algorithm.
- Advanced: Applies a more advanced filtering algorithm, but is more resource intensive. Use the Advanced Filter Mode on particularly noisy shots.

Criteria box Select the ranking criteria by which the median value is chosen. Options are:

- Luminance :Uses the pixel luminance value to calculate the median value.
- RGB Vector: Uses the RGB coordinate values to calculate the median value.
- RGB Component: Uses the R, G and B channels independently to calculate the median value.

Radius field Displays the size of the filtering region in pixels from the centre. A higher value results in more pixels being taken into account when calculating the median value. Editable.

Iterations field Displays the number of times that the filter is applied recursively. Editable.

Opacity field Displays how much the result of one median iteration is combined with the original input. Editable.

Depth of Field

Use Depth of Field to create a blur that is applied to out-of-focus points of light to simulate a shallow focus.

To access the Depth of Field menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front, Z-depth and matte clip, and outputs a result, out Z-depth and outmatte clip. The output matte clip can have a different level of depth of field than the result clip.

Depth of Field Menu Settings

Blur and Blooming Settings

Blur Width field Displays the horizontal blur amount in pixels. Editable.

Blur Height field Displays the vertical blur amount in pixels. Editable.

Blur Proportional button Enable to constrain blur amount proportions.

Bokeh Blur field Displays the amount of smoothness applied to sharp bokeh edges. This creates the blur that is applied to out-of-focus points of light to simulate a shallow focus. Editable.

Basic/Additive Blooming button Switch between basic blooming and additive blooming bokeh effects. The basic blooming mode displays the gain applied to highlights in non-HDR images, to allow the creation of bokeh patterns without affecting colour integrity. The additive blooming mode allows you to create higher intensity bokeh patterns from any source image, using minimum and maximum thresholds for highlight segregation.

Basic Blooming field Displays the gain applied to highlights in non-HDR images, to allow the creation of bokeh patterns without affecting colour integrity. This creates the glow effect that is applied to the bright spots of the image to simulate light bleeding, or blooming, over the edges. Editable.

Additive Blooming field Displays the amount of high intensity bokeh patterns that can be created from any source image generating extreme highlight content . Editable.

Additive Blooming minimum field Displays the minimum threshold for highlight segregation. Editable.

Additive Blooming maximum field Displays the maximum threshold for highlight segregation. Editable.

Bokeh Settings

Sides field Displays the number of sides in the kernel shape. Editable, if kernel information is not attached to the node.

Rotation field Displays the angle of rotation of the kernel shape. Editable, if kernel information is not attached to the node.

Bokeh Type box Select whether to use a round or angle bokeh curve to define the kernel shape.

Curvature field Displays the amount of curvature applied to a round bokeh kernel shape. Editable.

Slices and Edge Artifacts Settings

Slices Number field Displays the number of slices to blend to determine the Z-Depth interpolation of a depth-of-field focus blur. You can see the slices in the depth-o-gram to allow a better understanding of the focus plane behaviour, and to help define the number of slices required, depending on your Z-depth colour information. Editable.

Slices Overlap field Displays the amount of blending overlap between adjacent slices. Editable.

Foreground Expand field Displays the amount of mixing between the edges of selected objects and their surroundings in the foreground. Editable.

Background Blend field Displays the amount of mixing between the edges of selected objects and the background image. Editable.

Z-Depth Settings

Z-Depth Minimum field Displays the lower limit of the Z-Depth values. Pixels with lower values are mapped to black. Editable.

Z-Depth Z Maximum field Displays the upper limit of the Z-Depth values. Pixels with higher values are mapped to white. Editable.

White Value box Select whether white pixels represent the furthest point or nearest point on the Z-axis.

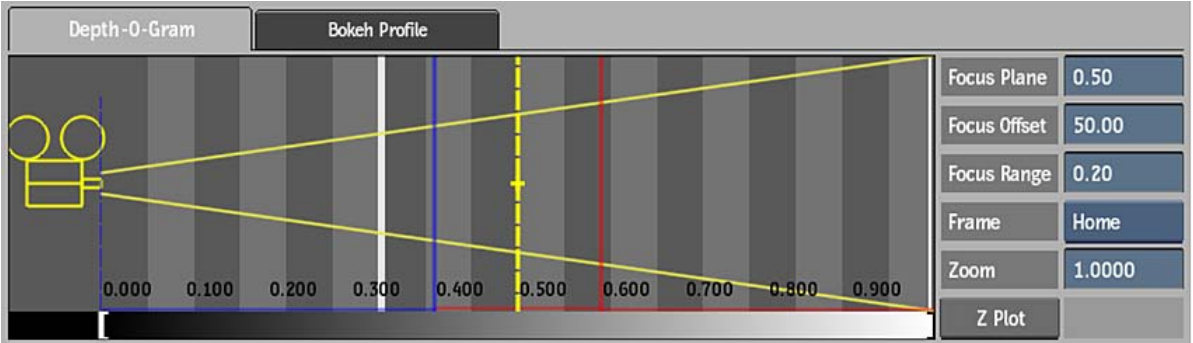

Premultiplied Depth button Enable to have the alpha channel information premultiplied with the colour depth data. Use to prevent a black halo from forming around blurred areas.

Max Blur Field Displays the maximum total horizontal and vertical blur amount to clamp the value and avoid unnecessary rendering. The cumulative effect of the high blur amount (Basic tab), and gamma and gain correction applied to the Depth map (Depth tab) may result in very large values, which greatly increases the rendering time. Editable.

Slopes field Displays the gamma value. Applies a gamma curve to the Z-depth map before it is used. Editable.

Depth-O-Gram Settings

Use the Depth-O-Gram settings to refine focus values.

Depth blur effects control the amount of blur based on a depth of field matte. Depth blur settings are displayed in the Depth-O-Gram tab.

A depth of field map (Z-depth map) can be connected to the node. Black portions of the map are in focus. White portions display the highest level of blur. Note that a Z-depth map imported from another application may use the opposite convention and may need to be inverted.

Focus Plane field Displays the distance of your focus point, which is the point at which there is no blur on the image. Editable.

Focus Offset field Displays the distance between the focus plane and the near offset represented as a percentage of the total offset range. Select 50% to make the near and far offsets equidistant from the focus point. Editable.

Focus Range field Displays the distance the near and far offset. Editable.

Frame option box Select how you want to frame the histogram.

Zoom field Displays a vertical zoom value for the histogram to display. You can zoom horizontally by pressing Ctrl+spacebar and dragging left or right in the histogram. To pan horizontally, click spacebar and drag left or right in the histogram. Editable.

Z Plot button Click to activate the pick cursor. Use to select a pixel in the image to display its depth.

Z Plot Colour pot Displays the colour that indicates the plane on which the plotted value is located.

Modifying Depth of Field Gesturally

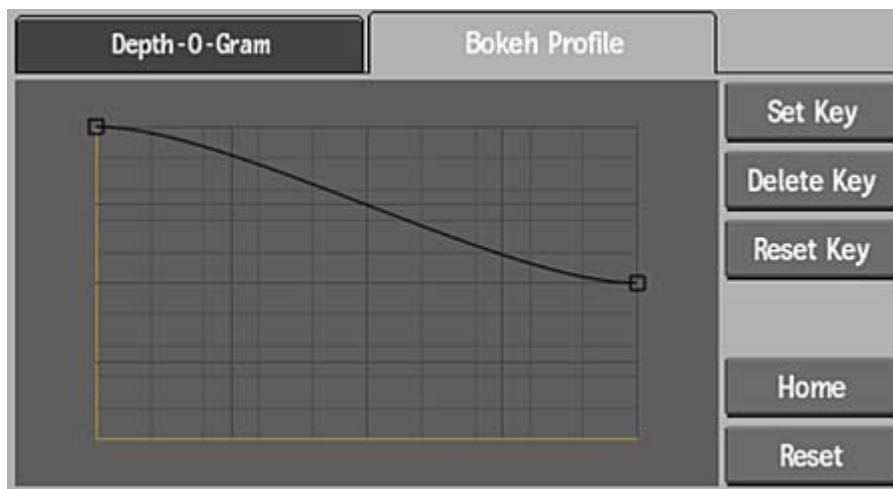

Depth blur effects can be modified gesturally by dragging the focus, near offset, and far offset planes in the graphic representation of the depth of field. As you drag these elements, the planes are also displayed in the Result view as a preview of the areas that will be in focus. Use the depth control fields to change the gamma and gain, and to change the focus range while keeping the focus plane constant. These parameters are updated in the depth of field display automatically.

(a) Plot Value Plane (b) Near Focus Offset Plane (c) Focus Offset (d) Focus Plane (e) Far Focus Offset Plane (f) Focus Range

Bokeh Profile Settings

Use the Bokeh Profile tab to edit the blur kernel pattern.

The kernel is the basic blur shape. The shape of the kernel is determined by its number of sides, its rotation, and the shape of its S-curve. This curve represents the shape of the pattern, from its centre to the outside. The default S-curve defines the softness of the blur. You can change the curve by manipulating the two points that define the curve, or you can add points to the curve. Use the Tools box to add and delete points on the curve.

Set Key button Sets a keyframe at the selected frame.

Delete Key button Deletes the selected keyframe.

Reset Key button Resets the curve at the selected keyframe.

Home button Resets the profile view.

Reset button Resets the blur pattern profile curve to its default values.

Difference Matte

Use the Difference Matte to generate a matte clip from two source clips with the same background but different foreground elements.

To access the Difference Matte menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front and back clip as input, and outputs a result.

The Difference Matte allows you to remove an image from one context and add it to another. The matte is created using the Tolerance and Softness values that you specify.

Difference Matte Menu Settings

General Settings

You can enable the RGB or the YUV settings to generate a matte clip.

RGB Settings

RGB button Enable to use values in the RGB colour space to generate a matte.

R button Enable to use the red colour channel to create the matte.

G button Enable to use the green colour channel to create the matte.

B button Enable to use the blue colour channel to create the matte.

Red Tolerance colour pot Displays the value of the red channel used to create the matte. Editable.

Red Tolerance field Displays the value of the red channel used to create the matte. Editable.

Green Tolerance colour pot Displays the value of the green channel used to create the matte. Editable.

Green Tolerance field Displays the value of the green channel used to create the matte. Editable.

Blue Tolerance colour pot Displays the value of the blue channel used to create the matte. Editable.

Blue Tolerance field Displays the value of the blue channel used to create the matte. Editable.

Red Softness colour pot Displays the softness value applied to the red channel to create the matte. Editable.

Red Softness field Displays the softness value applied to the red channel to create the matte. Editable.

Green Softness colour pot Displays the softness value applied to the green channel to create the matte. Editable.

Green Softness field Displays the softness value applied to the green channel to create the matte. Editable.

Blue Softness colour pot Displays the softness value applied to the blue channel to create the matte. Editable.

Blue Softness field Displays the softness value applied to the blue channel to create the matte. Editable.

Gain field Displays the value that the resulting pixel values are multiplied by to create the final matte. Editable.

Lift field Displays the value added to the resulting pixels to create the final matte. Editable.

YUV Settings

YUV button Enable to use values in the YUV colour space to generate a matte.

Y button Enable to use the Y channel (luminance) to create the matte.

U button Enable to use the U channel (chrominance) to create the matte.

V button Use the V channel (chrominance) to create the matte.

Y Tolerance colour pot Displays the value of the Y channel used to create the matte. Editable.

Y Tolerance field Displays the value of the Y channel used to create the matte. Editable.

U Tolerance colour pot Displays the value of the green channel used to create the matte. Editable.

U Tolerance field Displays the value of the U channel used to create the matte. Editable.

V Tolerance colour pot Displays the value of the V channel used to create the matte. Editable.

V Tolerance field Displays the value of the V channel used to create the matte. Editable.

Y Softness colour pot Displays the softness value applied to the Y channel to create the matte. Editable.

Y Softness field Displays the softness value applied to the Y channel to create the matte. Editable.

U Softness colour pot Displays the softness value applied to the U channel to create the matte. Editable.

U Softness field Displays the softness value applied to the U channel to create the matte. Editable.

V Softness colour pot Displays the softness value applied to the V channel to create the matte. Editable.

V Softness field Displays the softness value applied to the V channel to create the matte. Editable.

Gain field Displays the value that the resulting pixel values are multiplied by to create the final matte. Editable.

Lift field Displays the value added to the resulting pixels to create the final matte. Editable.

Distort

Use Distort to create warps and morphs of clips. The node uses spline-based shapes to create these effects.

To access the Distort editors, use:

- [Batch](#), then select a node from the [Node bin](#). (page 1175)
- [Timeline](#), then use [Batch FX](#). (page 1175)
- [Tools](#), then select the [menu](#). (page 1175)

Distort accepts two front clips, two matte clips and one back clip as inputs, and outputs a result and an outmatte.

Distort Menu Settings

Accessing the Distort Menu

Input1 Display box Select a display mode for Input1.

Input2 Display box Select a display mode for Input2.

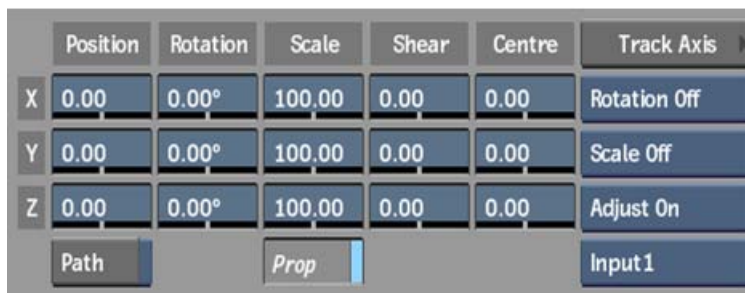

Matte1 Display box Select a display mode for Matte1.

Matte2 Display box Select a display mode for Matte2.

Back Display box Select a display mode for the background clip.

Input box Toggles between Input1 and Input2 clips based on the selection in the View box.

If Input is selected in the View box, this box toggles between Front1 and Front2. If Matte is selected in the View box, this box toggles between Matte1 and Matte2. If Result is selected in the View box, this box toggles between showing the splines for Front1 and Front2 drawn on top of the result.

X Position field Displays the position of the X axis. Editable.

Y Position field Displays the position of the Y axis. Editable.

Z Position field Displays the position of the Z axis. Editable.

Motion Path button Enable to animate the position of the axis using a spline drawn in the scene.

X Rotation field Displays the rotation value of the X axis. Editable.

Y Rotation field Displays the rotation value of the Y axis. Editable.

Z Rotation field Displays the rotation value of the Z axis.

X Scale field Displays the scale value of the X axis. Editable.

Y Scale field Displays the scale value of the Y axis. Editable.

Z Scale field Displays the scale value of the Z axis. Editable.

Prop Scale button Enable to scale the X, Y, and Z axes proportionally.

X Shear field Displays the shear value of the X axis. Editable.

Y Shear field Displays the shear value of the Y axis. Editable.

Z Shear field Displays the shear value of the Z axis. Editable.

X Centre field Displays the centre value of the X axis. Editable.

Y Centre field Displays the centre value of the Y axis. Editable.

Z Centre field Displays the centre value of the Z axis. Editable.

Track Axis button Opens the Stabilizer menu to apply tracking data to an axis.

Tracking Rotation box Select whether tracking rotation is On, Off, or Inverted.

Tracking Scale box Select whether tracking scaling is On, Off, or Inverted.

Tracking Adjust box Select whether an offset is applied relative to the spline's axis.

Track Clip box Select the clip to track.

Warper button Select whether to display the Warp or Morph menu.

Interpolation field Displays the percentage of mixing between the Input1 spline and the Input2 spline when source splines are linked for source interpolation. Editable.

You independently set an interpolation value for each set of linked Front1 and Front2 source splines.

Blend field Displays the level of blend between the Input1 and Input2 clips when morphing. Editable.

NOTE The Blend field is only available from the Morph menu.

Source button Enable to display source splines for manipulation. Also use to display the unwarped input clip.

Source Show button Enable to display source splines for reference when working with destination splines.

Source colour pot Displays the colour of all source splines. Editable.

Destination button Enable to display destination splines for manipulation. Also use to display the warped input clip.

Destination Show button Enable to display destination splines for reference when working with source splines.

Destination colour pot Displays the colour of all destination splines. Editable.

Correspondences button Enable to display correspondence points and connector lines, which indicate how the source spline maps to the destination spline.

You can add, edit, animate, and delete correspondence points. The more correspondence points a spline has, the greater effect it has on the overall warp.

Active button Enable to allow greater control over an animated spline by toggling selected vertices on and off.

Lasso Fit field Displays the number of vertices in freehand segments of a spline. Editable.

Increasing the value decreases the number of vertices, while decreasing the value increases the number of vertices. Only segments of the spline drawn using freehand mode are affected, while segments created by simple clicks remain unaffected. The Lasso Fit parameter loses its influence over freehand segments of a spline if you edit vertices.

Link box Controls whether source and destination splines are linked together or manipulated independently.

Set this to Lnk Src & Dst to keep the source and destination splines linked as you draw and animate the source spline. Set this to Enable Warping to control the destination spline independently to create a warp.

You can also independently link and unlink the axis nodes that are the parents of a source spline and its corresponding destination spline.

Toggle Input button Switch between an Input1 spline and an Input2 spline.

This is useful when you have animated a spline on one input and wish to apply it to the other.

Iterations field Displays a value for the distance that the distortion follows the destination spline. Editable.

If Z-mode is disabled, the maximum distance of the distortion is limited to avoid overlapping. When there is a large distance between a source and destination spline, you will achieve better results by increasing the number of iterations. For smaller warps or morphs, there is no advantage in using a greater number of iterations—it will increase processing time unnecessarily.

Z-mode button Enable to allow overlapping in the image to create 3D-like effects where parts of the image are pulled over other parts.

NOTE When Z-mode is enabled, the Iterations field is disabled.

Range field Displays the size of the region affected by the warping effect. Editable.

The greater the value, the larger the portion of the image affected. A value of 100% affects the entire image, a value of 33% affects one-third of the image, for example.

Weight field Displays the relative weight on the selected spline, to control its influence. Editable.

For example, you can set a higher weight on a spline in an area of the image that you do not want to move.

Resolution field Displays the pixel resolution of the clip being warped or morphed. A lower pixel resolution creates warps and morphs that better follow the contours of the distortion splines, although it can slow down system performance.

Track Shape button Opens the Stabilizer menu to apply tracking data to a spline's vertices.

Adjust box Select whether an offset is applied relative to the spline's tangents.

Distort Setup Settings

Repeat button Enable to fill in gaps by repeating the clip.

Repeat Value box Select 4 to fill gaps by repeating the clip once on each side, or 8 to repeat the clip twice on each side.

Amount box Select the amount of clip to repeat.

Draw Grid button Enable to display the distortion grid.

Scale Setup button Enable to scale a loaded setup's splines to the resolution of the current project.

Icons button Enable to display splines, tangents, and vertices in the image.

Icons Transparency field Displays the transparency level of the icons in the image. Editable.

Tangent colour pot Displays the colour of tangents on the splines. Editable.

Schematic Transparency field Displays the transparency level of the schematic. Editable.

Undo Levels field Displays the levels of Undo available in the Undo/Redo lists. Editable.

Miscellaneous Settings

Exit button Exits the Distort module.

Load button Loads a setup.

Save button Saves a setup.

Setup Name field Displays the name of the last saved setup.

Revert button Reverts to the last saved setup.

Delete button Deletes the most recently processed clip.

Player button Opens the Player to view the last rendered clip.

Step Process field Displays the frame number interval to be processed (to see intermediate results, for example). Editable.

Preview button Displays the distort effect without processing.

Setup button Opens the Setup menu, where you can set various preference and display settings.

Animation button Opens the channel editor, where you can animate various distort settings.

Set Key button Sets a keyframe at the selected frame.

Delete Key button Deletes the selected keyframe.

Copy button Copies an object, a branch (object and its children), or all, depending on what is selected in the Selection Mode box.

Delete button Deletes an object, a branch (object and its children), or all, depending on what is selected in the Selection Mode box.

Selection Mode box Select whether to copy, delete, or reset.

Reset button Resets an object, a branch (object and its children), or all, depending on what is selected in the Selection Mode box.

Node Name field Displays the name of the selected node in the schematic. Editable.

Previous button Selects the previous node in the schematic.

Next button Selects the next node in the schematic.

Add button Adds an axis or spline, depending of the selection of the Node box.

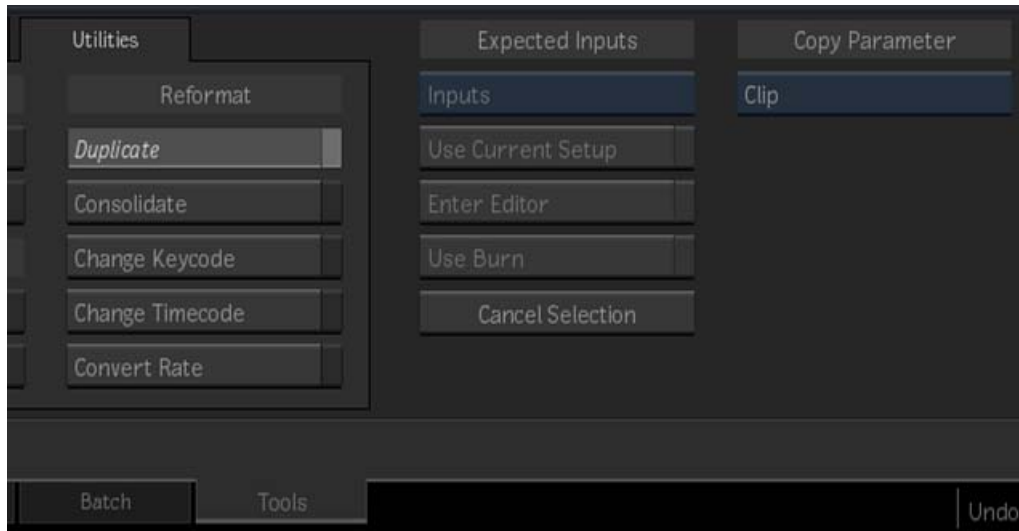

Node box Select whether to add an axis or spline, then click Add.

Close button Closes a spline at the first vertex.

Finish button Finishes a single-point or open spline at the last vertex.

Duplicate

Use Duplicate to create a copy based on the copy parameter selected.

To access the duplicate menu, use:

- Tools, then select from the menu.

Edge Detect

Use Edge Detect to trace the edges in a clip based on colour. This data can then be used to create a range of artistic effects in various colour spaces.

To access the Edge Detect menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and matte clip, and outputs a result and an outmatte.

Edge Detect Settings

General Settings

Colour Type box Select the colour space that you want to use to isolate the edge.

Result Output
Edge Only
Alpha Output
Input

Result Output box Select Result to output the composite of the input image, input matte, and the matte generated by the edge detection. Or, select Edge Only to output only the result of compositing the input image with the matte generated by the edge detection.

Matte Output button Select Input to output the input matte or Edge Matte to output the matte generated by the edge detection.

Edge Detection Settings

Edge Detection	
Weight	Threshold
Red 100.00	Min 0.00%
Green 100.00	Max 100.00%
Blue 100.00	Softness
Proportional	Width 0.00
	Gain 100.00

Red Weight field Displays a value for the relative intensity of red used to detect edges. This value is scaling factor, not the color value of the channel itself. Editable.

Green Weight field Displays a value for the relative intensity of green used to detect edges. This value is scaling factor, not the color value of the channel itself. Editable.

Blue Weight field Displays a value for the relative intensity of blue used to detect edges. This value is scaling factor, not the color value of the channel itself. Editable.

Proportional Weight button Enable to adjust the red, green, and blue weights proportionally.

Minimum Edge Detection Threshold field Displays the lower limit for edge detection. Editable.

Maximum Edge Detection Threshold field Displays the upper limit for edge detection. Editable.

Softness Width field Displays a value for the width of the edge. Editable.

Softness Gain field Displays a value for the softness of the edge. Editable.

Edge Effects Settings

Edge Effects	
<i>Double Edge</i>	<i>Directional</i>
Min 0.00%	Angle 0.00
Max 100.00%	Colour Offset
Softness	
Width 0.00	
Gain 100.00	

Double Edge button Enable to do a second edge detection pass and create twice as many edges.

Minimum Edge Detection Threshold field Displays the lower limit for edge detection. Editable.

Maximum Edge Detection Threshold field Displays the upper limit for edge detection. Editable.

Softness Width field Displays a value for the width of the edge. Editable.

Softness Gain field Displays a value for the softness of the edge. Editable.

Directional button Enable to create the edge in the direction indicated in the Angle field.

Edge Angle field Displays a value for the direction of the edge. Editable.

Colour Offset pot Displays a colour offset value for the image outside of the detected edges.

Colour Correction Settings

Colour Correction	
	Gain
	Red 100.0
	Green 100.0
	Blue 100.0
	Saturation 100.00
Gamma 1.000	Luma 100.0
Offset 0.000	<i>Proportional</i>

Saturation field Displays level of colour purity in the image. Editable.

Gamma field Displays the gamma level. Editable.

Offset field Displays a value that modifies all of the colour parameters. Editable.

Red Gain field Set the percentage of colour values in the red channel. Editable.

Green Gain field Set the percentage of colour values in the green channel. Editable.

Blue Gain field Set the percentage of colour values in the blue channel. Editable.

Luma Gain field Set the percentage of luma gain value to display. Editable.

Proportional button Enable to adjust the gain of the colour values proportionally.

Blending Settings

Blend Mode option box Select an operation to blend the input image with the matte created by the edge detection, and the input matte (if the Use Matte button is enabled).

Edge Transparency field Displays a value for the transparency applied to the edges. Editable.

Use Matte button Enable to use the input matte to constrain the blending of the input image and the matte created by the edge detection.

Exposure

Use Exposure to apply plausible exposure and contrast settings suitable to the image data type of an input clip. The values can be adjusted separately for each colour channel or controlled simultaneously.

Front view of a 16-bit floating point image

Result view of the image after the exposure and contrast have been modified

To access the Exposure menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip and a matte clip, and outputs a result. The matte input is used to limit the areas of the front clip that are affected by exposure and contrast changes.

NOTE To adjust the exposure, contrast, and image data type of the image for display purposes only, set the image display viewer options in the View menu or edit them gesturally in the current viewport. See [Displaying Multiple Views](#) (page 279).

Exposure Menu Settings

Exposure Node

Calculations for exposure and contrast adjustments are based on the type of image that is selected in the Exposure menu.

(a) Input Data Type box

Input Data Type box Select the type of image data being input to the node. Your selection determines the most suitable type of transformation to apply to the clip. The algorithm used to calculate the result is dependent on this option.

Select:	To:
Logarithmic	Apply a transformation to a logarithmic film scan.
Video	Apply a transformation to a video clip.
Linear	Apply a transformation to a 16-bit floating-point image, with a high dynamic range.

Red Exposure field Displays the exposure offset of the red channel.

Green Exposure field Displays the exposure offset of the green channel.

Blue Exposure field Displays the exposure offset of the blue channel.

Proportional button Enable to change the exposure offset value for a channel and update the values for the other channels proportionally.

Red Contrast field Displays the contrast level of the red channel.

Green Contrast field Displays the contrast level of the green channel.

Blue Contrast field Displays the contrast level of the blue channel.

Proportional button Enable to change the contrast value for a channel and update the values for the other channels proportionally.

Red Pivot field Displays the red value used as a pivot when generating contrast. The pivot value affects the way the contrast is calculated. The default value is mid-gray on a logarithmic scale.

Green Pivot field Displays the green value used as a pivot when generating contrast. The pivot value affects the way the contrast is calculated. The default value is mid-gray on a logarithmic scale.

Blue Pivot field Displays the blue value used as a pivot when generating contrast. The pivot value affects the way the contrast is calculated. The default value is mid-gray on a logarithmic scale.

Proportional button Enable to change the pivot value for a channel and update the values for the other channels proportionally.

Field Merge

Use Field Merge to remove field jitter by merging the fields of a clip.

To access the Field Merge menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Field Merge Menu Settings

General Settings

Level field Enter the percentage of blending between fields, or drag on the field to modify its value.

Filter

Use Filter to apply different effects to a clip, including textures, blurring, edge detection, embossing, and sharpening.

To access the Filter menu:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Filter Menu Settings

General Settings

Filter 1 button Modifies the set of image operations in the first filter element that is applied in the final composite filter.

Filter 2 button Modifies the set of image operations in the second filter element that is applied in the final composite filter.

Filter 3 button Modifies the set of image operations in the third filter element that is applied in the final composite filter.

Filter 4 button Modifies the set of image operations in the fourth filter element that is applied in the final composite filter.

Filter 5 button Modifies the set of image operations in the fifth filter element that is applied in the final composite filter.

Use Filter button Enable to apply the filter element to the final composite filter.

Effect field Displays the level of filtering required. Editable.

Bypass Chroma button Enable to ignore hue and saturation channels of an image.

Bypass Luminance button Enable to ignore luminance channels of an image.

Filter Type box Select whether to use matrix calculations or a predefined procedure to alter the image.

Matrix Settings

Gain field Displays the light values of the image. Editable.

Automatic button Enable to preserve the average luminance of the clip.

Balanced button Enable to activate a compensating algorithm when a value is entered in the matrix, where the value is divided by the remaining fields, and then the result is subtracted from each value in the matrix.

Symmetry Type box Select an arrangement used to change symmetrical elements.

Same button Enable to change a symmetrical field to the same value as a field that is being edited.

Invert button Enable to change a symmetrical field to the equal and opposite value as the field value that is being edited.

Copy button Click to copy the current matrix setup.

Paste button Click to paste a copied matrix setup.

Reset Matrix button Reset all values in the matrix.

3x3 button Enable to apply a matrix of three rows and three columns. The field in the centre represents the pixel that is currently being evaluated; the others represent surrounding pixels. The matrix displays the relative influence of each pixel surrounding the current one.

5x5 button Enable to apply a matrix of five rows and five columns. The field in the centre represents the pixel that is currently being evaluated; the others represent surrounding pixels. The matrix displays the relative influence of each pixel surrounding the current one.

7x7 button Enable to apply a matrix of seven rows and seven columns. The field in the centre represents the pixel that is currently being evaluated; the others represent surrounding pixels. The matrix displays the relative influence of each pixel surrounding the current one.

9x9 button Enable to apply a matrix of seven rows and seven columns. The field in the centre represents the pixel that is currently being evaluated; the others represent surrounding pixels. The matrix displays the relative influence of each pixel surrounding the current one.

11x11 button Enable to apply a matrix of eleven rows and eleven columns. The field in the centre represents the pixel that is currently being evaluated; the others represent surrounding pixels. The matrix displays the relative influence of each pixel surrounding the current one.

Procedural Settings

Invert button Enable to invert the image.

Rect button Enable to blur the image.

Width field Displays the height of the blur. Editable.

Height field Displays the width of the blur. Editable.

Sobel button Enable to apply an edge-detection filter that uses the Sobel operator.

Sobel Direction box Select the direction in which the filter is applied.

Prewitt button Enable to apply an edge-detection filter that uses the Prewitt operator.

Prewitt Direction box Select the direction in which the field is applied.

Flip

Use Flip to generate a mirror image of a clip. You can flip frames in a clip horizontally, vertically or both.

To access the Field Merge menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.

This node accepts a front clip, and outputs a result.

Flip Menu Settings

General Settings

Flip Direction box Select to flip the clip horizontally or vertically.

Reverse Dominance box Select an option for correcting the field dominance when flipping clips vertically.

Garbage Mask

Use the Garbage Mask to isolate particular areas of an image to include with, or exclude from, the opaque area of the matte.

To access the Garbage Mask menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and a matte clip as input, and outputs a result.

The Garbage Mask menu includes the Tracer and the region of Interest (ROI) functions, which can also be found in the Modular Keyer. The node processes gaps in clips set to No Media as black frames. An unconnected front clip will return an error, while an unconnected back clip will process black frames. You can save and load GMask setups directly in Batch or Batch FX.

Garbage Mask Menu Settings

Timeline Quick Menu Settings

Garbage Mask Quick Menu selector Select which menu to display.

Mask Selection box Apply changes to the selected mask or all masks.

Garbage Mask General Settings

Regenerate button Enable to get dynamic updating of your mask as you make changes.

X Position field Position the X axis.

Y Position field Position the Y axis.

Z Position field Position the Z axis.

Path button Enable to animate the position of the axis using a spline drawn in the scene.

X Rotation field Rotate the X axis.

Y Rotation field Rotate the Y axis.

Z Rotation field Rotate the Z axis.

X Scale field Scale the X axis.

Y Scale field Scale the Y axis.

Z Scale field Scale the Z axis.

Proportional button Enable to constrain proportions while scaling.

X Shear field Shear the X axis.

Y Shear field Shear the Y axis.

Z Shear field Shear the Z axis.

X Centre field Centre the X axis.

Y Centre field Centre the Y axis.

Z Centre field Centre the Z axis.

Stabilizer button Opens the Stabilizer menu where you track reference points in a clip.

Tracking Rotation option box Select Rotation Off for one-point tracking, Rotation On for two-point tracking, Rotation Inv to invert the rotation data.

Tracking Scale option box Select Scaling Off for one-point tracking, Scaling On for two-point tracking, Scale Inv to invert the scaling data.

Adjust box Select Adj Offset if the mask is parented to one axis. Select Adj Axis if the mask is parented to a hierarchy of objects. Select Adj Tangents to have the tangents for the selected points adjusted while the points are tracked.

Motion Blur button Enable the blur effect for the selected axis (Motion Blur must be enabled in the Setup menu).

Motion Blur button Toggles the blur effect for the selected geometry (Motion Blur must be enabled in the Setup menu).

Load button Loads a garbage mask setup.

Save button Saves a garbage mask setup.

Render Mask button Enable to see the mask and its effect on the image.

Region of Interest button Enable to reveal the matte of multiple garbage masks.

Outside button Enable to apply the effect to the part of the image outside the mask.

Colour field Set the blend between the outgoing and incoming image inside the mask.

Opacity field Set the transparency of the mask.

Lasso Fit field Set the number of points used in the freehand part of the mask.

Edge Softness box Select Softness to create a uniform gradient around the mask edge. Select Tracer to key out details around the mask edge.

Alpha field Set the transparency of the gradient from the mask edge.

Offset field Set the position of the gradient's border from the mask edge.

Distance field Specify the area over which the Inner and Outer Edge adjustments have an effect.

Inner Edge field Smoothen the softness gradient towards the inside of the mask edge.

Outer Edge field Smoothen the softness gradient towards the outside of the mask edge.

Active Points button Enable to use all points as a reference for the mask. Disable at a specific frame to mute picker values previously sampled at another frame.

Shape Animation button Enable to animate a mask using the Shape channel.

Linear Interpolation button Enable to use linear interpolation of the mask border between keyframes. Disable to use rounded interpolation. This button is active when the Shape Animation button is enabled.

Constant Shape button Enable to modify the mask's shape without setting keyframes.

Sample Status box Select how picker values are sampled. Active resamples picker values at every frame (the default). Passive disables resampling for one or more frames. This box is active when the Shape Animation button is disabled.

Interpolation Mode box Select the type of interpolation between keyframes when the Sample Status box is set to Active.

Splines button Enable to display inner and outer splines of the mask.

Borders button Enable to display inner and outer borders for advanced gradients.

Pickers button Enable to display elements that allow for detailed chroma and luma analysis when refining a detailed key.

X Axis Offset field Offset the mask from its X axis.

Y Axis Offset field Offset the mask from its Y axis.

Stabilizer button Opens the Stabilizer menu where you apply tracking data to selected vertices.

Adjust box Select Adj Tangents to have the tangents for the selected vertices adjusted while the points are tracked.

Add button Click to add a gmask axis or geometry node.

Node Type box Select whether to add an axis or geometry node.

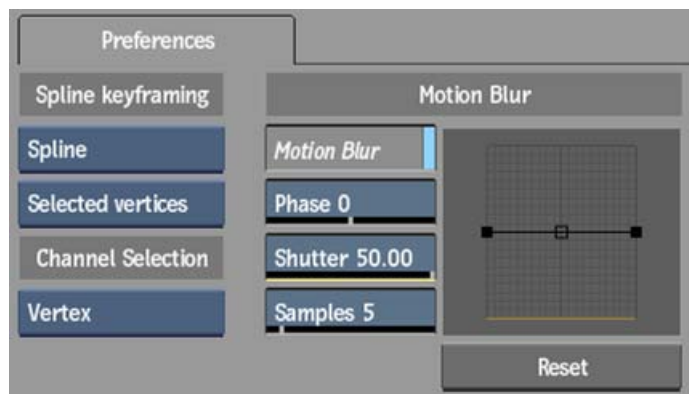

Close button Click to close the mask shape automatically.

Object Node Name field Displays the name of the selected object node.

Previous Node button Click to scroll to the previous similar node.

Next Node button Click to scroll to the next similar node.

Garbage Mask Node Setup Settings

Spline Keyframing box Select the parameters to use when animating a Garbage Mask spline. When Shape Animation is disabled in the Garbage Mask general settings, then the Spline & Tracer, Spline and Item options become available.

Vertex Keyframing box Select the conditions under which parameters are applied to specified vertices in the mask.

Channel Selection box Select which channels are selected in the Channel Editor when you select one or more vertices.

Motion Blur button Enable to apply motion blur to garbage masks that can be used to match the movement of objects in a clip.

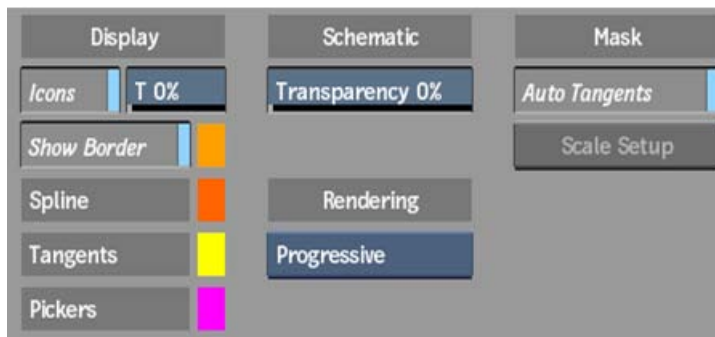

Phase field Displays whether the motion blur is based on the movement before or after the current frame. -100 places the motion blur before the frame; a value of 100 places it after the frame.

Shutter field Displays the duration of the motion blur at each frame. Editable.

Samples field Displays the number of samples taken at each frame to create the motion blur. Editable.

Motion Blur curve Displays the transparency of the samples that create the blur effect. Drag the curve or its handles to edit it gesturally.

Reset button Resets all motion blur controls and disables the Motion Blur button.

Icons button Enable to display garbage mask splines and axes.

Transparency field Displays the transparency of garbage mask splines and axes. Editable.

Show Border button Enable to display the Softness Offset wireframe border, defined in the Shape menu.

Show Border colour pot Select the colour for the Softness Offset wireframe.

Wireframe colour pot Select the colour of garbage mask splines.

Control Points colour pot Select the colour of garbage mask control points.

Pickers Display colour pot Select the colour of the pickers.

Transparency field Displays the transparency of nodes in the schematic. Editable.

Auto Insert button Enable to automatically insert a node when dragged between two connected nodes. When disabled, press Shift to auto insert.

Rendering box Select the rendering method.

Auto Tangents Enable to create tangents for new points.

Scale Setup button Enable to scale the GMask.

Glow

Use Glow to create and customize a glow effect on a clip.

To access the Glow menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and matte clip, and outputs a result an outmatte. You can add a Glow node to any part of the pipeline except to the Front and Matte pipes of MBlend nodes and the Matte pipes of CBlend nodes.

Glow Menu Settings

Using Glow Presets

A number of Glow presets are included, such as a basic glow effect or edge boost effect. These presets can help you learn how the glow effect works, or provide a good starting point to change settings to create better glow effects.

To use the Glow preset, select a preset from the Presets drop-down list in the Glow Setup menu. The Glow menu settings are changed to reflect the chosen preset.

Presets button Opens the Presets browser where you can select a preset.

Presets dropdown list Select a preset from the dropdown list. Menu settings are changed to reflect the chosen preset.

General Settings

Rendering Mode box Select whether to render in Automatic, Progressive or Interlaced mode.

Regen button Enable to get dynamic updating of the image as you make changes.

Setup Settings

Clamp Input button Enable to clamp colour and luminance values on input in the 16-bit floating point rendering pipeline.

Clamp Render box Select a clamping option for colour and luminance values on output in the 16-bit floating point rendering pipeline.

Glow Type Settings

Glow Type for Gaussian

Glow Type for Directional

Glow Type for Radial

Glow Type for Radial Stamp

Glow Type box Select the type or shape of glow filter to apply to the clip. For example, a Box blur has rectangular edges. Depending on the glow type, some of the other glow settings vary.

Radial Mode box Select whether a radial blur or glow moves in one circular direction (Spin) or two rotating directions (Twist). Available when Radial is chosen as the blur type.

Bias field Displays the direction of a blur. Enter a positive value for forward, a negative value for backward, or 0 for a blur that moves in both directions. Available when Directional or Radial Stamp is chosen as the blur type.

Samples field Displays the quality of a Radial Stamp blur or glow. Editable. Available when Radial Stamp is chosen as the blur type.

Centre Settings (Radial only)

Stabilizer button Opens the Stabilizer menu to track the centre of the blur from the source clip.

Centre X field Displays the X position of the centre of the radial blur (or gesturally move the red circle in the image). Editable.

Centre Y field Displays the Y position of the centre of the radial blur (or gesturally move the red circle in the image). Editable.

NOTE You can also move the red circle on the image to set the position of the centre of the blur. The Centre X and Y fields update accordingly.

Absolute/Relative box Select whether to position and offset the centre of the radial blur in a relative mode (expressed as a percentage) or absolute mode (expressed in pixels).

Offset X field Offsets the centre along the X axis (or press Ctrl and gesturally move the red circle in the image). This field is useful to apply changes to the centre after tracking has been performed. Editable.

Offset Y field Offsets the centre along the Y axis (or press Ctrl and gesturally move the red circle in the image). This field is useful to apply changes to the centre after tracking has been performed. Editable.

NOTE You can also press Ctrl and move the red circle on the image to set the offset of the centre of the glow. The Offset X and Y fields update accordingly.

Input Settings

Hue field Displays the colour range in the image before the glow effect is applied. Editable.

Saturation field Displays the colour purity level in the image before the glow effect is applied. Editable.

Contrast field Displays the level of gradations between light and dark areas before the glow effect is applied. Editable.

Gamma field Displays the level of grey in the image before the glow effect is applied. Editable.

Gain field Displays a value by which pixel colour values are multiplied. The offset value is added to this value to determine the final colour. Editable.

Offset field Displays the value to add to current pixel colour values. The resulting colour value is clipped at 0. Editable.

Front Settings

Front Settings for Gaussian or Box

Front Settings for Directional

Front Settings for Radial or Radial Stamp

Width field Displays the width of the blur. Increasing the blur increases the render time. Editable.

Height field Displays the height of the blur. Increasing the blur increases the render time. Editable.

Proportional button Enable to affect the width and height proportionally.

Pixel Ratio button Enable to blur the image using the same proportion as its aspect ratio.

Amount field (Radial, Radial Stamp) Displays the amount of radial blur. Editable.

Rotation field (Radial, Radial Stamp) Displays the angle of rotation for a radial blur. Editable.

Length field (Directional) Displays the radius amount of a directional blur. Editable.

Angle field (Directional) Displays the angle of a directional blur. Editable.

Matte Settings

Matte		Matte		Matte	
MWidth 3.01	Auto Matte	MLength 33.00	Auto Matte	MAmount 6.75	Auto Matte
MHeight 0.00	Max Level 255.0	MAngle 0.00	Max Level 255.0	MRotation 0.00	Max Level 255.0
Lock To Front	Min Level 0.00	Lock To Front	Min Level 0.00	Lock To Front	Min Level 0.00
Expand 0.0	Invert Matte	Expand 0.0	Invert Matte	Expand 0.0	Invert Matte
Lock Expand	Premultiply	Lock Expand	Premultiply	Lock Expand	Premultiply
Matte Settings for Gaussian or Box		Matte Settings for Directional		Matte Settings for Radial or Radial Stamp	

Matte Width field Displays the width of the blur for the matte. Editable.

Matte Height field Displays the height of the blur for the matte. Editable.

Matte Amount field Displays the amount of radial blur for the matte. Editable.

Matte Rotation field Displays the angle of rotation for a radial blur for the matte. Editable.

Matte Length field Displays the radius amount of a directional blur for the matte. Editable.

Matte Angle field Displays the angle of a direction blur of the matte. Editable.

Lock To Front button Enable to keep the matte values the same as their corresponding values for the front clip.

Expand field Displays the percentage of additional blur to the matte. Editable when the Lock Expand button is disabled.

Lock Expand button Enable to make the Expand value directly proportional to the value in the Width field.

Auto Matte button Enable to generate matte values from the front clip.

Max Level field Displays the upper limit of the luminance values included in the glow effect. Editable.

Min Level field Displays the lower limit of the luminance values included in the glow effect. Editable.

Invert Matte button Enable to apply the glow to the region outside the area defined by the matte.

Premultiply button Enable to multiply the matte clip to the front clip.

Colour Settings

Colour 1 box Enable to define the first colour used for the glow. If two colours are used, they are combined in additive mode to create the glow effect.

Colour 1 Colour pot Displays the hue and saturation colour of the first glow colour. Click to open the colour picker to select a different colour.

Colour 1 Trackball Adjusts the hue and saturation of colour 1.

Colour 1 Hue field Displays the colour range of colour 1. Editable.

Colour 1 Saturation field Displays the level of colour purity of colour 1. Editable.

Colour 1 Intensity field Displays the level of brightness of colour 1. Editable.

Colour 2 box Enable to define the second colour used for the glow. If two colours are used, they are combined in additive mode to create the glow effect.

NOTE If you are using both Colour 1 and Colour 2, they are combined in additive mode to create the glow effect.

Colour 2 Colour pot Displays the hue and saturation colour of the second glow colour. Click to open the colour picker to select a different colour.

Colour 2 Trackball Adjusts the hue and saturation of colour 2.

Colour 2 Hue field Displays the colour range of colour 2. Editable.

Colour 2 Saturation field Displays the level of colour purity of colour 2. Editable.

Colour 2 Intensity field Displays the level of brightness of colour 2. Editable.

Channels Settings

	Channels		
	Weight	Position X	Position Y
R	1.00	0.00	0.00
G	1.00	0.00	0.00
B	1.00	0.00	0.00

Weight field Displays the weighted value of the channel.

Position X field Displays the horizontal offset of the channel.

Position Y field Displays the vertical offset of the channel.

Blending Settings

Screen option box Select a logical operation that can be used to blend the front clip and the result clip.

Transparency field Displays the percentage of blending when the result is composited on the front clip. Editable.

Use Matte button Enable to include the matte in the blending.

Result Settings

Result Output button Select whether to output the combined result (with blending), or only the glow effect itself.

Matte Output Settings

Matte Output button Switch between blend matte and glow luma. Blend matte allows you to output the matte used internally to perform the blending of the glow effect over the input image. Glow luma allows you to generate a straight-forward luminance conversion of the actual glow effect.

Gradient

Use the Gradient to create an effect based on colours and patterns of your choosing.

To access the Gradient menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and matte clip, and outputs a result and outmatte.

Gradient Menu Settings

Setup Settings

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution.

Width field Displays the custom width resolution of the clip. Editable.

Height field Displays the custom width resolution of the clip. Editable.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the custom render/output aspect ratio. Editable

Bit Depth box Select the render/output bit depth of clips.

Scan Mode box Select the scan mode of clips.

Icons button Enable to display vertices, splines, and other gradient selection tools in the image window.

Transparency field Displays the transparency level of the gradient icons in the image window. Editable.

Vertex Colour Pot Displays the colour of vertices in the image window. Click to open the colour picker to select a different colour.

Spline Colour Pot Displays the colour of splines in the image window. Click to open the colour picker to select a different colour.

Amplitude Colour Pot Displays the colour of amplitude in the image window. Click to open the colour picker to select a different colour.

Type Settings

Gradient Type box Select the type of gradient to apply. Some of the gradient settings differ based on the gradient type you choose.

Select:	To create a gradient based on:
Directional	A single straight line spline.
Radial	Two circular geometries.
Spline	A spline that can be manipulated with vertices and tangents.
Point	Multiple coloured points.

For each gradient type, you can gesturally create your gradients in the image window with various widgets, such as splines and vertices. Make sure that Show Widgets is enabled in the Gradient Setup menu.

Orientation Settings

Swap UV button Enable to change the direction of the gradient.

Gradient Controls Settings

Position X field Displays the position of the gradient along the X axis. Editable.

Position Y field Displays the position of the gradient along the Y axis. Editable.

Rotation field Displays the degree of rotation of the gradient. Editable.

NOTE You can also manipulate the position and rotation of the gradient directly in the image window if Show Widgets is available.

Scale field Displays the scale of the gradient. Editable.

Centre field Directional gradient only: Displays the offset value of the centre of the spline as a percentage of its position on the spline. Editable.

Amplitude field Directional gradient only: Displays the pixel length of the spline. You can also drag either end of the spline directly in the image window. Editable.

Roundness field Radial gradient only: Displays the relative shape of the inner and outer circular patterns. A value of 1 displays the full rounded shape, whereas a value of 0 indicates a square shape. You can also enter a negative value to produce a concave shape. Editable.

Sharpness field Point gradient only: Displays the level of edge sharpness between the gradient point colours. Editable.

Softness field Displays the level of blur added to the gradient. A higher value produces a smoother transition between gradient colours. Editable.

Extrapolation box Select an extrapolation type for the gradient pattern.

Select:	To:
Constant	Keep the last value as a solid colour.
Repeat	Repeat the same gradient pattern.
Mirror	Repeat the gradient pattern in reverse order until the frame border is reached.

Offset Cycle field Displays the cycle position of the color creating the gradient. Editable.

Ramps Settings

NOTE The Colour and Alpha ramps are available for Directional, Radial and Spline gradients.

Colour Ramp Displays the gradations of the gradient colours. The triangles below the ramp represent each color in the gradient. You can add more colours to your gradient pattern.

A selected triangle's colour is displayed in the colour pot to the right of the ramp, and its position is displayed in the Position field. Also, when selecting a triangle, a smaller triangle appears representing the mid point between the colour and the next triangles' colour. You can move the triangles gesturally to achieve different gradations, and move the mid point triangle to shift the weight between the colours.

Colour Add button Adds a new colour triangle to the right of the currently selected triangle. Press Ctrl while clicking add to clone the selected triangle colour.

Colour Delete button Deletes the selected triangle.

Colour Ramp Copy list Select whether to copy the Colour ramp information to the Alpha ramp, or to preserve the Colour ramp information when switching gradient types.

NOTE The Alpha ramp under the Colour ramp is identical in functionality, except that it displays gradations in gradient transparency.

Alpha Ramp Displays the gradations of the gradient transparency. The triangles below the ramp represent each alpha colour in the gradient. You can add more alpha colours to your gradient pattern.

Alpha Add button Adds a new colour triangle to the right of the currently selected triangle. Press Ctrl while clicking add to clone the selected triangle colour.

Alpha Delete button Deletes the selected triangle.

Alpha Ramp Copy list Select whether to copy the Alpha ramp information to the Colour ramp, or to preserve the Alpha ramp information when switching gradient types.

Colour Interpolation Type box Choose a Linear or Smooth gradient interpolation curve.

Colour Colour pot Displays the colour of the selected triangle. Click to open the colour picker to select a different colour.

Reverse Colour button Click to reverse the colours of the gradient proportionally.

Colour Even Spacing button Click to space the ramp triangles evenly.

Alpha Interpolation Type box Choose a Linear or Smooth gradient interpolation curve.

Alpha Colour pot Displays the alpha colour of the selected triangle. Click to open the colour picker to select a different colour.

Reverse Alpha Colour button Click to reverse the alpha colours of the gradient proportionally.

Alpha Even Spacing button Click to space the ramp triangles evenly.

Colour Locator Position field Displays the location of the selected colour triangle along the colour ramp. Editable.

Colour Locator Mid field Displays the weight level between colours on the ramp (represented by the small triangle). Editable.

Alpha Locator Position field Displays the location of the selected alpha colour triangle along the alpha ramp. Editable.

Alpha Locator Mid field Displays the weight level between alpha colours on the ramp (represented by the small triangle). Editable.

Radial Shape Settings

Ramps	Shape
Geometries	
Inner	Outer
Width 72.0	Width 288.0
Offset X 0.0	Height 194.4
Offset Y 0.0	Proportional

Use these settings if you wish to further affect the shape of a radial gradient.

NOTE Radial Shape settings are available when Radial is selected from the Gradient Type box.

Inner Width field Displays the width of the inner radial circle. You can also gesturally drag the red square on the inner circle. Editable.

Inner Offset X field Displays the offset along the X axis of the inner radial circle. You can also gesturally drag the + inside the inner circle. Editable.

Inner Offset Y field Displays the offset along the Y axis of the inner radial circle. You can also gesturally drag the + inside the inner circle. Editable.

Outer Width field Displays the width of the outer radial circle. You can also gesturally drag the right-most red square on the outer circle. Editable.

Outer Height field Displays the height of the outer radial circle. You can also gesturally drag the left-most red square on the outer circle. Editable.

NOTE Drag the middle red square of the outer radial circle to affect both the width and the height at the same time.

Proportional button Enable to affect the outer radial width and height proportionally.

Spline Shape Settings

Ramps		Shape
Position		Amplitude
Vertex	Tangent	Position 50.0%
X -288.0	X 50.0	Start 194.4
Y 0.0	Y 0.0	End -194.4
Reset Shape		

Use these settings if you wish to further affect the shape of a spline gradient. All of these settings have gestural equivalents in the image window. Ensure that Icons is enabled in the Gradient Setup menu.)

NOTE Available when Spline is selected from the Gradient Type box.

Vertex X Position field Displays the position along the X axis of the selected vertex. Editable.

Vertex Y Position field Displays the position along the Y axis of the selected vertex. Editable.

Tangent X Position field Displays the position along the X axis of the selected tangent. Editable.

Tangent Y Position field Displays the position along the Y axis of the selected tangent. Editable.

Amplitude Position field Displays the position of the spline as a percentage of the distance between the first and last vertex. Editable.

Amplitude Start field Displays the start position of the spline. Use to set the pixel length of the spline. Editable.

Amplitude End field Displays the end position of the spline. Use to set the pixel length of the spline. Editable.

Reset Shape button Resets the spline shape.

Points Settings

Points									
Points	Colour	Alpha	X	Y	Weight	Radius		Add	
Point0	Red		-288.0	-194.4	1.00	0.00		Delete	
Point1	Green		-288.0	194.4	1.00	0.00		Clone	
Point2	Blue		288.0	194.4	1.00	0.00			
Point3	Yellow		288.0	-194.4	1.00	0.00			

NOTE Available when Point is selected from the Gradient Type box.

Points List Use the rows to set the colour, position, and other settings for each color of a Point gradient.

Points Column Displays the number of the point. By default, four points are added to a gradient; however, you can add more.

Colour Column Displays the colour of the point. Click the colour pot to open the colour picker to select a different colour.

Alpha Column Displays the alpha colour of the point. Click the colour pot to open the colour picker to select a different colour.

X Column Displays the position of the point along the X axis. You can also gesturally drag the point in the image window to position it.

Y Column Displays the position of the point along the Y axis. You can also gesturally drag the point in the image window to position it.

Weight Column Displays the weight of the colour in relation to the nearest point colour in the image.

Radius Column Displays the radius of the point colour.

Add button Adds a new colour point to the list and image.

Delete button Deletes the selected colour point from the list and image.

Clone button Clones the selected colour point settings in a new point in the list and image.

Blending Settings

Screen option box Select a logical operation that can be used to blend the front clip and the result clip.

Transparency field Displays the percentage of blending when the result is composited on the front clip. Editable.

Gain field Displays the level of gain applied to the chosen blending option. Editable.

Result Output Settings

Output Mode box Select whether to output the combined result (with blending), or only the gradient effect itself.

Alpha Output Settings

Alpha Output box Select whether to output the combined alpha result, or only the gradient effect itself.

Interlace

Use Interlace to connect the odd and even scanlines of a clip.

To access the Interlace menu:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

The Interlace node accepts a front clip as input, and outputs a result.

For each pair of frames in the input clip, the Field 1 scanlines of one frame are interlaced with the even scanlines of the second frame to produce a single frame in the generated clip.

Interlace Menu Settings

General Settings

First Rendered Frame field Displays the first frame at which output is rendered from the node. Unrendered output does not display any media.Editable.

Field Dominance box Select Field 1 or Field 2 dominance, or Auto to have the application detect automatically the field dominance.

Keyer 3D

Use the Keyer 3D to key out a given range of colours.

To access the Keyer 3D menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Keyer 3D Menu Settings

General Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Key button Select to open the Key menu, where you set the elements to key in the RGB viewer, or the Pref menu, where you customize the RGB Viewer display properties.

Regen button Enable to get dynamic updating of the image as you make changes.

Sampling Settings

Sampling box Select the type of key element value to sample in the image window.

Sampling Reset button Resets the values for the key element selected in the Sampling box.

Picking Settings

Picking box Select the key element to restrict selection in the RGB viewer. Select Free to select any element.

Rotation Axis Settings

NOTE The Rotation Axis Settings are available when you select the Pref menu from the Key button.

Rotation Axis box Select the centre of the RGB viewer or a key element as the axis of rotation of the RGB viewer.

Plot Regions Settings

NOTE The Plot Regions Settings are available when you select the Pref menu from the Key button.

Plot Region 1 button Enable to display the first plotted region.

Plot Region 2 button Enable to display the second plotted region.

Plot Region 3 button Enable to display the third plotted region.

Plot Point button Enable to display plotted colour value in the RGB viewer.

Tolerance Display Settings

Tolerance Display box Select to display the tolerance as an opaque, transparent, or wireframe ellipsoid.

Tolerance ConnexHull Settings

Tolerance Convex Hull option box Select to display the vertices, surfaces, or both the vertices and surfaces of the tolerance convex hull.

Softness Display Settings

Softness Display box Select to display the softness as an opaque, transparent, or wireframe ellipsoid.

Softness ConnexHull Settings

Soft Convex Hull option box Select to display the vertices, surfaces, or the vertices and surfaces of the softness convex hull.

Softness/Noise Settings

Colour box Select a YUV or RGB colour model.

Softness Scaling box Select to scale softness proportionally or to remove noise from softened areas.

Scaling field When Softness Scaling is set to Prop, adjust the X, Y, and Z-axis softness scaling values proportionally. When Softness Scaling is set to Min Noise, adjust the value to increase grain removal. (The scaling value resets to 1.00 after use.) Editable.

Scale X field Displays X-axis softness scaling. Editable.

Scale Y field Displays Y-axis softness scaling. Editable.

Scale Z field Displays Z-axis softness scaling. Editable.

Patches Settings

Patches box Select the Patch you want to sample.

Active button Enable to include the sample in the key.

Display box Select to display the current patch as a wireframe, a convex hull, both a wireframe and convex hull, or a transparent cloud.

Colour field Enter the percentage of the colour value to use to render the patch. Editable.

Opacity field Enter the percentage of opacity of the patch. Editable.

Softness field Enter the softness value of the patch. Editable.

Key Histogram Settings

Plot button Activates a pick cursor which you use to select a plot value in the image window. If Plot Point is enabled in the Pref menu, a cube with a dashed outline surrounds the point in the RGB viewer.

Home button Restores the RGB viewer to its original settings and position.

Invert Point button Inverts the direction of scaling of the softness ellipsoid.

Frame option box Select an option to display the entire histogram, or a selected range of values.

Range field Displays the percentage of the full range that is displayed in the histogram. Editable when the Frame option box is set to Free.

Store button Stores the value in the Range field in memory for later use. Active when the Frame option box is set to Free.

Buffer Value field Displays the Range value stored in the buffer. Non-editable.

Recall button Retrieves the last Range value that was stored in the buffer.

Pref Histogram Settings

NOTE The Pref Histogram Settings are available when you select the Pref menu from the Key button.

Histogram button Enable to display the 3D histogram in the RGB viewer.

Histogram Grid option box Select an option for the histogram grid resolution.

Opacity field Displays the percentage of opacity of the cubes. Editable.

Scaling field Resizes the cubes. Cubes representing less prevalent colours are scaled down more than those representing more prevalent colours. Editable.

Threshold field Enter a value to edit the display of colours that are less prevalent in the image. As you increase the threshold, less prevalent colours are increasingly removed from the histogram. Editable.

Canvas button Enable to display the canvas.

Canvas Light field Sets the lighting in the RGB viewer. The light source emanates from behind the viewer.

Lines button Enable to display a white outline of the borders of the RGB viewer, and a green wireframe around selected ellipsoids.

Cloud Opacity field Displays the overall opacity for all ellipses and patches.

Key Element box Select an element type to change its opacity.

Patch Opacity field Displays the opacity for the third patch in the RGB viewer.

Plot button Activates a pick cursor which you use to select a plot value in the image window. If Plot Point is enabled in the Pref menu, a cube with a dashed outline surrounds the point in the RGB viewer.

Home button Restores the RGB viewer to its original settings and position.

Invert Point button Inverts the direction of scaling of the softness ellipsoid.

Keyer Channel

Use the Keyer Channel to extract a key from a red, green, or blue channel, or from a custom value.

To access the Keyer Channel menu, use:

- Batch, then select a node from the Node bin.

- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Keyer Channel Menu Settings

General Settings

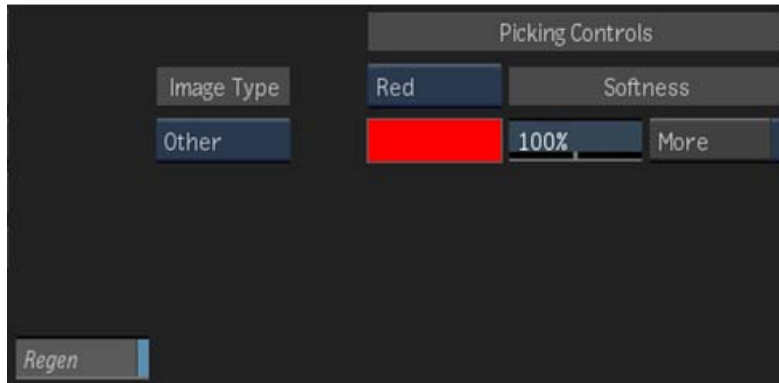

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Channel Mode box Select a predefined or custom colour channel.

Key colour pot Activates the pick cursor. Use to sample an area of the image to display an average colour value for a custom channel.

Softness field Displays the percentage of transparency of the key-in clip. Editable.

More button Enable to enhance the keying effect.

Spread field The Spread field is available when Custom is selected from the Channel Mode box. Displays a value for the range of colours extracted from the key-in clip. Editable.

Regen button Enable to get dynamic updating of the image as you make changes.

Keyer HLS

Use the Keyer HLS to extract a key by adjusting tolerance and softness using hue, luminance, and saturation ranges.

To access the Keyer HLS menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).

- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Keyer HLS Menu Settings

General Menu Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Regen button Enable to get dynamic updating of the image as you make changes.

Picking Controls Settings

Key Colour colour pot Activates the pick cursor. Use to sample an area of the image to display the average colour value.

Tolerance button Activates the pick cursor. Use to select the maximum and minimum values for the tolerance range in the image window.

Master Tolerance field Displays the value added to the existing tolerance of each channel. Resets to 0 after each use.

+ Increases tolerance values.

- Decreases tolerance values.

Softness button Activates the pick cursor. Use to select the maximum and minimum values for the softness range in the image window.

Master Softness field Displays the value added to the existing softness of each channel. Resets to 0 after each use.

+ Increases softness values.

- Decreases softness values.

Colour Control Settings

Hue button Enable to extract hue values for the key.

Minimum Softness field Displays the minimum hue value of the softness range. Editable.

Minimum Tolerance field Displays the minimum hue value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum hue value of the tolerance range. Editable.

Maximum Softness field Displays the maximum hue value of the softness range. Editable.

Luminance button Enable to extract luminance values for the key.

Minimum Softness field Displays the minimum luminance value of the softness range. Editable.

Minimum Tolerance field Displays the minimum luminance value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum luminance value of the tolerance range. Editable.

Maximum Softness field Displays the maximum luminance value of the softness range. Editable.

Saturation button Enable to extract saturation values for the key.

Minimum Softness field Displays the minimum saturation value of the softness range. Editable.

Minimum Tolerance field Displays the minimum saturation value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum saturation value of the tolerance range. Editable.

Maximum Softness field Displays the maximum saturation value of the softness range. Editable.

Plot button Activates the pick cursor. Use to sample an area of the image to display its colour value.

Frame option box Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Keyer Luma

Use the Keyer Luma to extract a key from the luminance of a clip.

To access the Keyer Luma menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Keyer Luma Menu Settings

General Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Master Tolerance field Displays the value added to the existing tolerance of each channel. Enter 100 for an entirely opaque matte.

Master Softness field Displays the softness. Drag left or right to adjust the percentage value or enter a new percentage value.

Relative To box Select to calculate softness and tolerance ranges relative to 0 and 1 colour values, or relative to the maximum luminance.

Relative To field Displays the maximum luminance. This field is active if the Maximum Luminance option is selected in the Relative To box.

Get Maximum Value button Analyses the image to determine the maximum luminance value.

Plot button Activates the pick cursor. Use to sample an area of the image to display its colour value.

Frame option box Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Keyer RGB

Use the Keyer RGB to extract a key by adjusting tolerance and softness using red, green, and blue ranges.

To access the Keyer RGB menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Keyer RGB Menu Settings

General Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Regen button Enable to get dynamic updating of the image as you make changes.

Picking Controls Settings

Key Colour colour pot Activates the pick cursor. Use to sample an area of the image to display the average colour value.

Tolerance button Activates the pick cursor. Use to select the maximum and minimum values for the tolerance range in the image window.

Master Tolerance field Displays the value added to the existing tolerance of each channel. Resets to 0 after each use.

+ Increases tolerance values.

- Decreases tolerance values.

Softness button Activates the pick cursor. Use to select the maximum and minimum values for the softness range in the image window.

Master Softness field Displays the value added to the existing softness of each channel. Resets to 0 after each use.

+ Increases softness values.

- Decreases softness values.

Colour Control Settings

Red Channel button Enable to extract red channel values for the key.

Minimum Softness field Displays the minimum red channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum red channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum red channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum red channel value of the softness range. Editable.

Green Channel button Enable to extract green channel values for the key.

Minimum Softness field Displays the minimum green channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum green channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum green channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum green channel value of the softness range. Editable.

Blue Channel button Enable to extract blue channel values for the key.

Minimum Softness field Displays the minimum blue channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum blue channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum blue channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum blue channel value of the softness range. Editable.

Plot button Activates the pick cursor. Use to sample an area of the image to display its colour value.

Frame option box Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Keyer RGBCMYL

Use the Keyer RGBCMYL to extract a key by adjusting tolerance and softness using red, green, blue, cyan, magenta, yellow, and luminance ranges.

To access the Keyer RGBCMYL menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Keyer RGBCMYL Menu Settings

General Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Regen button Enable to get dynamic updating of the image as you make changes.

Picking Controls Settings

Key Colour colour pot Activates the pick cursor. Use to sample an area of the image to display the average colour value.

Tolerance button Activates the pick cursor. Use to select the maximum and minimum values for the tolerance range in the image window.

Master Tolerance field Displays the value added to the existing tolerance of each channel. Resets to 0 after each use.

+ Increases tolerance values.

- Decreases tolerance values.

Softness button Activates the pick cursor. Use to select the maximum and minimum values for the softness range in the image window.

Master Softness field Displays the value added to the existing softness of each channel. Resets to 0 after each use.

+ Increases softness values.

- Decreases softness values.

Colour Control Settings

Red Channel button Enable to extract red channel values for the key.

Minimum Softness field Displays the minimum red channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum red channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum red channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum red channel value of the softness range. Editable.

Green Channel button Enable to extract green channel values for the key.

Minimum Softness field Displays the minimum green channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum green channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum green channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum green channel value of the softness range. Editable.

Blue Channel button Enable to extract blue channel values for the key.

Minimum Softness field Displays the minimum blue channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum blue channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum blue channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum blue channel value of the softness range. Editable.

Cyan Channel button Enable to extract cyan channel values for the key.

Minimum Softness field Displays the minimum cyan channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum cyan channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum cyan channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum cyan channel value of the softness range. Editable.

Magenta Channel button Enable to extract magenta channel values for the key.

Minimum Softness field Displays the minimum magenta channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum magenta channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum magenta channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum magenta channel value of the softness range. Editable.

Yellow Channel button Enable to extract yellow channel values for the key.

Minimum Softness field Displays the minimum yellow channel value of the softness range. Editable.

Minimum Tolerance field Displays the minimum yellow channel value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum yellow channel value of the tolerance range. Editable.

Maximum Softness field Displays the maximum yellow channel value of the softness range. Editable.

Luminance button Enable to extract luminance values for the key.

Minimum Softness field Displays the minimum luminance value of the softness range. Editable.

Minimum Tolerance field Displays the minimum luminance value of the tolerance range. Editable.

Maximum Tolerance field Displays the maximum luminance value of the tolerance range. Editable.

Maximum Softness field Displays the maximum luminance value of the softness range. Editable.

Plot button Activates the pick cursor. Use to sample an area of the image to display its colour value.

Frame option box Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Keyer YUV

Use the Keyer-YUV to extract a key by adjusting tolerance and softness using luma (Y) and video component (U,V) ranges.

To access the Keyer YUV menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip and outputs a result.

Keyer YUV Menu Settings

General Settings

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

Regen button Enable to get dynamic updating of the image as you make changes.

Picking Controls Settings

Key Colour colour pot Activates the pick cursor. Use to sample an area of the image to display the average colour value.

Tolerance button Activates the pick cursor. Use to select the maximum and minimum values for the tolerance range in the image window.

Master Tolerance field Displays the value added to the existing tolerance of each channel. Resets to 0 after each use.

+ Increases tolerance values.

- Decreases tolerance values.

Softness button Activates the pick cursor. Use to select the maximum and minimum values for the softness range in the image window.

Master Softness field Displays the value added to the existing softness of each channel. Resets to 0 after each use.

+ Increases softness values.

- Decreases softness values.

Colour Control Settings

- Y Channel button** Enable to extract luminance channel values for the key.
- Minimum Softness field** Displays the minimum luminance value of the softness range. Editable.
- Minimum Tolerance field** Displays the minimum luminance value of the tolerance range. Editable.
- Maximum Tolerance field** Displays the maximum luminance value of the tolerance range. Editable.
- Maximum Softness field** Displays the maximum luminance value of the softness range. Editable.
- U button** Enable to extract blue-luminance difference values for the key.
- Minimum Softness field** Displays the minimum blue-luminance difference value of the softness range. Editable.
- Minimum Tolerance field** Displays the minimum blue-luminance difference value of the tolerance range. Editable.
- Maximum Tolerance field** Displays the maximum blue-luminance difference value of the tolerance range. Editable.
- Maximum Softness field** Displays the maximum blue-luminance difference value of the softness range. Editable.
- V button** Enable to extract red-luminance difference values for the key.
- Minimum Softness field** Displays the minimum red-luminance difference value of the softness range. Editable.
- Minimum Tolerance field** Displays the minimum red-luminance difference value of the tolerance range. Editable.
- Maximum Tolerance field** Displays the maximum red-luminance difference value of the tolerance range. Editable.
- Maximum Softness field** Displays the maximum red-luminance difference value of the softness range. Editable.
- Plot button** Activates the pick cursor. Use to sample an area of the image to display its colour value.
- Frame option box** Select whether to frame the histogram based on minimum and maximum slider values, the full range of histogram values, the plot and reference colours, or the [0:1] vertical and horizontal range (Home).

Lens Distort

Use the Lens Distort to rectify or simulate lens distortions caused by camera lens or perspective irregularities that can result in skewed angles.

To access the Lens Distort menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).

This node accepts a front and matte clip, and outputs a result and an outmatte.

Lens Distort Menu Settings

General Settings

Distortion box Select whether to perform a lens distortion or rectification. All other radial distortion controls are implemented based on this selection.

Regen button Enable to get dynamic updating of the image as you make changes.

Centre box Select the size of the crosshair icon in your image.

Centre X field Displays the horizontal position of the centre of the lens. Editable.

Centre Y field Displays the vertical position of the centre of the lens. Editable.

Icon colour pot Displays the colour of the crosshair in your image. Editable.

Radial Settings

Lens Mag field Displays the magnitude of radial distortion or rectification. Editable.

Lens Adj field Displays the radial distortion or rectification. Editable.

Anamorph field Displays the ratio of distortion or rectification along the X or Y axis. A value greater than 1.00 stretches more on the X axis, while a value less than 1.00 stretches more on the Y axis. Editable.

Lens Distort Controls

	To	From
Upper Left	-0.50 0.50	-0.50 0.50
Lower Left	-0.50 -0.50	-0.50 -0.50
Lower Right	0.50 -0.50	0.50 -0.50
Upper Right	0.50 0.50	0.50 0.50

Perspective button Enable to perform a perspective rectification.

Perspective Type box Select an option to map the source anchor points to a rectangle, preserving either the horizontal or vertical edges of the image, or mapping one four-corner free-form shape to another. Active when Perspective button is enabled.

Range box Select whether to set the X and Y range from -0.5 to 0.5 (relative) or set the X and Y range to half of the image size (absolute).

Source colour pot Displays the colour of the source anchor points. Editable.

Destination colour pot Displays the anchor points of the destination shape. Editable.

Upper Left X field Displays the horizontal value for the upper left source anchor. Editable.

Lower Left X field Displays the horizontal value for the lower left source anchor. Editable.

Lower Right X field Displays the horizontal value for the lower right source anchor. Editable.

Upper Right X field Displays the horizontal value for the upper right source anchor. Editable.

Upper Left Y field Displays the vertical value for the upper left source anchor. Editable.

Lower Left Y field Displays the vertical value for the lower left source anchor. Editable.

Lower Right Y field Displays the vertical value for the lower right source anchor. Editable.

Upper Right Y field Displays the vertical value for the upper right source anchor. Editable.

NOTE The following fields are available when Free Form is selected from the Perspective Type box.

Upper Left X field Displays the horizontal value for the upper left destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Lower Left X field Displays the horizontal value for the lower left destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Lower Right X field Displays the horizontal value for the lower right destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Upper Right X field Displays the horizontal value for the upper right destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Upper Left Y field Displays the vertical value for the upper left destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Lower Left Y field Displays the vertical value for the lower left destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Lower Right Y field Displays the vertical value for the lower right destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Upper Right Y field Displays the vertical value for the upper right destination anchor. Editable (active when the Perspective Type box is set to Free Form).

Analyse button Enable to use the spline controls.

Add Spline button Enable to draw a spline along a feature that you want to straighten.

Clear button Click to clear splines at the selected keyframe.

Set Key button Click to set a keyframe based on the result of the analysis.

Compute button Click to analyse the image based on the splines you added.

Show Splines button Enable to display splines in the image window.

Filter box Defines the type of filter for your distortion or rectification.

Resize box Assigns the resize option you choose to apply to your image (if any distortion or rectification is present).

Reset All button Click to restore default settings.

LUT Editor

Use LUT Editor to convert logarithmic images to linear images or linear images to logarithmic images, while maintaining color accuracy.

To access the LUT Editor menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

The LUT Editor node can also be used to apply a conversion to 16-bit floating-point image in the OpenEXR file format.

When you import or export clips in Batch, default LUT parameters are used and the direction of the conversion is detected automatically. Use the LUT Editor to modify these default settings interactively or to import an existing LUT. You can also export a LUT from the LUT Editor.

When you load an OpenEXR-formatted clip into Batch, you cannot connect it directly to nodes that do not support 16-bit floating-point images. To work with a node that does not support this input, first connect the clip to a LUT Editor node to convert the clip into an 8- or 12-bit linear image. Whether or not you change the clip's bit depth, use the LUT Editor's EXR Display option to control the image's luminance and black point properties.

The LUT Editor node can be set to output a bit depth of 8, 10, 12, or 16 bits. You can also manually set the variables for output.

LUT Editor Menu Settings

General Settings

Conversion LUT Type box Select a basic LUT type, EXR Display, PhotoMap, or Gamma correction.

Destination box Select an output bit-depth.

Export button Opens the Export LUT menu where you select the location to export the LUT.

Basic button Enable to display the basic conversion LUT curve.

Advanced Editing button Enable to display advanced editing curves for each colour channel. RGB curves use blending to distinguish overlapping curves.

Final button Enable to display the final conversion LUT curve.

Edit Curve box Select to display the editing curve for the selected colour channel.

Zoom field Displays the zoom percentage of the histogram. Editable.

Home box Select whether to recenter the graph or center the frame.

Reset button Applies default settings.

Log to Lin, Lin to Log, and Gamma Settings

Red Reference White field Displays the lower limit at which red channel values are considered white. Editable.

Green Reference White field Displays the lower limit at which green channel values are considered white. Editable.

Blue Reference White field Displays the lower limit at which blue channel values are considered white. Editable.

Red Reference Black field Displays the upper limit at which red channel values are considered black. Editable.

Green Reference Black field Displays the upper limit at which green channel values are considered black. Editable.

Blue Reference Black field Displays the upper limit at which blue channel values are considered black. Editable.

Red Highlight field Displays the value at which greater red channel values are clamped. Editable.

Green Highlight field Displays the value at which green channel values are clamped. Editable.

Blue Highlight field Displays the value at which blue channel values are clamped. Editable.

Red Shadow field Displays the value at which lower red channel values are clamped. Editable.

Green Shadow field Displays the value at which lower green channel values are clamped. Editable.

Blue Shadow field Displays the value at which blue channel values are clamped. Editable.

Gamma Correction box Select preset gamma correction values (Video Display) or custom values. This setting is available for Log to Lin and Lin to Log.

Red Gamma Correction field Displays the gamma correction value for the red channel. Editable.

Green Gamma Correction field Displays the gamma correction value for the green channel. Editable.

Blue Gamma Correction field Displays the gamma correction value for the blue channel. Editable.

NOTE The following settings are available for Log to Lin and Lin to Log.

Red Film Gamma field Displays the gamma correction value for the red channel. Editable.

Green Film Gamma field Displays the gamma correction value for the green channel. Editable.

Blue Film Gamma field Displays the gamma correction value for the blue channel. Editable.

Red Soft Clip field Displays the level of adjustment to the shoulder of the conversion curve for the red channel. The upper limit is dependent on the channel's current reference white value. To create softer highlight, drag right when using a linear curve. Drag left when using a logarithmic curve.

Green Soft Clip field Displays the level of adjustment to the shoulder of the conversion curve for the green channel. The upper limit is dependent on the channel's current reference white value. To create softer highlight, drag right when using a linear curve. Drag left when using a logarithmic curve.

Blue Soft Clip field Displays the level of adjustment to the shoulder of the conversion curve for the blue channel. The upper limit is dependent on the channel's current reference white value. To create softer highlight, drag right when using a linear curve. Drag left when using a logarithmic curve.

Proportional button Enable to constrain channel value proportions.

EXR Display Settings

Red Exposure field Displays the luminance level of the red channel for the display image. Editable.

Green Exposure field Displays the luminance level of the green channel for the display image. Editable.

Blue Exposure field Displays the luminance level of the blue channel for the display image. Editable.

Red Defog field Displays the value to be subtracted from red color values to reduce fogging of the image. Editable.

Green Defog field Displays the value to be subtracted from green color values to reduce fogging of the image. Editable.

Blue Defog field Displays the value to be subtracted from blue color values to reduce fogging of the image. Editable.

Red Knee Low field Displays the lower limit of the compressed pixel range for the red channel. Editable.

Green Knee Low field Displays the lower limit of the compressed pixel range for the green channel. Editable.

Blue Knee Low field Displays the lower limit of the compressed pixel range for the blue channel. Editable.

Red Knee High field Displays the upper limit of the compressed pixel range for the red channel. Editable.

Green Knee High field Displays the upper limit of the compressed pixel range for the green channel. Editable.

Blue Knee High field Displays the upper limit of the compressed pixel range for the blue channel. Editable.

Red Gamma Correction field Displays the gamma correction value for the red channel. Editable.

Green Gamma Correction field Displays the gamma correction value for the green channel. Editable.

Blue Gamma Correction field Displays the gamma correction value for the blue channel. Editable.

Proportional button Enable to constrain channel value proportions.

Import Settings

Import button Open the file browser to select a 1D LUT for import.

3D LUT Settings

Import button Open the file browser to select a 3D LUT for import.

PhotoMap

Red Exposure field Displays the luminance level of the red channel for the display image. Editable.

Green Exposure field Displays the luminance level of the green channel for the display image. Editable.

Blue Exposure field Displays the luminance level of the blue channel for the display image. Editable.

Red Highlight Detail field Displays the value for the detail in the light areas of the red channel. Editable.

Green Highlight Detail field Displays the value for the detail in the light areas of the green channel. Editable.

Blue Highlight Detail field Displays the value for the detail in the light areas of the blue channel. Editable.

Red Highlight Contrast field Displays the value for the contrast in the light areas of the red channel. Editable.

Green Highlight Contrast field Displays the value for the contrast in the light areas of the green channel. Editable.

Blue Highlight Contrast field Displays the value for the contrast in the light areas of the blue channel. Editable.

Red Contrast field Displays the value for the midtone contrast in the red channel. Editable.

Green Contrast field Displays the value for the midtone contrast in the green channel. Editable.

Blue Contrast field Displays the value for the midtone contrast in the blue channel. Editable.

Red Shadow Contrast field Displays the value for the contrast in the dark areas of the red channel. Editable.

Green Shadow Contrast field Displays the value for the contrast in the dark areas of the green channel. Editable.

Blue Shadow Contrast field Displays the value for the contrast in the dark areas of the blue channel. Editable.

Red Shadow Detail field Displays the value for the detail in the dark areas of the red channel. Editable.

Green Shadow Detail field Displays the value for the detail in the dark areas of the green channel. Editable.

Blue Shadow Detail field Displays the value for the detail in the dark areas of the blue channel. Editable.

Proportional button Enable to constrain channel value proportions.

Encoding option box Select a standard format for the colour space.

Colour Transform Settings

Import button Use to browse and select a colour transform.

Custom button Apply a custom chain of color transforms.

Export button Export a custom chain of colour transforms as a single .CTF file.

Add button Add a new row to the end of the chain. Click in the Type column to select or change the transform type, and then click in the Transform column to select a transform.

Delete button Remove the selected transform from the chain.

Up button Move the selected transform earlier in the chain.

Down button Move the selected transform later in the chain.

Map Convert

Use Map Converter to provide conversion transformation for image-based lighting (IBL) and environment maps.

You can use the results of Map Convert in Action as an [IBL map](#) (page 540).

To access the 2D Transform menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and matte clip, and outputs a result an outmatte.

Map Convert Menu Settings

Input and Output Format Settings

Input Format	Output Format
Cubic	Spheric
Horizontal	

Input Format box Select the type of image you want to convert.

Cubic Type box Select horizontal or vertical to identify the type of cubic image you are inputting. Select Spliced Faces to stitch together multiple images to create a horizontal cubic image. Available when Cubic is selected in the Input Format box.

Output Format box Select the output format for the image you are converting.

The Map Convert effect accepts the following format types:

Type:	Description:
Spheric	Sometimes referred to as a chrome ball or mirrored ball. An image of a mirrored ball in an assumed orthogonal projection.
Angular	Similar to the mirrored ball format, except that the radial dimension is mapped linearly with the angle, giving better sampling around the edges.
Cylindrical	An image mapped onto an unfolded cylinder (also known as longitude and latitude maps).
Cubic (Horizontal or Vertical)	An unfolded six-sided cube.
Cubic (Spliced Faces)	A type of cubic map available as an input format using a different frames displayed as an unfolded cube showing six sides of the image. To use this input type, frames from the input clip are used as the 6 faces.
Polar	A coordinate system for locating points in which each point on a plane is determined by a distance from a fixed point and an angle from a fixed direction. When using this input format, only Cartesian is available as the output format.
Cartesian	A coordinate system for locating points on a plane by measuring the horizontal and vertical distances from an arbitrary origin to a point. When using this input format, only Polar is available as the output format.

Transform Settings

A vertical stack of four rectangular buttons. The top button is grey with the text 'Transform' in white. Below it are three blue buttons with white text: 'X 0.00', 'Y 0.00', and 'Z 0.00'.

These Transform settings apply to Cylindrical, Angular, Spheric, and Cubic, (Horizontal or Vertical) input formats.

Transform X Position field Displays the horizontal value of the image. Editable.

Transform Y Position field Displays the vertical value of the image. Editable.

Transform Z Position field Displays the depth value of the image. Editable.

Transform	Cycle	Face Assignment
X 0.00	Length 1	Clip 1 -> Front
Y 0.00		Clip 2 -> Back
Z 0.00		Clip 3 -> Right
		Clip 4 -> Left
		Clip 5 -> Top
		Clip 6 -> Bottom

In addition to the common transform settings, a Cubic (Spliced Faces) input format also contains the following settings:

Sequence Length field When creating a cubic map from spliced images, indicate how frequently images change in the sequence. Each change in the sequence gets mapped to a different face of the cube.

Face Assignments fields These locked fields display the order that the face assignment follows when creating the cubic map.

2D Transform	Repeat Mode
Position X 50.00	Mirror Repeat
Position Y 50.00	
Scale 100.00	
Rotation 0.00	

X Position field Displays the horizontal position of the output image. Editable.

Y Position field Displays the vertical position of the output image. Editable.

Scale field Displays the scale of the output image. Editable.

Rotation field Displays the rotation of the output image. Editable.

Repeat Mode box Select an option to fill the empty portions of the frame.

2D Transform	Radius	Angle
Position X 50.00	Scale 100.00	Scale 100.00
Position Y 50.00	Offset 0.00	Offset 0.00
Scale 100.00	Repeat Mode	Repeat Mode
Rotation 0.00	Mirror Repeat	Mirror Repeat

Radius Scale field Displays the scale of the radius for a cartesian to polar conversion. Editable.

Radius Offset field Displays the offset of the radius for a cartesian to polar conversion. Editable

Angle Scale field Displays the scale of the angle for a cartesian to polar conversion. Editable.

Angle Offset field Displays the offset of the Angle Scale for a cartesian to polar conversion. Editable.

Angular Repeat Mode box Select an option to fill the empty portions of the frame.

Output Size Settings

Output Size box Select whether to output the map at the size of the input image (Automatic), or select Custom to change the size of the output image.

Output Width field Displays the width of the output image. Editable when you select a custom output size.

Output Height field Displays the height of the output image. Editable when you select a custom output size.

Ratio field Displays the width to height ratio of automatic outputs. Non-editable.

Master Keyer

Use the Master Keyer to gesturally pull a key.

To access the Master Keyer menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front, back and key in clip, and outputs a result and an outmatte.

Add a Master Keyer node to the pipeline when you need to create an accurate key of a clip. Use the Master Keyer node to automatically suppress colour spill, to colour correct, and to remove noise or grain. See [Creating and Refining a Key in the Master Keyer](#) (page 838).

While there is no setup menu for the Master Keyer node, it can be saved as part of the Batch setup, or alternatively, as a Custom node. The Master Keyer is also available from the Keyer node.

Select an output type from the Select Output box.

(a) Select Output box

TIP In order for the keyboard shortcuts **M** and **D** to correspond to Matte and Degrain, the Master Keyer in Batch must have focus and the viewport cannot be set to a schematic view. If the schematic has focus, then **M** corresponds to Move and **D** corresponds to Delete.

The Master Keyer node processes gaps in clips set to No Media based on the input tab receiving the information.

Input	Result
Front	No media
Back	Black frames
Matte	White frames

Master Keyer Menu Settings

MasterK Settings

Primary Sample colour pot Activates a pick cursor. Use to sample an area of the image.

Mix field Displays the mix between the primary and secondary sample. Drag right to include more of the secondary sample or left to include less.

Secondary Sample colour pot Activates a pick cursor. Use to sample an area of the image where you do not want any softness in the matte.

Patch1 button Enable to isolate a range of colours to be included in, or excluded from, the key. This button is active when an area of the image is sampled and Patch1 is selected in the Sampling box.

Patch box Select the areas of the matte to which the patch is applied.

Patch Range field Displays the colour range value. Editable.

Patch Softness field Displays the softness value. Editable.

Patch2 button Enable to isolate a range of colours to be included in, or excluded from, the key. This button is active when an area of the image is sampled and Patch2 is selected in the Sampling box.

Patch box Select the areas of the matte to which the patch is applied.

Patch Range field Displays the colour range value. Editable.

Patch Softness field Displays the softness value. Editable.

Patch3 button Enable to isolate a range of colours to be included in, or excluded from, the key. This button is active when an area of the image is sampled and Patch3 is selected in the Sampling box.

Patch box Select the areas of the matte to which the patch is applied.

Patch Range field Displays the colour range value. Editable.

Patch Softness field Displays the softness value. Editable.

Degrain button Enable to modify the grain and de-sharpen the edges of the key.

Size field Displays the size of the grain in the image. Editable.

Edges field Displays the level of sharpness of edges in the image. Editable.

More button Enable to increase the overall Degrain effect.

Sampling box Select the sampling method required to refine the key.

Reset button Resets sampling parameters (excluding the mix value and key colour).

Primary Reference colour pot Activates a pick cursor. Use to sample an area of the image.

Secondary Reference colour pot Activates a pick cursor. Use to sample an area of the image where you do not want any softness in the matte.

Colour Settings

Luma field Displays the luminance value. Editable.

Edge Size field Displays the range for the blend. Both the Luma field and the Edge Balance trackball are affected. Editable.

Spill colour pot Displays the colour to suppress in the clip. Editable.

Range field Displays the range for the removal of colour spill along the edges of the key. Drag right to soften the edge and remove colour spill further into the key. Drag left to harden, or create a thinner, edge.

Hue field Displays the hue value. Editable.

Auto Colour Correct button Enable to apply colour settings to the front clip.

Reset button Resets the colour settings.

Result Output

Result Output button Select the output mode for the result.

Matchbox

About Matchbox

Matchbox is an interactive development tool that allows you to run generic OpenGL Shading Language (GLSL) shader code directly in Batch or Batch FX or through the Tools tab, to add specific functionality, or create custom effects. GLSL is a high-level shading language that is part of the OpenGL specification.

Because of the nature of GLSL fragment shaders, Matchbox works well on image processing effects. You can however, create simulated 3D effects using a number of image processing techniques, like using a Z-depth pass, for example.

The Matchbox node populates the user interface dynamically, based on the parameters required by the shader. You can also design and implement more sophisticated interface elements and naming, through the use of an XML sidecar file. A utility is included to test your shader code and help you create the sidecar XML UI file, if needed.

Re-purposing of existing effects is easy, since Matchbox shaders are simple generic GLSL fragment shader code, with no encryption, and no required customization. Included are a number of useful example shaders, that can be used as is, or serve as starting points for you to develop your own tools. Some of the included example shaders are:

- Vignetting
- Fabric
- Cross Hatching
- NaN Replace
- Switcher
- Ripples
- Twirl
- Warp
- Posterise
- Z-Glow (multipass shader)
- Z-Rays (multipass shader)
- Median Filter (multipass shader)

Accessing Matchbox

To access the Matchbox menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).

■ Tools, then select from the menu.

This node has six physical inputs, but you are not limited to the amount of actual inputs you can use in the effect, since you can use the same image for more than one input. It also outputs a result and an outmatte.

Matchbox Menu Settings

Most of the Matchbox menu is generated dynamically based on the GLSL (and optional XML) code, but there are a few UI elements that are constant.

Name field This locked field displays the name of the current shader.

Change Shader button Click to open the file browser to select a different shader.

Regen button Enable to automatically update the image as settings are changed.

Output Resolution box Select an output resolution for the effect. If you select Custom, settings appear with presets and custom options.

Output Width field Displays the width of the selected output resolution. Non-editable.

Output Height field Displays the height of the selected output resolution. Non-editable.

Creating Your Own Matchbox Effects

A great benefit of working with the Matchbox tool is being able to create your own effects, depending on your particular needs. Creating a Matchbox shader can be as simple as copying and pasting GLSL code snippets, or can be complex multipass effects with multiple inputs and dozens of UI elements. For example, here is the contents of a simple Add effect:

```
uniform sampler2D input1, input2;
uniform float adsk_result_w, adsk_result_h;

void main()
{
    vec2 coords = gl_FragCoord.xy / vec2( adsk_result_w, adsk_result_h );
    vec3 sourceColor1 = texture2D(input1, coords).rgb;
    vec3 sourceColor2 = texture2D(input2, coords).rgb;
```

```

    gl_FragColor = vec4( sourceColor1+sourceColor2, 1.0 );
}

```

Here's a quick high-level workflow to follow when creating Matchbox shaders:

- 1 Write or copy/paste GLSL fragment shader code.
- 2 Use the provided command line tool to test the shader.
- 3 Edit the Shader Description output from the test tool.
- 4 Package the XML and GLSL code together for use in Flame Premium.

Writing and Testing GLSL Fragment Shader Code

You can repurpose existing fragment shader code, or create an effect specific to your needs. In either case, you can use the *test_shader* utility to validate and debug your code, and optionally help you design user interface elements in a sidecar XML file. The *test_shader* utility also has an extensive Help file that lists the available uniforms (including a number of *adsk_* custom uniforms) and XML structure.

The *test_shader* utility can be found in */usr/discreet/<product home>/bin*. To access the Help file, from the bin directory, type *test_shader --help*.

To create and test a fragment shader:

- 1 Write or copy your fragment shader code in a text editor.
- 2 Save the file with the extension *.glsl*. For example, here is the contents of a scaling effect:

```

1 uniform float size;
2 uniform sampler2D myInputTex;
3
4 void main (void) {
5     vec4 tex0 = texture2D(myInputTex, gl_TexCoord[0] * size);
6     gl_FragColor = vec4 (tex0.rgb, 1.0);
7 }

```

- 3 Run your code through the test utility. For example, *test_shader scale.glsl* produces this result:

```
0(5) : warning C7011: implicit cast from "vec4" to "vec2"
```

```

XML :
<ShaderNodeDescription Description="" Name="Preset Name">
  <Shader Index="1">
    <Uniform RepeatMode="Off" InterpolationMode="Linear" Type="sampler2D"
Tooltip="" Name="myInputTex">
    </Uniform>
    <Uniform DisplayName="size" Type="float" Name="size">
      <SubUniform Inc="0.01" Max="1000000.0" Min="-1000000.0" Default="0.0"
Row="0" Col="0" Page="0" Tooltip="" Name="size">
      </SubUniform>
    </Uniform>
  </Shader>
  <Page Name="Page 1" Page="0">
    <Col Name="Column 1" Col="0" Page="0">
    </Col>
  </Page>
</ShaderNodeDescription>

```

In this case, the first line displays a compilation warning that you might want to fix. In some cases, you'll receive errors that need to be fixed for the shader to work properly in Flame Premium.

- 4 Fix any errors, and rerun the code through the *test_shader* utility.
- 5 Optional: Use the XML information in the test_shader output to help you set up the UI of the effect. This can be especially useful if different users are going to be working with these effects. Simply copy the XML shader node description section of the test output into a new file and save it using the same name, but with an *.xml* extension. In our example, you can edit *scale.xml* to add default values, better names for inputs and other UI elements, and even tooltips to help the user (see the bold sections below):

```
<ShaderNodePreset SupportsAdaptiveDegradation="0" Description="" Name="Next
Generation Scaling">
  <Shader OutputBitDepth="Output" Index="1">
    <Uniform Index="0" NoInput="Error" Tooltip="" DisplayName="Front"
Mipmaps="False" GL_TEXTURE_WRAP_T="GL_REPEAT" GL_TEXTURE_WRAP_S="GL_REPEAT"
GL_TEXTURE_MAG_FILTER="GL_LINEAR" GL_TEXTURE_MIN_FILTER="GL_LINEAR"

```

- 6 Add your *.glsl* and optional sidcar *.xml* file to the same directory. The existing shader example files are located in */usr/discreet/<product home>/matchbox*.
- 7 Try your effect in Smoke or Flame.

Creating Multipass Shaders

In order to build more efficient, complex, or sophisticated effects, you can split your effects into multiple passes. In order to do this, you can separate your effect into multiple *.glsl* files using advanced *adsk_* uniforms. For example, the existing Median Filter preset consists of *MedianFilter.1.glsl* and *MedianFilter.2.glsl*. In this case, when selecting this effect from the Load Shaders browser in Flame Premium, you need to select the root group *MedianFilter.glsl* file to incorporate all of the passes as one effect.

Optional: Creating Browser Proxy Files

Along with the *.glsl* and optional *.xml* files that comprise a fragment shader, you can also create a file that can display a proxy of your effect in the Load Shaders browser. You can use Flame Premium to create a proxy of your effect, but if you don't have access to Flame Premium, or want to create proxies programmatically, you can use the following header (byteswap). The standard width and height of the proxy is 126x92, and the file is RGB 8-bit. Save your proxy files as *.p*, and place them in the same folder as your *.glsl* and *.xml* files of the same name.

```
typedef struct {
    unsigned short Magic;
    float Version;
    short Width;
    short Height;
    short Depth;
    float Unused [ 6 ];
```

```

} LibraryProxyHeaderStruct;

#define PROXY_MAGIC 0xfaf0
#define PROXY_VERSION 1.1f
#define PROXY_DEPTH 130

```

Matte Curves

Use Matte Curves to adjust the luminance of input mattes.

To access the Matte Curves menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front, back and matte clip, and outputs a result.

NOTE The Matte Curves node is the same as the Modular Keyer Matte Curves node.

The Matte Curves node processes gaps in clips set to No Media based on the input tab receiving the information.

Input	Result
Front	Black frames
Back	Black frames
Matte	No media

Matte Curves Menu Settings

General Settings

Result box Select the type of clip you want to process.

Home button Reverts to the original view.

Reset box Resets the curve view.

Matte box Select the matte curve you want to adjust.

Set Key button Sets a keyframe at the selected frame.

Delete Key button Deletes the selected keyframe.

Reset Key button Resets the curves at the selected keyframe.

Matte Edge

Use the Matte Edge effect to create an image based on the detected edges, or use it to modify the edges of a matte to help in creating a key.

To access the Matte Edge menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front and matte clip as inputs, and outputs a result. You can add the Matte Edge node to any part of the pipeline except the Front pipe of the CBlend node. The Matte Edge node is not appropriate for this pipe because its result is a matte.

Matte Edge Menu Settings

General Settings

Rendering Mode box Select whether to render in Automatic, Progressive or Interlaced mode.

Regen button Enable to get dynamic updating of the image as you make changes.

Edges Settings

Edges button Enable to create an image composed of the edges in an image.

Matte Edge Mode box Select whether to use the Basic, Advanced or Smooth edge-detection algorithm. Certain settings change based on this selection.

Basic Settings

Edges	Basic
Min 0.00	Max 50.00
Width 0.50	

Width field Displays the value that affects how the edge-detection algorithm determines whether each pixel forms part of the edge. Editable.

Minimum Input field Displays the lower limit of the luminance values. Pixels with lower values are mapped to black. Editable.

Maximum Input field Displays the upper limit of the luminance values. Pixels with higher values are mapped to white. Editable.

Advanced Settings

Edges	Advanced
Min 0.00	Max 255.00
Width	Softness
Inner 1.00	Inner 0.00
Outer 1.00	Outer 0.00
Proportional	Proportional

Minimum Input field Displays the lower limit of the luminance values. Pixels with lower values are mapped to black. Editable.

Maximum Input field Displays the upper limit of the luminance values. Pixels with higher values are mapped to white. Editable.

Inner Width field Displays the width of the inner edges of the matte. Editable.

Outer Width field Displays the width of the outer edges of the matte. Editable.

Width Proportional button Enable to affect the inner and outer width proportionally.

Inner Softness field Displays the level of softness on the inner edges of the matte. Editable.

Outer Softness field Displays the level of softness on the outer edges of the matte. Editable.

Softness Proportional button Enable to affect the inner and outer softness proportionally.

Smooth Settings

Edges	Smooth
Min 0.00%	Max 100.00%
Softness 0.00	Gain 100.00

Smooth Minimum field Enter a lower limit for the edge detection. Editable.

Smooth Maximum field Enter the upper limit for the edge detection. Editable.

Smooth Softness field Enter a value for softness of the edge. Editable.

Smooth Gain field Enter a value for the softness gain of the edge. Editable.

Shrink Settings

Shrink
Single Pass
Width 1.00
Softness 1.00
Min 0.00
Max 255.00

Shrink button Enable to remove pixels from the edge of the matte.

Shrink Mode box Select whether to use shrink in a single pass or iterative mode. Single Pass mode allows you to control edge softness.

Shrink Width field Displays the width of the border that is removed from the edge of the matte. Editable.

Softness field Displays the amount of softness applied to the edges of the matte.

Minimum Input field Displays the lower limit of the luminance values. Pixels with lower values are mapped to black. Editable.

Maximum Input field Displays the upper limit of the luminance values. Pixels with higher values are mapped to white. Editable.

Erode Settings

Erode
Width 4.53

Erode button Enable to blend the light and dark edges of the matte.

Erode Width field Displays the width of the matte border to soften. Editable.

Blur Settings

Blur button Enable to apply a softening Gaussian blur filter to the edge of the matte.

Blur Width field Displays the width of the blur applied to the edge of the matte. Editable.

Blur Height field Displays the height of the blur applied to the edge of the matte. Editable.

Proportional button Enable to constrain blur amount proportions.

Matte Luminance Curve Settings

Matte Luminance Curve Controls the blending of the edges. You can add keyframes to the curve using Add mode, move keyframes with Move mode, and modify the curve's shape using tangent handles.

Reset box Resets the curve view.

Home button Reverts to the original view.

Noise Settings

Noise button Enable to add noise to the transparent areas of the matte.

Noise Mode box Select the mode of noise to apply throughout the length of the image. Static adds noise as a still frame; Impulse adds noise that changes at each frame.

Select:	To add noise:
Static	As a still frame. You can move the static noise using the Position X and Y fields.
Impulse	Changing at each frame, but always starting from the same seed.

Weight field Displays the level of noise in the clip. Values below 1 add more white noise, and values above 1 add black noise. Editable.

Softness field Displays the level of Gaussian softness added to the noise. Editable.

Position X field Displays the X position of the noise when using Static mode. Editable.

Position Y field Displays the Y position of the noise when using Static mode. Editable.

Size X field Displays the size of the noise along the X axis. Editable.

Size Y field Displays the size of the noise along the Y axis. Editable.

Proportional button Enable to affect the X and Y sizes proportionally.

Mono

Use Mono to generate a monochrome copy of the front clip.

To access the Mono menu, use:

- Batch, then select a node from the Node bin.

- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

Mono Menu Settings

General Settings

Luminance box Select the channel you want to use to create the monochrome clip.

Motif

Use the Motif node to create a tiled symmetrical texture.

To access the Motif menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front and a matte input, and outputs a result clip and a matte output.

Source clips can be transformed before symmetrical effects are applied. Transformations are applied to both the front and matte clips simultaneously. You can select the type of symmetry mode to use on the transformation, and define its parameters.

The radial symmetry mode displays a user-defined widget, which is a polygon with an equal number of sectors to the order of symmetry. You select the sector to use as the originating tile, the basis for a kaleidoscopic texture. Additional parameters allow you to define the center of symmetry of the image, and the angle and radius of the originating tile.

Front and Result views in radial symmetry mode

In Radial mode, you can also reuse the pixel on the edge of a sector to pad the space between outer tiles.

Result views with the repeating disabled and enabled

The region of interest (ROI) effect uses a user-defined rectangular or triangular selection as the originating tile to create a basic mirrored texture.

Front and Result views in region of interest symmetry mode

Image courtesy of The House

Motif Menu Settings

Motif Node

The Motif node displays 2D Texture Transform controls that allow you to simultaneously change the position, scaling, rotation, and type of image padding. The Symmetry Mode controls display a colour pot for the original tile selection.

2D Texture Transform settings

X Position field Displays the horizontal offset in pixels of the input and matte clips. Editable.

Y Position field Displays the vertical offset in pixels of the input and matte clips. Editable.

X Scaling field Displays the amount of horizontal scaling to apply to the front and matte clips.

Y Scaling field Displays the amount of vertical scaling to apply to the front and matte clips. Editable.

Scaling proportional button Enable to effect Scale X and Scale Y proportionally.

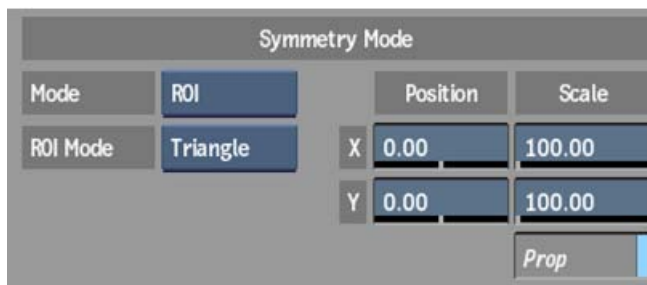

Rotation field Displays the angle of rotation of the front and matte clips. Editable.

Repeat button Select fill options to pad the empty portions of the frame with the last line of pixels, a repeated (rolled) image, or black pixels.

Symmetry Mode settings

Mode button Select the type of symmetry effect to apply to the transformation. Additional parameters are displayed in Radial mode.

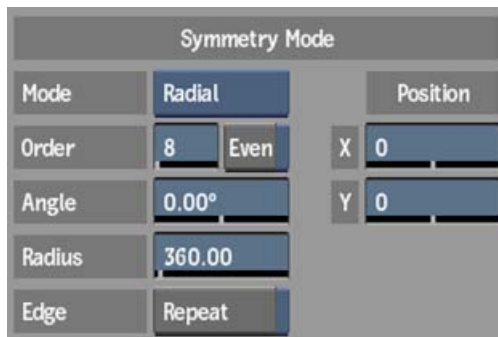

NOTE The following settings are available when the Symmetry Mode button is set to ROI.

Symmetry Mode box Select between a square or triangle region of interest mode.

Proportional button Enable to effect Scale X and Scale Y proportionally.

NOTE The following settings are available when the Symmetry Mode button is set to Radial.

Order field Displays the order of symmetry and indicates the number of sectors or sides of the polygonal widget. An order of 2 creates a basic mirrored image. An order of symmetry can have an odd number as a value. Tiles are mirrored in a counter-clockwise direction, therefore the sector to the right of the highlighted sector may not be its mirror image. Editable.

Even button Enable to maintain an even order of symmetry. If the order of symmetry is an odd value, an extra tile will be added, ensuring that adjacent tiles are mirror images of each other.

Angle field Displays angle of the axis of symmetry. Editable.

Radius field Displays the pixel length of the sector radius. Editable.

Edge Repeat button Enable to use the pixel colour on the sector's edge to pad the space between outer tiles. Displayed in Radial mode.

Position X field Displays the horizontal position of the centre of symmetry. Editable.

Position Y field Displays the vertical position of the centre of symmetry. Editable.

Softness settings

Softness field Displays the amount by which the motif effect is out of focus. Editable.

Display settings

Show Widgets button Enable to display the widgets in the clip.

Widget colour pot Select the colour used to highlight the originating tile. Editable.

Gestural Modifications

Modifications to the originating tile and symmetry mode parameters can be made gesturally in any view.

Drag:	To:
Outer edge of the region of interest	Change the width or height of the selection.
Corner of the region of interest	Change the width and height of the selection.
Inside the region of interest or widget	Move the selection.
The widget centre	Change the centre of symmetry.
Circle on the outer edge of the widget	Change the radius and the angle of symmetry.

Motion Analysis

Use Motion Analysis to analyse image displacement in a frame with respect to the frame before it.

- To access the Motion Analysis menu, use:
- Batch, then select a node from the Node bin.
 - Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
 - Tools, then select from the menu.

This node accepts a front clip, and outputs forward and backward vectors.

Motion Analysis Menu Settings

General Settings

Quality box Select Use Full Resolution to render the image at the current resolution, or an option with decreased motion analysis accuracy and increased rendering speed.

Motion Blur

Use Motion Blur to simulate the blur created by fast moving objects.

To access the Motion Blur menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts front, matte and forward vector clips and outputs a result, outmatte, or forward Vector clip.

Motion Blur Menu Settings

Vector Input Type Settings

Vector Input Type button Select whether the vector inputs are Absolute or Normalized.

Max Dispersion field Displays the level of motion displacement in the image. Set to the same value that was set in the 3D application. Editable.

Blue Channel Magnitude field Enable to use the blue channel as a magnitude multiplication of the maximum displacement value.

Black As No Movement button Enable to set black pixels as no movement in the motion vector. When enabled, you can set a threshold value for near-black pixels.

Threshold field Displays the level of near-black pixels taken into account in the conversion.

Vector Viewing Settings

Show Icons button Displays the forward motion vectors in the Result view.

Colour pot Changes the display colour of the forward and backward motion vectors.

Grid Step field Displays the length of the pixel area used to calculate each vector.

Scale field Displays the size of the motion vectors.

Blur Type Settings

Blur Type button Enable this button to select between trails and samples. Choose trails for a pixel-based motion blur. Choose sample for an accumulation-based motion blur.

Blur Type amount field Displays the amount of motion blur applied to the image. Editable.

Blur Type softness field Displays the amount of softness applied to the trails. Only available when trails is selected as the blur type. Editable.

Blur Type balance field Displays the amount of blur that either precedes or follows the image. The more positive the number, the more blur precedes the image. The more negative the number, the more blur follows the image. Editable.

Artefacts Settings

Vector Softness field Displays the amount of softness that is applied to reduce the quality of vectors, and therefor solve precision artefacts. Editable.

Post Blur field Displays the amount of global blur applied after other effects have been applied. Apply conservatively. Editable.

Matte Fill field Display the amount used to fill in gaps in the matte. Best applied after softness adjusted. Only available when the blur type is trials. Editable.

Colour Interpolation Settings

Colour Interpolation button Enable this button to verify that the source is already premultiplied. In this case, the colour interpolation effect must treat the image differently for the effect to work properly. This button is only functional when there is an input matte.

Motion Opacity Curve

Motion Opacity Curve Allows you to control the opacity of the trail by shaping it using the curve.

Home button Reverts to the original view.

Reset box Resets the curve view.

Motion Convert

Use Motion Convert to convert normalized 2D vectors into absolute vectors that you can work with in Flame.

To access the Motion Convert menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).

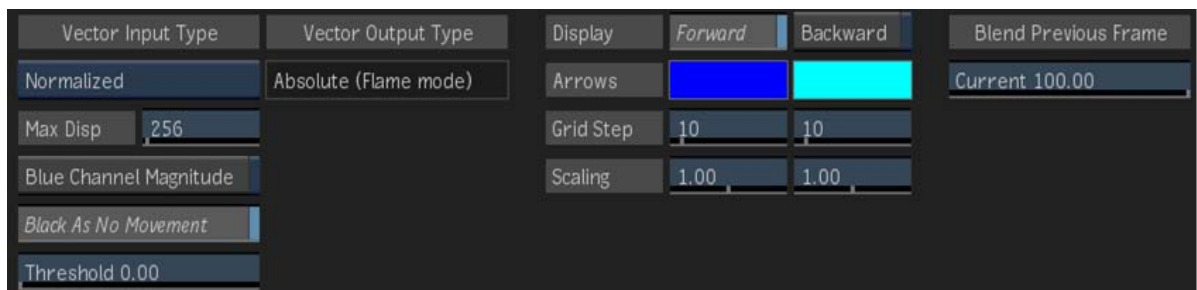

This node accepts a front clip, and forward and backward vectors. It outputs a result, as well as forward and backward vectors.

Motion Vectors are 2D vectors that represent the displacement in normalized pixel units of a pixel in the current frame to the next frame (forward motion vector), or its displacement from the previous frame (backward motion vector). Motion Vectors can be rendered by a 3D application when dealing with synthetic images, or produced through image analysis when images come from live action footage.

You can attach the forward and backward outputs from the Motion Analysis node or import motion data from another source.

Motion Convert Menu Settings

Motion Convert Node

Vector Input Type box Select whether the vector inputs are Absolute or Normalized.

Maximum Displacement field Displays the level of motion displacement in the image. Set to the same value that was set in the 3D application.

Blue Channel Magnitude button Enable to use the blue channel as a magnitude multiplication of the maximum displacement value.

Black As No Movement button Enable to set black pixels as no movement in the motion vector. When enabled, you can set a threshold value for near-black pixels.

Threshold field Displays the level of near-black pixels taken into account in the conversion. Editable.

Vector Output Type Displays the absolute vector output type mode.

Forward button Enable to display the forward motion vectors in the Result view.

Forward Arrow colour pot Displays the current colour of forward motion vectors. Editable.

Backward button Enable to display the backward motion vectors in the Result view.

Backward Arrow colour pot Displays the current colour of backward motion vectors. Editable.

Forward Grid field Displays the length of the pixel area used to calculate each forward motion vector. For example, enter 5 to sample an area of 25 pixels.

Backward Grid field Displays the length of the pixel area used to calculate each backward motion vector. For example, enter 5 to sample an area of 25 pixels.

Forward Scaling field Displays the size of forward motion vectors. Editable.

Backward Scaling field Displays the size of backward motion vectors. Editable.

Blend Previous Frame field Displays the level of opacity of the current frame, which is overlaid on the previous frame. Set the value to 100 to display the current frame only.

MUX

The MUX (multiplexer) node is a tool that helps you create cleaner schematics by allowing you to have multiple RGBA inputs feeding your outputs. The selection of the active input can be changed over time, therefore MUX also acts as an animated switcher. You can hide the input or output links of the MUX node to clean up a large schematic.

To access the MUX menu, use:

- The I/O tab in Batch.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts any number of front and matte clips, and outputs a result and outmatte.

Using the MUX Node

When entering Batch FX with existing Timeline FX or transitions, you may notice MUX nodes with multiple connections in the newly converted schematic. These MUX nodes are used to help recreate and represent your timeline in a flow graph environment.

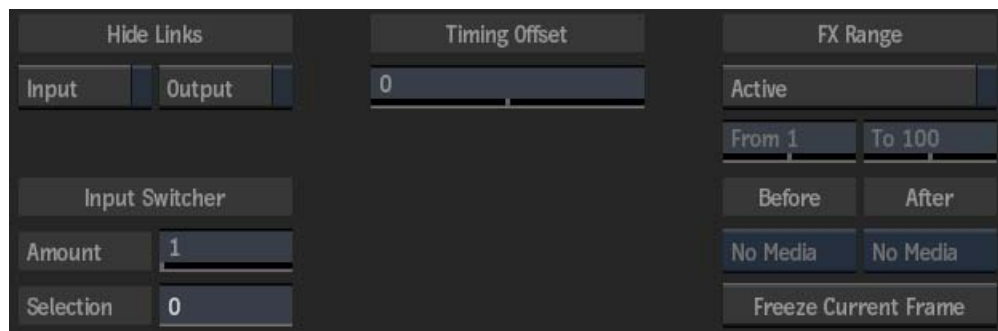

In the case of timeline transitions, the MUX node also acts as a switcher to allow the proper inputs to be selected at the correct time.

You can emulate this behaviour by adding your own MUX nodes to the schematic. If you need more inputs in your MUX node, use the Amount field in the MUX menu to set the number of inputs needed. To switch between inputs, use the Selection field to choose which input is active (this field can be animated with keyframes).

TIP If you add multiple inputs to a MUX node, you may have trouble seeing or connecting individual input sockets. In this case, you can expand the node by selecting it, and pressing **Shift + C**. Press the same keyboard shortcut again to collapse the node.

MUX Menu Settings

Hide Links Settings

Input button Enable to hide all input links to the MUX node.

Output button Enable to hide all output links to the MUX node.

Input Switcher Settings

Amount field Displays the number of inputs on the node. Editable.

Selection field Displays the number of the input that has its output displayed in the Result window. Editable.

Timing Offset Settings

Timing Offset field Displays the number of frames by which the timing of the MUX pipeline is offset. Editable.

FX Range Settings

Range Active button Enable to activate the range settings.

Range From field Displays the first impacted frame. Editable.

Range To field Displays the last impacted frame. Editable.

Range Before box Select an option to apply before the set frame range.

Range After box Select an option to apply after the set frame range.

NOTE There are two Ping Pong options included in the Range Before box and Range After box: Ping Pong and Ping Pong+. The Ping Pong repeat mode is inclusive, meaning that the last frame of the sequence is always repeated. For example, a five frame sequence would be: 1-2-3-4-5-5-4-3-2-1-1-2-3-4. The Ping Pong+ repeat mode is exclusive, meaning that the last frame of the sequence is never repeated creating a sequence that is always 1 frame shorter, but that does not create stuttering with a frame repeat.

Freeze Current Frame button Click to output the image of the currently selected frame for the duration of the clip.

Optics

Use Optics to add a glow effect to the clip in the process tree.

- To access the Optics menu, use:
- Batch, then select a node from the Node bin.
 - Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
 - Tools, then select from the menu.

This node accepts front, back, and matte clips, and outputs a result.
The Optics node processes gaps in clips set to No Media based on the input tabs receiving the information.

Input	Result
Front	No media
Back	Black frames
Matte	No media

Optics Menu Settings

Optics Node Settings

Size field Displays the size of the glow effect. Editable.

Intensity field Displays the intensity level of the glow effect. Editable.

Noise field Displays the jitter level in the glow effect. Editable.

Transparency field Displays the transparency level of the front clip. Editable.

Optics Front button Enable to use the front clip.

Optics Back button Enable to use the back clip.

Invert button Enable to invert the matte clip.

Random button Enable to produce a different glow effect.

Interior colour pot Select a colour for the interior of the glow effect.

Exterior Colour pot Select a colour for the exterior of the glow effect.

Paint Node

About Paint Node

Paint Node is a system that provides a scalable matte painting, retouching, or restoration workflow in Batch or Batch FX.

Due to its underlying technology, Paint Node automatically scales strokes when changing the resolution, ratio, or bit depth of input clips, or when switching from Full Resolution to Proxy mode. Paint Node supports “clipless” setups, which can be applied to any image input, while accurately reproducing the sequence of painted strokes.

The Paint Node accepts a front and matte clip as input, and creates a result and output matte clip, respectively. You can paint on the result and output matte, with a selection of brushes in different paint modes.

Paint Node also allows you to connect multiple sources and use them to paint the contents of source images onto the result. This paint operation, applied with the Reveal paint tool, can be used with in-context overlay over the result image. A front and matte clip can be connected as a source by connecting the clips to a source node. The content of source front and source matte input can be used to create brush strokes on the result and output matte.

Paint Node can be accessed from:

- [Batch FX](#). (page 1015)
- [Batch, then select a node from the Node bin](#). (page 1016)
- [Modular Keyer](#). (page 1016)

The following views are available in Paint Node.

Select:	To display:
Front (F1)	The front clip or Batch or Batch FX tree input. The modifications to the front create the result clip.
Matte (F3)	The matte clip or Batch or Batch FX tree input. The modifications to the matte create the output matte.
Source Front (F1 F1)	The source front that is selected in the Sources list.
Source Matte (F3 F3)	The source matte that is selected in the Sources list.

Select:	To display:
Result (F4)	The result image. Paint can be applied to the result.
Output Matte (F4 F4)	The output matte image. Paint can be applied to the output matte.

Paint Node Menu Settings

Source Controls

Displays the front clip, matte clip, and sources. The Sources list manages the sources attached to the current node. A source is composed of a front source and a matte source. See [Using Sources](#) (page 1017) .

Add button Click to add a new source node, and select the source front and source matte. Ctrl-click to add a source node only.

Source Front option box Select Front Lock to use the current frame for the duration of the source front clip. Select Front On to unlock the clip and apply it in its original state.

Source Matte option box Select Matte Off to paint anywhere on the canvas, Matte On to limit painting to areas on the source matte, or Matte Invert to limit painting to areas outside the source matte.

Hide Strokes button Hides the strokes associated with the current source.

Clear Strokes button Clears the strokes associated with the current source.

Current Frame box Select to clear strokes for the Current Frame or the entire Sequence.

Sources List Displays the sources attached to the current node.

Brush Attributes

Sets the size of the brush and other brush attributes affecting how paint is applied to the canvas. See [Brush Attributes and Attribute Modes](#) (page 1021).

Size field Set the radius of the brush in pixels. Editable.

Rate field Set the rate at which to apply brush strokes to the canvas. Use a higher percentage value to produce a smoother continuous stroke. Editable.

Fixed Rate button Enable to make the stroke dependent on the speed at which you move the brush.

Pressure field Set the transparency on the pressure and direction of the pen. Editable.

Jitter field Set the level of dispersion. A lower value produces a greater concentration of paint. Editable.

Direction field Set the percentage of a complete rotation to rotate the brush around the Z-axis. Editable.

Roll field Set the percentage of a complete rotation to rotate the brush around the X-axis. Editable.

Brush Attribute Modes

Brush Attribute Modes option box Select an attribute as a reference value. Select a clip to use its luminance as a reference.

Brush Attribute Modes option box Select an attribute as a reference value. Select a clip to use its luminance as a reference.

Brush Attribute Modes option box Select an attribute as a reference value. Select a clip to use its luminance as a reference.

Brush Attribute Modes option box Select an attribute as a reference value. Select a clip to use its luminance as a reference.

Brush Attribute Modes option box Select an attribute as a reference value. Select a clip to use its luminance as a reference.

Brush Attribute Modes option box Select an attribute as a reference value. Select a clip to use its luminance as a reference.

Paint Mode

Sets the type of paint operation that is applied to the brush. Some brushes paint in a colour; others use contents of the result or a source. See [Using Paint Modes](#) (page 1030) and [Using Blending Modes](#) (page 1034).

Paint Modes box Select the type of effect you want to apply to the brush.

Opacity field Displays the opacity of the brush. Use a lower value to apply a more transparent colour. Editable.

Fade field Displays how quickly the stroke fades when the Fade brush attribute mode is selected. A higher value fades the stroke faster.

Blending Modes box Select the blending operation to apply to the brush colour components.

Paint On box Select to apply strokes to the current frame, from the current frame to the last frame, or to all frames in the sequence.

Scale field Displays the scale value of the reference image. Editable.

Rotate field Displays the angle of rotation to rotate the reference image. Editable.

X Offset field Displays the horizontal coordinate for the Clone offset. Editable.

Y Offset field Displays the vertical coordinate for the Clone offset. Editable.

Overlay Controls

Overlay button Enable to show a reference clip overlaid onto the canvas.

Reference box Select the view with the reference clip you want overlay.

Transparency field Set the transparency percentage of the reference clip. Editable.

Colour Palette and Brushes

Current colour pot Select the current brush colour. Editable.

Preset colour pots Select preset brush colours. Editable.

Brushes Select a default brush profile to set it as the brush stroke.

Matte Controls

Defines the area that can be used to paint. You can paint on the entire canvas or areas delimited by the matte properties. See [Restricting Strokes with the Source Matte](#) (page 1020) and [Restricting Brush Strokes](#) (page 1028).

Use Matte button Enable to limit brush strokes on the canvas to areas inside the matte.

Invert button Enable to limit brush strokes on the canvas to areas outside the matte.

Both button Enable to paint on the result and output matte simultaneously.

Canvas Controls

Controls clearing and wiping the canvas at the current frame. See [Using the Canvas](#) (page 1036).

Clear box Select whether to clear all strokes from the result image and output matte at the current frame or to clear strokes from all frames.

Wipe button Select to apply a uniform colour in a single brush stroke to the entire result image, the front only or the output matte only at the current frame.

Wipe colour pot Select the wipe brush stroke. Editable.

Use Source button Enable to use the current source to wipe over the image.

Rotation field Displays the angle of rotation used to rotate the canvas in the image window. Editable.

Node Setup

Active Enable to activate smooth filtering of pixels for enhanced display.

Pixel Spread

Use Pixel Spread to create a stretching effect from the image edges delimited by a matte. This can be useful to solve keying problems resulting from dark edges around the area to be keyed, for example.

To access the Pixel Spread menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front, back and matte clip, as well as a vector map clip, and outputs a result and an outmatte.

Pixel Spread Menu Settings

Type Settings

Spread Type box Select the type of pixel spread distortion effect to apply to the clip.

Spread Mode box Select whether to have the distortion effect work in expansion mode or contraction mode. Active when Spread Type is set to Stretch, Parallax, or Interpolate.

Spread Settings

The following settings are available when Interpolate is selected from the Spread Type box.

Interpolation Softness Amount field Displays the amount of softness applied. Editable.

Edges Shrink Amount field Displays the amount of shrinking applied to the edges. Editable.

Edges Shrink Softness field Displays the softness of the edge. Editable.

Interpolation Source Premultiplied button Enable to verify if the source is already premultiplied, in which case the interpolation effect must treat the image differently for the effect to work properly.

Parallax	Edges	Spread Blur	Repeat Mode
Amount 1.00	Width 1.00	Amount 0.00	Repeat Off
BiasX 0.00	MidPoint 0.00		
BiasY 0.00			
Rotation 0.00			

The following settings are available when Parallax is selected from the Spread Type box.

Parallax Amount field Displays the amount of parallax distortion applied to the clip, in pixels. Editable.

Parallax X Bias field Displays the amount of horizontal offset applied to the parallax distortion effect, in pixels. Editable.

Parallax Y Bias field Displays the amount of vertical offset applied to the parallax distortion effect, in pixels. Editable.

Parallax Rotation field Displays the degree of rotation applied to the pixel distortion. Editable.

Edges Width field Displays the width of the distortion edge, in pixels. Editable.

Edges MidPoint field Displays the offset of the distortion edge from the middle. Editable.

Spread Blur Amount field Displays the amount of blur applied to the clip following the direction of the edge. Editable.

Parallax Repeat Mode box Select an option to fill the empty portions of the frame.

Stretch	Edges	Spread Blur
Amount 1.00	Width 1.00	Amount 0.00
	MidPoint 0.00	

The following settings are available when Stretch is selected from the Spread Type box.

Stretch Amount field Displays the amount of stretching distortion applied to the clip, in pixels. Editable.

Edges Width field Displays the width of the distortion edge, in pixels. Editable.

Edges MidPoint field Displays the offset of the distortion edge from the middle. Editable.

Spread Blur Amount field Displays the amount of blur applied to the clip following the direction of the edge. Editable.

Motion	Vector Origin	Vector Gain		Spread Blur
Distance 10.00	X 0.50	X	Y	Amount 0.00
Threshold 0.00%	Y 0.50	R	2.00	0.00
	Vector Overlap	G	0.00	2.00
	Under	B	0.00	0.00

The following settings are available when Vector Warp is selected from the Spread Type box.

Motion Distance field Displays the amount of distortion to be applied to the image based on a given motion vector. A negative amount inverts the direction of the spread. Editable.

Motion Threshold field Displays the percentage for the cut-off point below which motion data is not applied to the image. Editable.

Vector X Origin field Displays the starting point of any horizontal motion, which can be used to offset values entered for X Gain. Editable.

Vector Y Origin field Displays the starting point of any vertical motion, which can be used to offset values entered for Y Gain. Editable.

Vector Overlap button Enable to invert the effects of the vector warp.

Red X Gain field Displays the amount of gain used from the red channel to augment the horizontal motion of the distortion effect on the image. Editable.

Red Y Gain field Displays the amount of gain used from the red channel to augment the vertical motion of the distortion effect on the image. Editable.

Green X Gain field Displays the amount of gain used from the green channel to augment the horizontal motion of the distortion effect on the image. Editable.

Green Y Gain field Displays the amount of gain used from the green channel to augment the vertical motion of the distortion effect on the image. Editable.

Blue X Gain field Displays the amount of gain used from the blue channel to augment the horizontal motion of the distortion effect on the image. Editable.

Blue Y Gain field Displays the amount of gain used from the blue channel to augment the vertical motion of the distortion effect on the image. Editable.

Spread Blur Amount field Displays the amount of blur applied to the clip following the direction of the edge. Editable.

Output Settings

Result Output box Select whether to output a combined result or the pixel spread effect only.

Alpha Output box Select Input to output the input matte, or Spread Matte to output the matte generated by the pixel spread.

Proxy Extract

The Proxy Extract tool is available from the Tools tab, under Utilities.

Use the Proxy Extract tool to generate a proxy resolution clip from an existing clip in your project. This is useful when, for example, you have a 4K project, in which you've been working on 2K proxies and want to export a 2K version of your work.

To extract a proxy resolution clip:

- 1 Enable the Proxy Extract tool.
You are prompted to pick a Front clip.
- 2 Pick a Front clip from the Desktop or the Media panel.
You are prompted to pick a render location.
- 3 Pick a render location from the Desktop or the Media panel.
The proxy resolution clip is generated.

NOTE

- Proxies must be enabled in the project for the Proxy Extract tool to be available.
- The proxy resolution clip is generated based on the proxy settings in the Project and User Settings.

Proxy Regeneration

The Proxy Regeneration tool is available from the Tools tab, under Utilities.

Use the Proxy Regeneration tool to regenerate updated proxy media for a single or multiple clips in your project, overwriting the original proxies. This is useful when, for example, your proxies were generated from soft-imported media and that original media has changed (colour corrected, for example).

To regenerate proxies:

- 1 Enable the Proxy Regeneration tool.
You are prompted to pick a Front clip and the Proxy Regen Parameters menu appears.

- 2 Select the filter option, from the Proxy Quality box, to determine the quality of the proxy image.
- 3 Do one of the following:
 - To regenerate proxy media for a single clip, select Clip from the Proxy Regeneration Scope box.
 - To regenerate proxy media for all clips in a folder or reel, select Folder from the Proxy Regeneration Scope box.
- 4 Pick a Front clip from the Desktop or the Media panel.
The proxy media is regenerated and the original proxy media is overwritten.

NOTE Proxies must be enabled in the project for the Proxy Regeneration tool to be available.

Proxy Regeneration Menu Settings

General Settings

Proxy Scale Field Displays the proxy scale ratio. For example, a value of 0.50 generates proxies that are 50% of the clip's resolution. This parameter is set in the Project and User Settings.

Proxy Bit Depth field Displays the bit depth for generated proxies. This parameter is set in the Project and User Settings.

Proxy Quality box Set the quality of the proxy image. Proxy quality affects rendering and proxy generation duration since lower qualities are faster to calculate. However, the quality does not affect the amount of storage space required.

Proxy Regeneration Scope box Set the proxy regeneration scope. Options are:

- **Clip:** Regenerates proxy media for the selected clip.
- **Folder:** Regenerates proxy media for all clips in the same folder or reel as the selected clip.

Pulldown

Use the Pulldown to remove or add pulldown to a clip.

To access the Pulldown menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front clip as input, and outputs a result.

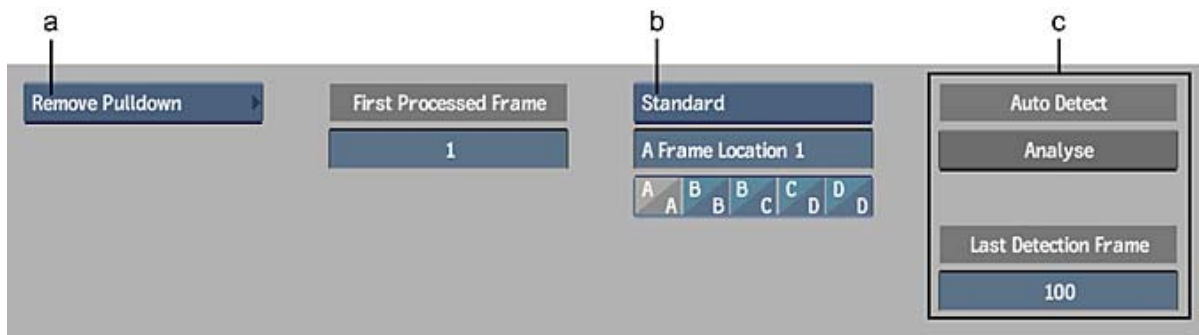

Additionally, the Pulldown node supports the following:

- 2:3 pulldown, also known as standard pulldown
- 2:3:3:2 pulldown, also known as advanced pulldown
- 24-to-25 fps conversion, also known as PAL pulldown

Pulldown Menu Settings

Pulldown Settings

When removing a pulldown, you can analyse the clip to automatically detect the type of pulldown and the A frame. If the analysis fails to determine the type of pulldown or the location of the AA frame, manually set the Pulldown and the A Frame Location options.

(a) Pulldown Mode option box (b) Pulldown Type option box (c) Remove Pulldown options; available when Pulldown Mode is set to Remove Pulldown

Pulldown type option box Select an option to add or remove pulldown from the clip.

First Rendered Frame field Displays the first frame at which output is rendered from the node. Unrendered output does not display any media. Editable.

Pulldown option box Select the type of pulldown process to apply to the clip.

A Frame Location field Displays the value of a reference (AA) frame. The selected frame becomes the frame of reference when adding or removing pulldown frames. Editable.

NOTE The following settings are available when Remove Pulldown is selected from the Pulldown Type option box.

Analyse button Click to determine the type of pulldown used and the A frame.

Last Detection Frame field Displays the value of the last frame of the clip used by the Analyse button. Selecting a subset of a clip speeds up the analysis. Editable.

NOTE When the node renders a transition, preceding and subsequent frames with no media are replaced with black frames.

Recursive Ops

Use Recursive Ops to perform a wide range of recursive, animation-based blending effects. Recursive Ops uses the processed result of the previous frame and blends it with the current frame using a selected blending mode. It features a built-in colour selection, which constrains the accumulation effect within that selection. Additionally, it accepts an external matte input which also conditions the way in which the internal blending occurs.

To access the Recursive Ops menu, use:

- Batch, then select a node from the Node bin.

- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts front and matte clips, and outputs a result and outmatte.

Recursive Ops Menu Settings

Regen button Enable to dynamically refresh the image as changes are made to the settings.

Repeat Mode Settings

Repeat Mode options box Select an option to fill the empty portions of the frame.

Range Settings

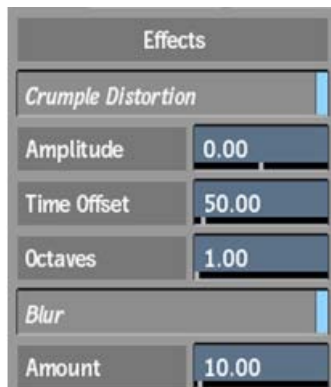

Range From field Displays the beginning of the range of frames that to be impacted by the effect. Editable.

Range To field Displays the end of the range of frames that to be impacted by the effect. Editable.

Range Before box Select an option to be applied before the set frame range. Bypass eliminates the effect, while Cycle repeats the effect.

Range After box Select an option to be applied after the set frame range. Bypass eliminates the effect, while Cycle repeats the effect.

Effects Settings

Crumple Distortion button Enable to activate the crumple settings.

Amplitude field Displays the amount of distortion. Increase the value to increase the crumple effect. Editable.

Time Offset field Displays the time offset interval of the crumpling. Editable.

Octaves field Displays the number of layers summed in the operation, from 0 to 10. Increase the value to increase the fractal crumple effect. Editable.

Blur button Enable to activate the blur settings.

Amount field Displays the amount of blur applied to the image. Editable.

2D Transform Settings

2D Transform		
<div>Active Show Icons</div>		
Position	Centre	Scale
X 0.00	0.00	105.00
Y 0.00	0.00	105.00
Rotation 3.00°		Prop

Active button Enable to activate the 2D Transform settings.

Show Icons button Enable to display the vertex editing tools in the image window.

Position X field Displays the horizontal position of the transformation. Editable.

Position Y field Displays the vertical position of the transformation. Editable.

Centre X field Displays the centre point value of the transformation along the horizontal axis. Editable.

Centre Y field Displays the centre point value of the transformation along the vertical axis. Editable.

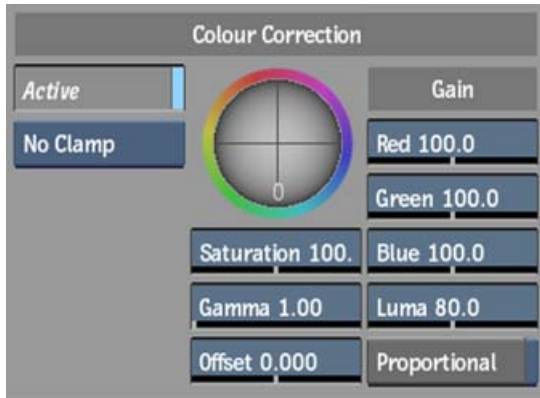

Scale X field Displays the horizontal scale factor. Editable.

Scale Y field Displays the vertical scale factor. Editable.

Proportional button Enable to scale X and Y values proportionally.

Rotation field Displays the rotation of the transformation. Editable.

Colour Correction Settings

Activate button Enable to activate the color correction settings.

Clamping box Select a clamping option.

Gain Trackball Adjusts the gain of the input.

Saturation field Displays level of colour purity in the image. Editable.

Gamma field Displays the gamma level. Editable.

Offset field Displays a value that modifies all of the colour parameters. Editable.

Red Gain field Set the percentage of colour values in the red channel. Editable.

Green Gain field Set the percentage of colour values in the green channel. Editable.

Blue Gain field Set the percentage of colour values in the blue channel. Editable.

Luma Gain field Set the percentage of luma gain value to display. Editable.

Proportional button Enable to adjust the gain of the colour values proportionally.

Blending Settings

Blending options box Select a logical operation that can be used to blend the front clip and the result clip.

Transparency field Displays the percentage of blending when the result is composited on the front clip. Editable.

Use Matte button Enable to apply the effect with the areas defined by the matte.

Rendering Settings

Clamp Render box Select a clamping option for colour and luminance values on output in the 16-bit floating point rendering pipeline.

Matte Output Settings

Matte Output options box Select an matte output option. Choose Selective to select the colour you wish to keep.

Selective Tolerance field Displays the tolerance level of the selected colour of the matte output. Editable. Available when Selective is chosen in the Matte Output options box.

Selective Colour box Click to enable the crosshair to select a colour in the image to be used as the matte output. Available when Selective is chosen in the Matte Output options box.

Regrain

Use Regrain to add grain from the RGB channels of a selected colour in an image.

To access the Regrain menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts front, back, and matte clips as input, and outputs a result.

Regrain Menu Settings

General Settings

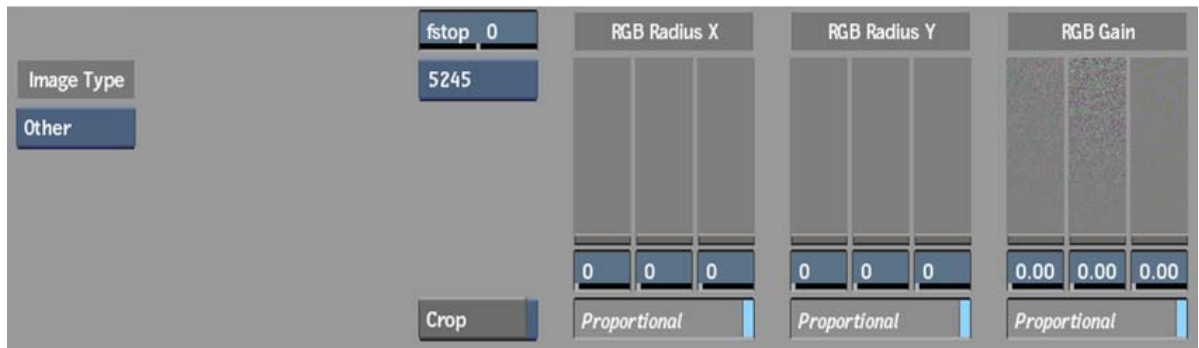

Image Type box Select the type of image data that is input into the node or tool. This determines the type of transformation applied to the input clip.

fstop field Displays the relative exposure offset. Use to compensate for under or over exposure. Editable.

Grain Signature box Select a film stock grain to add to the clip.

Crop box Applies the regrain to a specific region in the clip.

Red X Radius slider Displays the value of the radius on the x-axis for the red channel. Editable.

Red X Radius field Displays the value of the radius on the x-axis for the red channel. Editable.

Green X Radius slider Displays the value of the radius on the x-axis for the green channel. Editable.

Green X Radius field Displays the value of the radius on the x-axis for the green channel. Editable.

Blue X Radius slider Displays the value of the radius on the x-axis for the blue channel. Editable.

Blue X Radius field Displays the value of the radius on the x-axis for the blue channel. Editable.

Proportional RGB Radius X button Enable to adjust the radius on the x-axis of the red, green, and blue channels proportionally.

Red Y Radius slider Displays the value of the radius on the y-axis for the red channel. Editable.

Red Y Radius field Displays the value of the radius on the y-axis for the red channel. Editable.

Green Y Radius slider Displays the value of the radius on the y-axis for the green channel. Editable.

Green Y Radius field Displays the value of the radius on the y-axis for the green channel. Editable.

Blue Y Radius slider Displays the value of the radius on the y-axis for the blue channel. Editable.

Blue Y Radius field Displays the value of the radius on the y-axis for the blue channel. Editable.

Proportional RGB Radius Y button Enable to adjust the radius on the y-axis of the red, green, and blue channels proportionally.

Red Gain slider Displays the grain value in the red channel. Editable.

Red Gain field Displays the grain value in the red channel. Editable.

Green Gain slider Displays the grain value in the green channel. Editable.

Green Gain field Displays the grain value in the green channel. Editable.

Blue Gain slider Displays the grain value in the blue channel. Editable.

Blue Gain field Displays the grain value in the blue channel. Editable.

Proportional RGB Gain button Enable to adjust the grain on the red, green, and blue channels proportionally.

NOTE The following options are available when Mono or Custom are selected from the Grain Signature box.

Curves Display the curves for the luminance and each RGB channel.

Histogram box Select to display the red, green, blue, or luminance histogram in the graph. Select Current Curve to display the histogram for the currently selected Curves Channel.

Curves box Select to display the red, green, blue or all curves in the graph.

Home button Restores the position of panned or zoomed curves to the default setting.

Reset button Resets to default curve settings.

Resize

Use Resize to change a clip's resolution, frame depth, and aspect ratio.

To access the Resize menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.
- The Modular Keyer, then select a node from the Node bin.

This node accepts a front clip, and outputs a result.

You can also use Resize to pan and scan the destination image relative to the source. You can then select and animate the portion of the source clip that appears as the destination clip, and process to create the result image.

NOTE You can use Resize to output, for example, a HD project to a lower resolution for quick viewing.

Resize Menu Settings

Timeline FX Quick Menu Settings

To see the full Resize menu, click the Editor button.

Resize Quick Menu selector Displays the Resizing or Crop Box quick menu.

Source Settings

Use the Source settings to set or animate the position and size of the crop box.

Source							
Position		Scale		Crop Options		Source Pre-Processing	
X	0.00	100.00	Width 720	Source	Destination	Use Both Fields	
Y	0.00	100.00	Height 486	Source	Destination	Field Merge	
		Prop	Clip	Source	Destination	Deinterlace	
Ratio		1.333					Field 1
			Colour	[Green Color Picker]			

Position/Scale Settings

X Position field Displays the horizontal position from the centre of the crop box relative to the centre of the source frame, in pixels. Drag left or right, or click to enter a new X Position value.

Y Position field Displays the vertical position from the centre of the crop box relative to the centre of the source frame, in pixels. Drag left or right, or click to enter a new Y Position value.

X Scale field Displays the horizontal scale of the crop box relative to the Crop Box Width field value, as a percentage. Drag left or right, or click to enter a new X Scale value.

Y Scale field Displays the vertical scale of the crop box relative to the Crop Box Height field value, as a percentage. Drag left or right, or click to enter a new Y Scale value.

Crop Mode box Select an option to determine the scaling behaviour of the crop box while repositioning or rescaling. Use Free to adjust the crop box freely. Use Prop to use the current Crop Box Width and Crop Box Height settings proportionally. Use Source or Destination to use the respective aspect ratio for the crop box.

Source Ratio field Displays the aspect ratio of the crop box in the source frame. Editable.

Crop Options Settings

Crop Box Width field Displays the current width setting of the crop box, in pixels. Editable.

Crop Box Height field Displays the current height setting of the crop box, in pixels. Editable.

Source Width button Uses the width settings of the source frame for the Crop Box Width field.

Source Height button Uses the height settings of the source frame for the Crop Box Height field.

Source Frame button Uses the width and height settings of the source frame for the Crop Box Width and Crop Box Height fields, respectively.

Destination Width button Uses the width settings of the destination frame for the Crop Box Width field.

Destination Height button Uses the height settings of the destination frame for the Crop Box Height field.

Destination Frame button Uses the width and height settings of the destination frame for the Crop Box Width and Crop Box Height fields, respectively.

Crop Box Border colour pot Displays the current colour of the crop box border. Editable.

Crop Box Line Style box Select the line style for the crop box.

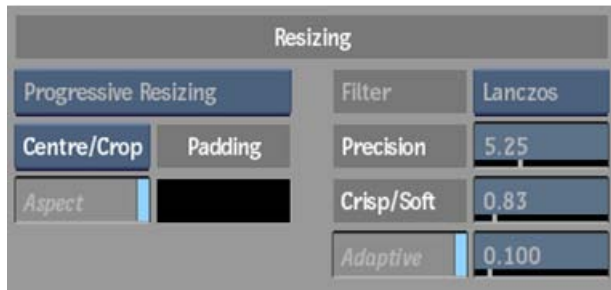

Source Pre-Rendering

Source Pre-Rendering buttons Select a conversion method to use for the resize. Use the Both Fields button when both source and destination formats are interlaced or progressive. Use the Field Merge button to combine the two fields of the source clip. Use the Deinterlace button to select one field, in which case the Source Pre-Rendering Field box is enabled.

Source Pre-Rendering Field box Select a field to use for the resize. Active when the Deinterlace Source Pre-Rendering button is enabled.

Resizing Settings

Use the Resize settings to change the size of a clip.

Resize Field Format box Select an option to determine whether the resize is performed on progressive or interlaced frames, if both source and destination clips are interlaced. If either clip is progressive, the resize operation is always progressive.

Fit Method box Select a fit method to be applied to the selected clip.

Precision field Displays the frequency cut-off point used during resize. Editable.

Crisp/Soft field Displays the amount of blurring used during resize. Editable.

Resize Filter box This option is available when Letterbox, Crop Edges or Fill is selected from the Fit Method box. Select the filter option to determine the quality of the interpolated resize result.

Aspect button This option is available when Letterbox or Crop Edges is selected from the Fit Method box. Enable to use non-square pixel formats. Active when Fit Method is set to Crop Edges or Letterbox.

Destination Padding colour pot Displays the colour used for padding the destination frame when the source image is smaller than the destination. Editable.

Adaptive Deinterlacing button Enable to use data from the adjoining interlaced field to improve the results of the resizing algorithm. This is most effective for clips containing stationary objects.

Adaptive Deinterlacing field Displays the amount of data used from the adjoining field for adaptive interlacing during resize. Active when Adaptive button is enabled.

Destination Settings

Use the Destination settings to define the format of the resized clip.

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution.

Width field Displays the custom width resolution of the clip. Editable.

Height field Displays the custom width resolution of the clip. Editable.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the custom render/output aspect ratio. Editable

Bit Depth box Select the render/output bit depth of clips.

Scan Mode box Select the scan mode of clips.

Crop/Lock Output button Enable to lock the destination resolution to match the crop box. Use this option to animate the resolution of a clip and change it on a per-frame basis. Available when you access Resize settings.

Sparks

Sparks are software plug-ins created by Autodesk or third-party developers.

To access Sparks, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.

The Autodesk Sparks API Reference Guide is available in PDF format. If you are interested in marketing or selling your Sparks, you must apply to the system Sparks program. To request an application, send an e-mail message to [email Sparks Manager](#).

Using a Sparks Plug-in

A Sparks plug-in functions in the same way as other commands or modules. Before using a Sparks plug-in, you will have to load it. After loading the plug-ins, you can replace them if all the Sparks buttons are already in use.

Loading and Replacing Sparks Plug-ins

To load a Sparks plug-in:

- 1 Do one of the following:
 - From the Tools menu, select the Plugins tab and then click one of the Sparks buttons.
 - In Batch or Batch FX, select the Sparks node and drag it into the schematic.
 - In the Timeline, select a clip and add a Sparks Timeline FX to it.

Once you have loaded a Sparks plug-in using one of these methods, the Sparks file browser will appear.

NOTE An L on a Sparks button indicates that you can load a Sparks plug-in. An E on a Sparks button indicates that there are settings for the plug-in. An S on a Sparks button indicates that you can enter the module using the same media from the previous session.

- 2 Navigate to *usr/discreet/sparks*.
You can also load Sparks from *usr//discreet/<product home>/sparks*.
- 3 Select a Sparks plug-in.
You are returned to your previous location. The name of the Sparks plug-in now appears on the selected button, however the L indicating that you can load a Sparks plug-in no longer appears.
To exit the Sparks plug-in file browser without loading a plug-in, click the Exit Sparks Browser button.

To replace a Sparks plug-in:

- 1 Press Alt and click the existing Sparks button.
The Sparks file browser appears.
- 2 Navigate to *usr/discreet/sparks* or *usr//discreet/<product home>/sparks* and select a Sparks plug-in.
You are returned to your previous location, and the name of the new Sparks plug-in appears on the selected button.

Using Sparks Plug-ins as a Node, Timeline FX, or Tool

To use Sparks plug-ins from Batch or Batch FX:

- 1 Select the Sparks node from the node bin and drag it into the schematic.
The Sparks Plug-in file browser appears.
- 2 Select a plug-in.
You are returned to the schematic and a Sparks node corresponding to the plug-in that you selected now appears in the schematic.
- 3 Double-click the Sparks node to access and adjust the settings for the Sparks node.

To use Sparks plug-ins from the timeline:

- 1 Select a clip on the timeline.
- 2 Click the FX button and add a Sparks Timeline FX to the clip.
- 3 Click the Sparks button to enter the Sparks Plug-in file browser.
- 4 Select a Sparks Plug-in.
You are returned to the timeline.
The Sparks button in the Timeline FX pipeline now appears with the name of the plug-in that you selected, and its settings, if any, are available in the quick menu. You can also double-click the Sparks button to enter the full editor, if the Sparks Plug-in has additional settings.

If you want to load a new Sparks plug-in, but all the Sparks buttons are already in use, you can replace an existing Sparks plug-in with the new one. This can be done from the Tools menu, Batch or Batch FX or the Timeline.

To use Sparks plug-ins from the Tools menu:

- 1 Click a loaded Sparks button.
The Sparks controls, if any, appear.
- 2 Enter the parameter values for the selected Sparks plug-in.
- 3 Select the source clips and the destination.
The processed clip appears in the destination.

Using Sparks in Batch or Batch FX

There are two Sparks nodes that you can access from Batch or Batch FX: the Sparks node and the Sparks Load node.

The Sparks node allows you to load Sparks Plug-ins by accessing the Sparks file browser. The number of inputs and bit depth that a Sparks node accepts depends on the Sparks plug-in. A Sparks node has light grey source tabs, since each Sparks plug-in varies in the type of clip it uses.

When working with a Sparks plug-in, missing media in front clips set to No Media can be converted into black frames while they are in use. When missing media is output from this node, it returns to a No Media state, regardless of whether it was set to display differently in the node.

NOTE When you attempt to use a Sparks plug-in, the error message "SPARK IS NOT SUPPORTED" may appear. This means the selected Sparks plug-in cannot be used with Batch or Batch FX. Contact the company that developed the Sparks plug-in for information on obtaining a compatible version.

The Sparks Load node allows you to populate multiple Sparks nodes at the same time into a destination bin. Populating a bin with predefined Sparks nodes saves you time since you do not have to access the Sparks browser each time you want to use one of the preloaded Sparks.

Unlike the Sparks node, the Sparks Load node itself cannot be dragged to the schematic; only the predefined node populated into a bin can be dragged to the schematic.

To create a predefined Sparks node in a bin:

- 1 Drag the Sparks Load node on top of any tab in the ALL Tools bin except the ALL Nodes tab.
The Sparks Plug-in file browser appears.
- 2 Select a Sparks Plug-in or select multiple plug-ins by Ctrl-clicking the Sparks you want to load.
- 3 Click load.

The selected Sparks are created as their own Sparks nodes in the destination bin. To use one of the preloaded Sparks, drag it from the destination bin to the schematic. You do not have to re-enter the Sparks browser to load a Sparks if you preloaded it into a bin.

For more information on Sparks plug-ins, see [Using a Sparks Plug-in](#) (page 1444).

Stabilizer

Stabilizing and Tracking

Use the Stabilizer to remove camera instability and motion jitter, and to track reference points in your clips. You can also use the Stabilizer to produce 2D or, in the context of Action, 3D motion, anchor a surface to the clip's background or anchor the UV points of the surface to features of a clip. With tracking, a point or points on the clip are tracked as they move through the scene. You can then apply the resulting motion path to an object on another layer so that it follows the same path as the object you tracked.

Stabilizing is the inverse of tracking. With stabilizing, the motion path is used to shift the scene so that the point that is tracked remains fixed at one position.

Tracking and stabilizing are often processes of trial and error. It is recommended that you track or stabilize using the default settings. If the tracker box strays from its original point, you can fine-tune the analysis.

Accessing the Stabilizer

Access the Stabilizer from:	To:
The Tools tab	Stabilize.
Action Axis node	Track or stabilize.
GMask	Track a garbage mask or the vertices of a GMask.
Distort	Track vertices or the axis of a spline when warping or morphing.
Warper	Track points or an axis of a mesh when warping or morphing.
Action Analyzer node	Provide a 2D tracking path for 3D manual tracking.
Paint Tool	Track an AutoPaint stroke.
Blur and Glow	Track the center point of the radial blur.
2D Transform	Provide correction for 2D motion, rotation and scaling.

Stabilizer Menu Settings

Miscellaneous Buttons

Return button Returns to the previous tool.

Load button Loads a setup.

Save button Saves a setup.

Setup Name field Displays the name of the last saved setup.

Revert button Reverts to the last saved setup.

Colour pot Displays the colour to fill the area where the image has been shifted after stabilization (available if Shift or Letterbox is chosen in the Scale and Shift Option box). Editable.

Context button Enable to view the tracking result with all of the Action scene, except for the selected node (and any children of the selected node).

Setup button Opens the Setup menu, where you can specify user interface and tracking preferences.

Animation button Opens the channel editor, where you can animate the various Stabilizer settings.

Expand/Collapse box Select whether to expand or collapse selected animation channels.

View box Select an option to set the view in the image window.

Auto Key button Enable to set a keyframe automatically each time you change a value at any frame.

Set Key button Sets a keyframe at the selected frame.

Delete Key button Deletes the selected keyframe.

Current Frame field Enter a frame number to jump to the corresponding frame.

Duration field Displays the duration of the clip in frames.

Reset box Select an option to reset shift, tracking, reference, or all data.

Reset All button Resets all parameters.

Grid button Accesses the overlay menu.

View button Accesses the viewing settings menu.

Undo button Undoes the last action performed.

Main Stabilizer Menu

Tracker box Select the Tracker to work with.

Add Tracker button Click to add a new tracker.

Active button Enable to activate the selected tracker.

Tracker colour pot Displays the colour of the selected tracker. Editable.

When you add a new tracker, the system automatically assigns it a unique colour so that you can easily distinguish between multiple trackers. You can change the colour of an individual tracker or of all the trackers at once.

Tolerance field Displays a value the Stabilizer uses to match reference points from frame to frame and to set keyframes. Editable.

Tracker Selection box Select which trackers are affected when you change a parameter.

Analyze button Click to generate stabilization or tracking data.

Step button Click to analyze a single frame and advance to the next frame.

Direction box Select to analyze forward or backward.

Snap button Click to redefine the reference at the selected frame.

Lock Key button Click to lock the selected keyframe as a point on the tracking path. Click again to unlock.

Delete Key button Click to delete the selected point on the tracking path.

Source option box Select whether to track in Progressive (frame mode) or Interlaced (field mode).

By default, the Stabilizer works in Progressive (frame mode). Select Interlaced from the Source Option box mode when working with interlaced images, or with images that display a lot of field jitter. In Interlaced (field) mode, the Stabilizer sets two keyframes for every frame: one for the even field and one for the odd field, and an asterisk appears in the image viewer's current frame display to indicate the second field for each frame.

Remove Vertical Jitter button Enable to remove vertical jitter.

Remove Horizontal Jitter button Enable to remove horizontal jitter.

Reference X field Displays the position of the reference box along the X axis. Editable.

Reference Y field Displays the position of the reference box along the Y axis. Editable.

Reference Width field Displays the width of the reference box. Editable.

Reference Height field Displays the height of the reference box. Editable.

Offset X field Displays the offset X axis value. Editable.

Offset Y field Displays the offset Y axis value. Editable.

Auto Update Reference button Enable to update the reference point at each frame during tracking. Disable to track the movement of the reference point specified in the reference frame.

Enabling Auto Update Reference is useful when tracking a pattern that changes considerably from the first frame to the last frame in the clip. For example, the pattern may be rotating or may change size or shape. In this case, disable the Auto Update Reference button. The reference point is then updated in each frame. In each frame of the analysis, the Stabilizer looks for the reference point from the previous frame.

When Auto Update Reference is disabled, the tracker box follows the movement of the reference point that you specified in the reference frame throughout the analysis.

NOTE Unless you are in Gang mode, you must set the Auto Update Reference button for each active tracker individually.

Tracker Y field Displays the position of the tracker box along the Y axis. Editable.

Tracker Width field Displays the width of the tracker box. Editable.

Tracker Height field Displays the height of the tracker box. Editable.

Import Track button Open the Import Stabilizer menu, where you to import a text file of saved tracking data.

Export Track button Click to open the Export Stabilizer menu, where you to export a text file of saved tracking data.

Shift X field Displays the difference between the position of the reference box (0,0) and the position of the tracker box in the current frame along the X axis. Editable.

Shift Y field Displays the difference between the position of the reference box (0,0) and the position of the tracker box in the current frame along the Y axis. Editable.

Import Shift button Click to open the Import Stabilizer menu to allow you to import a text file of saved shift data.

Shift Copy button Click to copy the selected Shift channel (including the aspect ratio of the clip).

Export Shift button Click to open the Export Stabilizer menu to allow you to export a text file of saved shift data.

Setup Menu

Pretracking button Enable to preview the motion path for a specified number of frames. Active when Path is enabled.

Before analysing, you can use the Pretracking option to preview the motion path for a specified number of frames. You can then adjust the tracker position, if necessary, to find the best reference point. The Pretracking option applies only to the selected tracker, regardless of whether you selected Solo, Selected, or Gang in the Tracker Selection box. If you move or resize a tracker with Pretracking enabled, the next frames are analysed.

Pretracking field Displays the number of frames to pretrack. Editable.

Auto Pan button Enable to allow the part of the image that is selected to stay in the image window when zoomed in.

Opacity field Displays the opacity of the reference image. Editable.

The reference image (the image where you placed the reference box) appears in transparency when you select a keyframe. Adjust the opacity of the image to make it more or less transparent. When the opacity is set to 0, the reference image does not appear. When the opacity is set to 100, the reference image is completely opaque.

Zoom field Displays the magnification factor of the reference box when selected. Editable.

By default, the reference box turns into a magnifying glass when you select it. Increase or reduce the magnification factor in the Zoom box.

Zoom:	Result:
0	No zooming. The crosshair appears in the tracker box after you analyse the clip.
1	No zooming and no crosshair.
2, 3, 4, 5	A magnification factor of 2, 3, 4, and 5, and a crosshair in the tracker box.

Path button Enable to display the tracking path.

The tracking path is the path that the reference point makes as it changes position from frame to frame. By default, the tracking path appears in the image window. You can turn it off by disabling the Path button.

Colour Corrector Input button Enable to display any Colour Corrector settings on the clip.

Linetest button Enable to display the context view at a lower resolution.

Stereo Filter

Use Stereo Filter to process an anaglyph, interlaced or dual image clip containing one video track from either a left and right eye mono clip, or an existing stereo track.

To access the Stereo Filter menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- The Modular Keyer, then select a node from the Node bin.

This node accepts a left eye mono clip and a right eye mono clip, and outputs an anaglyph, interlaced or dual image stereo clip. You can add a Stereo Filter node to any part of the pipeline except to the Front and Matte pipes of MBlend nodes and the Matte pipes CBlend nodes.

Stereo Filter Menu Settings

General Settings

Stereo Mode box Select a stereo mode to display the appropriate rendering method options. Different method settings appear based on the type selected.

Select:	To:
Anaglyph	Render a red/cyan clip.
Interlace	Render an interlaced RGB clip.
Dual Image	Render a clip containing adjacent images.

Method box Depending on the selected Stereo Mode, you have different options for modifying the effect.

Anaglyph Settings

Anaglyph Method box Select a method for your anaglyph result. For example, select Dubois to reduce the ghosting between the left and right eyes.

Select:	To:
Custom	Customize the RGB left and right gain factor values. With this option, you can create anaglyph results based on the 3D lenses that will be used. NOTE This option is available in Batch or Batch FX and the Modular Keyer.
Dubois	Reduce ghosting between the left and right eyes.
RGB	Create an anaglyph result based on the RGB values.
Mono	Remove the RGB values before creating an anaglyph result. With this option, you will see just the stereo effect.

Interlaced Settings

Interlace Method box Select whether your interlace result outputs the left eye input as field 1 or field 2.

Dual Image Settings

Output the left eye and right eye so that they are adjacent to each other in the same clip, either in a left and right or top and bottom orientation.

	Left			Right		
	Red	Green	Blue	Red	Green	Blue
Red Out	1.00	0.00	0.00	0.00	0.00	0.00
Green Out	0.00	0.00	0.00	0.00	1.00	0.00
Blue Out	0.00	0.00	0.00	0.00	0.00	1.00

Left and Right Custom Gain Factor Fields Displays the gain factor in the colour channel for the left eye and right eye. Enabled when Custom is selected in the Method box.

NOTE This option is available in Batch or Batch FX and the Modular Keyer.

Dual Image Method box Select whether your dual image result outputs the left eye and right eye so that they are adjacent to each other in the same clip, either in a left and right or top and bottom orientation.

Red in Red Output field Displays the red gain factor in the red channel for the Left eye. Editable.

Green in Red Output field Displays the green gain factor in the red channel for the Left eye. Editable.

Blue in Red Output field Displays the blue gain factor in the red channel for the Left eye. Editable.

Red in Green Output field Displays the red gain factor in the green channel for the Left eye. Editable.

Green in Green Output field Displays the green gain factor in the green channel for the Left eye. Editable.

Blue in Green Output field Displays the blue gain factor in the green channel for the Left eye. Editable.

Red in Blue Output field Displays the red gain factor in the blue channel for the Left eye. Editable.

Green in Blue Output field Displays the green gain factor in the blue channel for the Left eye. Editable.

Blue in Blue Output field Displays the blue gain factor in the blue channel for the Left eye. Editable.

Red in Red Output field Displays the red gain factor in the red channel for the Right eye. Editable.

Green in Red Output field Displays the green gain factor in the red channel for the Right eye. Editable.

Blue in Red Output field Displays the blue gain factor in the red channel for the Right eye. Editable.

Red in Green Output field Displays the red gain factor in the green channel for the Right eye. Editable.

Green in Green Output field Displays the green gain factor in the green channel for the Right eye. Editable.

Blue in Green Output field Displays the blue gain factor in the green channel for the Right eye. Editable.

Red in Blue Output field Displays the red gain factor in the blue channel for the Right eye. Editable.

Green in Blue Output field Displays the green gain factor in the blue channel for the Right eye. Editable.

Blue in Blue Output field Displays the blue gain factor in the blue channel for the Right eye. Editable.

Stereo Toolbox

About Stereo Toolbox

When working with Stereo3D content, it may happen that certain elements of the scene are present in one eye but not the other. When this is the case, you can apply a Floating Window that crops part of Stereo3D content that is only displayed in one eye, preserving the 3D illusion.

Specifically, the Floating Window tool has two main uses:

- To manipulate the Z-axis position of the 3D scene, without changing the overall depth bracket of the scene.
- To shape and position a floating window to mask out elements in the 3D scene.

NOTE You must be viewing the Stereo3D footage on a 3D monitor or on a 2D monitor in Anaglyph mode, in order to view the results of the Floating Window properly.

The controls allow you to position the corners of the floating window in Z-space. It also allows one, two or all four corners to be manipulated simultaneously.

There are 3 sets of parameters in the Floating Window menu:

- 1 The first set of controls consists of the Convergence slider. The convergence slider is used to set the initial horizontal offset between the left and the right eye. A higher convergence value results in a 3D scene with more depth along the Z-axis. A lower convergence value results in a 3D scene with less depth along the Z-axis.
- 2 The second set of controls consists of four numerical sliders labeled Top/Left, Top/Right, Bottom/Left and Bottom/Right.
These controls allow you to "pull in" or "push out" the corresponding corner of the Floating Window. This translates to a black mask being drawn on the edges of the image in the left or the right eye. Depending on whether the slider value is positive or negative, they affect each eye's mask differently. For example:
 - Increasing the value of the Top/Left slider results in the Floating Window's corner being "pushed out" away from the viewer. The mask is applied on the left edge of the right eye in that case.
 - Decreasing the value of the Top/Left slider results in the Floating Window's corner being "pulled in" towards the viewer. When the values are negative, the corner is in theater space (i.e. virtually in front of the monitor) and a black edge becomes visible on the left edge of the left eye.
 - The other controls affect the Floating Window in the same way. Increasing the value of a slider "pushes out" the corresponding corner of the Floating window, whereas decreasing the value results in the corner being "pulled in".
- 3 The third set of controls will affect the Post-Render-Shift (PRS) value, which effectively displaces the whole scene (including the Floating Window) along the Z-axis.
The PRS is implemented as a horizontal translation of one, or both eyes. You can select which eye remains fixed by selecting a value from the Alignment box. 'Align Left' applies the PRS entirely to the right eye, while Align Right applies it to the left eye and Center applies it to both eyes.
Aux and Offset values are simply additive extensions of the PRS value. For example, if you have PRS=1, Offset=2 and Aux=4, the overall PRS value is 7.

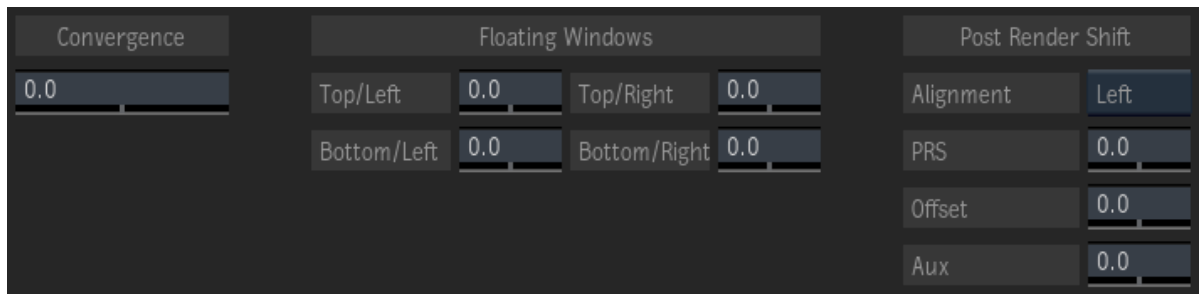

All the slider values can be animated.

Accessing the Stereo Toolbox

To access the Stereo Toolbox use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.

Stereo Toolbox Menu Settings

Convergence Settings

Convergence field Set the initial horizontal offset between the left and the right eye. A higher convergence value results in a 3D scene with more depth along the Z-axis. A lower convergence value results in a 3D scene with less depth along the Z-axis.

Floating Windows Settings

Top/Left field Affects the displacement value of the Top/Left corner of the Floating Window. Increasing the value results in the Floating Windows's Top/Left corner being "pushed out" away from the viewer. Decreasing the value results in the Floating Window's Top/Left corner being "pulled in" towards the viewer.

Bottom/Left field Affects the displacement value of the Bottom/Left corner of the Floating Window. Increasing the value results in the Floating Windows's Bottom/Left corner being "pushed out", away from the viewer. Decreasing the value results in the Floating Window's Bottom/Left corner being "pulled in", towards the viewer.

Top/Right field Affects the displacement value of the Top/Right corner of the Floating Window. Increasing the value results in the Floating Windows's Top/Right corner being "pushed out", away from the viewer. Decreasing the value results in the Floating Window's Top/Top Right corner being "pulled in", towards the viewer.

Bottom/Right field Affects the displacement value of the Bottom/Right corner of the Floating Window. Increasing the value results in the Floating Windows's Bottom/Right corner being "pushed out", away from the viewer. Decreasing the value results in the Floating Window's Bottom/Right corner being "pulled in", towards the viewer.

Post Render Shift Settings

Alignment box Select whether the offsets affect the Left, Right, or both eyes (Center).

PRS field Affects the horizontal translation offset value applied between the two shots in the scene. This parameter is relative to the setting if the Alignment box.

Offset field Affects the horizontal translation offset value applied between the two shots in the scene. This parameter is relative to the setting if the Alignment box.

Aux field Affects the horizontal translation offset value applied between the two shots in the scene. This parameter is relative to the setting if the Alignment box.

Stylize

Use Stylize on an image sequence to create a wide range of visual styles, including painting, printing and sketching. Stylize allows you to build your look by stacking layers with different effects.

Stylize includes a collection of 10 core effects that are stacked and blended together as layers. The core effects fall into four major categories: canvas texture, patterns, colour fillings, and outlines. Each of the core effects has its own settings, which display when an effect is selected:

- Canvas
- Dots
- Hatch Pattern
- Palette Reduction
- Colour Smudge
- Drawing
- Selective Drawing
- Sketched Outlines
- Scribbled Outlines
- Sharp Outlines

Since the possible combinations of core effects are endless, over 80 presets are available to help you get started with Stylize. These presets can also help you learn how Stylize layer stacking works. The presets are divided into a number of categories and are easily added to your scene.

To access the Stylize menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Tools, then select from the menu.

This node accepts a front, back and matte clip, and outputs a result and an outmatte result.

Stylize Menu Settings

Using Stylize Presets

Use the Stylize presets to create a specific look or to create a starting point to build your effect. Presets are available in 4 categories: Comic, Paint, Print, and Sketch.

Presets button Opens the Presets browser where you can select a preset.

TIP In the browser, switch to Proxies view (press **P**) to see a visual representation of the preset.

Presets dropdown list Select a preset from the dropdown list. Menu settings are changed to reflect the chosen preset.

Setup and General Settings

Clamp Input box Select a clamping option for colour and luminance values on input in the 16-bit floating point rendering pipeline.

Clamp Output box Select a clamping option for colour and luminance values on output in the 16-bit floating point rendering pipeline.

Regen button Enable to dynamically refresh the image as settings are changed.

Layer Table Settings

Use the Layer Table to organize the layers that make up your Stylize effect. The top layer in the Layer Table has the highest priority in the overall effect. Selecting a preset populates the Layer Table with the necessary layers and settings.

Priority		Name	Effect	Blend	Matte	Transp
	Up	layer3	Hatch Pattern ↕	Subtract ↕	Invert ↕	20.0%
		layer2	Sketched Outlines ↕	Blend ↕	On ↕	0.0%
	Down	layer1	Drawing ↕	Spotlight Blend ↕	On ↕	0.0%
Solo						
Seed 0.0 Add Copy Delete Rename Reset Background						

Visibility column Displays the visibility of each layer. Click the eye icon to change a layer from visible to invisible or vice-versa.

Name column Displays the name of the layer. Click the Rename button to change the name of a selected layer.

Effect column Displays the effect applied per layer. Use the scroll arrows to change the effect. Different settings appear based on the effect chosen.

Blend column Displays the blend operation per layer. Use the scroll arrows to change the blend value.

Matte column Displays whether a matte is on, off, or inverted per layer. Use the scroll arrows to change the value.

Transparency column Displays the transparency level per layer. Scroll to change the value, or click to display the calculator.

Priority Up button Click to move the selected layer up in priority in the layer list.

Priority Down button Click to move the selected layer down in priority in the layer list.

Solo button Enable to hide all other layers except the selected layer. You can also turn specific layers on or off using the eye icon on the left of each layer.

Seed field Displays the random seed variation value to use in the stylize effect. Editable.

Add button Click to add a new layer to the layer list.

Copy button Click to copy the existing layer to a new layer.

Delete button Click to delete the selected layer from the layer list.

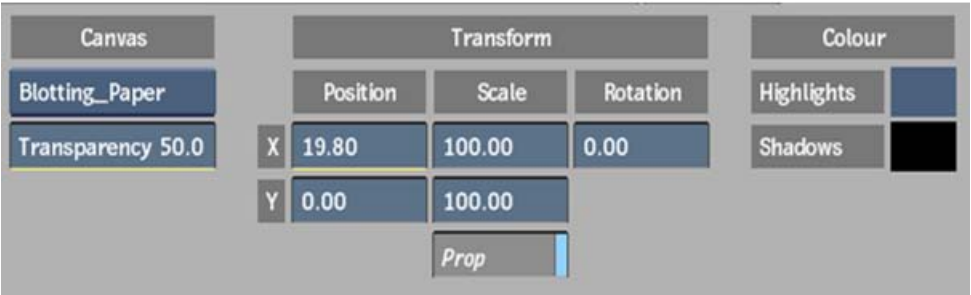

Rename button Click to open the online keyboard to rename the selected layer in the layer list.

Reset button Click to reset all of the attributes associated with the selected layer and returns them to default values.

Background colour pot Displays the background colour used in a blending operation. Click to change the colour.

Canvas Effect Settings

These settings are available when a layer is selected in the Layer Table with Canvas as the effect.

Pattern Type box Select a pattern type to apply to the image.

Transparency field Displays the percentage of transparency applied to the Canvas effect. Editable.

Position X field Displays the position of the pattern along the horizontal axis. Editable.

Position Y field Displays the position of the pattern along the vertical axis. Editable.

Scale X field Displays the change in size of the pattern along the horizontal axis. Editable.

Scale Y field Displays the change in size of the pattern along the vertical axis. Editable.

Proportional button Enable to change the scale fields proportionally.

Rotation field Displays the angle of rotation of the pattern along the Z-axis, from its centre point. Editable.

Highlights colour pot Displays the colour applied to the light areas of the Canvas effect. Click to change the colour.

Shadows colour pot Displays the colour applied to the dark areas of the Canvas effect. Click to change the colour.

Dots Effect Settings

These settings are available when a layer is selected in the Layer Table with Dots as the effect.

Dots		Shape	Print on Colour
Colour 		Square	Tolerance 75.00%
Scale 10.00		Scale 1.00	Colour Selection
Angle 0.00		Angle 0.00	User GrayScale
Softness 40.00		Ratio 1.00	

Effect colour pot Displays the colour applied to the effect. Click to change the colour.

Scale field Displays the change in size of the effect. Editable.

Angle field Displays the change in the angle applied to the effect. Editable.

Softness field Displays the change in softness applied to the effect. Editable.

Shape box Select the shape of the Dots effect.

Scale field Displays the size of the Dots shapes. Editable.

Angle field Displays the change in angle of the Dots shapes. Editable.

Ratio field Displays the change in ratio of the Dots shapes. Editable.

Tolerance field Displays the tolerance level applied to the colour selection of the effect. Editable.

Colour Selection option box Select an option to apply a colour to the image.

Colour Selection colour pot Displays the colour applied to the image. Click to change the colour. Only active if User Colour or User GrayScale is selected.

Blur field Displays the amount of blur applied to the input image before other effects are applied. Editable.

Hatch Pattern Effect Settings

These settings are available when a layer is selected in the Layer Table with Hatch Pattern as the effect.

Hatch Pattern	Shape	Print on Colour	Source
Colour 	Threshold 10.00	Tolerance 50.00%	Blur 0.00
Scale 10.00	Thickness 20.00	Colour Selection	
Angle 0.00	Variation 10.00%	User Colour	
Softness 40.00			

Effect colour pot Displays the colour applied to the effect. Click to change the colour.

Scale field Displays the change in size of the effect. Editable.

Angle field Displays the change in the angle applied to the effect. Editable.

Softness field Displays the change in softness applied to the effect. Editable.

Threshold field Displays the amount of colour constraint applied to the shape. Editable.

Thickness field Displays the amount of thickness applied to the shape. Editable.

Variation field Displays the percentage of variance applied to the shape. Editable.

Tolerance field Displays the tolerance level applied to the colour selection of the effect. Editable.

Colour Selection option box Select an option to apply a colour to the image.

Colour Selection colour pot Displays the colour applied to the image. Click to change the colour. Only active if User Colour or User GrayScale is selected.

Blur field Displays the amount of blur applied to the input image before other effects are applied. Editable.

Palette Reduction Effect Settings

These settings are available when a layer is selected in the Layer Table with Palette Reduction as the effect.

Palette Reduction	Warp Pattern	Pattern Transform			Source
Colours 63	Alveolus	Position	Scale	Rotation	Blur 0.00
Single Palette	Amount 10.00	X 0.00	100.00	0.00	
Frame 2		Y 0.00	100.00		
Softness 0.00			Prop		

Colours field Displays the number of colours applied to the Palette Reduction effect. Editable.

Palette box Select between Single Palette to display image stability by using a single colour palette as a reference, and Dynamic Palette to display image transition by using a new colour palette at each frame.

Frame field Displays the frame selected when Single Palette is enabled in the Palette box. Editable.

Softness field Displays the amount of softness applied to the Palette Reduction effect. Editable.

Pattern Type box Select a pattern type to apply to the image.

Amount field Displays the amount of the selected warp pattern that is applied to the image. Editable.

Position X field Displays the position of the pattern along the horizontal axis. Editable.

Position Y field Displays the position of the pattern along the vertical axis. Editable.

Scale X field Displays the change in size of the pattern along the horizontal axis. Editable.

Scale Y field Displays the change in size of the pattern along the vertical axis. Editable.

Proportional button Enable to change the scale fields proportionally.

Rotation field Displays the angle of rotation of the pattern along the Z-axis, from its centre point. Editable.

Blur field Displays the amount of blur applied to the input image before other effects are applied. Editable.

Colour Smudge Effect Settings

These settings are available when a layer is selected in the Layer Table with Colour Smudge as the effect.

Amount field Displays the amount of Colour Smudge effect that is applied to the image. Editable.

Distortion field Displays the amount of distortion applied to the Colour Smudge effect. Editable.

Emboss colour pot Displays the colour applied to the embossing. Click to change the colour.

Amount field Displays the amount of embossing applied to the image. Editable.

Softness field Displays the amount of softness applied to the embossing. Editable.

Angle field Displays the angle applied to the embossing. Editable.

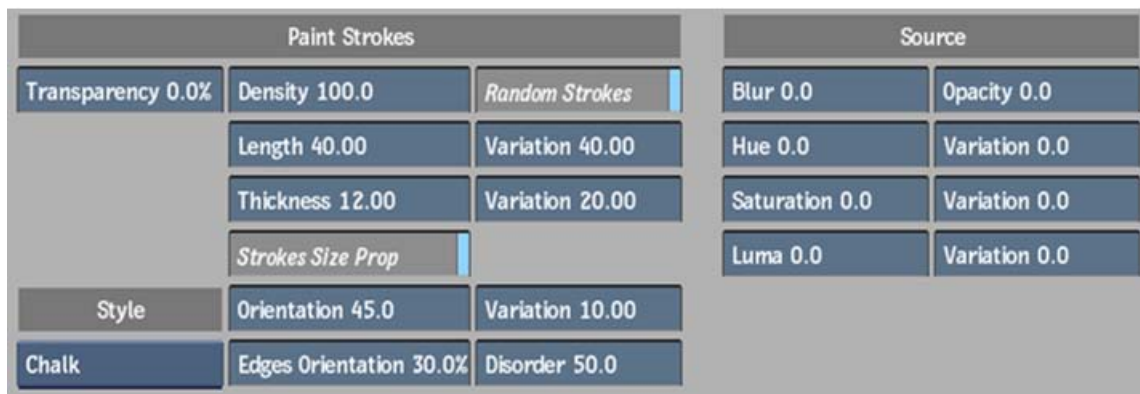

Anti-Aliasing Active button Enable to use anti-aliasing on the edges of the image.

Anti-Aliasing Samples box Select an option to determine the size of the samples. Available when anti-aliasing is enabled.

Anti-Aliasing Softness field Displays the amount of softness applied to the anti-aliasing. Available when anti-aliasing is enabled. Editable.

Drawing Effect Settings

These settings are available when a layer is selected in the Layer Table with Drawing as the effect.

Transparency field Displays the percentage of transparency applied to the paint strokes. Editable.

Style Type box Select the style type of the paint strokes.

Density field Displays the amount of density applied to the paint strokes. Editable.

Length field Displays the length applied to the paint strokes. Editable.

Length Variation field Displays the amount of variance applied to the length of the paint strokes. Editable.

Thickness field Displays the amount of thickness applied to the paint strokes. Editable.

Thickness Variation field Displays the amount of variance applied to the thickness of the paint strokes. Editable.

Paint Each Frame button Enable to apply a random variation in the length and thickness values.

Preserve Stroke Ratio button Enable to allow proportional values to be applied to the length and thickness of paint strokes.

Orientation field Displays the orientation applied to the paint strokes. Editable.

Orientation Variation field Displays the amount of variance applied to the orientation of the paint strokes. Editable.

Edges Orientation field Displays the percentage orientation applied to the edges of the paint strokes. Editable.

Disorder field Displays the amount of random distribution applied to the paint strokes. Editable.

Blur field Displays the amount of blur applied to the input image before other effects are applied. Editable.

Opacity field Displays the amount of opacity applied to the input image before other effects are applied. Editable.

Hue field Displays the amount of hue applied to the input image before other effects are applied. Editable.

Hue Variation field Displays the amount of variance applied to the hue. Editable.

Saturation field Displays the amount of saturation applied to the input image before other effects are applied. Editable.

Saturation Variation field Displays the amount of variance applied to the saturation. Editable.

Luminance field Displays the amount of luminance applied to the input image before other effects are applied. Editable.

Luminance Variation field Displays the amount of variance applied to the luminance. Editable.

Selective Drawing Effect Settings

These settings are available when a layer is selected in the Layer Table with Selective Drawing as the effect.

Paint Strokes			Selective Inclusion		Source	
Transparency 0.0%	Density 3.00	Random Strokes		Tolerance 100.0	Blur 0.0	Opacity 0.0
Color 	Length 40.00	Variation 40.00	Selective Exclusion		Hue 0.0	Var 0.0
Front Mix 0.00	Thickness 12.00	Variation 20.00		Tolerance 5.0%	Sat 0.0	Var 0.0
	Strokes Size Prop 		Selective Global		Luma 0.0	Var 0.0
Style	Orientation 45.0	Variation 10.00	Use Colour 	Softness 100.0%		
Pencil	Edges Orientation 30.0%	Disorder 50.0	Length 50%	Thickness 50%		

NOTE Most of the settings in the Paint Strokes section are the same as for the Drawing effect. Selective Drawing also has two extra settings.

Paint Strokes colour pot Displays the colour applied to the paint strokes. Click to change the colour.

Front Mix field Displays the amount of colour from the source image that is visible. Editable

Inclusion colour pot Displays the colour on which the paint strokes are created. Click to change the colour.

Inclusion Tolerance field Displays the percentage of tolerance applied to the selected colour. The higher the tolerance, the more paint strokes are created. Editable.

Exclusion colour pot Displays the colour on which the paint strokes are eliminated. Click to change the colour.

Exclusion Tolerance field Displays the percentage of tolerance applied to the selected colour. The higher the tolerance, the more paint strokes are eliminated. Editable.

Global Colour box Switch between the use of colour selections or grayscale versions of these colour selections.

Global Length field Displays the percentage of length by which semi-transparent strokes are modified. Editable.

Global Softness field Displays the percentage by which the range of transparency of semi-transparent strokes is modified. Editable.

Global Thickness field Displays the percentage by which the range of thickness of semi-transparent strokes is modified. Editable.

NOTE The settings in the Front Controls section are the same as for the Drawing effect.

Sketched Outlines Effect Settings

Edge Detect	Outlines				Source	
Threshold	Transparency 0.0%	Density 1.00	Random Strokes		Blur 0.0	Opacity 0.0
Min 0.00	Colour 	Length 40.00	Variation 30.00		Hue 0.0	Variation 0.0
Max 100.00	Front Mix 0.00%	Thickness 12.00	Variation 20.00		Saturation 0.0	Variation 0.0
Softness		Strokes Size Prop			Luma 0.0	Variation 0.0
Width 0.00	Style	Orientation 0.0	Variation 10.0			
Gain 100.00	Pencil	Follow Edges 100.0%				

These settings are available when a layer is selected in the Layer Table with Sketched Outlines as the effect.

Minimum Threshold field Displays the minimum amount of colour restraint applied to the outline edges. Editable.

Maximum Threshold field Displays the maximum amount of colour restraint applied to the outline edges. Editable.

Softness Width field Displays the amount of softness applied to the width of the edges. Editable.

Softness Gain field Displays the amount of softness applied to the gain of the edges. Editable.

Transparency field Displays the percentage of transparency applied to the outlines. Editable.

Outlines colour pot Displays the colour applied to the outlines. Click to change the colour.

Front Mix field Displays the percentage of colour from the source image that is visible. Editable.

Style Type box Select the style type of the outlines.

Density field Displays the amount of density applied to the outlines. Editable.

Paint Each Frame button Enable to apply a random variation in length and thickness values.

Length field Displays the length applied to the outlines. Editable.

Length Variation field Displays the variance applied to the length of the outlines.

Thickness field Displays the amount of thickness applied to the outlines. Editable.

Thickness Variation field Displays the variance applied to the thickness of the outlines.

Preserve Stroke Ratio button Enable to allow proportional values to be applied to the length and thickness for the outlines.

Orientation field Displays the orientation applied to the outlines. Editable

Orientation Variation field Displays the variance applied to the orientation of the outlines.

Follow Edges field Displays the percentage by which the outlines follow their original position. Editable.

NOTE The settings in the Front Controls section are the same as for the Drawing effect.

Scribbled Outlines Effect Settings

The Edge Detect, Softness, and Front Controls settings are the same as for the Sketched Outline effect. Some of the Outlines settings are similar also. The following Outlines settings are specific to the Scribbled Outlines effect.

Edge Detect	Outlines			Source	
Threshold	Transparency 0.0%	Smallest Details 25.00	Random Strokes	Blur 0.0	Opacity 0.0
Min 0.00	Colour	Longest Outlines 100.00		Hue 0.0	Variation 0.0
Max 100.00	Front Mix 0.00%	Thickness 8.00	Variation 20.00	Saturation 0.0	Variation 0.0
Softness		Strokes Size Prop		Luma 0.0	Variation 0.0
Width 0.00	Style	Straight Lines 8.00			
Gain 100.00	Pencil	Pressure 60.00			

Smallest Details field Displays the amount by which the smallest outlines will be filtered out. Editable.

Longest Outlines field Displays the amount by which the length of the longest outlines will be increased. Editable.

Straight Lines field Displays the amount of the straightest outlines that are visible. Editable.

Pressure field Displays the variation in the pressure applied to the outlines. Varies with the style of the outline. Editable.

Sharp Outlines Effect Settings

The Edge Detect, Softness, Outlines, and Front Controls settings are the same as for the Sketched Outline effect. The Pattern Transform settings are the same as for the Canvas effect. The following Warp Pattern settings are specific to the Sharp Outlines effect.

Pattern Type box Select a pattern type to apply to the image.

Amount field Displays the amount of warp applied to the image. Editable.

Substance Noise and Splatter

The Substance nodes are procedural noise pattern generators, allowing you to create highly-customizable, repeatable patterns such as cells or concentric shapes to use in your Batch or Batch FX process tree.

Substance Noise node: Use this node to generate a noise pattern based on a chosen preset to use as an input for other nodes.

Substance Splatter node: This node accepts front and matte inputs as the seed that you feed through a chosen preset pattern.

To access the Substance nodes:

- 1 Drag the Substance Noise node or Substance Splatter node to the Batch or Batch FX schematic.

The file browser appears, pointing to the default location of the presets:

- `usr/discreet/<product home>/substance_presets/NOISE` or
- `usr/discreet/<product home>/substance_presets/SPLATTER`

TIP Switch to Proxies view to see a visual representation of the presets.

- 2 Select a preset.

NOTE The Splatter presets include normal and additive blend versions.

The preset is automatically loaded into Batch or Batch FX.

- 3 If you are working with a Substance Splatter node, attach front and matte input clips.
- 4 Double-click the Substance node in the schematic to access the menu.
Some of the settings in the menu are dependant on the preset you loaded.
- 5 Change the menu settings, as needed. Enable Regen to update the image as fields are updated.
- 6 Optional: Enable Force Tile to ensure that your resulting image tiling is repeatable. In this case, the Crop Output and Zoom options are greyed out.

NOTE If your rendering network is set up with GPU-enabled Burn nodes, you can burn Substance clips. See your *Autodesk Burn Installation and User Guide* for installation and configuration information.

To change a Substance preset:

- 1 Select the Substance Noise or Substance Splatter node in the schematic.
- 2 Click Change Preset.

The file browser appears, and you can select a different preset to load.

NOTE All menu parameters are reset when a new preset is loaded.

Setting Substance Parameters and Behaviours

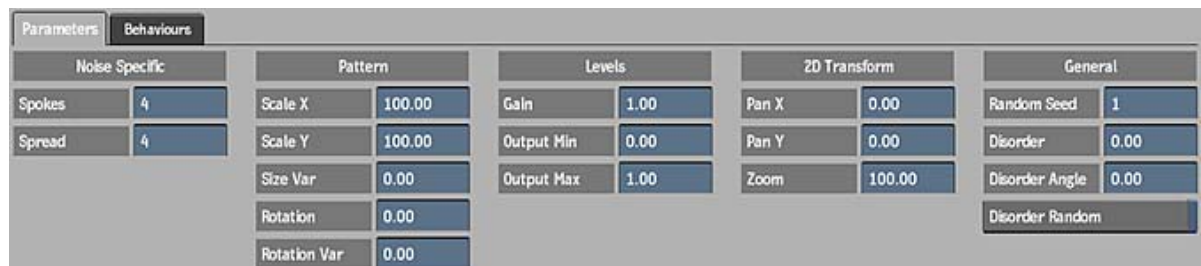

Once you have loaded your preset, you can use the Parameters and Behaviours settings in the Substance menu to change and animate the pattern.

Some of the settings in the Parameters tab vary depending on the chosen preset, while other settings, such as Zoom, Random Seed, and Disorder are present in every Substance preset. You can get a quick description of each setting by viewing its tooltip.

NOTE If Force Tile is enabled, the Zoom field is greyed out.

Example of Noise parameters

Example of Splatter parameters

Use the settings in the Behaviours tab to apply preset motion to your pattern, and to help you quickly animate your patterns. For example, you can choose a Flow behaviour and animate your pattern to resemble a flag waving.

The behaviours are divided into a number of categories, each with their own settings.

Organic Pulse Slow pulsing evolution of width and height of the pattern.

Wind Directional force that spins the pattern with intensity.

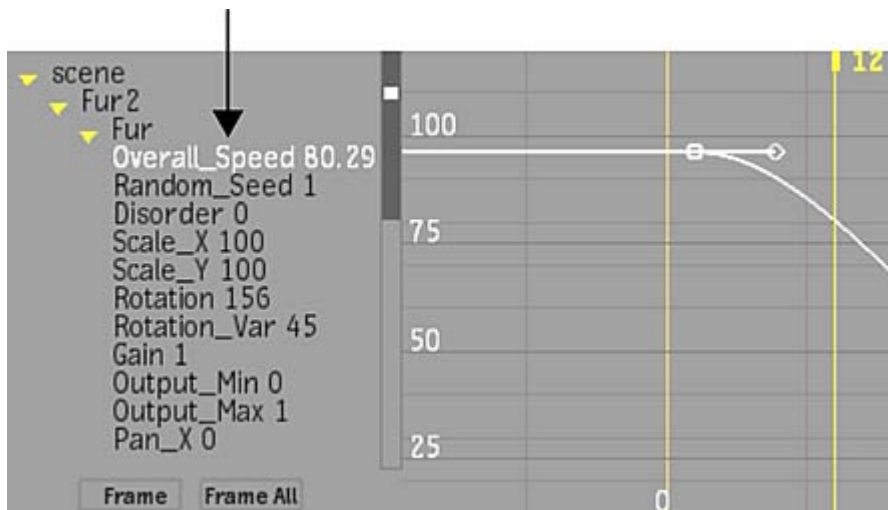

Flow Directional force that displaces the pattern in different direction.

Oscillation Evolution of size and luminance of the pattern.

Wave Distort Directional warping effect that deforms the pattern with different wavelength warps.

You can adjust the playback rate and timing of your chosen behaviour animation by using the Overall Speed and Time Offset settings (available for all behaviours).

You can also adjust the Overall Speed in the Channel Editor.

Substance Menu Settings

Preset Selection Settings

Preset Name field This locked field displays the name of the current preset.

Change Preset button Click to open the file browser to select a different preset.

Preset Memory Settings

The Memory section of the Noise or Splatter menu allows you to store up to five variations of the current preset. This is useful if you want to compare a certain preset type with different settings and animations.

Use the following preset memory buttons to clear, store, or recall menu parameters. A blue LED indicates that a preset memory is stored in the slot.

(a) Preset stored in this preset memory slot **(b)** No presets stored in these slots

Clear button Clears the selected preset memory.

Store button Stores the menu parameters in the selected preset memory.

Recall button Recalls the last stored parameters for the selected preset memory.

Preset Memory buttons Use to clear, store, or recall menu parameters. A blue LED indicates that a preset memory is stored in the slot.

Proxy image window Displays a proxy of the stored preset memory.

Output Settings

Use the settings in the Output section to set the size and resolution of clips that are output from the Substance node.

Texture Resolution box Select the resolution of the pattern.

Bit Depth box Select the render/output bit depth of clips.

Crop Output button Enable to crop the output of the pattern by the amounts displayed in the Width and Height fields.

NOTE The crop options are greyed out if the Force Tile button is enabled.

Ratio field Displays the aspect ratio of the pattern clip. The ratio is calculated by W:H to output a square pixel ratio. Non-editable.

Crop Width field Displays the width of the cropped output. Editable.

Crop Height field Displays the height of the cropped output. Editable.

Splatter Pattern Resize Settings

Use the Pattern Resize settings to change the input size and filtering type of a Splatter pattern.

Pattern Resize box Select the input size of the Splatter pattern.

Filter box Select a resize filtering option.

Other Settings

Regen button Enable to automatically update the image as fields are updated.

Force Tile button Enable to ensure that your resulting image tiling is repeatable. In this case, the Crop Output and Zoom options are greyed out.

Behaviours Settings

Behaviour Type box Select the type of preset motion to apply to the pattern.

Overall Speed field Displays the rate at which the animation plays. Editable.

Time Offset field Displays the start point of the animation. With a value of 0, the animation starts at frame 1. With a value of 100, the animation begins as if it has been generating for 99 frames. You cannot animate this field. Editable.

Text

Use Text to make text spin, dance, and change colour over time.

To access the Text menu, use:

- Batch, then select a node from the Node bin.
- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).
- Tools, then select from the menu.

This node accepts a background clip. If a background clip is not connected to the Text node, you can select a resolution for the output of the Text node. Additionally, this node outputs a result and an outmatte.

NOTE The Prerender Text preference does not apply when you access Text from Batch or Batch FX.

Text is compromised of layers, paragraphs, and characters. You can create effects such as a text roll of credits, text crawls, bumpers, and a text that moves on a motion path. You can also use logo images in a text roll so that the logo of a sponsor appears in the credit list.

Text Menu Settings

Timeline FX Quick Menu Settings

To see the full Text menu, click the Editor button.

Alpha Rendering Mode box Select whether a front clip, matte, or both are used to create the text layer.

General Settings

Use Transparency button Enable to create a text effect in which the background clip is used as the text's fill. Also select RGBA from the Alpha Rendering Mode box.

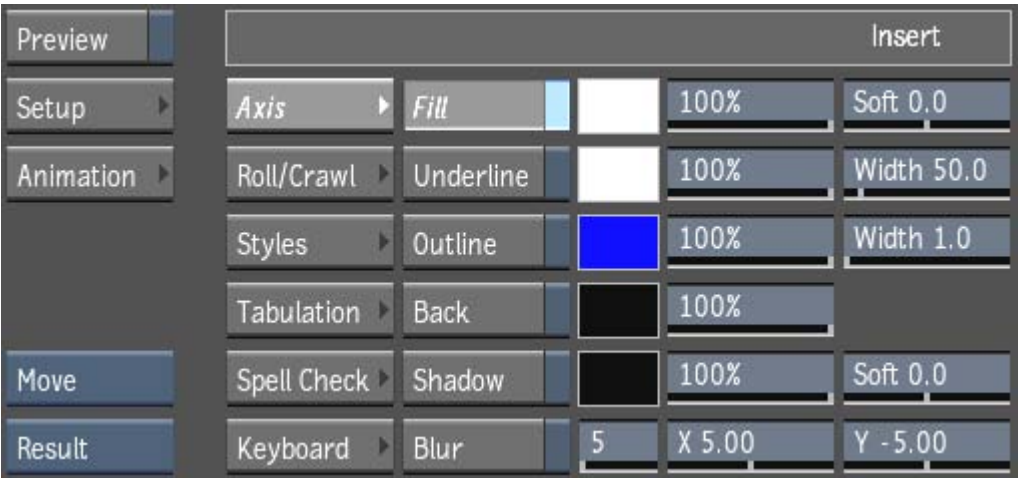

Rendering Mode box Select whether to render in Automatic, Progressive or Interlaced mode.

Preview button Enable to preview the text effect.

Preview Options box This box is available when you access the Text Menu settings from the Timeline. Select to enable Preview FX or Context, to preview the effect.

Setup button Displays the Text Setup menu.

See [Setup and Rendering Options](#) (page 1140).

(a) Setup button (b) Animation button (c) Attribute controls (d) Text Mode box

Attribute controls Changes the appearance of text by setting properties such as fill and shadow. See [Creating Text Effects](#) (page 1148).

Animation button Creates a text animation by setting different text properties at specific keyframes in a clip.

See [Animating Text](#) (page 1157).

Text Mode button Select a text mode to select text, edit text in layers, modify text attributes, or enter text strings.

Applies various text settings to layers, paragraphs, and characters. Use text modes to manipulate layers, add text to a clip, or edit existing text in a clip. See [Modifying Layer and Character Properties](#) (page 1148).

Result button Select an option to set the view to either the composited text, the matte of the text, or the original back clip.

Reset box Select an option to reset the selected text layer, the layer axis, the roll/crawl, or the style templates.

Reset All Click to reset the text tool to the default values set in Preferences.

Edit button Opens the Edit menu.

Resolution Presets box Select a resolution for the new clip. Select Custom to specify a non-standard resolution.

Bit Depth box Select the render/output bit depth of clips.

Scan Mode box Select the scan mode of clips.

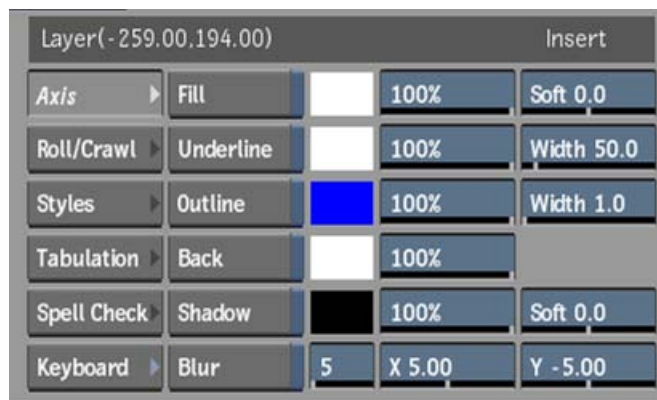

Width field Displays the custom width resolution of the clip. Editable.

Height field Displays the custom width resolution of the clip. Editable.

Aspect Ratio Presets box Select a standard frame aspect ratio. Select the Set to w:h option to set the clip to use square pixels. Select Custom to define a custom frame aspect ratio in the Aspect Ratio field.

Aspect Ratio field Displays the custom render/output aspect ratio. Editable

Insert Settings

Axis button Opens the Axis menu to set properties for layers and characters.

Roll/Crawl button Open the Roll/Crawl menu to set text motion properties for vertical or horizontal text scrolling.

See [Creating Text Rolls and Text Crawls](#) (page 1154).

Styles button Opens the Styles menu to create preset text style formats.

See [Defining Styles](#) (page 1163)

Tabulation button Open the Tabulation menu to set text tabs.

See [Tabulating Text](#) (page 1153)

Spell Check button Open the Spell Check menu to check text for spelling errors.

See [Spell Checking](#) (page 1154)

Keyboard button Opens the on-screen keyboard to enter text.

See [Entering Text](#) (page 1145)

Fill button Enable to use fill on the text selection.

Sets fill colour, transparency, and softness. Set fill softness using the Soft field. To increase the softness, enter a value close to the maximum of 100. To decrease the softness, enter a value close to the minimum of -100. Enter 0 for no softness.

Fill colour pot Displays the colour of the fill. Editable.

Fill Transparency field Displays the transparency level of the fill. Editable.

Fill Softness field Displays the softness level of the fill. Editable.

Underline button Enable to underline the text selection.

Underlines the characters using the associated colour, transparency, and width. Click the colour pot to choose a colour from the colour picker. To set underline transparency, enter a percentage in the Transparency field. To make the underline more opaque, enter a value close to the maximum of 100. To make the underline more transparent, enter a value close to the minimum of 0. To set the outline width, enter a value in the Width field.

Underline colour pot Displays the colour of the underline. Editable.

Underline Transparency field Displays the transparency level of the underline. Editable.

Underline Width field Displays the width of the underline. Editable.

Outline button Enable to outline the text selection.

Outlines the characters with a solid colour using the associated colour, transparency, and width. Click the colour pot to choose a colour from the colour picker. To set outline transparency, enter a percentage in the Transparency field. To make the outline more opaque, enter a value close to the maximum of 100. To make the outline more transparent, enter a value close to the minimum of 0.

To set the outline width, enter a value in the Width field. Use anti-aliasing rendering options with outlined text. These options are found in the Text Setup menu. See [Setup and Rendering Options](#) (page 1140).

Outline colour pot Displays the colour of the outline. Editable.

Outline Transparency field Displays the transparency level of the outline. Editable.

Outline Width field Displays the width of the outline. Editable.

Back button Enable to apply a solid colour background using the associated text layer colour and transparency to the text selection.

Click the colour pot to choose a colour from the colour picker. To set back transparency, enter a percentage in the Transparency field. To make the back more opaque, enter a value close to the maximum of 100. To make the back more transparent, enter a value close to the minimum of 0.

Back colour pot Displays the colour of the background. Editable.

Back Transparency field Displays the transparency level of the background. Editable.

Shadow button Enable to apply a drop shadow to the text selection.

Applies a shadow to text characters using the associated colour, softness, transparency, and Pos X and Pos Y fields. Click the colour pot to choose a colour from the colour picker. To set shadow transparency, enter a percentage in the Transparency field. To make the shadow more opaque, enter a value close to the maximum of 100. To make the shadow more transparent, enter a value close to the minimum of 0. To set shadow softness, use the Soft field. To increase the softness, enter a value close to the maximum of 100. Enter 0 for no softness.

To set the shadow position on the X-axis, enter a value in the X field. A positive value places the shadow to the right and behind the text characters. A negative value places the shadow to the left and in front of the text characters. To set the shadow position on the Y-axis, enter a value in the Y field. A positive value moves the shadow up. A negative value moves the shadow down.

Shadow colour pot Displays the colour of the shadow. Editable.

Shadow Transparency field Displays the transparency level of the shadow. Editable.

Shadow Softness field Displays the softness level of the shadow. Editable.

Shadow X field Displays the shadow position along the X-axis.

Shadow Y field Displays the shadow position along the Y-axis.

Blur Shadow button Enable to apply a blur effect to a drop shadow created with the Shadow button.

The type of blur applied depends on whether Box Blur or Gaussian Blur is selected in the Text Setup menu. Choose a higher value for a greater shadow blur effect. Using Blur Shadow with animated text decreases processing performance.

Blur Shadow field Displays the level of blur applied to the drop shadow. Editable.

Font Settings

Font field Displays the current font. Click to open the font browser to select a different font.

Font Reset button Resets to the default font.

Font Size field Displays the character size for the selected font. Editable.

Font Italic field Displays the angle of italicized text. Positive values make the characters slope to the right. Negative values make them slope to the left.

Font Kerning field Displays the amount of spacing between characters. Positive values increase the spacing. Negative values decrease the spacing.

Paragraph Settings

Justification box Select an alignment option for the paragraph.

Select Left, Right, Centre, or Justified.

Width field Displays the width of the layer. Editable.

Left Margin field Displays the amount of space in the left margin. Editable.

Leading field Displays the space between lines in the selected paragraph. Editable.

Indent field Displays the left indentation value for the first line in the paragraph. Editable.

Separation field Displays the space between the selected paragraph and the one above it. Editable.

Character Channels

Copy Attributed button Copies attribute settings from the selected text character.

Copy Transformations button Copies transformation settings from the selected text character.

Copy Transformations button Copies transformation settings from the selected text character.

Paste button Pastes any copied text character channel information.

Text on Path

On Path button Enable to place the selected text on a motion path.

Closed button Enable to close the path by connecting the first and last vertices. Text continues around the shape.

Offset field Displays the position of the text on the path. Animate the Offset value to make the text follow the path for the duration of the clip.

Invert button Reverses the order of the vertices on the path so that the text follows the opposite side of the path.

Text On Path Mode box Select an option to manipulate the selected path spline.

Clear button Resets the text path at the current frame. To reset the path for the entire duration of the clip, click Reset Layer.

Axis Settings

NOTE The Axis settings are available when the Axis button is enabled in the Insert settings.

Axis menu buttons Select whether to display the Layer Axis menu or the Characters Axis menu.

Show Axis button Enable to display the axis in the image window. This button is only available when the Character Axis menu button is selected.

Position X field Moves the layer or selected characters along the X-axis. By default, the value is 0 (for characters). Increase the value to move right and decrease it to move left. Editable .

Y Position field Moves the layer or selected characters along the Y-axis. By default, the value is 0 (for characters). Increase the value to move up and decrease it to move down. Editable .

Lock Position button Enable to lock the position of the text layer. You can lock text in either the Top/Left or Centre position using the box beside this button.

Centre Axis button Moves the axis to the center point of the character. This button is only available when the Character Axis menu button is selected.

X Position Character Axis field Sets the X-axis for the selected characters. Set each letter in a word spinning on its own axis in a different way. This button is only available when the Character Axis menu button is selected.

Using the Axis Pos X field, you set each letter in a word spinning on its own axis in a different way.

Y Position Character Axis field Sets the Y-axis for the selected characters. Set each letter in a word spinning on its own axis in a different way. This button is only available when the Character Axis menu button is selected.

Using the Axis Pos Y field, you set each letter in a word spinning on its own axis in a different way.

X Scale field Scales the layer or selected characters along the X-axis. This value is a percentage, so entering 50 means 50 percent. Use a larger value to increase the scale along the X-axis. Use a negative value to create a mirror image on the X-axis. Enter 0 to make a layer or selected characters disappear. The default is 100. Editable.

Y Scale field Scales the layer or selected characters along the Y-axis. This value is a percentage, so entering 50 means 50 percent. Use a larger value to increase the scale along the Y-axis. Use a negative value to create a mirror image on the Y-axis. Enter 0 to make a layer or selected characters disappear. The default is 100. Editable.

Proportional Scale button Proportionally changes the Scale X and Y values.

X Shear field Shears or slants the layer or selected characters along the X-axis. Use a positive value to slant right and a negative value to slant left. The maximum and minimum values are 60 and -60, respectively. The default value is 0.

Y Shear field Shears or slants the layer or selected characters along the Y-axis. Use a positive value to slant right and a negative value to slant left. The maximum and minimum values are 60 and -60, respectively. The default value is 0.

Rotation field Rotates a layer around its axis or selected characters around their axis. Use a negative value to rotate clockwise and a positive value to rotate counter-clockwise. The default is 0. Editable.

Roll/Crawl Settings

NOTE The Roll/Crawl settings are available when the Roll/Crawl button is enabled in the Insert settings.

Roll/Crawl Settings

New Layer button Creates a layer to contain a text roll or text crawl.

Roll button Enable to create text that scrolls vertically over an image.

Crawl button Enable to create text that scrolls horizontally across an image.

Scrollbar

Scrollbar X field Displays the X position of the roll or crawl layer inside the crop box. The value changes when you move the scrollbar at the right of the text layer for a roll or at the bottom of the layer for a crawl. Editable.

Scrollbar Y field Displays the Y position of the roll or crawl layer inside the crop box. The value changes when you move the scrollbar at the right of the text layer for a roll or at the bottom of the layer for a crawl. Editable.

Fit Best Speed button Creates a broadcast quality text roll based on the number of frames in the clip and the lines of text in the text roll. Enable this button to make corrections to a text roll without altering the speed or duration of the clip.

For NTSC and PAL, broadcast quality is calibrated at four pixels per frame. This rate ensures no flicker in the text roll.

Roll Speed button Select the speed of the text roll, in pixels per second.

Changes the speed of the text roll. For 1X, the speed rate is 120 p/s (pixels/second) in NTSC, and 100 p/s in PAL. For 2X, it is 240 p/s in NTSC, and 200 p/s in PAL, and so on.

Lock Leading & Scroll button Enable to lock the leading of the paragraph text so that you can insert another paragraph into the text roll. If the duration of the clip lengthens after you make modifications, click Fit Best Speed to adjust the length.

Best Roll Duration field Displays the suggested duration for the text roll. The duration is calculated using the start/end position of the roll and the currently selected speed. Non-editable.

Crop Box

Crop Box X field Displays the X position of the crop box inside the image window. The crop box determines the X coordinates of the text roll or text crawl on the clip. Editable.

Crop Box Y field Displays the Y position of the crop box inside the image window. The crop box determines the Y coordinates of the text roll or text crawl on the clip. Editable.

Width field Displays the width at which to crop the text within the text roll or crawl layer. Editable.

Height field Displays the height at which to crop the text within the text roll or crawl layer. Editable.

Styles Settings

NOTE The Styles settings are available when the Styles button is enabled in the Insert settings.

Apply Style 1 button Saves or applies Style 1.

Apply Style 2 button Saves or applies Style 2.

Apply Style 3 button Saves or applies Style 3.

Apply Style 4 button Saves or applies Style 4.

Apply Style 5 button Saves or applies Style 5.

Apply Style 6 button Saves or applies Style 6.

Apply Style 7 button Saves or applies Style 7.

Apply Style 8 button Saves or applies Style 8.

Apply Style 9 button Saves or applies Style 9.

Load Style button Opens the file browser where you can select a saved style to load.

Save Style button Opens the file browser where you can save a style.

Style Mode box Select whether to work with all styles or one style.

Style Save Number box Select the number of the style to save. Available when One Style is selected from the Style Mode box.

Style Name button Sets the name of a defined style.

Style Option box Select an option for creating styles. AutoStyle assigns styles from an existing layer.

Tabulation Settings

NOTE The Tabulation settings are available when the Tabulation button is enabled in the Insert settings.

Add button Adds a tab stop on the text layer ruler. By default, tab stops are set at every 100 pixels.

Delete button Removes the selected tab stop.

Previous button Selects the previous tab stop on the text ruler. Tab stops appear in yellow when selected.

Tab ID field Display the tab number in the current paragraph. When you click Next or Previous, the Tab ID field changes, showing the number of selected tab stops. Editable.

Next button Selects the next tab stop on the text ruler. Tab stops appear in yellow when selected.

Position field Displays the exact tab stop position on the X-axis, in pixels. This value is set in pixels. Editable.

Ruler button Enable to display the tabulation ruler in the text layer.

Justification box Select the text alignment at the tab stop.

Spell Check Settings

NOTE The Spell Check settings are available when the Spell Check button is enabled in the Insert settings.

Spell Check Settings

Language box Select the language for the spell checker.

Check All Layers button Runs the spell checker on the text layers. When the spell checker encounters a misspelled word, it draws a red line through it.

Hide Spelling Errors button Enable to hide the red strike through the line that appears in each misspelled word.

Custom Dictionary button Enable to use your custom dictionary with the spell checker. Disable this button to check all spelling. Disable to check all spelling.

Error Navigation Settings

Previous button Navigates to the previous misspelled word.

Next button Navigates to the next misspelled word.

Add To Custom Dictionary button Adds a word that the spell checker has flagged to the custom dictionary. The next time the spell checker encounters this word, it will be ignored.

Setup and Processing Options

Auto-Softness box Sets the auto-softness and software sampling level.

Auto-Softness mode is set by default and provides a softness equal to the display quality you see in the Text node.

Anti-Aliasing Softness field Displays the softness value of the anti-aliasing sample. Editable.

PreRender button Enable to accelerate rendering on a static layer, such as a text roll (has no effect on text layers with animation).

PreRender has no effect on text layers with animation.

Hardware Anti-aliasing Sample box Select a hardware anti-aliasing sampling level to accelerate edge anti-aliasing with no performance penalty. Available values are dependent on graphics card and project graphic bit depth.

The graphics hardware automatically renders the image at full speed with approximately the equivalent of up to 32 samples of anti-aliasing (depending on your graphics card and project graphic bit depth). Hardware anti-aliasing also gives anti-aliasing during normal interaction instead of only while rendering.

You can combine hardware anti-aliasing level with software anti-aliasing to obtain the desired level of image quality. For example, with hardware anti-aliasing set to 4 samples, and with 4 samples of software anti-aliasing selected, your results should be similar to selecting 16 samples of software anti-aliasing, but with a processing time much closer to that of 4 samples. You should experiment with different combinations to determine what works best for you.

Animation Update button Enable to update animated text dynamically in the image area when you play the clip.

Controls the playback of animated text. When enabled, animated text is updated dynamically in the image area when you play the clip.

Play Lock button Enable to update the animation settings according to the frame or timebar position as you move through the clip while keeping it locked at the current frame.

Controls the playback of frames and displays the playback of animated clips exclusively. When enabled, the first frame is locked while you play the clip.

Crop button Enable to create a custom-sized crop box to define an area in which to render text.

Use this box to define an area in which to render text. When working with a crop box, you view all text, whether it is inside or outside the crop box. You can use the Left, Right, Bottom, and Top fields to set the size of the crop box. You can also drag the vertices at the corners of the crop box in the image window.

Crop Border button Enable to display a coloured border representing the crop area.

You can change the colour by clicking the colour pot.

Crop Border colour pot Displays the colour of the crop border. Editable.

Top Crop field Displays the top boundary value for the crop box. Editable.

Left Crop field Displays the left boundary value for the crop box. Editable.

Bottom Crop field Displays the bottom boundary value for the crop box. Editable.

Right Crop field Displays the right boundary value for the crop box. Editable.

Wireframe colour pot Displays the colour of the text path. Editable.

See [Animating Text on a Motion Path](#) (page 1160).

Points colour pot Displays the colour of the vertices on a text path. Editable.

See [Animating Text on a Motion Path](#) (page 1160).

Global/Layer Blur box Select whether to apply blurring globally or on a per layer basis.

Global Blur makes all shadows appear together, blurred with a single unique colour, on top of the background of all layers. Layer Blur blurs each layer individually according to its priority—background, blurred shadow, and fill.

When using Global Blur with prerendering, the layers are prerendered once and blurred on the front clip. These layers must not have any animation—they are static. For Layer Blur, there are two possible cases:

- All layers are static, without background. Only fill or shadow can be enabled for all layers—no blur. The layers are prerendered once and blurred on the front clip.
- Auto-Softness On, Progressive Rendering, or All Layers Static. Static layers (up to two) are prerendered once and blurred on the front clip as other layers are rendered.

Shadow Blur box Select whether to use a smooth blur with rounded edges (Gaussian), or a rectangular, rougher edged blur (Box).

Clear Undo Buffer button Resets the Undo entries.

Entering Text

Font Type box Select the type of font to display in the font browser list.

Font Preview window Previews the selected font. Click to enter text.

Exit Load Font button Exits the font browser.

Modifying Layer and Character Properties

Layer Axis box Select an alignment option for the selected text layer.

Select:	To move the axis:
Top/Left	To the upper-left corner of the text layer.
Centre	To the centre point of the text layer.

X Scale field Displays the scale of the text layer along the X axis. Editable.

This value is a percentage, so entering 50 means 50 percent. Use a larger value to increase the scale along the X-axis. Use a negative value to create a mirror image on the X-axis. Enter 0 to make a layer or selected characters disappear. The default is 100.

Y Scale field Displays the scale of the text layer along the Y axis. Editable.

This value is a percentage, so entering 50 means 50 percent. Use a larger value to increase the scale along the Y-axis. Use a negative value to create a mirror image on the Y-axis. Enter 0 to make the layer or selected characters disappear. The default is 100.

Proportional Scale button Enable to proportionally change the X Scale and Y Scale values.

X Shear field Displays the shear or slant value of the text layer along the X axis. Editable.

Use a positive value to slant right and a negative value to slant left. The maximum and minimum values are 60 and -60, respectively. The default is 0.

Y Shear field Displays the shear or slant value of the text layer along the Y axis. Editable. Use a positive value to shear up. A negative value near the minimum value -60 shears down. The maximum and minimum values are 60 and -60, respectively. The default is 0.

Rotation field Displays a rotation value for a layer rotating around its axis. Editable.

Use a negative value to rotate clockwise and a positive value to rotate counter-clockwise. The default is 0.

Timewarp

A timewarp is an effect in which the speed of the action taking place appears faster or slower than when it was originally recorded. A freeze-frame effect, in which a single frame is repeated, is another form of a timewarp. Timewarps can have a constant or variable speed. In some cases, such as when creating a fit to fill edit on the timeline, a timewarp is added automatically to a clip.

To access the Timewarp, use:

- Timeline, then add Timeline FX from the Effects ribbon. (See [Adding Timeline FX](#) (page 343)).

- Timeline, then use Batch FX (See [Creating Batch FX](#) (page 362)).
- Batch, then select a node from the Node bin.

In Batch or Batch FX, the Timewarp node accepts front and matte clips, as well as forward and backward vectors.

Motion Vectors are 2D vectors that represent the displacement in normalized pixel units of a pixel in the current frame to the next frame (forward motion vector), or its displacement from the previous frame (backward motion vector). Motion Vectors can be rendered by a 3D application when dealing with synthetic images, or produced through image analysis when images come from live action footage.

Timewarp Menu Settings

Timeline FX Quick Menu Settings

To see the full Timewarp menu, click the Editor button.

Timewarp Quick Menu selector Select which Timewarp quick menu to display.

NOTE There are also some [Timeline Timewarp](#) (page 1726) preferences that you can set in the Preferences menu.

Timing Info Settings

Timing Info	
Source In 1.00	Source Out 22.00
TW In 1.00	TW Out 22.00
Rec In 5.00	Rec Out 26.00
	Length 22.00

These settings are only available if you accessed Timewarp as a Timeline FX, and entered the full editor. They are informational settings only, to give you information about the segment on the timeline.

Source In field Displays the frame or timecode of the In point of the source segment. Non-editable.

Source Out field Displays the frame or timecode of the Out point of the source segment. Non-editable.

Timewarp In field Displays the frame or timecode of the In point of the timewarp result. Non-editable.

Timewarp Out field Displays the frame or timecode of the Out point of the timewarp result. Non-editable.

Record In field Displays the frame number or Record timecode of the In point of the segment in the sequence. Non-editable.

Record Out field Displays the frame number or Record timecode of the Out point of the segment in the sequence. Non-editable.

Length field Displays the length of the segment. Non-editable.

Rendering Mode Settings

Rendering Mode box Select whether to render in Automatic, Progressive or Interlaced mode.

Interpolation Mode box Select an interpolation mode (available if Interlaced or Automatic is selected in the Rendering Mode box). Interpolation helps remove field jitter artefacts that are produced when a reversal of fields occurs during the timewarp.

Select:	To:
No Interpolation	Use no field interpolation.
Half Interpolation	Interpolate only on displaced fields.
Full Interpolation	Interpolate on all fields. Note that this option has the least aliasing, but you may notice some softening of the image due to the blending of the fields.
Shift Up	Shift the image up by a single line. This may help reduce artefacts that appear in reverse timewarps of 100%.
Shift Down	Shift the image down by a single line. This may help reduce artefacts that appear in reverse timewarps of 100%.

Mode Settings

Timewarp Type box Select between Speed and Timing. Different settings appear depending on the type selected. Speed and Timing timewarps are mutually exclusive, that is, animation settings are remembered for each type.

Speed field Displays the timewarp speed. Editable.

Speed Type box Select whether to display the speed as a percentage, or as frames per second.

Speed Timing field This locked field displays the timing animation value for the current time. Non-editable.

Reverse button Enable to create a reverse timewarp effect; that is, change the speed field value to negative or positive.

Timing field Displays the source frame or timecode value for the current time. Editable.

Strobe Settings

Repeat field Displays the number of frames or fields to be repeated to create a strobe effect. The strobe effect is applied after the timewarp effect, so any speed or timing animations are respected when applying the strobe effect. Editable.

Anchoring Settings

When you access Timewarp as a Timeline FX or within Batch FX, you can see these Anchoring settings:

Anchoring box Select where to set the anchor frame so that its timing is not affected when modifying a timewarp.

Select:	To anchor:
Start	The In frame value as the value not to change.
End	The Out frame value as the value not to change.
Start and End	Both the In and Out frame values. In this case, any speed changes affect the length of the media (and the state of the Ripple button has an effect).

When you access Timewarp as a Batch node, you can see these Anchoring settings:

Source field Displays the anchor frame or timecode value of the timewarp. Editable.

Offset field Displays the amount of offset to apply to the anchor point. Editable.

Repeat Mode Settings

NOTE Not available if Timewarp is accessed as a Batch node.

Repeat Mode box Select how out of range timing values are handled.

Select:	To:
Lock to Segment Range	Only use timing values within the range of the segment. The Timing field is displayed in red when reaching a timing value that is impossible to achieve with the current source clip frame range (heads and tails).

Select:	To:
Repeat Last Frame	Not clamp or limit the timing values, by repeating the last frame when reaching the last frame of the segment range.
Trim Segment	Trim the segment (based on the selected ripple settings), when any modification to the speed or timing cause the range of source frames to exceed the available frames.

Frame Interpolation Settings

Frame Interpolation Type box Select which type of interpolation to use to blend timewarped frames. Different settings appear below depending on the type selected.

Type:	Description:
Mix	When mixing frames, you are combining multiple frames together to create one blended frame using an additive mix. Each result frame is a blend of an equal number of frames from both sides of the given frame.
Trails	With Trails blending, you have more control than in a simple mix. You can blend the frames before and after a given frame by different amounts. Do this to create a trail that comes before or after any motion in the clip. You can also set the amount of fall-off for the blend so that the trail fades away completely, partially, or not at all.
Motion	Motion estimation blends frames with subpixel accuracy, and is well-suited for particularly challenging timewarps. Motion estimation is good for processing slow-motion, constant, or variable speed timewarps of interlaced and progressive material. It is particularly good for material that introduces artefacts or for which you cannot get satisfactory results using Trail or Mix values.

Sample Mode box Select whether the interpolated position of the timewarp is set in relation to the beginning, middle or end of each frame or field. Available for Mix and Trails types.

Mix Amount field Displays the mix value for the timewarp. Each result frame is a blend of an equal number of frames from both sides of the given frame. Editable.

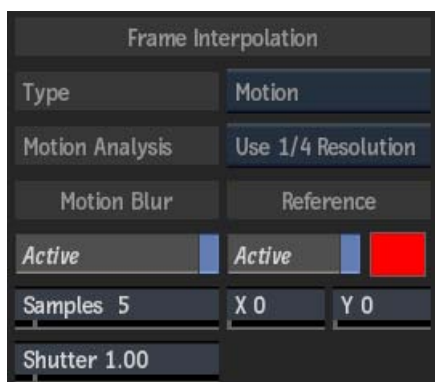

Pre Amount field Displays the value to mix the frames that precede the current frame with the current frame. Editable.

Pre Weight field Displays the fall-off value for the pretrail. When the value is 0%, the image in the current frame is at 100% intensity and the first image in the trail is at 0% intensity. When the value is at 100%, there is no fall-off. Editable.

Post amount field Displays the value to mix the frames that follow the current frame with the current frame. Editable.

Post Weight field Displays the fall-off value for the posttrail. When the value is 0%, the image in the current frame is at 100% intensity and the first image in the trail is at 0% intensity. When the value is at 100%, there is no fall-off. Editable.

Motion Analysis Quality box Select the level of motion analysis accuracy and rendering speed. Select Use Full Resolution to render the images at the current resolution. In Batch or Batch FX, this setting is unavailable if an external input is attached to the node's forward vector or backward vector tabs.

Motion Blur Active button Enable to apply a motion blur to the selected clip.

Sample field Displays the number of frames to sample when creating the timewarp. The samples include the current frame, and an equal distribution of past and future frames. Editable.

Shutter field Displays the number of frames for which the shutter stays open. For example, when the shutter value is set to 3, every third frame is as a sample. Editable.

Reference Active button Enable to apply the timewarp only to objects that do not have the same relative motion as the selected pixel. When enabled, you can edit values in the X and Y fields.

Reference colour pot Displays the colour of the crosshair that marks the reference point. Editable

Reference X field Displays the horizontal position of the pixel to use as a reference point at the selected frame. Editable.

Reference Y field Displays the vertical position of the pixel to use as a reference point at the selected frame. Editable.

Warper

Use the Warper to warp a clip or morph from a source clip to a result clip. Warping is free-form distortion of an image; it is a transition effect that matches the morphology of one clip gradually to that of another clip, such as when a human is morphing into an alien.

You can access the Warper Tool through:

- [Tools, then select from the menu.](#) (page 1213)

Warper Menu Settings

Miscellaneous Buttons

Exit button Exits the Warper tool.

Load button Loads a setup.

Save button Saves a setup.

Setup Name field Displays the name of the last saved setup.

Revert button Reverts to the last saved setup.

Source option box Select a field rendering mode.

Player button Opens the Player to view the rendered clip.

Step Render field Displays the frame number interval to be rendered (to see intermediate results, for example). Editable.

Preview button Previews the distort effect without rendering.

Setup button Sets playback options, changes display colours, and inputs slip values.

Animation button Opens the channel editor.

View box Select an option to set the view in the image window.

Auto Key button Enable to set a keyframe automatically each time you change a value at any frame.

Reset All button Resets all parameters.

Setup Menu

Decimation field Displays the number of subdivisions for the main patches of the mesh. Editable.

Decimation is the number of subdivisions for the main patches of the mesh (not the small subdivided elements). The default decimation value is 10, which means that each patch is divided into 10 by 10 elements. You should increase this value when:

- You want to use smoother curves along the edges of the patches.
- A patch has been greatly subdivided. When the Decimation value is too low, the subdivided sections will appear to “swim” instead of locking to points and splines.
- A patch is twisted extensively. When the Decimation value is too low, the interior of the patch may appear to fold or break up unexpectedly. Increase the value to smooth the interior of the patch.

Keep the following points in mind when you are adjusting the decimation value:

- Increasing the Decimation value will cause interaction and processing speed to decrease dramatically.
- The Decimation value remains in effect during final processing.
- There is no relationship between the Decimation value and the TexPrec value. The Decimation value defines the precision of the geometry, whereas the TexPrec value affects the precision of the image that is mapped to this geometry.

Samples field Displays the anti-aliasing factor (the number of samples per pixel during final rendering). Editable.

The Samples field specifies the anti-aliasing factor. This number specifies the number of samples per pixel during final processing.

Texture Repeat button Enable to allow pixels to repeat when a source mesh goes outside of the borders of an image.

Texture Quality box Select a texture rendering option.

Provides three texture rendering options.

Select:	To:
High Quality	Use high-quality hardware texture rendering. This option always uses the highest level of precision. High Quality tiles images according to the available texture memory. This option is the default and is the recommended rendering option for film images or any image that is greater than the available texture memory.
Low Quality	Use low-quality hardware texture rendering, specifically during interactive rendering mode or when you want to render an image quickly. This option uses the precision level that you set in the Precision field.
Pixel Rendering	Use polygon rendering.

Click Preview to hide the mesh and preview the resulting frame.

Texture Precision field Displays the speed/quality ratio for interaction, as well as the rendering quality when Low Quality is selected as the rendering option. Editable.

The higher the value, the higher the quality of the display during interaction, and the higher the quality of final processing when rendering under Low Quality.

Motion Update button Enable to use the same values for properties such as position, rotation, and colour in the scene. Disable to manually copy keyframe values from one frame to another.

When disabled, animated objects do not move, but keep the position of their current value. Disable Motion Update when you want to copy keyframe values from one frame to another.

Play Lock button Enable to update the animation settings according to the frame or timebar position as you move through the clip while keeping it locked at the current frame.

Front Slip field Displays the number of frames to slip the front clip. Editable.

Back Slip field Displays the number of frames to slip the back clip. Editable.

Front Matte Slip field Displays the number of frames to slip the front matte clip. Editable.

Back Matte Slip field Displays the number of frames to slip the back matte clip. Editable.

Icons button Enable to display splines, tangents, and vertices in the image.

Spline colour pot Displays the colour of splines in the image. Editable.

Tangent colour pot Displays the colour of tangents in the image. Editable.

Vertex colour pot Displays the colour of vertices in the image. Editable.

Shape Interpolation box Select an interpolation type.

Main Menu

Add Mesh button Enable to add a mesh or patch to the image.

Xcells field Displays the number of patches along the X axis. Editable.

Ycells field Displays the number of patches along the Y axis. Editable.

Proportional button Enable to keep the XCells and YCells fields proportional.

Delete Mesh button Deletes the selected mesh.

Front Clip Setup box Select an option for using the front clip.

Back Clip Setup box Select an option for using the back clip.

Matte Clip Setup box Select an option for using the matte clip.

Back Matte Clip Setup box Select an option for using the back matte clip.

Background Clip Setup box Select an option for using the background clip.

Warp button Displays the warping controls.

Morph button Displays the morphing controls.

Front Source button Enable to create a front source mesh.

Show Front Source button Enable to display the front source mesh in the image.

Front Source colour pot Displays the colour for the front source mesh. Editable.

Front Destination button Enable to create a front destination mesh.

Show Front Destination button Enable to display the front destination mesh in the image.

Front Destination colour pot Displays the colour for the front destination mesh. Editable.

Back Source button Enable to create a back source mesh in a morph.

Show Back Source button Enable to display the back source mesh in the image.

Back Source colour pot Displays the colour for the back source mesh. Editable.

Back Destination button Enable to create a back destination mesh in a morph.

Show Back Destination button Enable to display the back destination mesh in the image.

Back Destination colour pot Displays the colour for the back destination mesh. Editable.

Source Interpolation button Enable to use source interpolation in a morph.

Show Source Interpolation button Enable to display source interpolation in the image.

Front Source Mapping box Select the area that the front source is mapped to.

Front Destination Mapping box Select the area that the front destination is mapped to.

Back Source Mapping box Select the area that the back source is mapped to.

Back Destination Mapping box Select the area that the back destination is mapped to.

X Position field Displays the position of the control points along the X axis. Editable.

Y Position field Displays the position of the control points along the Y axis. Editable.

Z Position field Displays the position of the control points along the Z axis. Editable.

Curves button Enable to activate the interpolation and dissolve curves.

Dissolve field Displays the percentage change in the colour of the pixels at the current frame. Editable.

Interpolate field Displays the percentage change in the position of the pixels at the current frame. Editable.

Move button Enable to move a vertex, an edge, or a tangent handle.

Move Mode box Select an option to change the position, size, and orientation of part or all of the mesh.

Subdivide button Enable to divide patches in a mesh into smaller subpatches and split the edges into smaller segments.

Auto button Enable to reset broken tangent handles.

Select button Enable to select multiple control points to translate, scale, or rotate all or part of the mesh.

Split button Enable to add a vertex along the edge of a patch.

Copy button Copies the selected mesh.

Paste button Pastes the copied mesh.

Freehand button Enable to perform intricate mesh modelling by clicking to create a freehand mesh.

Break button Enable to break tangent handles.

Delete button Enable to delete edges or vertices of the mesh.

Magnet button Enable to use the Magnet tool to define the shape of the warped image.

Magnet Mode box Select a transformation type to use when Magnet is enabled.

Magnet Curve Editor Defines the weighted polarity from the centre to the edge of the magnet.

Magnet Curve Home button Resets the position of the magnet curve after panning.

Magnet Curve Reset button Resets the Magnet Curve Editor.

Magnet Curve Tools box Select an option to modify the magnet curve.

Magnet Load button Loads a custom magnet setup.

Magnet Save button Saves a custom magnet setup.

Stabilizer button Opens the Stabilizer menu to track movement in the clip to help in creating meshes.

Stabilizer Clip box Select the clip to be loaded into the stabilizer.

Tracking Mode box Select whether to track the axis or vertices of the clip.

Tracking Mesh box Select whether to apply the tracking data to the source or destination mesh.

Animating Keyframes

25

You can build animations simply by editing the values of parameters in any effect editor or menu. When you animate a parameter, you create an animation channel that you can use to control the values of the parameter over time.

To use auto key to build animations automatically in the editor for an effect or tool:

- 1 Enable Auto Key.
- 2 Go to the frame where you want to add the keyframe.
- 3 Change the value of the parameter. Enter a new value in the field using the calculator, or click and drag left or right to change the value.

A keyframe is added to the animation channel for the parameter you edited.

NOTE When auto key is enabled, you create keyframes whenever you change the value for a parameter. You also change the value of any parameter that you have already set.

To set keyframes manually in the editor for an effect or tool:

- 1 Disable Auto Key.
- 2 Go to the frame where you want to add the keyframe.
- 3 Change the value of the property. Enter a new value in the field using the calculator, or click and drag left or right to change the value.
- 4 Right-click the field and select Set Keyframe (Current Value).

To delete keyframes:

- 1 Go to the frame that contains the keyframe you want to delete.
- 2 Right-click the parameter that contains the keyframe and select Delete Keyframe.

NOTE A yellow bar appears under values that are keyframed at the current frame.

To reset keyframe values:

- 1 Right-click the parameter and select one of the following options.

Select:	To:
Reset (Default Value)	Reset the value of the keyframe to the original value.

Select:	To:
Reset Channel (Current Value)	Reset the value of the entire channel to the current value.
Reset Channel (Default Value)	Reset the entire channel to the original value.

Keyframe Indicator Reference

A number of colours are used in numeric fields to indicate that keyframes are set for a parameter.

Indicator	Example
An asterisk in a field indicates that a value has changed from the default, but a keyframe is not set. Once a keyframe is set, the asterisk disappears.	
A blue line under a numeric field indicates that one or more keyframes are present on this channel, but not at the current frame.	
A yellow line under a numeric field indicates that a keyframe is present on this channel at this point in time.	
A dotted yellow line under a numeric field indicates that this channel is linked to another channel using an expression. In this case, the numeric value is also greyed out, as the value can not be modified. The name of the linking channel is also displayed as part of the tooltip.	

Animating Keyframes in the Animation Channel Editor

The Animation Channel Editor offers more control over your animation than is offered when editing the values of parameters in an effect or tool editor. Use the Animation Channel Editor to fine-tune changes across all animation channels available for the effect or tool you are working on.

To display the Channel Editor:

- 1 Click Animation.

The Animation Channel Editor is displayed in the bottom area of the window.

To display the Animation Channel Editor in a viewport:

- 1 Click the View box.
- 2 Select one of the following from the Animation menu:

Select:	To display:
Channels	Animation curves.
Tracks	Animation channels as tracks. This view can help you visualize and align keyframes.
Info	A table displaying keyframe values in text format.

Panning and Zooming in the Animation Channel Editor

To center the Animation Channel Editor on your work, click one of the following:

- **Frame:** to center the display on the currently selected channel.
- **Frame All:** to center the display on all the animation channels that have at least one keyframe set on them.

NOTE These buttons are located at the bottom left corner of the Animation Channel Editor.

To pan the Animation Channel Editor:

- 1 From the Tools box, select Pan.
- 2 Click and drag the cursor to pan the view.

To zoom the Animation Channel Editor:

- 1 From the Tools box, select Rect Zoom.
- 2 Click and drag a rectangle on the area you want zoom.

NOTE You can zoom x and y independently. Use the Zoom command from the Tools box. Click and drag up or down to zoom the y axis. Click and drag left or right to zoom the x axis.

Adding Keyframes to Channels in the Animation Channel Editor

To add keyframes automatically:

- 1 In the Animation Channel Editor, enable Auto Key.
- 2 Select the channel you want to add keyframes to.
- 3 Click the value next to the channel name to open the calculator.
- 4 Enter a value and click enter to close the calculator.
A keyframe is added to the channel you selected.

To set keyframes manually:

- 1 In the Animation Channel Editor, disable Auto Key.
- 2 Select the channel or channels you want to add keyframes to.
- 3 Drag the positioner to the frame where you want to set the keyframe.
- 4 Click Set Key.

The current values for the selected channels are set at the current frame.

TIP It can be useful to set keys across multiple channels using the Track Editor since this view focuses on channels, and their composing keyframes, in time. To view the Track Editor, select Track from the Channel View box.

To add keyframes at different locations on the animation channel:

- 1 From the Tools box, select Add Points.
- 2 Click the spot on the channel where you want to add the keyframe.

NOTE You can snap the keyframes you add to a frame (rather than in between frames). From the Curve Functions box, select FrmSnap.

To insert a keyframe:

- 1 Select the channel or channels you want to add keyframes to.
- 2 Drag the positioner to the frame where you want to set the keyframe.

- 3 Click Insert Key. The Insert Key button behaves differently depending on the current frame:
 - If the current frame is the last keyframe, a new keyframe is created *<duration>* number of frames after the last keyframe (*duration* is the value in the Duration field). The current frame advances to the new keyframe.
 - If the current frame is a keyframe other than the last keyframe, a new keyframe is created *<duration>* number of frames after the present keyframe. Other keyframes are moved by the same duration causing a ripple effect.
 - If the current frame is between keyframes, Insert acts the same as the Set button: a new keyframe is created and the duration is unchanged.

Changing Keyframe Values in the Animation Channel Editor

You can change keyframe values in the Channel or Track View of the Animation Channel Editor.

To gesturally change keyframe values:

- 1 In the Animation Channel Editor, select the channel that includes the keyframes you want to change.
- 2 Click Frame to view the channel.
- 3 From the Tools box, choose Select.
- 4 Select the keyframes. To select multiple keyframes, press Ctrl+drag to create a rectangular selection.

NOTE To select keyframes in only the selected channel, press Ctrl+F and drag a rectangular selection around the keyframes you want to select.
- 5 Drag the keyframes to the new values. Press Alt to snap the frame value (vertical axis) to the nearest integer. Press Ctrl+Alt to snap to the nearest multiple of ten.

NOTE Enable Track Snap on the Filter tab to snap keyframes to frames (not in-between frames). Or, press Alt+Z to snap when Track Snap is disabled.

To set a specific value for a keyframe in the Animation Channel Editor:

- 1 Select the Channel that has the keyframe you want to change.
- 2 Set the positioner to the frame where the keyframe is located.
- 3 Click the value next to the channel name and enter a new value in the calculator. Or click the number and drag to change its value gesturally.

Copying and Pasting Channels or Keyframes in the Animation Channel Editor

You can copy and paste animation curves or keyframes between channels.

You can copy and paste folders provided the folder to which you are pasting has the same number of channels and folders as the folder you copied.

For example, in Action, you can copy the Scale folder from an axis and paste it into the Scale folder of another axis because they have the same channels (X scale, Y scale, for example). Trying to copy and paste the Camera folder to the Scale folder will not work because the two folders do not contain the same number and kinds of channels.

NOTE If an expression is applied to the selected channel, the expression is copied instead.

To copy and paste a selection of keyframes:

- 1 Select keyframes on a channel, and click Copy.

TIP Keyframes do not have to follow one another to be copied and pasted to another channel.

- 2 Drag the positioner to a new frame.
- 3 Select the channel and the frame where you want to paste the keyframes, then click Paste.

NOTE With the Select tool active, you can also *Shift+spacebar*-click a channel to paste keyframes starting from the location of the cursor. For example, *Shift+spacebar*-click frame 10 on a channel to paste the copied keyframes into the channel starting at frame 10.

The keyframe values for the selected channels are pasted and set in the current frame.

To copy and paste a curve:

- 1 From the Channel View box in the Keyframe tab, select Channels. The Channel View box is to the left of the Insert Key button.
- 2 Select the channel containing the animation curve.

TIP Select a folder to copy all the channels in a folder.

- 3 Click Copy.
- 4 Select the channel where you want to paste the copied curve.
- 5 Click Paste.

The channel values you copied are applied to the selected channel or folder.

Changing the Duration of an Animation in the Animation Channel Editor

You can change the duration of an animation by scaling its channel horizontally in the Channel Editor. This allows you to change the number of frames it takes for an animation to play through, without having to move each keyframe manually.

There are three ways to change the duration of an animation in the Animation Channel Editor:

- Use the X Scale tool to scale the channel using any keyframe as the origin of the scale.
- In the Tracks view, Drag the track handle to scales the track proportionally.
- Using the Duration field.

When changing the length of channels, you may want to adjust the number of frames of the clip in the Total Frames field. For example, if you shorten the length of all the clip's channels, you can then shorten the clips' frames accordingly. Or, if you scale the channels longer than the duration of the clip, you can then add frames to account for this.

To change the duration of an animation in the Channel View:

- 1 From the Tools box, select X Scale.
- 2 Select the keyframes or channels you want to scale.
You may have to click Frame to view the curve.
- 3 Click the keyframe that will act as the centre of the X Scale. Drag left to decrease the value or drag right to increase the value of the other keyframes along the X-axis, relative to the selected keyframe.

(a) Original animation curve

(a) XScale used to compress curves

To scale a channel in the Track Editor:

- 1 From the Channel View box, select Tracks.
- 2 From the Tools box, select Select.
- 3 Select the channels you want to scale.
- 4 Drag the last handle to the left to decrease the duration, or to the right to increase the duration.

NOTE To avoid adding keyframes between frames when scaling, press Alt-Z while scaling. If you have already scaled the track, Select Frame Snap from the Curve Functions box to snap keyframes in the selected channel to the closest frame numbers.

The track scales as you drag the handle. All keyframes are repositioned proportionally in time.

(a) Original animation track

(a) Dragging handle used to compress a track from 40 to 20 frames

TIP You can move the handle of a folder to scale all channels in the folder. For example, moving the handle of the Scene folder (the top level folder) causes all the folders and channels in the hierarchy to be scaled by the same amount.

To change the number of frames between the current and next keyframe:

- 1 Select a keyframe.
- 2 In the Duration field, which is next to the Insert Key button in the Animation Channel Editor, enter a value for the number of frames between the selected keyframe and the next keyframe.

Changing the Values of Keyframes Proportionally in the Animation Channel Editor

In the Animation Channel Editor, you can change the vertical scale of an animation curve or a selection of keyframes and change keyframe values for a channel or a group of keyframes while maintaining each keyframe's relative frame position.

(a) Original animation curve

(a) YScale used to scale the curve based on a selected keyframe

To change the values of keyframes proportionally:

- 1 In the Animation Channel Editor, select a channel or group of keyframes.
You can select more than one channel or a group of keyframes from more than one animation curve.
- 2 From the Tools box, select Y Scale.
- 3 Click the keyframe that will determine the centre of the Y Scale.
- 4 Drag up to increase the value or down to decrease the value of the other keyframes relative to the selected keyframe.

YScale works differently if you select more than one curve. For the other selected curves, the number of the frame that you select is verified in all animation curves. If the animation curve has a keyframe at the selected frame, this keyframe is used as the centre of the Yscale. This keyframe then sets the proportional scale calculation. If the animation curve does not have a keyframe at the selected frame, the curve remains unscaled.

Offsetting Select Keyframes or Channels in the Animation Channel Editor

You can offset a curve or a group of keyframes on the horizontal or vertical axis.

To offset a channel:

- 1 Select the channel or keyframes to offset.
- 2 From the Curve Functions box in the Keyframe tab, select Translate X to offset the channel horizontally or Translate Y to offset vertically.
- 3 Enter a value in the Curve Value field.

A negative value offsets the channel or group of keyframes to the left (Translate X) or down (Translate Y). A positive value offsets to the right (Translate X) or up (Translate Y). The value in the Curve Value field produced by the drag returns to zero after release.

The selected channel or keyframes are offset. The coordinates of each selected keyframe, relative to each other, remain unchanged. Translating along the Y-axis is only visible in the Animation Curve window.

Simplifying the Number of Keyframes in the Animation Channel Editor

You can change the number of keyframes in your animation curve or in a group of keyframes. Using the Simplify function, the peaks and valleys in the selection are analysed and keyframes are generated with a duration between them as specified in the Curve Value field. A large value such as 20 or 30 decreases the number of keyframes between peaks and valleys, whereas a small value such as 1 or 2 increases the number of keyframes. The ideal simplify value varies between animation curves.

For example, the following figure shows an animation curve created using the Stabilizer. Simplify is applied with a value of 20. In sections where the slope of the curve is fairly constant in one direction, keyframes are removed between the peaks and valleys. You can adjust the simplified animation curve more easily because there are fewer keyframes to modify.

(a) The Y curve before applying Simplify has a keyframe at each frame

(a) The Y curve after applying Simplify with a simplification value of 20.

To simplify a channel or a group of keyframes:

- 1 Select a channel or group of keyframes.
- 2 From the Curve Functions box in the Keyframe tab, select Simplify.
- 3 In the Curve Value field, enter a simplification value.

Use a large number to simplify the curve or group of keyframes. Use a small number to increase the number of keyframes. The value in the Curve Value field produced by the drag returns to zero after release.

Baking Keyframes

You can transform a curve or a group of keyframes by using the Bake function. This can be useful if you want to change an extrapolated cycle curve into a normal curve, with keyframes created along the cycle. You can also use the Bake function to remove the dependence of a curve linked to another curve with an expression.

To bake a cycled curve:

- 1 Select a curve that has a cycle extrapolation applied to it.
- 2 Set the current frame to the last frame that you want to be baked.
- 3 From the Curve Functions box in the Keyframe tab, select Bake.
- 4 In the Curve Value field, enter a bake value.

Use a large number to simplify the curve or group of keyframes. Use a small number to increase the number of keyframes. The value in the Curve Value field returns to zero after you have finished baking.

Swapping Animation Curves

You can swap animation curves between two channels. Swap works in conjunction with Copy or Cut. You can also swap single keyframes but not a group of keyframes.

To swap two channels:

- 1 Select the first channel to swap.
- 2 Click Cut or Copy.

The selection is copied to the clipboard.

- 3 Select the second channel to swap.
- 4 From the Curve Functions box in the Keyframe tab, select Swap.
The selected channel is swapped with the channel in the clipboard.
- 5 Select the first channel and click Paste.
The two channels are swapped.

Flipping Channels and Keyframes

Select Negate in the Curve Functions box to flip a channel or a group of keyframes vertically. Select Reverse to flip a channel or a group of keyframes horizontally. Typically, you reverse or flip keyframes so that you can create symmetry with an animation. For example, use Reverse on an image that is warping from a sphere to a flat plane so that it then goes from a flat plane back to a sphere again. Perform these functions in the Animation Curve window.

To negate or reverse a channel or group of keyframes:

- 1 In the Animation Channel Editor, select a channel or group of keyframes.
- 2 From the Curve Functions box in the Keyframe tab, select Negate or Reverse.
The selection is flipped horizontally (negate) or vertically (reverse).

Removing Jitter from an Animation Curve

Select Jitter in the Curve Functions box to remove jitter from an animation curve or within a group of keyframes. Use the Curve Value field to specify the Over value. As a general rule, start with a large Over value over n frames to remove slow jitter, and a small Over value to remove fast jitter. The Jitter option is typically used on shift data in the Stabilizer to remove jitter while keeping camera movement. See [Removing Jitter While Keeping Overall Motion](#) (page 881).

To remove jitter:

- 1 Select a channel or group of keyframes.
- 2 In the Curve Functions box in the Keyframe tab, select Jitter.
- 3 In the Curve Value field, specify the Over value.

Applying an Average

Select Average in the Curve Functions box to remove jitter from a jittery animation track. While the Jitter option is used for removing jitter caused by trackers in the Stabilizer, the Average option is used to remove jitter from an animation track. Enter the number of keyframes used to calculate the average in the Curve Value field.

You can change the timing of a motion path animation without changing the motion path spline by adding a keyframe to the speed curve.

To average a channel:

- 1 Select a channel or group of keyframes.
- 2 In the Curve Functions box in the Keyframe tab, select Average.

- 3 In the Curve Value field, specify a value.
The jitter is removed from the spline animation.
- 4 From the Tools box, select Break.
- 5 Click a keyframe on the speed channel.
The keyframe breaks into two tangents.

(a) Keyframe tangents

- 6 From the Tools box, select Move.
- 7 Adjust the tangents.
In this example, the speed curve makes the apple accelerate rapidly until it reaches frame 29, where it stops and continues moving slowly.

You can also apply the preceding procedure to a group of keyframes.

Modifying Tangents to Reshape the Animation Curve

To modify the tangents in the Animation Channel Editor.

- 1 From the Tangents box, select Auto.
- 2 From the Interpolation box, select an interpolation type. Only animation curves that use Bézier, Hermite, or Natural interpolation have keyframes with tangent handles.
- 3 From the Tools box, choose Select and move the tangent handles.
As you move the handles, the slope on each side of the keyframe is modified independently.

NOTE You must break tangent handles to move them independently. From the Tools box, select Break Tangents and click the tangents you want to break.

To reset tangents to their default:

- 1 From the Tools box, select Auto Tangent.
- 2 Click the handle of the tangent you want to reset.

Changing the Value of a Tangent Handle by a Specific Amount

You can modify the shape of an animation curve by rotating its keyframe tangent handles to control the smoothness and speed of the animation.

To rotate a keyframe's tangent handles:

- 1 Select a channel or group of keyframes.
- 2 From the Curve Functions box in the Keyframe tab, select Tangent R to rotate each right tangent handle or Tangent L to rotate each left handle.

NOTE Tangent R and Tangent L only work on curves and keyframes that use Bézier, Hermite, or Natural interpolation. Select your option from the Interpolation box.

- 3 Enter a value in the Curve Value field.

A negative value rotates each tangent counter-clockwise. A positive value rotates each tangent clockwise. The tangent handle first breaks into two and then the handles are rotated.

The following example shows the results of applying Tangent L with a rotation value of 36 to the keyframes of an entire curve. No keyframes were broken before Tangent L was applied.

(a) The Hermite curve before applying Tangent L. Note that none of the keyframes are broken.

(a) The same Hermite curve after applying Tangent L of 36. A break is applied to all keyframes before the tangents are rotated.

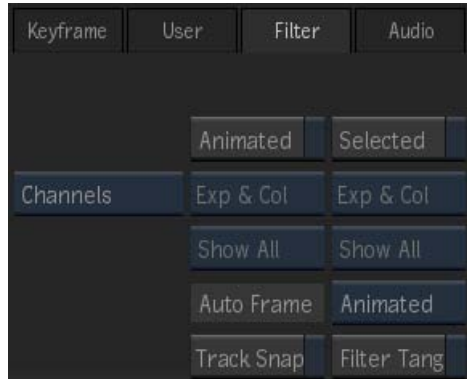

Setting Display Preferences in the Animation Channel Editor

Use the options in the Filter tab to control the display preferences in the Animation Channel Editor. The Animation Channel Editor display preferences can help you focus on the channels you are working on in the editor when many channels are displayed.

You can go in and out of the same tool in one session, and your display preferences are remembered. But if you restart, the your display preferences are not remembered. You must save and load your display preferences manually to access them when you restart the application.

To set display preferences:

- 1 In the Animation Channel Editor, select the Filter tab.

- 2 Select the type of channels you want to appear in the filtered view, animated or selected.

Select:	To:
Animated	Display channels that are animated.
Selected	Display channels that are selected.

- 3 Select how you want to expand or collapse channels that appear in the filtered view.

Select:	To:
Exp & Col	Expand animated or selected channels and collapse all others.
Expand Only	Expand animated and selected channels. All previously expanded channels remain selected.
No Expand	Not expand animated or selected channels.

- 4 Select how you want to display folders that contain channels in the filtered view.

Select:	To:
Hide All	Show only the animated or selected properties, for example, the X and Y values of an axis. All other properties in the same parent folder are hidden. All other folders are also hidden.

Select:	To:
Hide Group	Show only the animated or selected channel, its parent folder, and all channels in the same group, where a group includes all folders in the same parent folder. All other parent folders and groups are hidden. NOTE If multiple channels are animated or selected, all corresponding parent folders and groups are shown.
Show All	Show all animated or selected channels.

- 5 From the Auto Frame box, select an option for framing your view of the Animation Channel Editor. If you select All, Animated or Selected, your view of the Animation Channel Editor changes as you change your channel selection.

Select:	To frame:
All	All channels. This option is the same behavior as clicking the Frame All button in the Animation Channel Editor.
Animated	All animated channels.
Selected	All selected channels. This option is the same behavior as clicking the Frame button in the Animation Channel Editor.
None	No channels. This option enables the Frame and Frame All buttons in the Animation controls.

- 6 Enable Track Snap to force key frames to snap to whole frame numbers as you drag them.
- 7 Enable Filter Tangent to display tangents only on selected channels. This can help you cleanup the display.

To save display preferences:

- 1 Click the User tab.

- 2 Click Save Prefs.

To load display preferences:

- 1 Open the Animation Channel Editor from the tool where you saved your display preferences in.
- 2 On the User tab, click Load Prefs.
- 3 Click the Filter tab. Display preferences you saved are now activated on the Filter tab.

Using Selection Sets to Control the Channels and Folders You Want to Display

With a selection set, you can control the channels and folders you want to display in the Animation Channel Editor.

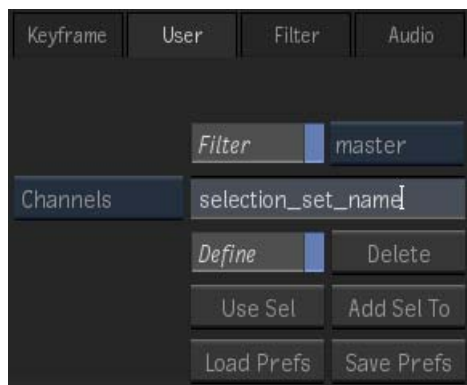

Selection sets can be particularly helpful if you access the Animation Channel Editor from a complicated Batch or Batch FX schematic, where all the selected nodes are displayed in the editor. With a selection set you can limit the number of channels or folders displayed to just those you are working on.

Selection sets are saved and available throughout a session. However, they are not saved between sessions. This means that you do not have access to the selection sets you create after you restart the application.

To create a selection set:

- 1 Select the User tab in the Animation Channel Editor.
- 2 Enable Filter.
- 3 Type a name in the Selection Set Name field and press `Enter`.

The selection set is created and selected in the Selection Set box. Notice that the Define button is also enabled and the channels and folders in the Animation Channel Editor are colored red.

- 4 Select the channels or folders you want to in your selection set. If you are displaying the Batch or Batch FX schematic, you can select the nodes that you want in your selection set.

Notice that channels and folders in Animation Channel Editor turn green as you make selections. This helps you identify the channels and folders in the selection set.

- 5 Do one of the following:
 - Click Use Sel to save the channels and folders you selected to a selection set.
 - Click Add Sel To, to add the selection to an existing selection set.
- 6 Disable Define.

To switch between selection sets:

- 1 Select the User tab.
- 2 Select a selection set from the Selection Set box.

To modify a selection set:

- 1 Select a selection set from the Selection Set box.
- 2 Enable Define.
- 3 Select the channels and folders you want to display in the selection set.
- 4 Click Add Sel To. The selection is added to the selection set and the selection set is saved.
- 5 Disable Define.

Generating Keyframes Based on Audio Analysis

In the Channel Editor, you can use an audio clip to automatically generate keyframes on any video or audio channel based on the analysis of the audio.

To map keyframes based on audio analysis:

- 1 In the Channel Editor, select the Audio tab.

NOTE The Audio menu has a number of submenus with various settings. You may not need to use every setting to analyse your audio clip. See the sections after this procedure for an explanation of each setting.

- 2 From the Media Source box, select whether you want to analyse the current audio clip (Clip) or import an audio clip (File).

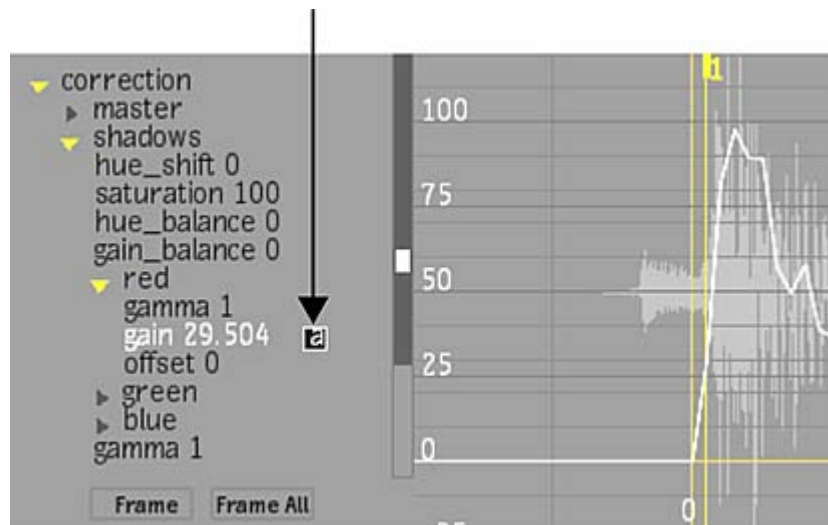

If there is more than one audio clip associated with your choice (for example, Front, Back, or Matte), you can choose which one to use in the Name box. If only one audio clip is available, the name of the clip appears in a locked field.

If you select File, click Import to open the Import Audio browser, and select an audio file to import.

- 3 In the Channel hierarchy, select the channel or channels you want to link the audio to.
- 4 Use the settings in the Media submenu to prepare the audio track you want to use. See [Audio Keyframe Settings](#) (page 1510).
- 5 From the Mapping submenu, enable Link To Channel.

The letter 'a' appears next to the channel in the Channel hierarchy, indicating that this channel is linked to the audio.

- 6 Use the settings in the Mapping submenu to determine how the audio track is mapped to the selected channel. Keyframes are adjusted automatically as changes are made to the settings.
- 7 Use the settings in the Filtering submenu to filter the exact frequencies you want to analyse. Keyframes are adjusted automatically as changes are made to the settings.
- 8 Disable Link To Channel or exit the module when you are satisfied with the analysis. The generated keyframes are automatically baked to the animation curve.

You can use different audio tracking settings on different channels. Disable Link To Channel and select a different channel in the hierarchy and restart the mapping process.

NOTE If you want to be able to tweak the settings, you can save the analysis settings in an audio tracker setup.

Audio Keyframe Settings

The animation controls Audio tab has a number of submenus with numerous settings to help you work with your audio clips.

Common Settings

There are a few common settings found in the Audio submenus.

Play button Plays the audio media.

Stop button Stops the audio playback.

Reset box Available in the Media, Mapping, and Filtering submenus. In the Setup submenu, only Reset All is available. Select whether to reset the current Audio submenu, or all of the Audio settings.

Media Submenu

(a) Media Source box

Media Source box Select whether to analyse the current audio clip (audio attached to the front, back, or matte clips, for example), or the imported audio file.

Import button Opens the import audio browser to load a file.

Clip Name box If multiple audio clips are available, select which clip to use as source media. If only one audio clip is available, the name of the clip appears in a locked field.

W+ button Displays the selected media's waveform in the Channel Editor.

W- button Hides the waveform.

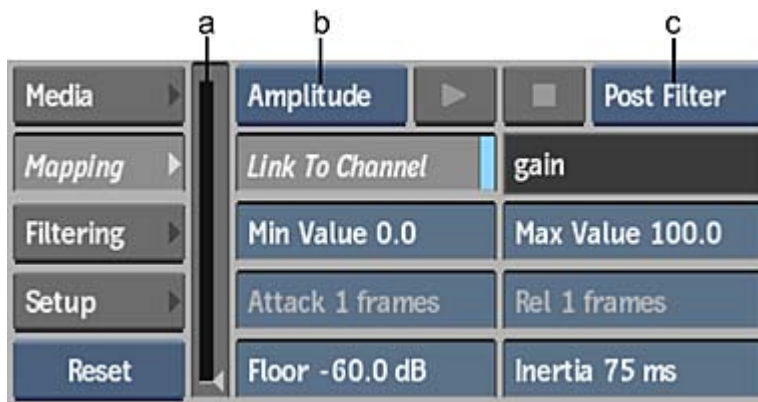

Track box Select which audio track to use as source media.

Slip field Displays the amount of frames to slip the media. Editable.

Handles field Displays the amount of handles (frames) to analyse before and after the current shot duration. Editable.

For example, with a shot of 100 frames, if you enter 30 in this field, the total number of frames becomes 160 (30 frames before and 30 frames after the original 100 frames).

Mapping Submenu

(a) Audio Level Indicator (b) Tracking Mode box (c) Listening Mode box

Tracking Mode box Select whether to use an Amplitude or Transient tracking mode. In Amplitude tracking mode, a keyframe is generated at each frame, following the envelope of the audio signal. In Transient tracking mode, a keyframe is generated for each audio transient (sudden rise in amplitude), provided that the signal rises above the specified threshold.

Listening Mode box Choose between Pre Filter (audio as it was imported) and Post Filter (audio with any changes made) monitoring when playing back audio media. Does not affect the analysis.

Link to Channel button Enable to map the tracked audio to the selected animation channel. An 'a' appears in the channel list next to the name of the linked channel. Multiple channels can be selected simultaneously.

Channel Name field This locked field displays the name of the selected channel being linked to the tracked audio. Multiple Channels is displayed if more than one channel is selected.

Min Value field Displays the minimum value at which keyframes can be set in the linked channel. Editable.

Max Value field Displays the maximum values at which keyframes can be set in the linked channel. Editable.

NOTE The minimum value can be higher than the maximum value to get an inverse mapping of the tracking mode in the animation channel.

Attack field Displays the number of frames needed for the channel to reach the Max Value before a transient. Available only in Transient tracking mode. Editable.

Release field Displays the number of frames needed for the channel to reach the Min Value after a transient. Available only in Transient tracking mode. Editable.

Threshold field (Not shown). Displays the value at which a keyframe is generated each time the signal rises above it. Available only in Transient tracking mode. Editable.

TIP Start with a high threshold, and lower it until all required peaks are detected.

Floor field Displays the minimum level of the audio media to be considered for the analysis (typically used to remove analysis noise between audio transients). Available only in Amplitude tracking mode. Editable.

Inertia field Displays the rate at which the signal decreases after a transient. Editable.

In Transient tracking mode, the Release field can be increased to avoid the generation of several consecutive keyframes when the transient is not clearly defined in the input signal. Conversely, if the Release field is set to 0 ms, each transient rising above the threshold generates a keyframe, even if each occurs within a few milliseconds of another.

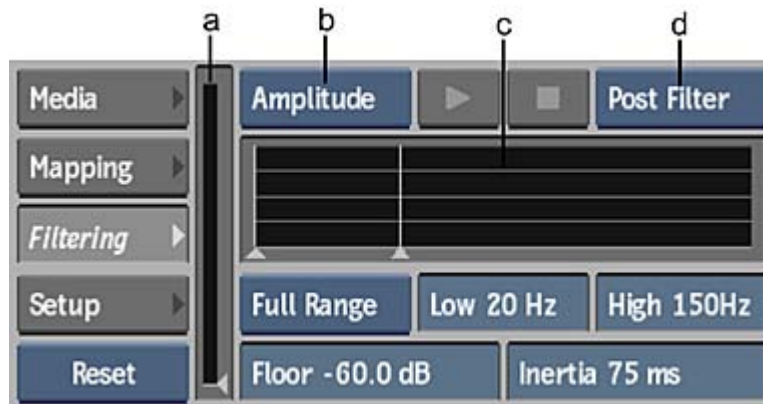

Audio Level Indicator A visual representation of the audio level and the current Threshold or Floor value.

Audio Level Indicator A visual representation of the audio level and the current Threshold or Floor value.

Reset box Select Reset to reset the Mapping submenu settings only. Select Reset All to reset all of the Audio tab settings.

NOTE Some of the settings in the Mapping submenu are repeated in the Filtering submenu so that you do not have to switch tabs to change the settings. The same settings are reflected in both submenus.

Filtering Submenu

(a) Audio Level Indicator (b) Tracking Mode box (c) Frequency Graph (d) Listening Mode box

Frequency Graph A visual frequency representation of the audio signal being tracked. The audio display is always Pre Filter.

Frequency Range Preset box Select a frequency range preset to determine the cutoff frequencies for Low and High filters.

Low field Displays the lowest frequency of the input signal used in the analysis (also represented by a triangle under the frequency graph). Use the slider or field to adjust. Editable.

High field Displays the highest frequency of the input signal used in the analysis (also represented by a triangle under the frequency graph). Use the slider or field to adjust. Editable.

NOTE Some of the settings in the Filtering submenu are repeated in the Mapping submenu so that you do not have to switch tabs to change the settings. The same settings are reflected in both submenus.

Setup Submenu

Load button Click to load a saved audio mapping setup.

Save button Click to save an audio mapping setup.

Setup Name field This locked field displays the name of the loaded setup

Animation Menu Settings

The Animation menu has some common settings, and a number of settings specific to certain operations, organized in submenus. For specific Audio submenu settings, see [Audio Keyframe Settings](#) (page 1510).

Common Settings

Regen button Enable to automatically update the scene when an animation change is made.

Channel View box Select a view of Channels, Tracks, or Info to control and coordinate your animation.

Auto Select button Enable to select the channel automatically when you modify a channel value in the field for an effect or tool.

Set Key button Sets the current values for the selected channels in the current frame (when Auto Key is disabled).

Delete Key button Deletes the selected keyframes or curve.

Keep button Deletes all keyframes except the current keyframe.

Cut button Cuts the selected keyframes or curve.

Copy button Copies the selected keyframes or curve.

Paste button Pastes the selected keyframes or curve.

Link button Creates an expression by linking one channel to another.

Expressions button Applies an expression to one or more channels.

Animation Reset box Select to reset the selected channel or all channels.

Keyframe Submenu

Curve Functions box Select an operation to apply to your animation.

Curve Value field Displays the value for the selection in the Curve Functions box. Editable.

Insert Key button Inserts a keyframe. Its behaviour changes depending on where the keyframe is inserted.

Duration field Displays the number of frames between keyframes. Editable.

Absolute/Relative box Select whether the value in the Duration field is absolute or relative to the present keyframe value.

Tangents box Select the behaviour of the keyframe tangents to help refine the shape of an animation curve between keyframes.

Tangent Mode	Tangent Behaviour
Auto	Tangents are fixed in an horizontal position to prevent the curve from over- or under-shooting keyframes. Moving a keyframe higher or lower than its neighboring keyframes alters their tangents so the curve remains as uniform as possible. The handles of tangents set to Auto are empty circles. Manually moving a keyframe's tangent voids this setting for that tangent. It will now perform as a Fixed tangent.
Fixed	Tangents are fixed in their current position so that moving a keyframe does not alter its tangents nor those of its neighboring keyframes. The handles of tangents set manually are filled circles.

Tangent Mode	Tangent Behaviour
Smooth	Legacy setting to ensure compatibility with previous versions of a setup. Tangents are not locked like when using the Auto setting; they are affected by the movement of adjacent keyframes. There are no other benefit from using this setting.

Interpolation box Select an interpolation type to define the shape of an animation curve between keyframes.

Extrapolation box Select an extrapolation type to define the shape of an animation curve before the first keyframe and after the last keyframe of the curve.

User Submenu

Filter button Enable to create and name a selection set (the channels, folders, and folder elements that you want to display as part of a set).

Selection Set box Select a user-defined selection set. Select <new user> to create a selection set.

Name field Enter a name for the selection set. Editable.

Define button Enable to display channels in red and green to indicate the channels contained in the current user-defined selection set.

Delete button Removes the currently selected selection set from the Selection Set box.

Use Selection button Displays the current selection set in the Channel Editor and at the same time saves the current selection set.

Add Selection To button Adds the current selection to the active selection set.

Load Filter Preferences button Loads the filter preferences last saved for the module.

Save Filter Preferences button Saves the current filter settings as preferences for the module.

Filter Submenu

Animated button Enable to display channels that have animation keyframes. Use in conjunction with the Animated Expansion and Animated Show/Hide boxes to further control the content displayed.

Selected button Enable to display only channels that are selected in the Channel Editor. Use in conjunction with the Selected Expansion and Selected Show/Hide boxes to further control the content displayed.

Animated Expansion box Select an expansion option for animated folders.

Selected Expansion box Select an expansion option for selected folders.

Animated Show/Hide box Select to display or hide animated folders.

Selected Show/Hide box Select to display or hide selected folders.

Auto Frame box Select an option to frame channels automatically. If None is selected, the Frame and Frame All buttons are enabled.

Track Snap button Enable to force keyframes to snap to frames when dragging tracks by their left or right handles.

Filter Tangents button Enable to display only the tangent handles of selected channels.

Advanced Animation: About Expressions

Use expressions to apply animation dynamically to one or more channels. For example, use expressions to easily simulate real-world forces such as gravity, momentum, and centrifugal force. Expressions save time since you can animate one channel, and then refer other channels to the first channel so that the other channels automatically behave in relation to the first one. You can use arithmetic operators, such as addition and multiplication, as well as predefined functions to precisely control the behaviour of an animation.

Expressions are available through all modules that use the Channel Editor.

Working with Expressions in the Channel Editor

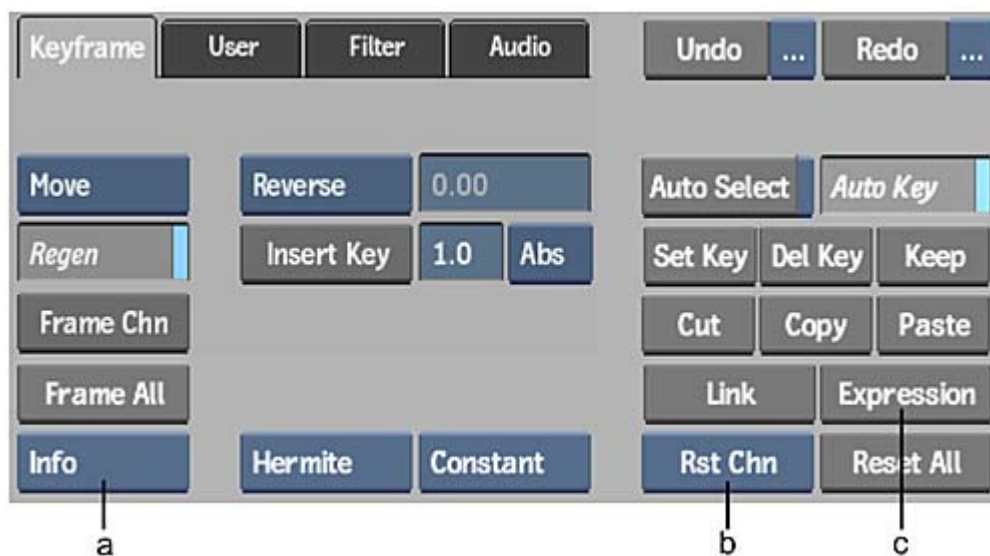

You can apply, modify and view expressions using the Channel Editor. You can use the copy and link functionality to quickly apply basic expressions to multiple channels.

WARNING Expressions override interpolation modes and previously set keyframes for a selected channel.

To apply an expression to a channel:

- 1 In any module menu, click Animation.

The Animation controls appear.

(a) Channel View box (b) Reset Channel button (c) Expressions button

- 2 From the Channel View box, select Info.
Channel information appears in a tabular grid for easier viewing of expressions and channel details. From Info view, you can click the Expressions column heading to sort by expressions and view them more easily.

Channel ▾	Component	Value	# Keys	Expression
image3.material.transparency	transparency	0	0	eval(image1.material.trans
image4.material.transparency	transparency	0	0	eval(image1.material.trans
image5.material.transparency	transparency	0	0	eval(image1.material.trans
axis1	axis1			
axis1.position	position			
axis1.position.x	x	0	2	
axis1.position.y	y	132	2	
axis1.position.z	z	0	2	

- 3 Select the channel to which you want to apply an expression.
- 4 In the Animation controls, click Expression.

The Expression field appears below the Channel Editor.

(a) Expression field

- 5 Enter an expression according to the guidelines described in [Operator Reference](#) (page 1523) and [Function Reference](#) (page 1525) and press Enter.

The letter 'e' appears next to the channel in the channel hierarchy, indicating that this channel contains an expression.

(a) Expression indicator

NOTE Entering an invalid expression will result in the message “Error: Expression: parse error” and the entered expression will not be applied to the channel.

To modify an expression:

- 1 Click Animation to display the Animation controls.
- 2 In the channel hierarchy or Info view, select the expression that you want to edit.

- 3 In the Animation controls, click Expression.
The Expression field appears below the Channel Editor.
- 4 Modify the expression in the field and press Enter.
The modified expression appears in the table.

TIP When you are in the Expression field, you can press **Up** one or more times to retrieve its previous contents. This can be useful if you want to correct an invalid expression that you recently entered.

To remove an expression:

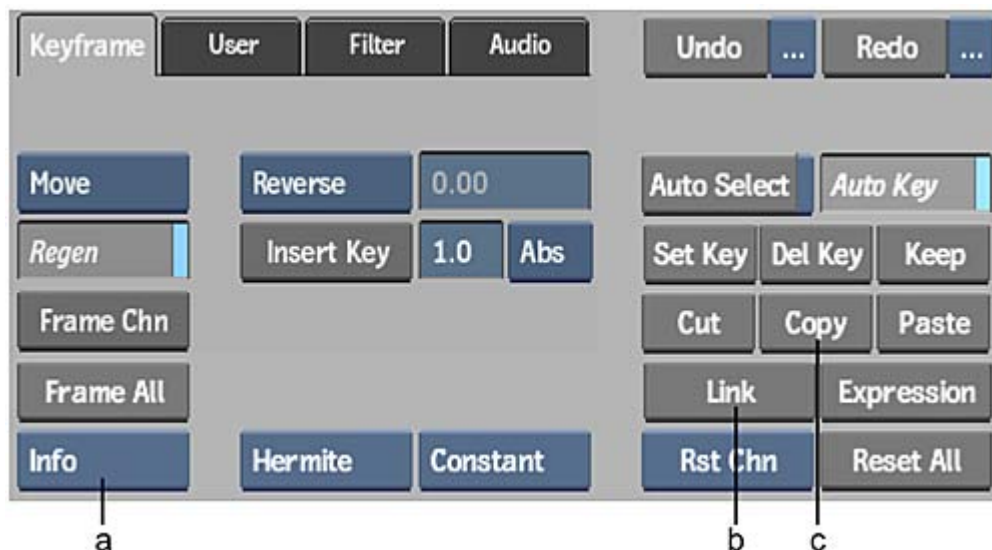

- 1 Click Animation to display the Animation controls.
- 2 In the channel hierarchy or Info view, select the channel with the expression that you want to remove.
- 3 Click Rst Chn to remove the expression.
The channel is reset.

Linking Channels

You can create an expression by linking the behaviour of one channel to another using Copy and Link. You can link different types of channels together. For example, make the scaling of a layer affect the rotation of another layer, or blur a layer by linking it to the position of an axis. Any change that occurs in the position of the axis is reflected dynamically in the layer blur.

To create an expression by linking one channel to another:

- 1 Click Animation to display the Animation controls.
- 2 From the Channel View box, select Info.

(a) Channel View box (b) Link button (c) Copy button

TIP Enable the Hierarchy View button

to better view the channel hierarchy.

- 3 Select a source channel from which to link and click Copy.
For example, copy the x position of axis1 and link it to the x blur value of a layer.
- 4 Select the destination channel and click Link.
The x blur value of layer1 is linked to the x position value of axis1, so as the position increases, so does the blur. This is shown in the following illustration.

Copying Nodes with Expressions

When working in Action, Keyer or Garbage Masks, if you copy a branch in Schematic view, or append to a setup by loading a second setup, any nodes with the same name as existing ones are renamed with unique names. Likewise, if expressions are associated with those nodes, the expressions are replicated and the associated channels are renamed to correspond with the new node names. This preserves the integrity of the expression within the copied branch or appended setup.

If you copy a portion of a branch that has expressions associated with it, the expressions related to the copied portion of the branch will be associated with the new copy. Expressions related to uncopied portions of the branch will maintain their association with the original branch.

Cascading Expressions

You can copy a single expression to multiple channels that build on the result in the previous channel using the *SelectionOrder* and *CascadeChannel* keywords. These keywords increment the channel number or name as follows:

- Each instance of *SelectionOrder* increments the channel number.
- Each instance of *CascadeChannel* replaces the occurrence of the channel name with the name of the preceding channel, relative to the order in which the channels are selected.

In general, experiment with the *SelectionOrder* and *CascadeChannel* keywords to determine which results are optimal for your animation.

To apply cascading expressions using *SelectionOrder*:

- 1 Click Animation to display the Animation controls.
- 2 From the Channel View box, select Info.
- 3 Select multiple channels to which you want to apply the cascaded expression, in the desired order.
As you select each channel, the selection order is shown next to the channel name in Info view.

TIP To select a range of channels, click the first channel that you want to include in the range. Then click the last channel to include in the range while holding **Shift**. To add to a range of files, hold **Ctrl** or the stylus button while selecting the channels from the Channel Editor.

- 4 Enter an expression that includes the keyword `SelectionOrder`.

Every instance of the keyword `SelectionOrder` will be substituted in your expression by a different number for each channel, which corresponds to the order in which you selected them.

To animate four channels using `SelectionOrder`:

- 1 In Action, add four axes named `axis1`, `axis2`, `axis3` and `axis4`.
- 2 Animate `axis1.position` by creating a few keyframes.
- 3 Select the channels `axis2.position`, `axis3.position` and `axis4.position` in this order.
- 4 Enter the following expression: `eval(axis1.position, frame - 5 * SelectionOrder)`.

The following expressions are applied:

- `axis1.position`: no expression
- `axis2.position`: `eval(axis1.position, frame - 5 * 1)`
- `axis3.position`: `eval(axis1.position, frame - 5 * 2)`
- `axis4.position`: `eval(axis1.position, frame - 5 * 3)`

To apply cascading expressions using `CascadeChannel`:

- 1 Click Animation to display the Animation controls.
- 2 From the Channel View box, select Info.
- 3 Apply an expression to a base channel to which the other channels will relate.
- 4 Select multiple channels, starting with the base channel, to which you want to apply the cascaded expression, in the desired order.
- 5 Enter an expression that includes the keyword `CascadeChannel`.

The base channel (the first channel selected) will remain unmodified. In the expressions for the other selected channels, every instance of the keyword `CascadeChannel` will be substituted by the name of the channel that preceded it, in the order in which you selected them.

To animate four axes using `CascadeChannel`:

- 1 In Action, add four axes named `axis1`, `axis2`, `axis3` and `axis4`.
- 2 Animate `axis1.position` by creating a few keyframes.
- 3 Select, in this order, the channels `axis1.position`, `axis2.position`, `axis3.position` and `axis4.position`.
- 4 Enter the following expression: `eval(CascadeChannel, frame - 5)`.

The following are applied:

- `axis1.position`: no expression
- `axis2.position`: `eval(axis1.position, frame - 5)`
- `axis3.position`: `eval(axis2.position, frame - 5)`
- `axis4.position`: `eval(axis3.position, frame - 5)`

NOTE This results in the same animation as the `SelectionOrder` example given above.

Expression Content

An expression is composed of numeric values, constants, channel references, or combinations of these used with arithmetic operators. Expressions are calculated from left to right, according to a specific order defined in [Operator Precedence](#) (page 1524).

For example, the following expression contains channel references and multiplies the transparency value of image1 by 2 to affect the transparency of image2 across all keyframes.

Channel	Expression
image2.material.transparency	image1.material.transparency* 2

Vectors

Certain channels such as Position, Rotation, Scale, and Shear are vector based since they represent 3D space and include X-, Y-, and Z-axes. A vector contains three elements that represent the individual components of the channel. Vectors are written using the convention (x, y, z) where x, y, and z represent separate scalar values.

Expressions can either affect the components of a vector individually or collectively. For example, the following expression sets the individual rotation for the x, y, and z axes to 30°, 45° and 90°, respectively.

Channel	Expression
axis1.rotation	(30, 45, 90)

The following expression sets the rotation for axis2 twice that of axis1, affecting the vector collectively.

Channel	Expression
axis2.rotation	axis1.rotation* 2

Functions

Flame Premium includes many predefined functions that can be used to perform calculations in an expression. You pass function-specific values, called *arguments*, and they return another value back to the expression that called it. A function call in an expression begins with the function name, followed by an opening parenthesis, the arguments for the function separated by commas, and finally a closing parenthesis.

NOTE Function names are case-sensitive.

Arguments for functions can be either scalar values or vectors. When you use a function, make sure that you pass it the correct type of parameter. See [Function Reference](#) (page 1525) for information on the arguments and return values for each function.

You can nest function calls by using the return value of a function as one of the arguments of another function. When a nested function is used as an argument, it must return a value that conforms to the type and range that the argument requires.

You can define your own functions and use them in your expressions just as you would with any of the predefined functions. See [Defining Your Own Functions](#) (page 1545).

Examples

The following expression uses the noise function to create a random positioning effect for axis1.

Channel	Expression
axis1.position.x	noise(frame)*5

The following expression uses the eval function to make the position of axis2 the same as that of axis1, but delayed by 10 frames.

Channel	Expression
axis2.position	eval(axis1.position, frame - 10)

The following expression uses the eval function to make the animation of axis3 the same as that of axis1, but at half the speed.

Channel	Expression
axis3	eval(axis1, frame / 2)

Keywords and Constants

Use the keyword *frame* in an expression to get the value of the current frame number in your animation. This allows you to create an animation by specifying how a value changes over a sequence of frames.

Use the constant *PI* instead of the literal numeric value of π (3.1416...).

NOTE Keywords and constant names are case-sensitive.

Select:	To display:
PI	3.1416...
e	Euler's number (2.7182818284...)
phi	Golden Ratio (1.6180339887...)
c	Speed of light in vacuum (299792458 m/sec)
freefall	Standard free fall acceleration near the earth's surface (9.80665 m/sec^2)
echarge	Elementary charge (1.602176487e-19 Coulomb)

Simplified Expressions

A reference to another channel does not have to be fully qualified when it is at the same hierarchical level as the channel to which the expression is being applied. For example, the following simplified expressions

are valid when applied to the specified channel. The fully qualified versions of the expressions are also provided.

Channel	Simplified Expression	Fully Qualified Expression
axis1.position.y	x + 50	axis1.position.x + 50
axis1.rotation	position / 2	axis1.position / 2
image1.material.diffuse	specular * 3	image1.material.specular * 3

References to other channels also work when referring to the siblings of any parent. For example, consider the following structure.

You can apply the expression position.x to axis.rotation.x because position is a sibling of rotation, and rotation is a parent of rotation.x.

Operator Reference

Operators specify a mathematical or logical calculation to be performed between various elements of an expression.

Arithmetic Operators

Use the following arithmetic operators to perform basic mathematical operations.

Operator	Description
+	Addition
-	Subtraction
*	Multiplication
/	Division
%	Modulo (this is a binary operator)

Operator	Description
(x, y, z)	Vector where x , y , and z are scalar values

Comparison Operators

Use the following operators to compare two values with each other. When two values are compared using these operators, the result is 1 if the comparison is true and 0 if the comparison is false.

Operator	Description
<code>==</code>	Equal to
<code>!=</code>	Not equal to
<code><</code>	Less than
<code><=</code>	Less than or equal to
<code>></code>	Greater than
<code>>=</code>	Greater than or equal to
<code>&&</code>	Boolean AND
<code> </code>	Boolean OR
<code>!</code>	Boolean NOT

Operator Precedence

When you combine several operators in a single expression, the operations are performed in the following order.

Order	Operator	Description
1	<code>!</code>	Boolean NOT
2	<code>-</code>	Negation (as in -1)
3	<code>*</code> , <code>/</code> and <code>%</code>	Multiplication, division, and modulus
4	<code>+</code> and <code>-</code>	Addition and subtraction
5	<code><</code> , <code><=</code> , <code>></code> , and <code>>=</code>	Comparison
6	<code>==</code> and <code>!=</code>	Equivalence
7	<code>&&</code>	Boolean AND

Order	Operator	Description
8		Boolean OR

When operators with the same precedence are encountered, operators are evaluated from left to right. However, when part of a formula is enclosed in parentheses, it is evaluated first.

Function Reference

You can easily create very complex expressions by using the available functions. This function reference provides detailed information about each function. Function arguments in square brackets are optional. However, if you give a value to an optional argument, you must also give a value to every optional argument before that one.

Animation Functions

Use the following functions to animate channels in a general way.

NOTE Arguments shown in square brackets are optional. For example, in the syntax of the align function, the options [AxisToAlign] and [BankingAngle] are optional.

align

Returns a rotation vector such that a designated axis of an object is aligned with the direction of the object's movement. You can also bank the rotation around the axis. The result should usually be assigned to a rotation channel.

Syntax:	align(PosToFollow, [AxisToAlign], [BankingAngle])
Arguments:	<ul style="list-style-type: none"> ■ <i>PosToFollow</i> is the vector representing the channel to align on, typically an animated position. ■ <i>AxisToAlign</i> is the vector representing the axis with which to align, by default the X-axis (1,0,0). ■ <i>BankingAngle</i> is the angle in radians by which to rotate the result about the AxisToAlign (performs banking). If the BankingAngle argument is specified, the AxisToAlign argument must also be specified.
Example:	align(axis.position, (0,0,1), frame * PI / 8) returns a rotation vector that points the object's Z-axis in the direction of its motion while the rest of the axis rotates along this axis.

lookat

Returns a rotation vector based on an object's position that points it towards a second moving object. The result should usually be assigned to a rotation channel.

Syntax:	lookat(TargetPos, ObserverPos, [AlignVector], [UpVector])
---------	---

Arguments:	<ul style="list-style-type: none"> ■ TargetPos is the vector of an object's position channel that you want the rotation vector to point towards. ■ ObserverPos is the vector of the position channel from which you are looking. ■ AlignVector is the vector of the direction that you want to have looking at the target, by default the Z-axis (0,0,1). ■ UpVector is the vector of the direction that you want to be pointing upwards, by default the Y-axis (0,1,0). The UpVector should be set to a different vector than the AlignVector. If the UpVector argument is specified, the AlignVector argument must also be specified.
Examples:	<ul style="list-style-type: none"> ■ <code>lookat(followed_axis.position, follows_axis.position)</code> returns the rotation vector required so that <code>follows_axis</code> points its Z-axis towards <code>followed_axis</code>. ■ <code>lookat(followed_axis.position, follows_axis.position, (0,1,0),(1,0,0))</code> returns the rotation vector required so that <code>follows_axis</code> points its Y-axis towards <code>followed_axis</code>, with its X-axis pointing upwards.

eval

Returns the value of a given expression at another point in time.

Syntax:	<code>eval(Expression, FrameNumber)</code>
Arguments:	<ul style="list-style-type: none"> ■ Expression is the expression to be evaluated. This can be any valid channel value. ■ FrameNumber is the frame to simulate when evaluating the given expression.
Examples:	<ul style="list-style-type: none"> ■ <code>eval(axis1.position.x, 5)</code> returns the value of <code>axis1.position.x</code> at frame 5. ■ <code>eval(axis1.position, frame - 10)</code> returns the <code>axis1.position</code> vector at 10 frames behind the current frame. ■ <code>eval(axis1, frame / 2)</code> returns the entire <code>axis1</code> channel at half the normal speed.

if

Returns one of two values based on the result of a conditional test. You can nest multiple functions inside each other to handle multiple results.

Syntax:	<code>if(Condition, TrueValue, FalseValue)</code>
Arguments:	<ul style="list-style-type: none"> ■ Condition is any channel or expression. When comparison operators are used, a true expression evaluates to 1 and a false expression evaluates to 0. See Comparison Operators (page 1524). ■ TrueValue is the value to be returned for any non-zero result. ■ FalseValue is the value to be returned if Condition evaluates to 0.
Examples:	<ul style="list-style-type: none"> ■ <code>if(axis.position.y >= 100, 5, -5)</code> returns 5 when <code>axis.position.y</code> is greater than or equal to 100, and -5 otherwise.

- `if(frame < 10 || frame > 20, 100, 200)` returns 100 when the current frame is less than 10 or above 20, and 200 otherwise.
- `if(axis.position.x, 6, 7)` returns 6 when `axis.position.x` is something other than 0, and 7 when it is 0.
- `if(axis.position.x == 100 && axis.position.y != 200, 8, 9)` returns 8 when `axis.position.x` is 100 and `axis.position.y` is not 200, and 9 otherwise.
- The next four examples all equivalently return 5 when neither `axis.position.x` nor `axis.position.y` are greater than or equal to 0, and -5 otherwise.

`if(!(axis.position.x >= 0 || axis.position.y >= 0), 5, -5)`

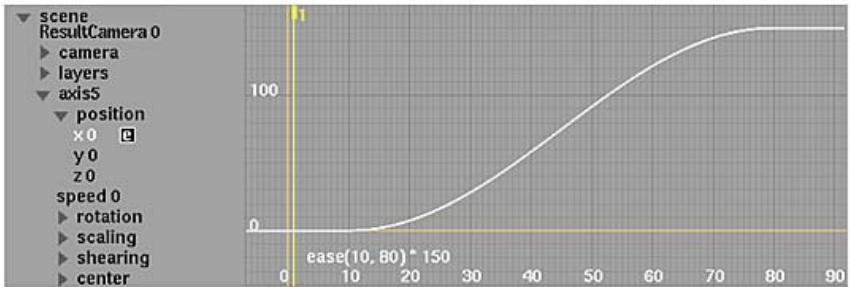

`if(!(axis.position.x >= 0) && !(axis.position.y >= 0), 5, -5)`

`if(axis.position.x < 0 && axis.position.y < 0, 5, -5)`

`if(axis.position.x < 0, if(axis.position.y < 0, 5, -5), -5)`

ease

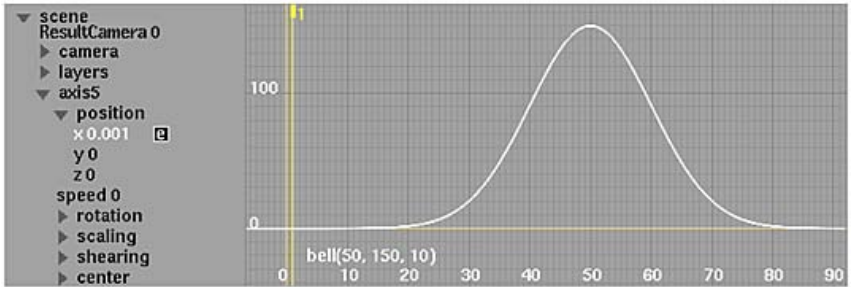

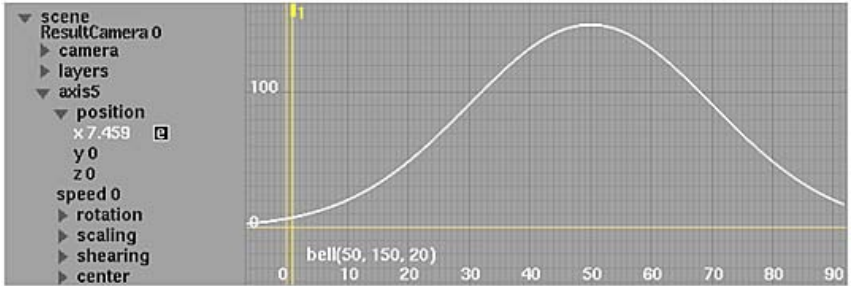

Returns a number from 0 to 1 representing a smooth S-curve transition between a given range of frames. All frames before the start frame are assigned 0 and all frames after the end frame are assigned 1. A start weight and end weight specify how the S-curve is formed.

Syntax:	<code>ease(StartFrame, EndFrame, [StartWeight], [EndWeight])</code>
Arguments:	<ul style="list-style-type: none"> ■ <code>StartFrame</code> and <code>EndFrame</code> are the frames at which the transition starts and ends respectively. ■ <code>StartWeight</code> and <code>EndWeight</code> are numbers that specify how curvature is distributed at the start and end of the curve respectively. To get an S-curve, their sum should be less than 1, otherwise a square curve will result. In addition, if either of these two arguments are specified, the other must also be specified.
Examples:	<ul style="list-style-type: none"> ■ <code>ease(10, 50) * 100</code> returns a standard S-curve from 0 to 100 between frames 10 and 50. ■ <code>80 - ease(1, 40) * 20</code> returns a standard S-curve from 80 to 60 between frames 1 and 40. ■ <code>ease(1, 30, 0.2, 0.2) * 50 + 10</code> returns a tight S-curve from 10 to 60 between frames 1 and 30. ■ <code>ease(10, 80) * 150</code> yields the following curve:  <ul style="list-style-type: none"> ■ <code>ease(10, 80, 0.2, 0.2) * 150</code> yields the following curve:

bell

Returns a set of values representing a bell (normal distribution) curve over time. You can specify the centre frame number and height and width characteristics of the curve.

Syntax:	<code>bell(CentreFrame, Height, Width)</code>
Arguments:	<ul style="list-style-type: none"> ■ CentreFrame is the frame number at which the bell curve will reach its maximum height. ■ Height is the maximum height of the bell curve. ■ Width specifies the horizontal distribution of the curve.
Examples:	<ul style="list-style-type: none"> ■ <code>bell(10, 100, 3)</code> returns a bell curve centred around frame 10 with a maximum height of 100 and a width distribution of 3. ■ <code>bell(50, 150, 10)</code> yields the following curve:  <ul style="list-style-type: none"> ■ <code>bell(50, 150, 20)</code> yields the following curve: 

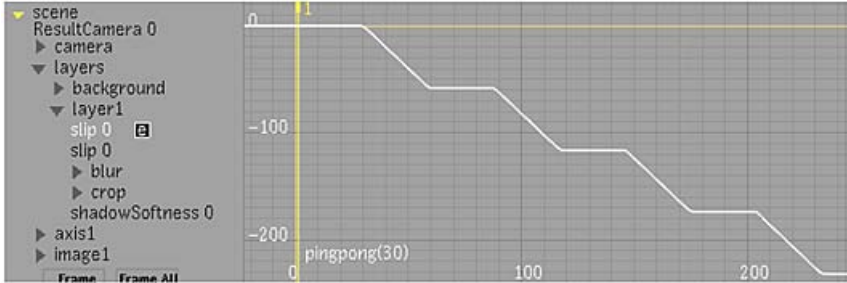

Slip Functions

Use the following functions to slip the starting frame of a clip backwards or forwards using the slip channel. In effect, the displayed frame in a layer's clip will be the animation's current frame number plus the slip value. For example, a slip value of -15 holds the clip at the first frame and repeats it 15 times before the clip begins. In this way, you can create a freeze frame effect with one layer while animating another layer. A slip value of 10 begins the clip at frame 11. See [Modifying Surfaces](#) (page 474).

NOTE Slip functions are actually implemented as user-defined functions in the functions file. See [Defining Your Own Functions](#) (page 1545).

pingpong

Returns a slip value that makes a clip continuously cycle forwards and backwards. The result should usually be assigned to the slip channel of a layer.

Syntax:	pingpong(length)
Arguments:	<ul style="list-style-type: none">length is the number of frames to display before starting to play backwards. This is usually the length of the original clip.
Examples:	<ul style="list-style-type: none">pingpong(10) returns a slip value that makes a clip continuously play in a forward and backward cycle from frame 1 to frame 10.pingpong(30) yields the following curve: 

repeat

Returns a slip value that makes a clip continuously repeat forwards. The result should usually be assigned to the slip channel of a layer.

Syntax:	repeat(length)
Arguments:	<ul style="list-style-type: none">length is the number of frames to display before repeating from the beginning. This is usually the length of the original clip.
Examples:	<ul style="list-style-type: none">repeat(10) returns a slip value that makes a clip repeat forwards from frame 1 to frame 10.repeat(30) yields the following curve:

repeatback

Returns a slip value that makes a clip continuously repeat backwards. The result should usually be assigned to the slip channel of a layer.

Syntax:	<code>repeatback(length)</code>
Arguments:	<ul style="list-style-type: none"> length is the number of frames from the beginning to display backwards before repeating. This is usually the length of the original clip.
Examples:	<ul style="list-style-type: none"> <code>repeatback(10)</code> returns a slip value that makes a clip repeat backwards from frame 10 to frame 1. <code>repeatback(30)</code> yields the following curve:

frametoslip

Returns a slip value that makes a clip display at a given timebar frame. If the given frame number is constant, the resulting clips will freeze at that frame. The result should usually be assigned to the slip channel of a layer.

Syntax:	<code>frametoslip(TimebarFrame)</code>
Arguments:	<ul style="list-style-type: none"> TimebarFrame is the timebar frame at which to display the clip.
Examples:	<ul style="list-style-type: none"> <code>frametoslip(10)</code> returns a slip value that makes a clip freeze at frame 10. <code>frametoslip(frame / 2)</code> returns a slip value that makes a display at half the normal speed. <code>frametoslip(14)</code> yields the following curve:

Simple Mathematical Functions

The following functions are useful for performing various simple mathematical calculations.

abs

Returns the absolute value of a given number. The absolute value is the positive value of any number.

Syntax:	abs(Number)
Arguments:	<ul style="list-style-type: none"> Number is the number of which you want the absolute value.
Examples:	<ul style="list-style-type: none"> abs(3) returns 3. abs(-3) returns 3.

sign

Returns the sign of a given number. The sign function returns 1 if the number is above or equal to zero, and returns -1 if less than zero.

Syntax:	sign(Number)
Arguments:	<ul style="list-style-type: none"> Number is the number of which you want the sign.
Examples:	<ul style="list-style-type: none"> sign(5) returns 1. sign(0) returns 1. sign(-0.001) returns -1.

pow

Returns a number raised to the power of an exponent.

Syntax:	pow(Number,Power)
---------	-------------------

Arguments:	<ul style="list-style-type: none"> ■ Number is the base number to be raised. ■ Power is the exponent to which the base number is raised.
Examples:	<ul style="list-style-type: none"> ■ <code>pow(3, 2)</code> returns 9. ■ <code>pow(4, 3)</code> returns 64. ■ <code>pow(5, 0)</code> returns 1. ■ <code>pow(-2.5, 4)</code> returns 39.0625.

sqrt

Returns the square root of a given number.

Syntax:	<code>sqrt(Number)</code>
Arguments:	<ul style="list-style-type: none"> ■ Number is the non-negative number of which you want the square root.
Examples:	<ul style="list-style-type: none"> ■ <code>sqrt(25)</code> returns 5. ■ <code>sqrt(abs(-25))</code> returns 5. ■ <code>sqrt(0)</code> returns 0.

max

Returns the larger of two given numbers.

Syntax:	<code>max(Number1, Number2)</code>
Arguments:	<ul style="list-style-type: none"> ■ Number1 and Number2 are numbers of which you want to find the maximum value.
Examples:	<ul style="list-style-type: none"> ■ <code>max(5.9, 8.1)</code> returns 8.1. ■ <code>max(-14, -32)</code> returns -14. ■ <code>max(axis1.position.x, axis2.position.x)</code> returns the larger of <code>axis1.position.x</code> or <code>axis2.position.x</code>.

min

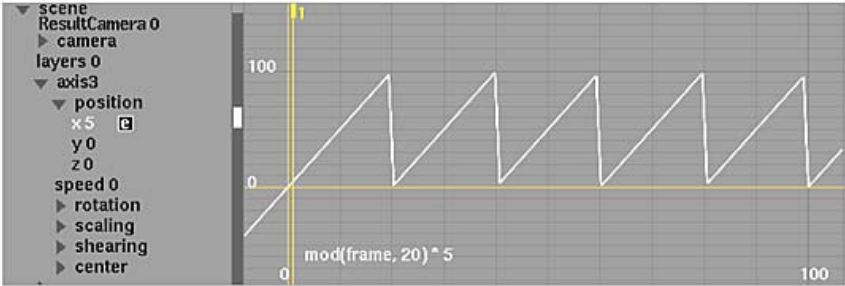

Returns the smaller of two given numbers.

Syntax:	<code>min(Number1, Number2)</code>
Arguments:	<ul style="list-style-type: none"> ■ Number1 and Number2 are numbers of which you want to find the minimum value.
Examples:	<ul style="list-style-type: none"> ■ <code>min(5.9, 8.1)</code> returns 5.9.

- `min(-14, -32)` returns -32.
- `min(axis1.position.x, axis2.position.x)` returns the smaller of `axis1.position.x` or `axis2.position.x`.

mod

Returns the integer remainder from dividing one number by another. This function is useful for repeating an animation every given number of frames.

Syntax:	<code>mod(Number, Divisor)</code>
Arguments:	<ul style="list-style-type: none"> ■ Number is the number to divide. ■ Divisor is the number by which you want to divide Number.
Examples:	<ul style="list-style-type: none"> ■ <code>mod(8, 3)</code> returns 2 because 8 divided by 3 is 2 with 2 as the remainder. ■ <code>mod(-8, 3)</code> returns -2. ■ <code>mod(8, -3)</code> returns 2. ■ <code>mod(-8, -3)</code> returns -2. ■ <code>mod(7.5, 2.25)</code> returns 0.75. ■ <code>mod(frame, 20) * 5</code> yields the following curve: 

Random Number Functions

Use the following functions to create curves based on random values.

rand

Returns a random value between -1 and 1, based on the value used as an argument, called the *seed*. Using the same seed in the `rand` function for multiple channels produces the exact same results. To create completely random results, use the `true rand` function.

Syntax:	<code>rand(Seed)</code>
Arguments:	<ul style="list-style-type: none"> ■ Seed is the value used to generate the random return value. This is usually set to a changing value such as the current frame number.

Examples:	<ul style="list-style-type: none"> ■ <code>rand(frame % 10) * 50 + 50</code> returns a set of random values between 0 and 100 that repeats every 10 frames. ■ <code>rand(frame) * 100</code> returns a random value between -100 and 100 for every frame in the animation. The following curve shows the result of this function:
-----------	---

truerand

Returns a truly random value between two given numbers. The sequence of returned values will constantly change, never reproducing past results.

Syntax:	<code>truerand(Low, High)</code>
Arguments:	<ul style="list-style-type: none"> ■ Low and High are the upper and lower bounds, respectively, of the random number to generate.
Example:	<ul style="list-style-type: none"> ■ <code>truerand(-5.5,10.8)</code> returns a truly random value between -5.5 and 10.8.

noise

Returns a random value between -1 and 1, based on a given vector. If the parameter varies smoothly, this function will return a continuously changing value that also varies smoothly.

Syntax:	<code>noise(Position)</code>
Arguments:	<ul style="list-style-type: none"> ■ Position is a vector used as a seed for the returned random value.
Examples:	<ul style="list-style-type: none"> ■ <code>noise(frame) * 5</code> returns a continuous random value between -5 and 5. ■ <code>(noise(axis1.position) + 1) / 2 * 100</code> returns a continuous random value between 0 and 100. ■ <code>noise(axis1.position) * 100</code> yields the following curve:

noise3

Returns a random vector for all elements in a vector between -1 and 1. If the parameter varies smoothly, this function will return a vector of continuously changing values that also vary smoothly.

Syntax:	<code>noise3(Position)</code>
Arguments:	<ul style="list-style-type: none"> Position is a vector used as a seed for the returned random vector.
Examples:	<ul style="list-style-type: none"> <code>noise3(frame) * 5</code> returns a vector of continuous random values between -5 and 5. <code>(noise3(axis1.position) + 1) / 2 * 100</code> returns a vector of continuous random values between 0 and 100. <code>noise3(axis1.position) * 100</code> returns the following three curves:

fnoise

Returns a random value between -1 and 1, based on a given vector. If the parameter varies smoothly, this function will return a continuously changing value that also varies smoothly to a fractal pattern. This function is similar to the noise function, but it applies a fractal pattern to the result.

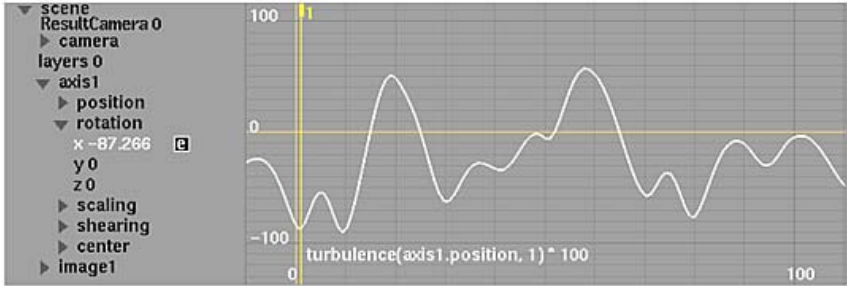

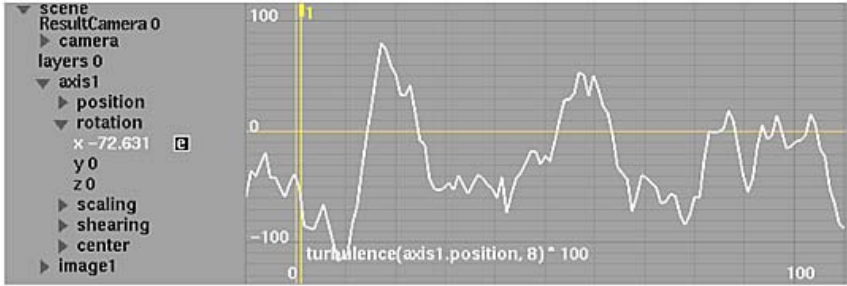

Syntax:	<code>fnoise(Position)</code>
Arguments:	<ul style="list-style-type: none"> Position is a vector used as a seed for the returned random value.
Examples:	<ul style="list-style-type: none"> <code>fnoise(frame) * 5</code> returns a continuous random value between -5 and 5. <code>(fnoise(axis1.position) + 1) / 2 * 100</code> returns a continuous random value between 0 and 100.

- `fnoise(axis1.position) * 100` yields the following curve:

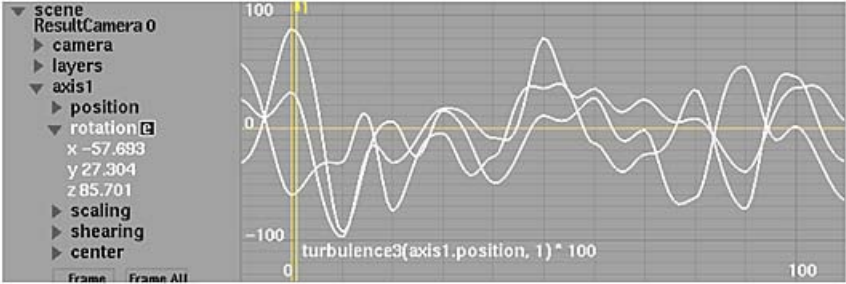

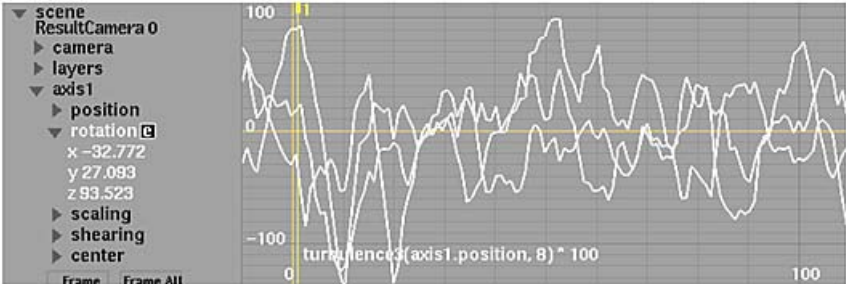

turbulence

Returns a random value between -1 and 1, based on a given vector and with the ability to control the level of smoothness for the resulting curve.

Syntax:	<code>turbulence(Position, Level)</code>
Arguments:	<ul style="list-style-type: none"> ■ Position is a vector used as a seed for the returned random value. ■ Level is a positive integer where the greater the value, the greater the jitter applied to the resulting curve. If this argument is set to a value less than 1, the level will be treated as if 1 were used. If it is set to a number with a fractional component, the number will be rounded down to the nearest integer.
Examples:	<ul style="list-style-type: none"> ■ <code>turbulence(axis1.position, 1) * 100</code> yields the following curve:  <ul style="list-style-type: none"> ■ <code>turbulence(axis1.position, 8) * 100</code> yields the following curve: 

turbulence3

Returns a random vector for all elements in a vector between -1 and 1, along with the ability to control the smoothness of the resulting curve. If the position parameter varies smoothly, this function will return a vector of continuously changing values that also vary smoothly.

Syntax:	turbulence3(Position, Level)
Arguments:	<ul style="list-style-type: none">■ Position is a vector used as a seed for the returned random vector.■ Level is a positive integer used to control the level of jitter of the resulting curve. If this argument is set to a value less than 1, the level will be treated as if 1 were used. If it is set to a number with a fractional component, the number will be rounded down to the nearest integer.
Examples:	<ul style="list-style-type: none">■ turbulence3(axis1.position, 1) * 100 returns the following three curves: ■ turbulence3(axis1.position, 8) * 100 returns the following three curves: 

Rounding Functions

The following functions are useful for performing various rounding calculations.

NOTE Although you can use these rounding functions as you would any other predefined function, they are actually implemented as user-defined functions in the functions file provided with the Flame Premium installation. See [Defining Your Own Functions](#) (page 1545).

round

Returns a number rounded to the nearest integer.

Syntax:	round(Number)
Arguments:	■ Number is the number to round.
Examples:	■ round(2.8) returns 3. ■ round(-2.8) returns -3. ■ round(2.3) returns 2.

ceil

Rounds a number up to the next integer value regardless of its value.

Syntax:	ceil(Number)
Arguments:	■ Number is the number to round up.
Examples:	■ ceil(2.8) returns 3. ■ ceil(-2.8) returns -2. ■ ceil(4) returns 4.

floor

Rounds a number down to the nearest integer regardless of its value.

Syntax:	floor(Number)
Arguments:	■ Number is the number to round down.
Examples:	■ floor(2.3) returns 2. ■ floor(-2.3) returns -3. ■ floor(4) returns 4.

trunc

Returns the integer value of a number by truncating its fractional part.

Syntax:	trunc(Number)
Arguments:	■ Number is the number that you want to truncate.

Examples:	<ul style="list-style-type: none"> ■ <code>trunc(3.8)</code> returns 3. ■ <code>trunc(-3.8)</code> returns -3. ■ <code>trunc(PI)</code> returns 3.
-----------	---

Trigonometric Functions

The following functions are useful for working with angles and performing various trigonometric calculations.

degrees

Converts angle units from radians into degrees.

Syntax:	<code>degrees(Angle)</code>
Arguments:	<ul style="list-style-type: none"> ■ Angle is the angle in radians that you want to convert.
Examples:	<ul style="list-style-type: none"> ■ <code>degrees(PI)</code> returns 180. ■ <code>degrees(PI/2)</code> returns 90.

radians

Converts angle units from degrees into radians.

Syntax:	<code>radians(Angle)</code>
Arguments:	<ul style="list-style-type: none"> ■ Angle is the angle in degrees that you want to convert.
Example:	<ul style="list-style-type: none"> ■ <code>radians(225)</code> returns 3.927 ($5 \cdot \text{PI} / 4$).

cos

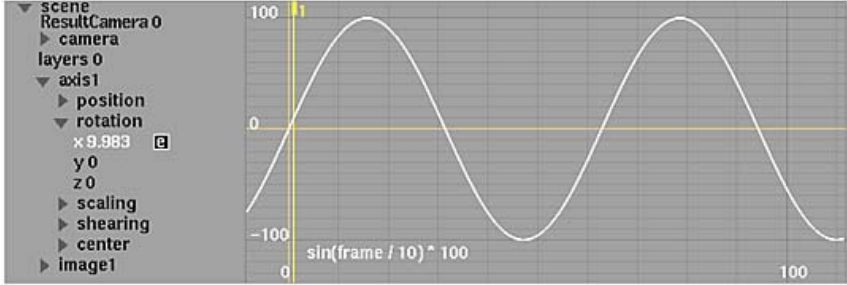

Returns the cosine of a given angle.

Syntax:	<code>cos(Angle)</code>
Arguments:	<ul style="list-style-type: none"> ■ Angle is the angle in radians of which you want the cosine.
Examples:	<ul style="list-style-type: none"> ■ <code>cos(0)</code> returns 1. ■ <code>cos(PI / 3)</code> returns 0.5. ■ <code>cos(frame / 10) * 100</code> yields the following curve:

sin

Returns the sine of a given angle.

Syntax:	<code>sin(Angle)</code>
Arguments:	<ul style="list-style-type: none"> Angle is the angle in radians of which you want the sine.
Examples:	<ul style="list-style-type: none"> <code>sin(0)</code> returns 0. <code>sin(PI / 6)</code> returns 0.5. <code>sin(frame / 10) * 100</code> yields the following curve: 

tan

Returns the tangent of a given angle.

Syntax:	<code>tan(Angle)</code>
Arguments:	<ul style="list-style-type: none"> Angle is the angle in radians of which you want the tangent.
Examples:	<ul style="list-style-type: none"> <code>tan(0)</code> returns 0. <code>tan(PI / 4)</code> returns 1. <code>tan(PI / 3)</code> returns 1.7321. <code>tan(frame / 10) * 50</code> yields the following curve:

acos

Returns the arccosine—the inverse function of the cosine—of a given number. The returned angle is given in radians within the range 0 to PI.

Syntax:	acos(Number)
Arguments:	<ul style="list-style-type: none"> Number is the cosine of the angle you want and must be between -1 and 1.
Examples:	<ul style="list-style-type: none"> acos(0.5) returns 1.0472 (PI/3 radians). degrees(acos(0.5)) returns 60.

asin

Returns the arcsine—the inverse function of the sine—of a given number. The returned angle is given in radians within the range -PI/2 to PI/2.

Syntax:	asin(Number)
Arguments:	<ul style="list-style-type: none"> Number is the sine of the angle you want and must be between -1 and 1.
Examples:	<ul style="list-style-type: none"> asin(0.5) returns 0.5236 (PI/6 radians). degrees(asin(0.5)) returns 30.

atan

Returns the arctangent—the inverse function of the tangent— of a given number. The returned angle is given in radians within the range -PI/2 to PI/2.

Syntax:	atan(Number)
Arguments:	<ul style="list-style-type: none"> Number is the tangent of the angle you want.
Examples:	<ul style="list-style-type: none"> atan(1) returns 0.7854 (PI/4 radians). degrees(atan(1)) returns 45.

atan2

Returns the arctangent of y/x , using the signs of both arguments to determine the quadrant of the return value. The arctangent is the angle from the origin to the vector (x,y) . The returned angle is given in radians within the range $-\pi$ to π .

Syntax:	<code>atan2(x, y)</code>
Arguments:	<ul style="list-style-type: none"> ■ <code>x</code> and <code>y</code> are the components of the vector to be used in the function.
Examples:	<ul style="list-style-type: none"> ■ <code>atan2(1, 1)</code> returns 0.7854 ($\pi/4$ radians). ■ <code>atan2(-1, -1)</code> returns -2.3562 ($-3\pi/4$ radians). ■ <code>atan2(1, 0)</code> returns 1.5708 ($\pi/2$ radians). ■ <code>degrees(atan2(1,1))</code> returns 45.

Vector Functions

Use the following functions for performing various vector-related operations.

length

Returns the euclidean length (magnitude) of a given vector. The euclidian length is equivalent to the expression `sqrt(pow(Vector.x, 2) + pow(Vector.y, 2) + pow(Vector.z, 2))`.

Syntax:	<code>length(Vector)</code>
Arguments:	<ul style="list-style-type: none"> ■ <code>Vector</code> is the vector of which you want the euclidean length.
Examples:	<ul style="list-style-type: none"> ■ <code>length((2, 0, 0))</code> returns 2. ■ <code>length((1, 1, 0))</code> returns 1.4142. ■ <code>length((-1, -1, -1))</code> returns 1.7321. ■ <code>length(axis1.position - axis2.position)</code> returns the distance between <code>axis1</code> and <code>axis2</code>.

dot

Returns the scalar dot-product of two given vectors. The *dot-product* is the product of the lengths of two vectors and the cosine of the angle between them. If the two vectors are at a right angle (90 degrees), their dot-product is 0.

If the product of their lengths equals 1 and they point in opposite directions (180 degrees), their dot-product is -1. The dot-product is equivalent to the expression `V1.x * V2.x + V1.y * V2.y + V1.z * V2.z`.

Syntax:	<code>dot(V1, V2)</code>
---------	--------------------------

Arguments:	<ul style="list-style-type: none"> ■ V1 and V2 are the vectors of which you want the dot-product.
Examples:	<ul style="list-style-type: none"> ■ <code>dot((1, 1, 0), (0, 0, 1))</code> returns 0. ■ <code>dot((2, 0, 0), (0.5, 0, 0))</code> returns 1. ■ <code>dot((0, 2, 0), (0, -0.5, 0))</code> returns -1. ■ <code>dot((2, 0, 1), (4, 5, 5))</code> returns 13.

cross

Returns the vector cross-product of two given vectors. The cross-product is the vector perpendicular to the plane containing the two vectors. In effect, there will be a right angle between the returned vector and the first given vector, as well as a right angle between the returned vector and the second given vector. The length of the resulting vector is equal to the product of the two vectors and the sine of the angle between them. The cross-product is equivalent to the vector $(V1.y * V2.z - V1.z * V2.y, V1.z * V2.x - V1.x * V2.z, V1.x * V2.y - V1.y * V2.x)$.

Syntax:	<code>cross(V1, V2)</code>
Arguments:	<ul style="list-style-type: none"> ■ V1 and V2 are the vectors of which you want the cross-product.
Examples:	<ul style="list-style-type: none"> ■ <code>cross((1, 0, 0), (0, 1, 0))</code> returns (0, 0, 1). ■ <code>cross((1, 1, 0), (0, 1, 1))</code> returns (1, -1, 1). ■ <code>cross((2, 0, 0), (0, 0.5, 0))</code> returns (0, 0, 1).

Logarithmic Functions

Use the following functions for performing various logarithmic calculations.

log

Returns the natural logarithm of a given number. The log function is the inverse of the exp function.

Syntax:	<code>log(Number)</code>
Arguments:	<ul style="list-style-type: none"> ■ Number is the positive number of which you want the natural logarithm.
Examples:	<ul style="list-style-type: none"> ■ <code>log(1)</code> returns 0. ■ <code>log(2)</code> returns 0.6931. ■ <code>log(exp(5))</code> returns 5. ■ <code>log(256) / log(2)</code> returns 8. ■ <code>log(frame / 20) * 50</code> yields the following curve:

log10

Returns the base-10 logarithm of a given number.

Syntax:	log10(Number)
Arguments:	<ul style="list-style-type: none"> Number is the positive number of which you want the base-10 logarithm.
Examples:	<ul style="list-style-type: none"> log10(1) returns 0. log10(10) returns 1. log10(100) returns 2.

log1p

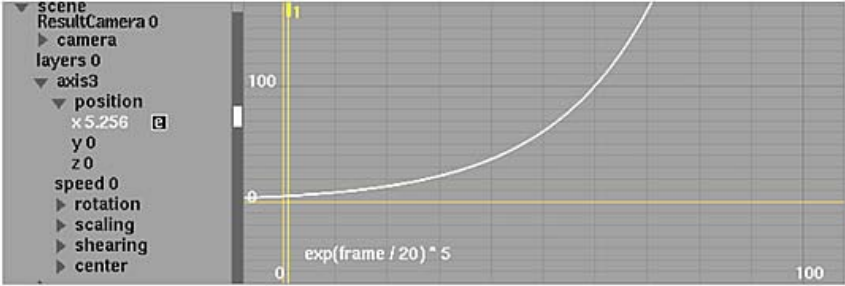

Returns the natural logarithm of 1 plus a given number. The log1p function is the inverse of the expm1 function.

Syntax:	log1p(Number)
Arguments:	<ul style="list-style-type: none"> Number is the positive number less 1 of which you want the natural logarithm.
Examples:	<ul style="list-style-type: none"> log(0) returns 0. log(1) returns 0.6931. log1p(expm1(5)) returns 5. log1p(frame) returns the equivalent of log(1+frame). log1p(frame / 20) * 50 yields the following curve:

exp

Returns the constant e (the base of the natural logarithm) raised to the power of a given number. The exp function is the inverse of the log function.

Syntax:	exp(Number)
Arguments:	<ul style="list-style-type: none">■ Number is the exponent applied to the base e.
Examples:	<ul style="list-style-type: none">■ exp(0) returns 1.■ exp(1) returns 2.7182.■ exp(2) returns 7.3890.■ exp(log(5)) returns 5.■ exp(frame / 20) * 5 yields the following curve: 

expm1

Returns the constant e (the base of the natural logarithm) raised to the power of a given number, minus 1. The expm1 function is the inverse of the log1p function.

Syntax:	expm1(Number)
Arguments:	<ul style="list-style-type: none">■ Number is the exponent applied to the base e.
Examples:	<ul style="list-style-type: none">■ expm1(0) returns 0.■ expm1(1) returns 1.7182.■ expm1(2) returns 6.3890.■ expm1(log1p(5)) returns 5.■ expm1(frame) returns the equivalent of exp(frame) - 1.

Defining Your Own Functions

Flame Premium allows you to define your own functions and use them like any other predefined function. By defining functions in terms of existing functions, you can simplify the creation of complex expressions in your animations.

NOTE You should have a good understanding of how to use functions in expressions before you define your own functions.

The Functions File

There are two text files in which you can enter user-defined functions:

- Project-specific file: `/usr/discreet/project/<user_name>/expressions/userfun.expressions`
- Template file: `/usr/discreet/<product_name>/expressions/userfun.expressions`

To define a function for your current project, add it to the project-specific file. Modifying this file will affect only that project and not any other existing or future projects.

If you decide that you want to use the function in future projects, copy it from the project-specific file to the template file. When you create a project, the template file is copied to your project directory as the project-specific file for that new project. This functionality allows you to modify user-defined functions in new projects without affecting the behaviour of your animations in older projects.

To edit the functions file:

- 1 Open a command window.
- 2 Use the mouse to position the cursor in the shell and type one of the following commands, depending on which file you want to edit.

Enter:	To:
nedit /usr/discreet/project/<user_name>/expressions/userfun.expressions	Edit the project-specific file.
nedit /usr/discreet/<product_name>/expressions/userfun.expressions	Edit the template file.

The functions file opens in a shell and you can edit it as you would any other text file.

Defining a Function

A function is composed of a function name, with the list of arguments, and the expression that forms its definition. You start a function by its name, followed by an opening parenthesis, the arguments for the function separated by commas, and finally a closing parenthesis. The following rules apply for function and argument names:

- The first character of a function name must be a letter, and subsequent characters can only contain letters or numbers. For example, `sin100` is a valid function name, although `100sin` is not.
- The first character of an argument must be a dollar sign (`$`), the second character must be a letter, and subsequent characters can only contain letters or numbers. For example, `$arg1` is a valid argument name, although `$1` and `arg3` are not.
- Function names and arguments are case sensitive, meaning that lowercase and uppercase make a difference.

The function name and its definition are separated by a colon (`:`). The definition itself can be any valid expression, except that channel names are not accepted since user-defined expressions are not related to any particular setup. In the definition, the arguments can appear, complete with the dollar sign preceding it. Finally, the definition must end with a semicolon (`;`) and it can span several lines.

NOTE Errors in the functions file will be reported when it is first read. This file is read every time that an unknown function is used in an expression.

Comments

You can include comments in the functions file by starting the line with a number sign (#). The comments extend through the end of the line on which they appear and are ignored by Flame Premium when the user-defined functions file is interpreted. Comments are useful for describing the purpose of a function and adding any notes you feel are pertinent. They can be introduced anywhere in the file, except for inside of function definitions that span several lines.

Sample Function Definitions

The following sample functions are found in the functions file that is installed with Flame Premium.

- This function creates a sine curve for a given channel that oscillates between 0 and 100. The `sin100` function takes one argument, named `$arg1`, that it uses in conjunction with the predefined `sin` function. The return value for `sin100` is the sine of `$arg1` times 50, plus 50.

`sin100($arg1) : sin($arg1)*50 + 50;`

- This function creates a sine curve based on the specified frequency and amplitude. The `sinfreqamp` function takes three arguments, named `$pos`, `$freq` and `$amp`.

`sinfreqamp($pos,$freq,$amp) : sin($pos*$freq)*$amp;`

- This function provides an approximation of the speed, or more precisely, the derivative (rate of change), of a given channel. The `speed` function takes one argument, named `$channelName`.

**`speed($channelName) :eval($channelName,frame+0.1) -
eval($channelName,frame-0.1))/0.2;`**

NOTE For information on the other example functions in the functions file, see [Slip Functions](#) (page 1529) and [Rounding Functions](#) (page 1537).

Sample Expression Setups

A few Action setups with sample expressions are provided in the directory `/usr/discreet/<product_name>/examples/action`.

To load an setup file from Action accessed from the Tools tab, click the Load button in the Action menu. To load an Action setup from Batch or Batch FX, select the Action node in the schematic, then click Node Prefs and Load Node.

Animated Text

To see this example, load the example setup named `expressions_text` into Action. This example involves multiple text objects that move along a path, with each letter following slightly behind the last.

Each letter's position and rotation are created through the expressions in the following folder. The letter 'o' rotates its X-axis towards the direction of its movement. The align function is used to generate the rotation vector.

Each preceding letter sets its position and rotation an increasing number of frames behind the letter 'o'. The channel dummy_axis.position.x is used here to store a value determining the distance between each letter. The eval function is used to determine the values of the o_axis.position and o_axis.rotation channels at different points in time.

NOTE A series of expressions that differ only by a numeric value, such as in this example, can be entered quickly using the SelectionOrder keyword. See [Cascading Expressions](#) (page 1519).

Channel	Expression
o_axis.rotation	align(o_axis.position)
n2_axis.position	eval(o_axis.position, frame - dummy_axis.position.x * 1)
r_axis.position	eval(o_axis.position, frame - dummy_axis.position.x * 2)
e_axis.position	eval(o_axis.position, frame - dummy_axis.position.x * 3)
f_axis.position	eval(o_axis.position, frame - dummy_axis.position.x * 4)
n_axis.position	eval(o_axis.position, frame - dummy_axis.position.x * 5)
i_axis.position	eval(o_axis.position, frame - dummy_axis.position.x * 6)

Channel	Expression
n2_axis.rotation	eval(o_axis.position, frame - dummy_axis.position.x * 1)
r_axis.rotation	eval(o_axis.position, frame - dummy_axis.position.x * 2)
e_axis.rotation	eval(o_axis.position, frame - dummy_axis.position.x * 3)
f_axis.rotation	eval(o_axis.position, frame - dummy_axis.position.x * 4)
n_axis.rotation	eval(o_axis.position, frame - dummy_axis.position.x * 5)
i_axis.rotation	eval(o_axis.position, frame - dummy_axis.position.x * 6)

Spinning Dagger

To see this example, load the setup named *expressions_spinning_dagger* into Action. This example features a dagger moving in an arc. The dagger's Y-axis is aligned with the direction of its movement and the rest of the dagger spins around its axis.

The dagger's rotation is created through the dagger's rotation of its negative Y-axis towards the direction of its movement and the rest of the dagger spins one full rotation around this same axis every 32 frames. The align function is used to generate the rotation vector.

Channel	Expression
dagger_axis.rotation	align(dagger_axis.position, (0,-1,0), frame * 2 * PI / 32)

Dagger, Apple, and Cherry

To see this example, load the setup named *expressions_dagger_apple_cherries* into Action. This animation points a dagger at either a moving apple or moving cherries, whichever is closer in position at the time.

The dagger's rotation is created by the dagger's position as the dagger points its negative Y-axis in the direction of either the apple or the cherries, whichever happens to be closest. The length function is used to find the distance between the dagger and the other objects, while the if function is used to determine which is the shorter distance. The lookat function is used to generate the rotation vector.

Channel	Expression
dagger_axis.rotation	if(length(cherries_axis.position - dagger_axis.position) < length(apple_axis.position - dagger_axis.position), lookat(cherries_axis.position, dagger_axis.position, (0,-1,0), (1,0,1)), lookat(apple_axis.position, dagger_axis.position, (0,-1,0), (1,0,1)))

Dampened Pendulum

To see this example, load the setup named *expressions_dampened_pendulum* into Action. This examples involves a pendulum (a ball attached to a rope) that swings freely back and forth under the force of gravity until it comes to a stop.

The ball oscillates in a dampened harmonic motion that is created by animating the position of the ball and the rotation of the rope. The ball's x position is defined as the sine of the swing angle between the rope and centre axis, multiplied by the length of the rope. This angle is initially $\pi/2$ and decreases logarithmically. In addition, the ball oscillates with a period of 30 frames. The sin function is used to calculate the sine of the swing angle and the exp function is used to create the logarithmic dampening effect. The cos function is used to create the oscillation.

The ball's y position is defined as the negative cosine of the swing angle between the rope and centre axis, multiplied by the length of the rope. This expression is formed similarly to that of the ball_axis.position.x channel. The rope rotates such that its Y-axis is always pointing toward the centre of the ball. The lookat function is used to generate the rotation vector.

Channel	Expression
ball_axis.position.x	$\sin(\pi / 2 / \exp(\text{frame} / 100) * \cos(\text{frame} * 2 * \pi / 30)) * 200$
ball_axis.position.y	$-\cos(\pi / 2 / \exp(\text{frame} / 100) * \cos(\text{frame} * 2 * \pi / 30)) * 200$
rope_axis.rotation	$\text{lookat}(\text{ball_axis.position}, \text{rope_axis.position}, (0,1,0), (0,0,1))$

Modifying Clips with Clip History

26

To create clip history while rendering:

- 1 In the Preferences menu, click the General tab.
- 2 Under Default Rendering Options, select Render & Create History in the Render box.

NOTE In Batch and Tools editors, you also have this option in the Render box, but by setting it in the Preferences menu, you can make sure that history is enabled for all renders (including tools that render a result directly in the workspace without entering the editor).

To view clip history in the timeline:

- 1 Select a source or sequence clip with history.
- 2 From the Timeline View Mode box, select History.

The view changes to a history view of the selected clip. Batch FX and Timeline FX applied to a clip are included in its history. From the history view you can see and edit all of the effects or tools applied to a clip. Double-click effects to re-enter the editor, or use the right-click context menu for other editing options.

TIP To quickly enter the history view, double-click the "H" icon on a clip on the desktop. To bypass history view, and quickly re-enter the last tool used on a desktop clip with history, press **Shift** and double-click the "H" icon on the clip.

To modify clip history through History View:

- 1 Display the clip history of a clip.
- 2 Double-click a node (in schematic view) or an entry (in list view) to open the corresponding tool or Timeline FX editor.
- 3 Edit the settings as needed.
- 4 If you loaded the clip into a tool editor, do one of the following:
 - To save your changes, select Return from the Exit Options box.
 - To exit without saving your changes, select Cancel from the Exit Options box, and then confirm.

- 5 If you loaded the clip into a Timeline FX editor, click Exit.

To replace sources in a clip's history:

- 1 Display the history of a clip.
- 2 Do one of the following.

Do this:	To swap:
Double-click a source	The original source with another.
Press <code>Ctrl</code> and double-click a tool node	All of the sources used in a tool.

The cursor becomes a coloured crosshair to indicate what type of source you can select.

- 3 Click the source clips you want to swap in to the clip history. The sources you swap must be of the same resolution and bit depth.

NOTE If the new source is longer than the original source, the new source is shortened to fit the duration of the original source. If the new source is shorter than the original, the last frame of the new source is repeated to the end of the segment.

The sources are swapped and the Render button becomes active.

- 4 Click Render to render the swapped sources.

To explode clip history in Batch or Batch FX:

- 1 Double-click a clip with history in the Batch or Batch FX schematic to view its clip settings.
- 2 In the History section, select Explode History to expand the entire clip history into the process tree, or Explode One to expand only the most recent step of the clip's history.

If the input clip to the last node also contains history, you can also expand the history for that clip.

NOTE These history options are not available for Batch or Batch FX clips with non-supported effects (the clip appears with a lowercase "h" next to its name in the schematic). In this case, if you double-click the clip again, you are returned to the timeline view. You can switch to History view to see its clip history.

About Clip History

Use clip history to track and update operations you have applied to a clip. The Timeline History view expands a clip, providing a view of your operations. You can also use the clip history in Batch or Batch FX as an

access point for modifying clips. Clips with history have a "H" icon when displayed on the desktop. In the Batch or Batch FX schematic, a [H] appears beside the clip name under the clip proxy.

Desktop clip with history

Batch clip with history

Certain tools, including those that do not have an equivalent Batch node, such as Warper or Reverse, appear with a lowercase "h" icon when rendered. In this case, you can view the clip's history in the History view, but not make changes to that tool, or any upstream tools in the pipeline. To edit these effects, you need to rebuild the effect in the tool originally used to create it. You can use the Match button in the timeline History view to help you locate the clip to its source in the workspace.

Clips that have a clip history contain sources and intermediates. Sources are any of the original clips used to build an effect, for example, clips captured using an EDL. Intermediates are clips that are created when building a clip that uses multiple effects or operations.

A simple way of using clip history is to load a rendered clip back into the last editor that was used to create the clip. For instance, you load a clip into the Colour Corrector, modify the colour, and render a new clip. You decide that you want to change the colour slightly, so you press **Shift** and double-click the "H" icon of the new clip to go back into the Colour Corrector with the settings restored. You tweak the values slightly, and then render another clip (which has its own clip history).

If multiple tools were used to create a clip, you can load the result into a Batch setup, explode the history, and make modifications at any point in the process tree. For instance, you may have created a composite by bringing a colour-corrected back layer into the Keyer with a front and key-in layer that may also have been modified (for example, with a Flip). By loading the resulting clip into Batch, you can modify it at any point in the process tree, and then process a new clip.

NOTE You can also use a [Create BFX clip](#) (page 402) instead of, or in addition to, clip history for added flexibility in reusing or versioning complex pipelines.

Clip History Tips

- In the Batch or Batch FX preferences Rendering tab, you can enable Fill with Intermediates in the Cache section so that each node's cache is filled with the intermediate clips contained in the history. Filling a history tree's cache increases interaction speed and avoids the need to reprocess effects that were already rendered. If an intermediate clip corresponding to a step in the history is deleted, the cache for that particular node is not filled.
- If you modify and then render an intermediate that is part of a clip history, all the clip history elements after the rendered event are also rendered. Additionally, all instances of the intermediate used in the clip history are modified. If the same intermediate appears in another clip history, however, it is not modified — once you modify an intermediate in a clip history, any copies you made of the intermediate in other clip histories are discrete.
- If you have a Paint or Stabilizer element in your clip history, all modules that precede the Paint or Stabilizer module will not be editable. You can, however, modify the elements before the Paint or Stabilizer element by selecting the element immediately preceding the Paint or Stabilizer element in the history, and then using Match to create a clip with the same history in the Source Area. You can then use the result clip from the match. The history is expandable and editable.

- The duration of a clip created in the Paint tool is not retained. For example, enter the Paint tool with None selected, and then create a scene that is 30 frames. Then go into a tool such as Action and make some changes. When you view the clip history and click the Paint tool element, the clip will contain one frame only.
- When you enter a tool from clip history, in and out points mark the duration in the source clip that was used in the clip history (unless the entire clip was used). If you then make a modification and process the result, only the duration of the clip marked by in and out points is rendered, unless you park the cursor before the in point. If the cursor is parked before the in point, media is added to the head frames, starting from the cursor position.
- Note the following when accessing the history of Action clips:
 - When accessing the history of stereo output, you can change either the left or right eye output or both.
 - When accessing the history of clips containing multiple outputs, you can change the output enabled in the Action Output List but you can only have one output enabled.
 - You cannot change an Output mode to Stereo if the previous output was not stereo.

Clip History Reference

Timeline History View

History View box Select a list or schematic representation of the clip's history.

History box Select to display the history of the selected source or sequence clip.

Render button Click to render sources that were replaced through the clip's history.

Match button Click to match the clip to its source in the workspace.

History View horizontal scroll bar Drag the horizontal scroll bar to pan the schematic.

History View vertical scroll bar Drag the vertical scroll bar to pan the schematic up or down.

Home button Returns the schematic to its default position.

Current Timecode field Displays the timecode of the current position. Editable.

Clip History Media Management Options

These settings can be found in the Timeline Gear menu's Commit section.

Delete History button Click to delete intermediates from selected timeline elements. If no elements are selected, intermediates for the entire edit sequence are deleted. Use when you want to free up disk space or shorten the time it takes to perform a wire transfer or archive clips with clip history.

Commit History button Click to commit a clip with history. When committing a clip, you delete the clip history without removing the clip or element's soft properties.

Clip History Preferences

These history-related preferences can be found in **Preferences ► General**.

Render box Select whether you want to include history and/or Burn when rendering.

Keep History Mode box Select whether Sources or Intermediates and Sources appear on the workspace when working with clip history.

Batch or Batch FX History Settings

These history options are available in the clip settings of a clip with history.

Explode History button Click to expand the entire clip history into the rendering tree.

Explode One button Click to expand only the most recent step of the clip's history. If the input clip to the last node also contains history, you can also expand the history for that clip.

The following setting is available in the Batch or BFX Prefs Rendering section, under Cache.

Fill with Intermediates button Enable to fill each node's cache with the intermediate clips contained in the history. If a clip was rendered in proxy mode, the history is not cached.

Colour Management

27

Colour management enables the desired colour values to be represented as accurately as possible throughout the finishing process. It is different from colour correction in that its intention is not to change colours but instead to preserve the perceived colour in different situations.

NOTE Colour management is performed with the LUT Editor and other controls that are labelled "LUT", but other operations including colour transforms and gamma functions are supported in addition to look-up tables.

Colour Management Workflow

Colour management works by applying colour transforms and other operations at various stages of the pipeline. Typically, you use colour management when:

- Importing media. Images from different sources (such as digital cameras, scanned film, 3D renders, and matte paintings) often use different colour spaces and encodings, and they should be converted to a single working colour space.
- Outputting media. Different output formats require different encodings depending on the medium and expected viewing conditions.

You might also want to apply colour transforms to convert into and out of a specific colour space in order to perform a particular operation. For example, operations like compositing or lens blur work best in a linear colour space, while operations like tracking and edge detection work best in video or log colour space.

In addition, colour management is used to display images in Flame Premium to ensure that the colours on the monitor and projector match what will be displayed on the final output as closely as possible. For example, if you are working in the ACES colour space, you can apply the ACES_to_current-monitor transform.

Applying Colour Management to Clips

Use the LUT Editor to apply colour management to clips. This changes the underlying colour values of the clips' pixels. You should do this when you want the changes to flow through the pipeline to the final output. If you want to apply colour management to the display only, see [Applying Colour Management to Displayed Images](#) (page 1576) instead.

Accessing the LUT Editor

You can access the LUT Editor from Batch, from Batch FX, from the Tools tab, from the Import menu and from the Export menu.

To access the LUT Editor from the Import menu, see [Importing File-Based Media](#) (page 55).

To access the LUT Editor from the Export menu, see [Exporting Clips and Sequences to Files](#) (page 56).

Accessing the LUT Editor in Batch or Batch FX

You can use the LUT Editor from the LUT Editor, Read File, Write File and Render nodes in Batch and the BFX Output node in Batch FX to import or create a LUT or colour transform.

To access the LUT Editor using the LUT Editor node:

- 1 Drag the LUT Editor node to the schematic.
- 2 Parent the output of another node to the front input socket of the LUT Editor node.

- 3 Select the LUT Editor node to view its menu.

To access the LUT Editor as an integrated part of clip input and output processes

- 1 Select the BFX Output node in Batch FX or drag the Read File, Write File, or Render node to the schematic.
- 2 Set up the node so the LUT you create is applied to the clip that you want to convert:
 - If you selected the BFX output node in Batch FX, double click the node to display the LUT Editor menu.
 - If you dragged the Read File to the schematic, use the file browser to locate the clip that you want to import.
 - If you dragged a Write File or Render node to the Batch schematic, parent outputs from the process tree you are working on to the input socket(s) of the node.
- 3 Select the clip.
- 4 Select the RGB LUT or Matte LUT menu.

- 5 Enable Active to apply the current LUT settings to the front clip.

NOTE Active is always enabled if the bit-depth needs to be changed.

The LUT Editor menu is displayed.

TIP The RGB LUT button in the Basic menu of the Write File and Export nodes is linked to the Active button in the RGB LUT menu. Toggling either button enables the LUT.

Accessing the LUT Editor from the Tools Tab

- 1 Click the Tools tab.
- 2 From the Tools menu, select the Look tab.
- 3 Click Lut Editor.
The cursor turns red, prompting you to select a front clip.
- 4 Select a clip from the Viewing panel, the Desktop or the Media panel by clicking it.
The cursor turns white, prompting you to select a destination for the result.
- 5 Click the Viewing panel, a Desktop reel or the Media panel to select the destination.

The LUT Editor menu is displayed.

Specifying a Colour Management Operator

To apply colour management to a clip, you must first specify the type of operation to perform in the [LUT Editor](#) (page 1559). You can:

- Apply a preset LUT and then modify its values.
- Choose an operator type. Depending on the type you choose, you can either import a baked operator or modify its values.

Applying a Preset

- 1 Select an option from the Presets box in the LUT Editor.
- 2 Confirm that you want to replace the existing settings.
The Conversion LUT Type and the field values are all updated with preset conversion parameters. In Batch or Batch FX, a note is added with a description of the preset's usage.
- 3 If desired, modify the curve values as described in [Modifying Basic Conversion LUT Curves](#) (page 1565) and [Advanced Editing of the Conversion LUT Curve](#) (page 1571).

TIP To make your own preset available, save a setup to the /lut/presets subfolder of the application home directory. This does not work with 3D LUTs.

Choosing an Operator Type

- 1 Select an output bit-depth option from the Destination box in the LUT Editor.

- 2 Select an option from the LUT Type box.

Log to Lin	Ref White	170.748	170.748	170.748	Prop
	Ref Black	23.680	23.680	23.680	Prop
	Highlight	255.000	255.000	255.000	Prop
Destination	Shadow	0.000	0.000	0.000	Prop
8-bit	Custom	1.000	1.000	1.000	Prop
	Film Gamma	0.600	0.600	0.600	Prop
Export	Soft Clip	0.000	0.000	0.000	Prop

Select:	To:
Colour Transform	Apply a colour transform based on the Academy/ASC colour transform XML format, as well as several other supported LUT and transform formats.
PhotoMap	Begin with a default curve for tone mapping.
3D LUT	Import a 3D LUT. Note that 3D LUTs are not available for floating-point values.
1D LUT	Import a 1D LUT. Note that some 1D LUTs are intended for integer values and others are intended for floating-point values.
EXR Display	Begin with a default curve for tone mapping.
Gamma	Begin with a default curve for modifying linear data.
Lin to Log	Begin with a default curve for converting linear or video data to logarithmic data.
Log to Lin	Begin with a default curve for converting logarithmic data to linear or video data.

- 3 Do one of the following:
 - If you chose 1D LUT or 3D LUT, import a LUT operator.
 - If you chose Colour Transform, you can import an colour transform operator. Alternatively, you can define a custom colour transform — see [Building Custom Colour Transforms](#) (page 1564).
 - If you chose any other option, you can modify the curve values as described in [Modifying Basic Conversion LUT Curves](#) (page 1565) and [Advanced Editing of the Conversion LUT Curve](#) (page 1571).

Importing an Operator

- 1 Click Import.
The file browser appears.

- 2 Locate and select the file that you want to import. See [Colour Management Files and Locations](#) (page 1581).

When importing a colour transform, see [Autodesk Color Transform Collection](#) (page 1602) for a description of the available categories.

You are returned to the LUT Editor. The LUT name appears in the field next to the Import button.

- When you import a 1D LUT, the conversion curves appear in the LUT Editor. You can modify them only with the Advanced settings.
- When you import a colour transform, information about the transform and the operations it contains appears in the LUT Editor.

Building Custom Colour Transforms

You can build a chain of colour transforms using the Custom mode of the [LUT Editor](#) (page 1559). The transforms are applied in order from beginning to end. For example, you can build a colour transform that first modifies the gamma and then changes the primaries.

- 1 In the LUT Editor, set the LUT type box to Colour Transform.
- 2 Enable the Custom button.
- 3 Click Add to insert an empty row.
- 4 Click in the Type column and select a type:
 - **Shared:** The location for shared custom colour transforms (available to all applications that use Autodesk Colour Management).
 - **Project:** The project transform folder (saved and archived with the project).
 - **Autodesk:** The default location for preset colour transforms supplied with the application. See [Autodesk Color Transform Collection](#) (page 1602).
 - **Import:** Browse for colour transforms on your file system. You can select native .ctf format files, as well as several other supported LUT and transform formats.
- 5 After you've selected a colour transform type, click in the Transform column and select a transform. Information about the transform and the operations it contains appears in the LUT Editor.
- 6 To add more transforms to the end of the chain, repeat steps 3 to 5.

You can also:

 - Click in the Type or Transform columns again to change a transform in the chain.
 - Select a row and click Delete to remove a transform from the chain.
 - Use the Up or Down buttons to reorder the chain. Moving a transform up applies it earlier in the chain, and moving it down applies it later.
 - Use the visibility icon to mute a transform in the chain.

TIP You can create subfolders in the Shared or Project locations to define custom colour transform types.

Modifying Basic Conversion LUT Curves

NOTE The procedures in this section apply only to Gamma, Lin to Log, and Log to Lin operators.

Once you define a basic LUT type in the [LUT Editor](#) (page 1559), you can modify:

- The reference white and reference black values
- The highlights and shadows
- The gamma of the conversion curve
- The gamma of the incoming film negative
- The degree to which the shoulder at the upper end of the conversion curve is softened

When you modify these values, the basic LUT curves are updated to reflect the changes. For all procedures, you can monitor the R, G, and B channels independently while modifying the LUT.

To monitor the R, G, and B channels independently:

- 1 From the Edit Curve box, select Red, Green, or Blue to monitor the red, green, or blue channels independently.

Modifying Reference White and Reference Black Values

The reference white and reference black values define the intensity levels at which incoming pixels are considered white or black respectively. For example, selecting a logarithmic-to-linear basic conversion LUT curve sets the reference white to 685 and the reference black to 95. (These have been shown to be good values for Kodak™ film stock.) As a result, source pixels with values from 685 and 1023 will produce white pixels, while those from 0 and 95 will be set to black.

Reference white and black are affected by the values assigned to highlights and shadows. White pixels are mapped to the value set for highlights, while black pixels are mapped to the value set for shadows. See [Modifying Highlights and Shadows](#) (page 1567).

To modify reference white or black values using the Ref White and Ref Black fields:

- 1 Do one of the following:
 - To set proportional R, G, and B values, enable Prop and then enter the value in one of the (left-to-right) R, G, and B Ref White and Ref Black fields.

- To set independent R, G, or B values, disable Prop and then enter the value in the corresponding (left-to-right) R, G, or B Ref White and Ref Black fields.

Log to Lin Destination 8-bit Export	Ref White	170.748	170.748	170.748	Prop
	Ref Black	23.680	23.680	23.680	Prop
	Highlight	255.000	255.000	255.000	Prop
	Shadow	0.000	0.000	0.000	Prop
	Custom	1.000	1.000	1.000	Prop
	Film Gamma	0.600	0.600	0.600	Prop
	Soft Clip	0.000	0.000	0.000	Prop

(a) Ref White/Black fields and Prop (Proportional) buttons

To modify reference white or black values using the LUT Editor graph:

- 1 Do one of the following:
 - To set proportional R, G, and B values, select All from the Edit Curve box, and then drag the vertical reference white or reference black line left or right.
 - To set independent R, G, or B values, select Red, Green, or Blue from the Edit Curve box, and then drag the vertical reference white or reference black line left or right.

(a) Highlight line (b) Reference White line (c) Edit Curve box

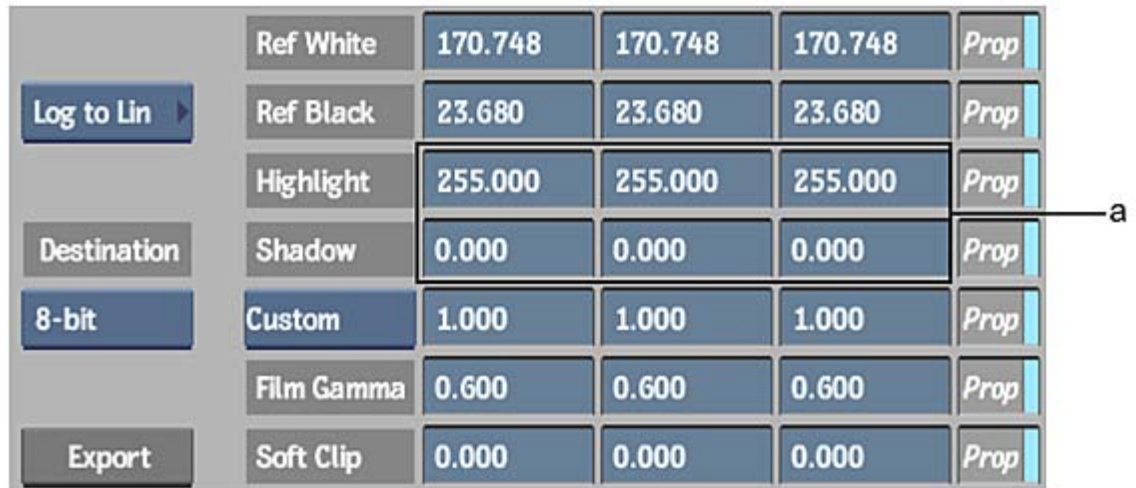

TIP If you already entered independent values and want to modify the R, G, and B values proportionally, you must drag the reference white or reference black line that corresponds to the corresponding channel. To view the selected R, G, or B luma values as a greyscale luma image in the Import Image menu, enable the Exclusive button.

Modifying Highlights and Shadows

Highlight and shadow values define the maximum and minimum values permitted for each channel. All values above the highlight are clamped down to it. Similarly, all values below the shadow are clamped up.

To modify highlight and shadow values using the Highlights and Shadows fields:

- 1 Do one of the following:
 - To set proportional R, G, and B values, enable Prop and enter a value in one of the (left-to-right) R, G, and B Highlights and Shadows fields.
 - To set independent R, G, or B values, disable Prop and enter the value in the corresponding (left-to-right) R, G, or B Highlights and Shadows fields.

	Ref White	Ref Black	Highlight	Shadow	Custom	Film Gamma	Soft Clip
	170.748	23.680	255.000	0.000	1.000	0.600	0.000
	170.748	23.680	255.000	0.000	1.000	0.600	0.000
	170.748	23.680	255.000	0.000	1.000	0.600	0.000
	Prop	Prop	Prop	Prop	Prop	Prop	Prop

(a) Highlight/Shadow fields

To modify highlight or shadow values using the LUT Editor graph:

- 1 Do one of the following:
 - To set proportional R, G, and B values, select All from the Edit Curve box, and then drag the horizontal highlight or shadow line up or down.
 - To set independent R, G, or B values, select Red, Green, or Blue from the Edit Curve box, and then drag the horizontal highlight or shadow line up or down.

Modifying the Gamma of the Conversion Curve

Set the gamma correction value to correspond to the display gamma you set your system to use. You can select a preset from the Gamma Correction box or enter a custom value.

To modify the gamma correction curve using the Gamma Correction fields:

- 1 Select an option from the Gamma Correction box.

	Ref White	170.748	170.748	170.748	Prop
Log to Lin ▶	Ref Black	23.680	23.680	23.680	Prop
	Highlight	255.000	255.000	255.000	Prop
Destination	Shadow	0.000	0.000	0.000	Prop
8-bit	Custom	1.000	1.000	1.000	Prop
	Film Gamma	0.600	0.600	0.600	Prop
Export	Soft Clip	0.000	0.000	0.000	Prop

(a) Gamma Correction fields (b) Gamma Correction box

Select:	To:
Video Display	Set video gamma correction presets.
Custom	Enter custom gamma values.

2 If you selected Custom, do one of the following:

- To set proportional custom R, G, and B gamma correction values, enable Prop, and then enter the value in one of the (left-to-right) R, G, and B Gamma Correction fields.
- To set independent custom R, G, or B gamma correction values, disable Prop, and then enter the value in the corresponding (left-to-right) R, G, or B Gamma Correction field.

To modify the gamma correction curve using the LUT Editor graph:

1 Do one of the following:

- To modify the combined R, G, and B gamma correction curves proportionally, select All from the Edit Curve box, and then drag the gamma correction curve left or right.
- To set independent R, G, or B values, select Red, Green, or Blue from the Edit Curve box, and then drag the gamma correction curve left or right.

(a) Gamma correction curve

Modifying the Gamma of the Incoming Film Negative

The values in the Film Gamma fields affect the gamma correction curve inversely to the Gamma Correction fields. This is because the gamma correction performed using these controls is based on the gamma of the original film negative. Typically, the gamma of a film negative is 0.6. Only adjust this value if your film negative is of a non-standard gamma. You should not have to modify this value by very much.

To modify the gamma correction curve using the Film Gamma fields:

- 1 Do one of the following:
 - To set proportional custom R, G, and B gamma correction values, enable Prop and then enter the value in one of the (left-to-right) R, G, and B Film Gamma fields.
 - To set independent custom R, G, or B gamma correction values, disable Prop and then enter the value in the corresponding (left-to-right) R, G, or B Film Gamma field.

Log to Lin ▶ Destination 8-bit Export	Ref White	170.748	170.748	170.748	Prop
	Ref Black	23.680	23.680	23.680	Prop
	Highlight	255.000	255.000	255.000	Prop
	Shadow	0.000	0.000	0.000	Prop

	Soft Clip	0.000	0.000	0.000	Prop

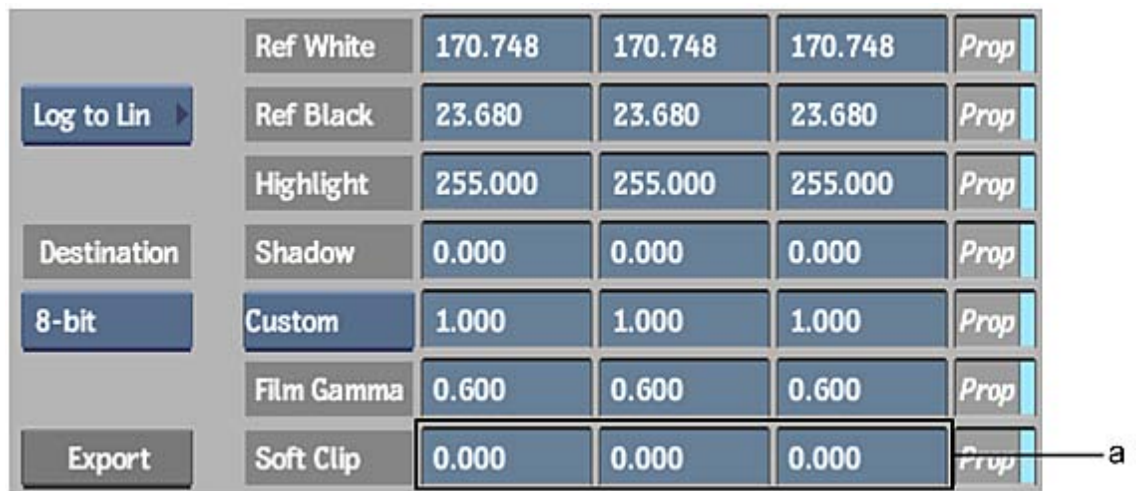

(a) Film Gamma fields

Adjusting the Softclip Values

You can soften the shoulder of the gamma correction curve by adjusting the Softclip values. When you soften the shoulder of the conversion curve, you soften the transition of colours toward the reference white value. This results in less harsh highlights in your clip.

To soften the shoulder of the gamma correction curve using the Softclip fields:

- 1 Do one of the following:
 - To set proportional custom R, G, and B gamma correction values, enable Prop, and then enter the value in one of the (left-to-right) R, G, and B Softclip fields.
 - To set independent custom R, G, or B gamma correction values, disable Prop, and then enter the value in the corresponding (left-to-right) R, G, or B Softclip field.

Log to Lin Destination 8-bit Export	Ref White	170.748	170.748	170.748	Prop
	Ref Black	23.680	23.680	23.680	Prop
	Highlight	255.000	255.000	255.000	Prop
	Shadow	0.000	0.000	0.000	Prop
	Custom	1.000	1.000	1.000	Prop
	Film Gamma	0.600	0.600	0.600	Prop
	Soft Clip	0.000	0.000	0.000	Prop

(a) Soft Clip fields

To soften the shoulder of the gamma correction curve using the LUT Editor graph:

- 1 Do one of the following:
 - To soften the shoulder of the combined R, G, and B gamma correction curves proportionally, select All from the Edit Curve box, and then Shift-drag the gamma correction curve left or right.
 - To soften the shoulder of the R, G, or B curves separately, select Red, Green, or Blue from the Edit Curve box, and then Shift-drag the gamma correction curve left or right.

(a) Softened shoulder

Advanced Editing of the Conversion LUT Curve

NOTE The procedure in this section does not apply to colour transforms or 3D LUTs.

After you modify the basic conversion curves in the [LUT Editor](#) (page 1559), you may want to further refine the final result. To do so, you can use advanced editing tools. With advanced editing, you modify additional curves for the red, green, and blue channels to fine-tune the final conversion LUT and bring out or hide detail in specific areas. These curves have editable points, adding flexibility in how they affect each channel in the final conversion LUT.

You can modify the shape of each advanced editing curve using control points. Modifications you make to these curves influence the curve of corresponding channels in the final conversion LUT. For example, you can add points to the advanced editing curve for the red channel, and by dragging the points, affect the slope of the red channel's final conversion LUT curve.

The modifications you make to the basic conversion LUT curves and the advanced editing curves are independent. The final LUT that you generate, however, is a single curve (or set of R, G, and B curves) that consists of basic LUT curves and adjustments you make with advanced editing curves.

To perform advanced editing of the conversion LUT curve:

- 1 In the LUT Editor, click Advanced.

Additional advanced editing curves appear for the red, green, and blue channels. RGB curves use blending to distinguish overlapping curves. For example, when all RGB curves overlap, a white curve is produced, whereas green and blue overlapping curves produce a cyan curve.

(a) Red, blue and green overlapping advanced editing curves (b) Control point (c) Basic button (d) Final button (e) Edit Curve box (f) Reset button

- 2 To adjust the R, G, and B curves more easily, select one of the channels from the Edit Curve box. The corresponding channel's basic and advanced editing curves are displayed. The histogram only displays values for the selected channel.

(a) Color channel selected in Edit Curves box (b) Color channel's advanced editing curve

- 3 To modify the advanced editing curves, use the Tools box.

Select:	To:
Add	Add control points to an advanced editing curve. With Add selected, click either the red, green, or blue advanced editing curve.
Delete	Delete control points from an advanced editing curve. With Delete selected, click a point on the red, green or blue advanced editing curve.
Move	Move control points. With Move selected, drag the points, or press Ctrl-drag to select multiple points. TIP Since the advanced editing curves use B-spline interpolation, the control points you manipulate will not necessarily rest on the curve itself. Points have a weighted influence on the curve depending on the position of the other points on the curve.
Zoom	Zoom in on the curves. With Zoom selected, drag over the curves right or left to zoom in or out.
Rect Zoom	Zoom in on a section of the curves. With Rect Zoom selected, drag a selection box to zoom in on the area of the curves contained by the selection box.
Pan	Pan the curves. With Pan selected, drag over the curves to pan the curves in any direction.

Dragging control points of advanced editing curves affects the basic curves and the colour effect is immediately reflected in the clip.

- 4 To view the basic and final conversion LUT curves, toggle the Basic LUT and Final LUT buttons.
5 To reset the advanced editing curves only, click Reset.

Comparing Colour Values Using Colour Patches

NOTE The procedures in this section do not apply to 3D LUTs.

While using the [LUT Editor](#) (page 1559), you may want to sample image channel values in the source, result, and reference clips to compare values of similar colours, or even corresponding pixels. The colour patches appear to the right of the LUT Editor graph.

To sample colours in the LUT Editor accessed from the Import Image menu:

- 1 Click the Source or Result Colour patch.

The cursor changes to a colour picker.

- 2 Click the image.
Both source and result colours are sampled simultaneously. The RGB values for the selected pixel are displayed, and the sampling boxes take on the corresponding colour.
- 3 To sample a set of reference values, click the Reference sampling box and use the colour picker to sample the image.
The values are taken from either the result or reference image, depending on which clip display option is currently selected.

To use colour patches in the LUT Editor menu in Batch orBatch FX:

- 1 Click the Source or Result sampling box.

The cursor changes to a colour picker.

- 2 Click the image.

Both source and result colours are sampled simultaneously. The RGB values for the selected pixel are displayed, and the sampling boxes take on the corresponding colour.

Exporting LUTs and Colour Transforms

Exporting a LUT or colour transform from the [LUT Editor](#) (page 1559) is different from saving a setup:

- PhotoMap, EXR Display, Gamma, Lin to Log, and Log to Lin are exported as baked 1D LUTs (.lut files). When imported, you can modify their curves only with the Advanced settings.
- A chain of colour transforms is exported as a single .ctf file that losslessly preserves each component operation. When imported, you cannot modify it.

Exporting a LUT

- 1 Access the LUT Editor.
- 2 Click Export.
The file browser appears.
- 3 Type a file name for the LUT in the Export field.
- 4 If you want to generate an inverse LUT with the *_inv* suffix appended to the file name, make sure that the Generate Inverse Lut option is active.
- 5 Click Export.
The LUT is exported to the specified location.

Exporting a Colour Transform

- 1 Access the LUT Editor.
- 2 Click Export.
The file browser appears.
- 3 Type a file name in the Export field. The .ctf extension is added automatically.
- 4 If desired, type a nickname for the colour transform in the Nickname field. The nickname is displayed in the metadata panel of the LUT editor, and is also shown in the Viewer Colour Management pop-up (in the lower left of image windows) when loaded in your LUT preferences.

- 5 If desired, type a description for the colour transform. The description is displayed in the metadata panel of the LUT editor.
- 6 Select the destination location using the location shortcut under the EXIT Export LUT button:
 - **Shared** is a useful location for storing transforms that can be used by other Autodesk applications on the same workstation that use Autodesk Colour Management.
 - **Project** (/usr/discreet/project/<project name>/synColor/transforms) is a useful location for storing the transforms that are specific to the current project, for example, for archiving.
 - Saving transforms to the **Autodesk** location is not recommended.

- 7 Click Export.

The colour transform is exported to the specified location.

Applying Colour Management to Displayed Images

When you apply colour management to displayed images, the colours on the monitor or projector are affected but the underlying colour values of the clips' pixels are not changed. You should do this when you want to preview images in different colour spaces. For example, if you are working in the ACES colour space, then you can apply the `ACES_to_current-monitor` transform to display the images.

Configuring Flame Premium to Use LUTs and Colour Transforms for Display

Before you can apply colour management to displayed images, you must add the LUTs and colour transforms that you want to use to your preferences. This makes them available for use in image windows.

Making 1D LUTs Available for Display

- 1 Click Flame > Preferences, and select LUT.
- 2 On the 1D LUT tab at the right, click in a slot.
- 3 Do one of the following:
 - Select Gamma in the LUT Type box, and set a value.
 - Select LUT File in the LUT Type box, then click Import and select a 1D LUT file.

Making 3D LUTs and Colour Transforms Available for Display

- 1 Click Flame > Preferences, and select LUT.
- 2 On the 3D LUT tab at the right, click in a slot.
- 3 Click Import and select a native 3D LUT (.3dl) or Colour Transform (.ctf) file. You can also select files in several other supported LUT and transform formats.

Configuring the Colour Transform Aliases

Some colour transforms include references to one or more of several aliases. You can configure which colour transforms are used in place of these aliases. This lets you change the value of the aliases while still using the same colour transform files. For example, you can:

- Use the same colour transforms for display on different computers with different monitors.
- Change the default look applied by a colour transform without changing the transform file itself.

To set the colour transform aliases:

- 1 Click Flame > Preferences, and select LUT.
- 2 Set the transform to use for each of the following:
 - **Broadcast Monitor Transform.** This is the transform that gets used when another transform includes a reference to the `broadcastMonitor` alias, as well as when another transform includes a reference to the `currentMonitor` alias for images displayed on the broadcast monitor or projector. Click **Browse**, select **Autodesk** at the lower left, and choose one of the transforms in the display/

folder that convert from CIE-XYZ to whatever is appropriate for your broadcast display, or use one of your own transforms.

- **Graphics Monitor Transform.** This is the transform that gets used when another transform includes a reference to the graphicsMonitor alias, as well as when another transform includes a reference to the currentMonitor alias for images displayed on the local monitor. Click **Browse**, select **Autodesk** at the lower left, and choose one of the transforms in the display/ folder that convert from CIE-XYZ to whatever is appropriate for your local display, or use one of your own transforms.
- **Default Look Transform.** This is the transform that gets used when another transform includes a reference to the defaultLook alias. It should be set to the transform that you are using to re-create the look used on set.

Applying 1D LUTs to the Monitor

Applying a Gamma or 1D LUT to the monitor affects all images displayed on the workstation in Flame. Any 3D LUTs or colour transforms that are being used to display specific viewports become deactivated automatically. The last-used 1D LUT is displayed at the bottom right of the Player or Viewport, and is highlighted when the LUT is in use.

NOTE You can also apply a 1D LUT to the monitor from the LUT preferences.

Applying 1D LUTs to the Monitor Using the View Menu

- 1 Do one of the following:
 - From the Player, select Show Viewing Settings from the Options box.
 - From Src-Seq or Triptych, select Edit Viewing Settings from the Options box.
 - From any other view, such as Tools, Batch or Batch FX effect, open the View menu.
- 2 Enable Use 1D LUT.
The 1D LUT displayed in the 1D LUT List box is applied to the display.
- 3 To change 1D LUTs, select an option from the list in the Monitor LUT List box.

Applying 1D LUTs to the Monitor Using the Keyboard

Press:	To do:
Ctrl+Shift+1	Apply the first 1D LUT defined in the 1D LUT list.

Press:	To do:
Ctrl+Shift+[2-9]	Apply the second through ninth 1D LUT defined in the 1D LUT list.
Ctrl+Shift+0	Apply the tenth 1D LUT defined in the 1D LUT list.
Ctrl+Shift+~	Toggle the last-used 1D LUT on and off.

Applying 3D LUTs and Colour Transforms to Viewports

You can apply 3D LUTs and colour transforms to individual viewports, and use different ones in different viewports. Any 1D LUT that is being used on the monitor becomes deactivated automatically. The file name of the last-used 3D LUT or colour transform is displayed at the bottom right of the viewport, and is highlighted when in use.

The nicknames of the available colour transforms also appear on the Viewer Colour Management pop-up menu, and can be used quickly apply a colour transform to the viewport.

NOTE 3D LUTs are assumed to require colour values in log space. Depending on your display mode, a linear-to-log or video-to-log conversion is automatically applied.

NOTE 3D LUTs and color transforms are not applied to every view. For example, Sparks uses the basic Image Data Type, while other views and modules such as Text, the MediaHub preview, desktop reels, and thumbnails have no color management at all. If necessary, you can apply a 1D LUT to the whole interface to affect the colors displayed in these views.

Applying Colour Transforms to a Viewport Using the Viewer Colour Management Pop-up Menu

- 1 Click on the Image Display pop-up menu in the bottom left of an image viewport.

- 2 Select a colour transform.

NOTE 3D LUTs are not available on the Image Display pop-up menu.

Applying 3D LUTs and Colour Transforms to a Viewport Using the View Menu

- 1 Do one of the following:
 - From the Player, select Show Viewing Settings from the Options box.
 - From Src-Seq or Triptych, select Edit Viewing Settings from the Options box.
 - From any other view, such as Tools, Batch or Batch FX effect, open the View menu.

- 2 If multiple image views are displayed, click in the one you want to affect.
- 3 Enable Use 3D LUT.
The 3D LUT or colour transform displayed in the 3D LUT List box is applied to the display.
- 4 To change the 3D LUT or colour transform, select an option from the list in the Monitor LUT List box.

- 5 If multiple image views are displayed, repeat steps 2 to 4 to affect other views.

Applying 3D LUTs and Colour Transforms to a Viewport Using the Keyboard

- 1 If multiple image views are displayed, click in the one you want to affect.
- 2 Press one of the following keys.

Press:	To apply:
Alt+Shift+1	The first 3D LUT or colour transform defined in the 3D LUT & Colour Transform list.
Alt+Shift+[2-9]	The second through ninth 3D LUT or colour transform defined in the 3D LUT & Colour Transform list.
Alt+Shift+0	The tenth 3D LUT or colour transform defined in the 3D LUT & Colour Transform list.
Alt+Shift+~	Toggle the last-used 3D LUT or colour transform on and off.

Applying a 3D LUT or Colour Transform to the Projector or Broadcast Monitor

You can apply a different 3D LUT or colour transform to the projector or broadcast monitor than the one used for display on the workstation.

- 1 Click Flame > Preferences, and select Broadcast.
- 2 Under Broadcast LUT, enable Use 3D LUT In Monitor.
- 3 To change the 3D LUT or colour transform, select an option from the list in the 3D LUT List box.

(a) 3D LUT List box

Modifying Exposure and Contrast with Display Transforms

If you apply a 1D or 3D LUT for display, then you can modify the exposure and contrast in the usual way.

However if you apply a colour transform to an image view or the broadcast monitor, then you cannot adjust the exposure and contrast interactively. The exception is when there is a dynamic ExposureContrast operator in the CTF file. In that case, the exposure and contrast values defined in the CTF file are not used. Instead, the values set in the Image Display options are used.

Controlling the Look in Viewports

When some transforms are applied as viewing transforms in a viewport, you can toggle portions of the transform on and off interactively. This can be helpful when working with looks.

Looks are basic colour grades that are created by a cinematographer to establish a visual mood for a scene during principal photography. However, the look must not be baked into the raw footage or visual effects because it is only the starting point for the final grading. Therefore, it is useful to be able to toggle the look on and off during finishing.

The Look on/off switch is available when:

- The current viewing transform in a viewport contains a reference to the Default Look Transform set in LUT Preferences.
- The current viewing transform is an ASC colour decision list (.cdl) file.
- The current viewing transform is a custom Colour Transform (.ctf) file that contains one or more operators with the LOOK_SWITCH dynamic parameter.

You can click directly on the Look switch at the bottom of the viewport to toggle the look on and off. Alternatively, you can use the Enable Look Transform button in the Image Display Viewer settings.

Setting Up the Default Look

- 1 In LUT Preferences, specify a transform as the Default Look Transform. You can select a transform file in any supported format.

- 2 In LUT Preferences, add one or more viewing transforms that reference the default look to the 3D LUT and Colour Transform list. The transforms that reference the default look include the following:
 - The transforms in the RRT+ODT directory of the Autodesk location are available for displaying ACES material on various devices.
 - The ADX10_to_current-monitor and ADX16_to_current-monitor transforms in the film\ADX\ directory are available for displaying scanned film on the system or broadcast monitor.

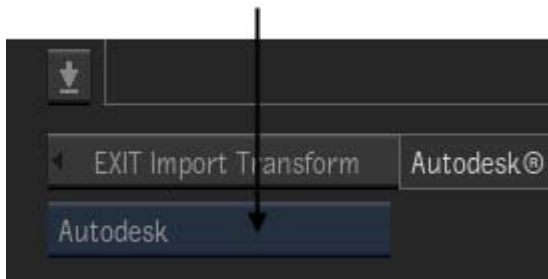

NOTE The default_look transform in the misc\ directory simply applies the default look transform, and the default_look-ACESproxy transform applies the default look transform in the ACESproxy color space that is typically used on set (first converting from the ACES color space and then back again). These transforms are not intended to be used directly as viewing transforms, but should be used as building blocks for creating your own custom chain of transforms.

- 3 Display an image in a viewport, and apply a viewing transform.
The Look switch appears at the bottom of the viewport.

Colour Management Files and Locations

The colour management files consist of 1D LUTs, 3D LUTs, and colour transforms. You can use files created in other applications as long as they are in a compatible format.

You can use the location shortcut button at the lower left of file browsers to switch between the standard file locations.

You can use files located anywhere on your file system, but it is recommended to store your custom LUTs and colour transforms in either the **Project** or **Shared** location.

1D LUTs

All 1D LUT files have the *.lut* extension. They are stored in the **Project** (/usr/discreet/project/<project name>/lut) location.

3D LUTs

All standard 3D LUT files have the *.3dl* extension; encrypted 3D LUTs have the *.e3dl* extension.

The 3D LUTs installed with Flame Premium are in the **Lustre Colour** (/usr/discreet/Lustre_Color/lut/Lustre_Color_3DLUTs) location. Use the **Project** (/usr/discreet/project/<project name>/lut) location to store 3D LUTs specific to a particular project.

Colour Transforms

Colour transforms are based on the Academy/ASC XML colour transform format and have the *.ctf* extension. They are stored in the following locations:

- **Shared** (/opt/Autodesk/Synergy/SynColor/Shared/transforms by default) is a useful location for storing transforms that can be used by other applications that use Autodesk Colour Management.
- **Project** (/usr/discreet/project/<project name>/synColor/transforms) is a useful location for storing the transforms that are specific to the current project, for example, for archiving.
- **Autodesk** (/opt/Autodesk/Synergy/SynColor/<version>/transforms) contains the transforms installed with Flame Premium. See [Autodesk Color Transform Collection](#) (page 1602).

Autodesk Color Management

About Autodesk Color Management

Autodesk Color Management (also known as the Synergy color management component or SynColor) is a shared technology component that is integrated into several Autodesk applications. This allows for consistent processing, interpretation, and communication of colors throughout a mixed pipeline.

Autodesk Color Management is designed to support a variety of color management methodologies, including ACES, ICC, OpenColorIO, and ASC CDL. It allows you to work with different color spaces and encodings so that you can adopt new workflows or emulate legacy ones.

Autodesk Color Management consists of a color engine together with a collection of transformations suitable for input, output, display, and other situations. The transforms are provided as separate files in *.ctf* format, an extension of the Academy/ASC XML color transform format. You can combine multiple files to create complex transformations, and in addition you can author your own files for custom purposes.

The color engine supports a wide variety of color operations, including 1D look-up tables (LUTs), 3D LUTs, gamma, log/antilog, exposure-contrast, matrix multiplication, and more.

In addition to native *.ctf* files, Autodesk Color Management can import many common color transform file formats, including the legacy Autodesk *.lut* and *.3dl* formats as well as third-party formats such as Cinespace, Iridas, Pandora, and Nuke.

NOTE Not all features are available in every application that supports Autodesk Color Management. For information about how to work with the features available in a specific Autodesk application, see the documentation for that application.

Color Management Concepts

Color management enables colors to be reproduced as accurately as possible across different devices and media. Unlike color correction, the intention of color management is not to change colors but instead to preserve perceived colors in different situations.

What Is a Color Space?

A color space allows people and software to communicate colors unambiguously using a numeric representation.

When a color is specified as a triplet of code values such as [0.506, 0.266, 0.266], those code values must be interpreted with respect to a particular color space. The color represented by those three numbers will be different in different color spaces.

To fully match a triplet of code values to a specific color, a device-independent color space must define the following characteristics:

- The meaning of the three primary values in terms of CIE colorimetry.
- One or more data types and encodings.
- The image state.
- The associated viewing conditions.

Examples of device-independent color spaces include ACES and the ICC Profile Connection Space.

Color spaces can also be device-dependent. Device-dependent color spaces rely on the characteristics of a particular camera, monitor, projector, printer, or other device. For example, sending a given numeric color code value to a digital cinema projector and to a motion picture film recorder will result in different color stimuli as seen by an observer.

However, various devices can be characterized. Characterization involves precisely measuring their responses in terms of absolute colorimetry. In this way, characterization provides a means to convert between device-dependent and device-independent color spaces. sRGB and AdobeRGB are essentially virtual device-dependent spaces that have been characterized well enough to use them as if they were device-independent.

In order for the characterization to remain valid, a device must be calibrated. Calibration involves adjusting the device to meet the "aim" (that is, the intended primaries, white point, and gamma) corresponding to that characterization. This process must be performed periodically as devices' responses drift with use over time. For more information, see [Calibrating Your Monitor](#) (page 1593).

Primary Values

The primary values can be thought of as the coordinate axes used to define a color "point" in a color space. Device-independent color spaces define their primaries with reference to CIE colorimetry values - in that respect, you can think of CIE colorimetry as providing a universal reference frame or "world" coordinate system. In a given viewing environment, two colors with the same colorimetry will appear to match to a typical human observer.

Some examples of primaries include:

- The coordinates of red, green, and blue specified by ITU-R BT.709 (also known as "Rec. 709") for HD video. These primaries are also used for sRGB (which has a different gamma).
- The coordinates specified by ITU-R BT.601 (Rec. 601) for SD video.
- The "P3" primaries specified by DCI and SMPTE for digital cinema projectors.

Data Type & Encoding

To interpret the code values, it is necessary to know the data type of the numbers, for example, whether they are meant to be 8-bit, 10-bit, 12-bit, or 16-bit integers, or floating-point values. In addition, it's necessary to know the values' encoding, that is, whether the code values represent intensities on a linear scale or a logarithmic scale, or whether gamma has been applied.

Image State

The notion of "image state" is a standard framework (ISO 22028-1) for grouping color spaces that share similar characteristics and which require similar processing. There are three main image states.

- Scene-referred images are high dynamic range images. They use code values that are proportional to the luminance or radiance in the scene, whether that is a live set or a virtual scene in a 3D application like Maya. No tone-mapping has been performed, and code values greater than 1.0 are allowed. If the code values are encoded on a linear scale, then the images are called scene-linear. Most OpenEXR files are scene-linear.
- Output-referred images are normal dynamic range images. They have been tone-mapped, for example, using an S-shaped curve to compress super-whites as well as increase contrast to compensate for viewing conditions. The maximum code value is 1.0 (after normalization in the case of integers), and the values are not proportional to luminance in the original scene. Output-referred images are theoretically ready for display. However, this does not necessarily mean that they are ready for display on a specific device — for example, they may have been tone-mapped but still require a specific gamma for display on a particular monitor. Examples of output-referred images include sRGB, HD video, digital cinema (DCI), and so on. Output-referred images are also called "display-referred".
- Intermediate-referred images are somewhere between scene-referred and output-referred. They have had some color processing performed, so the code values are not proportional to scene luminance, but they are still not ready for display. Examples of intermediate-referred images include log encodings like Cineon-style film scans, Academy Density Exchange (ADX), some digital cinema camera outputs, and so on.

There are many misconceptions around "linear workflows" for CG rendering and compositing. Much of the confusion comes from the word "linear" — there are actually different kinds of linear encodings: scene-referred and output-referred. It is extremely important to understand the difference between scene-linear images and output-linear images (also called "linearized output-referred").

In both cases, the encoding is proportional to luminance — in other words, no gamma encoding has been applied. However, in scene-linear images, the values are proportional to the luminance of the scene while in output-linear images, the values are proportional to the luminance of the display.

To prepare a scene-linear image for display, you need to do more than simply apply a gamma encoding. Because the scene-linear image has a high dynamic range and will be viewed on a monitor with a limited dynamic range in a different viewing environment, you need to apply a tone map before the gamma encoding to produce an image that looks correct.

Conversely, to convert a video image to scene-linear, it is not sufficient to simply remove the gamma encoding. You also need to apply an inverse tone map to restore the luminance values of the original scene.

The mathematics that are used to render computer graphics assume the color space is linear, and almost always this should be interpreted as a scene-linear color space rather than an output-linear one. Therefore to display these images, you must apply a tone map and a gamma encoding, and to convert back you must invert both of these operations.

There is one notable exception: if an output-referred image is used as a texture to control diffuse reflectance or a similar property, then it might not be suitable to apply an inverse tone map. See [Color Managing Textures and Maps](#) (page 1597).

To make matters more confusing, video images are also sometimes called "linear" (as opposed to "log"). As mentioned, video images must have their gamma encoding removed to become output-linear, and then must be "untone-mapped" to become scene-linear.

Viewing Conditions

Because human vision is adaptive, the appearance of color stimuli depends on the viewing environment. For example, a piece of paper will appear to be "white" under both bright daylight and a dimmer tungsten light bulb, even though it is lit by different amounts and hues of light.

Aspects of the viewing environment that control the appearance of a color include:

- The absolute luminance level of the image or scene. For example, a white shirt seen outdoors might have a luminance of 30,000 candelas per square meter, but its reproduction in a cinema might be only about 30 candelas per square meter — a factor of 1000 times dimmer.
- The "surround", that is, the color and brightness of objects in the field of view around the image. For example, the surround is dark in the case of cinema in a theater, dim (or rather, ideally dim) for television in a home environment, and normal (or none) for a real-world scene instead of an image.
- The adaptive white point. This is the color that is considered "white" after an observer has adapted to a given viewing environment.

The huge difference in absolute luminance level and surround between a typical outdoor daylit scene and a cinema or television viewing environment is one of the reasons that tone-mapping must include a contrast boost to scene-linear colors to make them look good on a projector or display.

The adaptive white point can be specified in one of several ways. One way is to refer to the chromaticity of a standard illuminant, such as illuminant A or the D series (D50, D55, D65, and D75) all specified by CIE. Another way is to refer to the correlated color temperature (CCT) as measured in Kelvins (K). A third way is to specify the chromaticity coordinates — for example, the DCI/SMPTE calibration white for digital cinema is CIE { $x = 0.314$, $y = 0.351$ }.

To compensate for differences in the adaptive white point between two environments, a chromatic adaptation transform is used to preserve the color appearance. For example, a chromatic adaptation that converts colors intended for a D65 display to the equivalent colors for a 9300K display must increase the saturation of the reds.

Color Management Workflow

Color management involves converting color values between color spaces. This conversion happens at specific points along a color pipeline.

- When importing media, color values must be converted to a common working space so that color information can be properly combined with other sources. For example, to combine on-set footage with 3D CG rendered elements and a painted matte background, the images should be in the same color space. If the images originated in different color spaces, they require different input transforms to convert them to a common working space.
- While working, color values in your current working space must be converted to a color space that is appropriate for your system's monitor. For example, if you are working in a scene-linear color space, then you need to apply a transform that tone-maps the images and converts them to values that are appropriate

for your display. This display transform is not baked into the underlying color values, but is only applied on-the-fly for previewing.

- Also while working, you may want to switch color spaces to perform specific operations. For example, some operations like compositing and blurring work best in a scene-linear space, but other operations like noise and grain operations, or tracking and stabilization, work best in a video or log space. When performing conversions like these, it's best to use an invertible transform to preserve the original color information. In addition, you need to change your display transform to match the new working space.
- Finally when outputting, you need to convert colors from your working space to the color space that is appropriate for your deliverables. For example, SD video, HD video, and digital cinema all use different color spaces, and require different output transforms.

Converting Between Color Spaces Using Connection Spaces

It is often necessary to convert between color spaces several times along an image pipeline. For example, you may need to convert several inputs from different spaces to a common working space so that they can be composited and blended, and then convert to another space for output.

To minimize the number of different color transforms needed to allow conversion from each color space to every other one, it is common to use one color space as an intermediate or *connection space*.

For example, to directly convert back and forth between 4 color spaces, you would need 12 different transformations. Adding a fifth color space would require 8 more, or 20 in total. In general, adding an Nth space requires an additional $2(N - 1)$ transforms, or $N^2 - N$ transforms in total.

However if you use a connection space, you only need 8 transformations to convert back and forth between 4 color spaces. Each additional color space requires only 2 additional transforms, or $2N$ transforms in total. But note that each conversion now requires two steps: the first to convert from the source space to the connection space, and the second to convert from the connection space to the target space.

Autodesk Color Management includes transforms that allow you to convert back and forth between color spaces using one of two connection spaces:

- ACES can be used as a connection space for scene-linear images.
 - The camera/ directory contains transforms for converting from various digital camera formats.
 - The film/ADX/ directory contains transforms for converting to and from Academy Density Exchange format.
 - The interchange/ACESproxy/ directory contains transforms for converting to and from the proxy ACES system used on set.
 - The RRT+ODT/ directory contains transforms for outputting to and from various output-referred spaces.

- CIE XYZ can be used as a connection space for output-referred images, that is, for images that do not require any tone-mapping. The transforms in the collection include any chromatic adaptation necessary to convert to and from a D65 white point, if required.
- The display/ directory contains transforms for converting to and from various RGB color space encodings for specific display devices.
- The interchange/ directory contains transforms for converting to and from color spaces commonly used for digital image exchange, including sRGB and AdobeRGB.

NOTE The transforms in the primaries/ directory convert only the primaries. They expect and produce a linear color space encoding, and they can be applied to either scene-linear or output-linear values.

ACES

The Academy Color Encoding System (ACES) is an image interchange framework being developed by the Science and Technology Council of the Academy of Motion Picture Arts and Sciences.

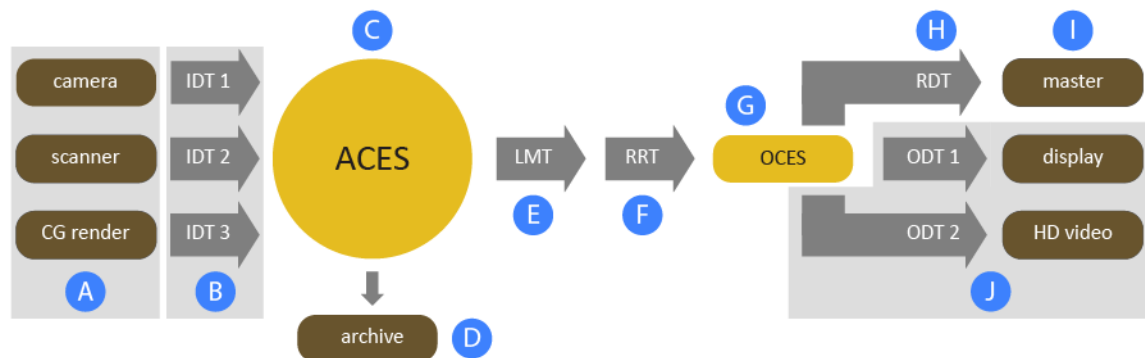

At the core of the ACES system is the Academy Color Encoding Specification (also known as ACES). This is an extremely wide gamut scene-linear space that can encode any visible color without using negative values.

The ACES system also includes a set of color transforms that can provide an innovative color managed workflow. In particular, the ACES system provides the first standard high-quality tone-mapping algorithm for converting scene-linear images to output-referred color spaces for viewing.

The ACES system is still in the "beta testing" phase and the Academy committee is still revising the color transforms that comprise the system. The ACES color space, the ADX color space, and the constrained OpenEXR container specifications are completed and have been published in the 2065 family of SMPTE standards.

The ACES Workflow

The ACES workflow uses standardized input and output transforms for each device.

A Inputs from different sources may use different color spaces and encodings.

B Input Device Transforms (IDTs) convert images to ACES. IDTs may be supplied by device vendors, software vendors such as Autodesk, other third parties, and AMPAS itself. In addition, you can author your own. The ADX to ACES transform is known as the "universal unbuild". Its inverse is the "universal build".

- C** The Academy Color Encoding Specification (ACES) is a scene-linear encoding and can be used as both a connection space and working space. The reference viewing environment is outdoor daylight with a white point of D60.
- D** ACES images can be saved for exchange or archiving in a constrained, or limited, version of the OpenEXR file format with extra metadata. The only allowable channel layouts are stereo and non-stereo RGB and RGBA. This is a SMPTE standard.
- E** The Look Modification Transform (LMT) is optional. It may be inserted before the RRT to provide an aesthetic effect, such as a shot-specific color grade that needs to be shared throughout a workflow. It is typically established by the cinematographer on set. It can be baked in to the final output, or simply used for dailies and as a reference for the final color grade.
- F** The reference rendering transform (RRT) applies a transformation as a first step in preparing the images for viewing. Among other things, the RRT:
 - accommodates for the difference between outdoor and cinema viewing environments.
 - applies color adjustments associated with pleasing image reproduction.
 - corrects for normal amounts of flare in images.

There is only one RRT allowed in the ACES system. However the RRT is still in public beta testing so there are several development versions available. Several of these development versions are supplied in the Autodesk Color Management transform collection.
- G** The Output Color Encoding Specification (OCES) represents the desired output colors if there were no dynamic range limitations. These values are the colors you would project in a cinema viewing environment if you had an idealized wide-gamut, high-dynamic range display device.
- H** The reference device transform (RDT) converts images from OCES so that they are viewable on a SMPTE reference projector. The RDT is used as a reference for developing ODTs for other devices.
- I** The output of the RDT forms the digital cinema distribution master (DCDM).
- J** Different output device transforms (ODTs) are applied to prepare the images for display on other devices. As with IDTs, the ODTs may be supplied by device vendors, software vendors such as Autodesk, other third parties, and AMPAS itself.

ACES in On-set "Look" Workflows

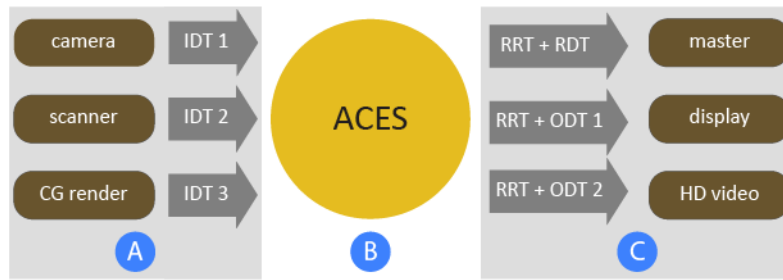

When working on set, it is generally not possible to use floating-point values for monitoring. To solve this issue, the ACES system includes an integer encoding that can be transmitted over an HD-SDI link for on-set monitoring, called ACESproxy. This is a lower-quality ACES encoding that should never be stored, but only used for on-the-fly previews.

Also on set, it is becoming common for the cinematographer to establish a "look", or basic color grade, so that the production team can see an approximation of the intended final grade early in the process. It is typically baked into dailies and footage for editorial. This look also serves as an initial reference for the final grade during the digital intermediate (DI) process. Because the effect of the look transform depends on what color space it is applied in, it is important to specify the intended space as part of the workflow.

The ACES system includes a standard for applying the look on-set in ACESproxy space, and then applying it again in DI such that the original look is preserved. This is the intended workflow for using ASC CDL looks.

ACES in Autodesk Color Management

The output transforms supplied with Autodesk Color Management combine the RRT and ODT, as well as the optional LMT, to convert directly to a format suitable for specific devices.

- A** Autodesk Color Management ships with a variety of IDTs. These transforms can be found in the camera and film categories. In addition, you can use IDTs from other sources.
- B** ACES can be used as a working space, or as a connection space for your chosen working space.
- C** There is a variety of combinations of RRT and ODT available in the RRT+ODT/ directory. The combination of RRT and RDT to render the DCDM is the ACES_to_DCI-D60 transform.

Most of the transforms in the RRT+ODT/ directory include a reference to the look transform (LMT). The transform currently set as the defaultLook alias in the Autodesk Color Management preferences is applied before the RRT. The look gets applied in ACESproxy space as recommended by the ACES standard.

All internal processing is performed at 32-bit floating-point precision, so the conversion to ACESproxy for application of a look transform (and then back to ACES) avoids the quantization and clipping imposed by the integer-based implementation of ACESproxy used on set.

The RRT+ODT/ transforms apply the look transform in such a way that the look is not applied for the final output, but can be activated for viewing. Some Autodesk applications, such as Smoke and Flame Premium, allow you to toggle the look transform on and off interactively for display. This provides a way to quickly preview the on-set look in VFX, in editorial, and as a starting point for final color grading.

If you need to bake in the look for output, you can use a custom color transform to apply the default_look-ACESproxy.ctf transform from the misc/ directory before the RRT+ODT transform. See [Custom Color Transforms](#) (page 1599).

Choosing a Working Color Space

Autodesk Color Management lets you use any color space as your working space, and provides transforms to support many of the common and standard color spaces. You can use these transforms to convert images to your chosen working space on import, and to convert images to a specific working space for particular operations.

In general, it's best to use a wide-gamut color space for working. This ensures that you can properly represent as many colors as possible. For example, digital cinema (DCI) contains colors that cannot be represented using the Rec. 709 primaries (used by sRGB and HD video) without using negative values. Autodesk Color Management is able to preserve negative values, but other tools may not. In spite of this drawback, the Rec. 709/sRGB primaries are still the most commonly used for scene-linear working spaces.

ACES is an extremely wide-gamut color space that can represent any visible color. It can be used as a working space, but some color operations may give unexpected results because the gamut is so wide.

The P3, ProPhoto-RIMM, or UHD TV (Rec. 2020) primaries are good in-between choices. They have wide gamuts, but they are not too wide.

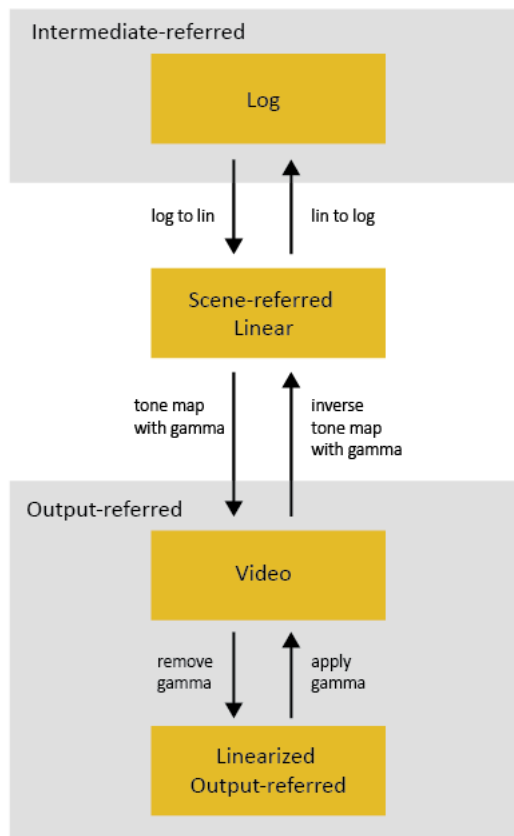

Some operations work best with colors in a specific type of space: scene-linear, video, or log. As you work, you may want to switch color spaces to perform some operations, and then switch back to your main working space or a different space for other operations.

In general:

- You can convert scene-linear to video by applying a tone map such as `PhotoMap_gamma_2.4` in the `tone-map/` directory. In general, a tone map uses an S-shaped curve to increase the contrast and compress highlights.
- You can convert video to scene-linear by applying an inverse tone map such as `inversePhotoMap_gamma_2.4` in the `tone-map/` directory. This will not be exact if the footage was originally shot as video or converted with a different tone map, but it can be a good approximation that works well in many cases. In particular, note that simply removing the display gamma from video images produces linearized output-referred values rather than scene-linear values - there are no values above 1.0.

NOTE There are special considerations for images that are used as textures and other maps. See [Color Managing Textures and Maps](#) (page 1597).

- You can convert scene-linear images to log space using one of the `Lin_to_Log` transforms in the `film/LogLin/` directory.
- You can convert log images to scene-linear using one of the `Log_to_Lin` transforms in the `film/LogLin/` directory.
- You can convert video images to log space by first converting to scene-linear and then to log.
- You can convert log images to video space by first converting to scene-linear and then to video.

Operations That Work Best with Scene-linear Colors

Some operations work best with scene-linear colors, that is, with code values that are directly proportional to light energy in the scene. These operations include:

- compositing and blending
- optical effects, including lens blur and defocus operations
- motion blur
- anti-aliasing
- resizing
- sub-pixel repositioning
- 3D rendering
- lighting and re-lighting

Operations That Work Best with Video or Log Colors

Some operations work best with video or log colors. These operations include:

- many color correction operations
- vectorscopes and histograms
- tracking and stabilizing
- grain and noise operations
- unsharp masking
- video transitions
- making gradients

Operations That Require Video Colors

Some operations require video colors, that is, colors that are restricted to the range [0, 1]. The operations include:

- color inversion
- converting RGB to HLS, HSV, or YCbCr

Common Color Management Scenarios

Although there's an unlimited number of possible situations that you may encounter in color management, they can be divided into categories that require similar treatment.

Color Managing Images on Input

When importing images, you should apply color transforms to convert them to a connection space and then to your chosen working space. Different types of images require different transforms.

In general, you need to apply two transforms to input images:

- 1 Convert images from their source space to a connection space. Several transforms are available:
 - Use the transforms in the camera/ directory to import images from various digital cinema cameras and convert them to ACES.

- Use the transforms in the `film/` directory to import scanned film plates in ADX or another Cineon-style log encoding and convert them to ACES.
- Use the transforms in the `display/` directory to import video images in HD, SD, or DCI formats and convert them to linearized output-referred CIE XYZ.
- Use the transforms in the `interchange/` directory to import other common color spaces and convert them to linearized output-referred CIE XYZ.

Even if there is no direct way to import and convert an image to ACES, there may be other ways to accomplish this. For example, there is no direct way to convert raw RED camera files to ACES. However, many applications have the ability to convert RED footage to AdobeRGB. When importing into Smoke, Flame, and Lustre, this can be achieved using by setting the **Colour Space** option to **Adobe 1998** and the **Gamma Curve** option to **Scene Linear (16bit fp)**. Other utilities such as RedCine-X also have this ability. After the RED images have been converted to AdobeRGB, they can be converted to ACES using the `LinearAdobeRGB_to_ACES` transform in the `primaries/` directory.

- 2 Once images have been imported and converted to ACES or CIE XYZ, you can use the other transforms to convert them to your working space. (However, keep in mind that a tone-map transform is needed when converting between scene-linear and output-referred color spaces.)

For example, suppose that you want to work with scene-linear values using the ProPhoto primaries. First convert the inputs to ACES, then apply `ACES_to_CIE-XYZ` followed by `CIE-XYZ_to_ProPhoto-RIMM` from the `primaries/` directory. If desired, you can export a custom `.ctf` file that applies all three transforms in order.

On the other hand, if you want to import raw digital cinema camera footage and work with it using video-encoded values, you can import the images using the appropriate transform from the `camera/` directory and then apply one of the transforms in the `RRT+ODT/` directory.

If you need to convert Digital Cinema Distribution Master (DCDM) values to HD video, you can apply `DCI_to_CIE-XYZ` from the `display/DCDM/` directory followed by `CIE-XYZ_to_HD-video` from the `display/broadcast/` directory assuming that the DCDM was mastered to the DCI calibration white point. However if colors that are supposed to be neutral have unequal RGB values, then you may need to replace the first transform with one that is relative to a different white point, such as `DCI-D65_to_CIE-XYZ`.

Color Managing Images for Display

When working with images, you need to transform them from your working space so that they appear correctly on your display. This involves defining your monitor transform and then converting from your working space. In addition, your monitor should be calibrated periodically.

Defining the Monitor Transform

The `display/` directory contains transforms that you can define as your `graphicsMonitor` alias (and `broadcastMonitor` alias, if appropriate) either in your application preferences or in the SynColor configuration file.

As an alternative to the transforms in that directory, you can use an ICC (International Color Consortium) profile as your `graphicsMonitor` or `broadcastMonitor` alias. ICC profiles are the standard method of color managing monitors in the computer industry. This is especially true on MacOS and Windows where it is integrated with the operating system, but even on Linux it is typically possible to obtain an ICC profile for a given monitor. Third-party monitor calibration products also typically generate ICC profiles.

Because ICC profiles are so common, it is not only convenient to use them as your monitor transform, but it also provides an easy way of interoperating with other software that uses ICC color management (such as Adobe products).

Converting from the Working Space

Once you have defined your `graphicsMonitor` and `broadcastMonitor` aliases, you can then apply a viewing transform that references the `currentMonitor` alias. The `currentMonitor` alias will use either `graphicsMonitor` or `broadcastMonitor`, depending on which display is being drawn to.

The following transforms are available:

- `display/broadcast/HD-video_to_current-monitor`
- `display/CIE-XYZ_to_current-monitor`
- `film/ADX/ADX10_to_current-monitor`
- `film/ADX/ADX16_to_current-monitor`
- `RRT+ODT/ACES_to_current-monitor`

If your images are not in the appropriate working space for one of those transforms, then you can export a custom `.ctf` file that performs the required conversions:

- If your images are scene-linear but not in ACES, then you can convert to ACES and then apply `ACES_to_current-monitor`. For example, if you are working with scene-linear ProPhoto values, use `ProPhoto-RIMM_to_CIE-XYZ` followed by `CIE-XYZ_to_ACES` from the `primaries/` directory, and then apply `ACES_to_current-monitor`.
- If your images are in log space, apply one of the transforms from the `film/` directory to convert them to scene-linear before converting them from scene-linear as above.
- If your images are video-encoded, convert them to CIE XYZ and then use the `display/CIE-XYZ_to_current-monitor` transform.

Calibrating Your Monitor

To ensure that the displayed images are an accurate representation of the intended colors, your monitor must be calibrated. Calibration must be performed periodically because the monitor's response drifts with use over time.

With respect to calibration, there are two classes of computer monitors:

- Some high-end monitors have internal calibration circuitry. These monitors can be calibrated to emulate another monitor that uses a different set of primaries. You use the manufacturer's software to adjust these monitors to your desired aim.
- Other monitors must be calibrated externally using a third-party product to generate an ICC profile that you can use as your monitor transform.

When working in a video color space for video deliverables on a wide-gamut monitor, there are two possibilities for getting an accurate preview of the final output:

- If your monitor has internal calibration circuitry, you can calibrate to a video aim. For example for HD video, you can calibrate your monitor to the Rec. 709 primaries, D65 white point, and 2.4 gamma. In this case, you do not need to apply any color management for display.
- Alternatively, you can leave your monitor calibrated to a wide-gamut aim, and use the `HD-video_to_current-monitor` transform from the `display/broadcast/` directory as your viewing transform.

Calibrating Autodesk Systems

For Autodesk Creative Finishing products that ship with an EIZO CG245 monitor, you can use the manufacturer's software for calibration. The CG245 monitor transforms in the `display/Eizo` directory assume that the monitor has been calibrated to the factory defaults: native primaries, D65 white point, and a gamma of 2.2. However, these are wide-gamut monitors, and it is sometimes desirable to calibrate to a different aim.

Older systems rely on a probe using procedures described in the [Lustre Color Management User Guide](#). These monitors may have different default settings.

Color Managing Images for Output

If your working color space does not match the color space of your deliverables, you can apply a transform on output.

If your images are scene-linear, you can convert them to ACES if necessary using one of the transforms in the primaries/ directory. After that:

- If you are targeting video or digital cinema, use one of the transforms in the RRT+ODT/ directory.
- If you are targeting a film recorder, use one of the ACES_to_ADX transforms in the film/ADX/ directory.

If your images are in a log space and you are not outputting to film, apply one of the transforms in the film/ directory to convert them to scene-linear and then continue as above.

Managing Gamut for Digital Cinema

Digital Cinema Distribution Masters (DCDMs) require images in the DCI/SMPTE X'Y'Z' color space. The RRT+ODT/ACES_to_DCI transforms produce images in this color space (with variations for different creative white points).

However, this color space is much larger than that of any real projector. A typical cinema projector has a gamut closer to that of the DCI/SMPTE reference projector (P3 primaries).

Therefore, it is sometimes desirable to limit the gamut of colors placed in the X'Y'Z' color space to that of a more representative projector. This has two advantages:

- The gamut mapping is performed by the ODT (which preserves hue) rather than by the projector (which typically clips).
- Assuming that the content was graded and approved on a projector with a typical P3 gamut, limiting the colors to that gamut assures there will be no unpleasant surprises if the content is later viewed on a device with a wider gamut.

To achieve this:

- 1 Select the RRT+ODT for the device whose gamut you want to limit to, for example, RRT+ODT/ACES_to_P3-D60.
- 2 Then add transforms to convert to X'Y'Z', for example, display/projector/P3-D60_to_CIE-XYZ followed by display/DCDM/CIE-XYZ_to_DCI-D60.

Color Managing Images from Scanned Film

Images from scanned film are typically supplied as DPX files with Cineon-style log encodings. However, the Cineon encoding was never fully standardized, and various vendors use slightly different implementations.

Academy Density Exchange (ADX) is a standard developed by AMPAS to eliminate any confusion and standardize on a single implementation. ADX is part of the ACES system, and is included in the SMPTE 2065 set of documents.

There are a couple of transforms for importing ADX-encoded images as scene-linear values. If you are importing DPX files from a properly calibrated ADX scanner, use one of these transforms:

- film/ADX/ADX10_to_ACES.ctf for 10-bit integer files
- film/ADX/ADX16_to_ACES.ctf for 16-bit integer files

If the images did not come from an ADX scanner, try importing them with one of the ADX transforms anyway as a first resort. If you are not satisfied with the result, you can try one of the Log_to_Lin transforms in the film/LogLin/ directory. However, be aware that these transforms modify each color channel independently (similar to 1D LUTs), and do not attempt to account for the channel cross-talk in film like the ADX_to_ACES transforms do.

Alternatively, you can try using one of the print-film emulation LUTs in the Lustre Color collection, if they are available to you. These transforms are installed with the Autodesk creative finishing products, as well as with Composite in various Autodesk product suites. The transforms are supplied in the legacy .3dl format, and can be imported by Autodesk Color Management. Refer to the [Lustre Color Management User Guide](#) for more information about the transforms in that collection.

NOTE DPX files may contain values other than Cineon-style log-encoded colors, such as video colors. When working with DPX files in general, you need to know the specific color encoding used. There may be metadata available in the files, but even when metadata is present it can be misleading.

Color Managing Digital Cinema Camera Footage

The camera/ directory contains transforms for importing and converting footage from various digital cinema cameras to ACES. Use the transform that matches the specific camera model and lighting conditions (e.g. daylight or tungsten), as appropriate.

The input transforms that specify the illuminant are not designed to perform white balancing — for example, using a transform for tungsten illumination will not turn whites blue-ish. Instead, the different transforms take into account the different spectral power distributions of the different illuminants.

Once the footage has been converted to ACES, you can use the other transforms in the collection to convert it to your working space, if necessary.

NOTE The camera/Canon/Technicolor_CineStyle_to_HD-video.ctf is a special transform for viewing and outputting video that was shot using the Canon CineStyle picture style.

Camera Black

Footage from digital cinema cameras can contain negative values in the noise around black. These negative values can cause problems during image processing, especially when adjusting hue and saturation.

All of the input transforms supplied with Autodesk Color Management for input from various cameras map negative values to small positive values losslessly. If you prefer to undo this correction and deal with the negative values in another way, you can apply the remove_camera_black transform after the camera input transform.

In other cases, you may receive images that have already had a third-party input transform applied, but still have negative values. In these cases, you can use the apply_camera_black transform to map the negative values to small positive values.

Color Managing Video Footage

When importing video, you can use the transforms in the gamma/ directory to remove the gamma that has been applied. The resulting color values are linear, but they are still output-referred and should not be combined with scene-referred linear images.

There are a few options to convert these images to a scene-referred linear state:

- If the footage is HD (Rec. 709), you can apply HD-video_to_ACES from the RRT+ODT directory.

- Alternatively, you can apply an inverse tone map such as `tone-map/inversePhotoMap_gamma_2.4`. This will not be exact if the footage was originally shot as video or converted with a different tone map, but it can be a good approximation that works well in many cases.

SMPTE Legal Video Levels

Digital video standards use integer pixel encodings, and typically define a reference black and white level such that there is some headroom and footroom left for values to exceed these levels without being clipped. For example, SMPTE 10-bit digital video places reference black at 64 and reference white at 940. Broadcasters often have requirements that content provided to them not exceed these "legal" limits. (Note that the precise definition of "legal" varies depending on the video format and broadcaster.)

Software applications that work with integer pixel encodings often follow a different convention which places black and white at the minimum and maximum values allowed by the integer (e.g. for the 10-bit case, black at 0 and white at 1023).

When converting between video and computer encodings, it is necessary to decide whether to keep the headroom and footroom (in which case black and white are not quite where they are expected on the computer), or to discard the headroom and footroom and map the reference video black/white to the computer black/white.

Typically, this choice is made as part of the video I/O process and is applied in the video hardware. However, it is sometimes useful to also have color transforms available so that the conversion may be performed elsewhere in the workflow.

The `full-range_to_legal_10bit` transform in the `levels/` directory scales, offsets, and clamps computer color values (i.e. 0 to 1023) so that they are within the legal SMPTE video range for broadcasting (i.e. 64 and 940). The `legal-range_to_full_10bit` transform inverts that operation.

Color Managing Rendered 3D CG Images

Images rendered from 3D scenes created in an application such as Maya are typically scene-referred linear RGBA images in a floating-point format such as OpenEXR.

To use these images in a scene-linear working space such as ACES, you typically need to use one of the transforms in the `primaries/` directory to convert from the native primaries, for example, from the Rec. 709 primaries.

If the linear CG images have incorrectly had a gamma applied but have not actually been tone-mapped, you can use one of the transforms in the `gamma/` directory to remove it first.

The alpha channel represents the pixel coverage and should remain unmodified by any transform.

Color Managing Matte Paintings

There are several different techniques used to produce painted matte backgrounds, and these affect how you should process the images.

For example, to composite in a scene-linear space:

- If the matte painting is supplied as output-referred gamma-encoded values, you can apply an inverse tone map such as `tone-map/inversePhotoMap_gamma_2.4`, and then use one of the transforms in the `primaries/` directory if needed. This will not be exact depending on the nature of the image, but it can be a good approximation that works well in many cases.
- If it is supplied as scene-linear values, it can be used as-is if the primaries match your working space. Otherwise, you can apply one or more of the transforms in the `primaries/` directory to convert them.

- If it is supplied as log values, you can remove the log encoding, for example, by using one of the transforms in the `film/` directory. After that, you can convert the primaries if necessary.

Color Managing Textures and Maps

As with matte paintings, images that are intended to be used as textures might be supplied as video (output-referred gamma-encoded), log, or scene-linear values.

Some maps should be scene-linear, but restricted to a 0-to-1 range. These include diffuse, specular, and ambient reflectance colors, as well as transparency color.

- If the image is supplied as a video-encoded images, it should have an inverse tone-map applied. However if a digital photograph was not flatly lit, or if a digital painting uses too-bright colors, then an inverse tone-map may create values greater than 1.0. In these cases, it may be better to use one of the `remove_gamma` transforms in the `gamma/` directory. This latter approach is not ideal, but is extremely common.
- If the image is supplied as scene-linear values, it can be used as-is if the primaries match your working space. Otherwise, you can apply one or more of the transforms in the `primaries/` directory to convert them.
- If it is supplied as log values, you can remove the log encoding, for example, by using one of the transforms in the `film/` directory. After that, you can convert the primaries if necessary.

In contrast to reflectance and similar maps, other maps should be scene-linear but can contain values greater than 1.0. These include reflection and environment maps, as well as some other effects such as incandescence.

- For video images, you need to apply an inverse tone map such as `tone-map/ inversePhotoMap_gamma_2.4`, and then use one of the transforms in the `primaries/` directory if needed. This will not be exact depending on the nature of the image, but it can be a good approximation that works well in many cases.
- Scene-linear images can be used as-is if the primaries match your working space. Otherwise, you can apply one or more of the transforms in the `primaries/` directory to convert them.
- Log images should be converted to scene-linear using one of the transforms in the `film/` directory.

If images are used to control non-color attributes, such as normals, depth, and so on, then the values should not have any color transform applied.

Color Management and Image-based Lighting (IBL)

Images that are intended for image-based lighting (IBL) are typically supplied as scene-linear HDR or OpenEXR images. They should be kept as scene-linear images, however, you may need to convert them to use the primary colors of your working space by applying one or more of the transforms in the `primaries/` directory.

White Point Conversion

The white point determines the color balance of an image. It should be adjusted depending on both the illumination of the original scene and the conditions under which the output is viewed — this process is also variously known as chromatic adaptation, white balancing, gray balancing, or neutral balancing.

It is sometimes necessary to convert media intended for one white point to a different one because the white point varies:

- Devices such as projectors and monitors are calibrated to specific white points.
- Cameras have different settings for various types of illumination.

- Well-defined color spaces have a specified viewing environment that determines the observer's state of chromatic adaptation.

Converting Between Different White Points

In most cases, you do not need to separately adjust the white point of images yourself — it is simply a matter of choosing the appropriate transform. The transforms supplied with Autodesk Color Management automatically make the proper white point adjustments for display and output, as well as when converting between color spaces with specified white points. For example, the RDT+ODT/ACES_to_sRGB transform includes a conversion from D60 (ACES) to D65 (sRGB). The description tags in the metadata of the color transform files provides detailed information about the white point that each transform is intended for.

However, you may need to compensate for a projector or display calibrated to a different white point, or mix images that are intended for different adaptive white points. In these cases, you can apply the transforms in the `whitepoint/` directory. Before doing this, first make sure to convert the images to the CIE-XYZ color space (either scene-referred or output-referred linear encoding).

Calibration Versus Creative White Point

White point issues for digital cinema projectors (and hence DCDMs) are particularly complex since there is both a calibration and a creative white point. The calibration white point is the white point that the device is calibrated to. However, since in a dark theater there are no other light sources to affect adaptation, the creative white point may be different.

For example, many people find the DCI white point used in digital cinema standards too green. So while theaters must still calibrate their projectors to this white point, neutral objects in a scene may be portrayed to another ("creative") white point such as D60. You can achieve this by using a transform such as RRT+ODT/ACES_to_DCI-D60 as the output transform, or by explicitly converting the white point yourself using the transforms in the `whitepoint/` directory.

Sometimes this technique is also used on video monitors when you want to match the white point of another device without actually recalibrating the monitor to that other white point. For example, if you have a monitor in a dark projection room, the colors on the monitor will not match the projected colors because the white points are different. To make the monitor colors match, you must convert the white point from, for example, D65 to DCI. Once this is done, neutral colors on the monitor no longer correspond to equal code values but rather to whatever code values are required to make the desired white despite the different calibration white.

Using Diagnostic Color Transforms

There are some transforms in the `levels/` directory that you can apply to the display to show potential problem areas in images.

- `show_negs` highlights pixels with negative color values. Other values are mapped towards middle values.
- `show_out-of-range` highlights pixels with negative color values, and darkens values that are above 1.0. Values in the `[0, 1]` range are mapped towards middle values.

Converting Images Between 12i or 16i and 16f Encodings

It is often useful or necessary to convert 12-bit integer (12i) or 16-bit integer (16i) to 16-bit floating-point (16f) encoding or vice-versa. When round-tripping between encodings like this, it's important that the transforms are as lossless as possible to avoid image degradation.

In Flame Premium and Smoke, it is typically desirable to promote 16i media to 16f as part of the import process in order to maximize the precision available for compositing and other operations. If you need to

convert back to 16i for export, you should do so only as part of the export process to preserve the maximal precision.

Similarly, when using 12i media in Flame Reactor, it will get promoted to 16f.

Converting from 16i Log Encoding

There are many varieties of 16-bit integer log encodings, but few standards. As such it is difficult to make general purpose recommendations on how to convert these images.

If you want to convert 16i images from log space to scene-linear, there are several options:

- If you know the images are in ADX16 color space, you can use the ADX16_to_ACES transform from the film/ADX/ directory, which will take into account film channel crosstalk and provide more accurate colors. Alternatively, you can use the Log_to_Lin--adx16 transform from the film/LogLin/ directory, which is a simple 1D-LUT-style transform that is slightly more invertible for round-tripping back to 16i.
- Alternatively, try one of the other Log_to_Lin transforms in the film/LogLin directory. However, be aware that these operate on each channel independently. This means that they are less accurate in terms of color reproduction, but are more invertible and give smaller errors than the ADX transforms when roundtripping.

Converting from 16i Video Encoding

If you want to convert 16i images from a video-like space to scene-linear 16f and then back to 16i while preserving the original values as much as possible when round-tripping, use the 16i_to_16f and 16f_to_16i transforms in the bitdepth/ directory. These are a special pair of transforms that are specifically designed to minimize quantization loss — the maximum error when round-tripping is 2 code values in 65535. However, because 16i_to_16f is very different from a typical inverse tone map, you should use the 16f_to_16i transform as your display transform as well as your output transform (when round-tripping back to 16i).

Converting from 12i Video Encoding

If you want to convert 12i images from a video-like space to scene-linear 16f and then back, use the 12i_to_16f and 16f_to_12i transforms in the bitdepth/ directory. These are a special pair of transforms that are specifically designed to provide a lossless round-trip. However as with the 16i transforms, 12i_to_16f is very different from a typical inverse tone-map so you should use the 16f_to_12i transform as your display transform as well as your output transform (when round-tripping back to 12i).

Custom Color Transforms

Autodesk Color Management lets you create your own .ctf files to define custom color transforms.

Building Custom Transforms

In Smoke, Flame, and Lustre, you can use Custom mode to assemble a chain of transforms, either from the installed collection or by importing transforms in ASC CDL or third-party LUT format. You can then export the whole chain as a single .ctf file to then load as a viewer transform, or to save time with conversions that you perform frequently.

Because the .ctf file format can represent arbitrary lists of color processing operations, the exported transform is a lossless representation of the original processing. In other words, it is much more accurate than baking the original transforms into a single 3D LUT.

The .ctf file format is XML-based, so you can also use any XML or text editor to create or modify color transforms. You can either create a transform from scratch, or use <Reference> elements to build a chain from existing transform files. See [Autodesk CTF File Format Version 1.3](#) (page 1604).

Dynamic Exposure and Contrast Controls

Some Autodesk applications, like Flame and Smoke, allow you to adjust exposure and contrast interactively for viewing if those controls have been declared as dynamic in a .ctf file. The exposure and contrast values set in the application are used for previewing, but the values set in the file are used for processing.

This means that you can create a transform that includes an ExposureContrast operator that does not affect color values (i.e., exposure of 0 and contrast of 1), and still adjust the exposure and contrast when the transform is applied to the display. This allows you to check the details in very bright or very dark areas. However when the same transform is used for processing, the output color values are unaffected.

You can take advantage of this in your own color transforms by referencing one of the exposure-contrast files in the misc/ directory. There are three versions, so that you can insert them in a scene-linear, logarithmic, or video color space. The algorithms have been adjusted so that, for example, exposure-contrast_log transform causes the exposure and contrast sliders to behave the same in a log color space as exposure-contrast_linear behaves in a scene-linear color space.

Dynamic Look Controls

Flame and Smoke allow you to toggle a look transform on and off for previewing purposes. The Look On/Off toggle appears whenever the viewing transform includes one or more operator elements with a LOOK_SWITCH dynamic parameter. If the same operators have their bypass attribute set to "true", they will be skipped during processing. This lets you include operators that will never affect values rendered to file but that can still be toggled on and off for display.

One way to take advantage of this is to define your look transform file as the defaultLook alias. The defaultLook alias can be set in the LUT preferences, and the setting is stored in the SynColor configuration file. You can then create a transform chain that includes a reference to one of the transforms in the misc/ directory that in turn references the defaultLook alias:

- The misc/default_look transform applies the look transform directly.
- If you are using an ACES workflow and ACESproxy was used on set, you can reference the misc/default_look-ACESproxy transform instead. This transform first converts from ACES to ACESproxy, then references the defaultLook transform, and finally converts back to ACES. If your look transform is an ASC CDL operator and you use the "noClamp" option, then ACES values are not clamped to the ACESproxy range. Because internal processing is done at 32-bit floating point precision, there will be negligible quantization loss.

By default, these transforms will be applied when rendering the output. However, you can edit the XML to add `bypass="true"` to the reference element (see [Common Operator Attributes](#) (page 1614)) so that the look can be toggled for display only but not applied when rendering the output.

This gives you complete control over the color space in which the look transform is applied, and allows you to match an arbitrary on-set workflow. For example, suppose that you are provided with a 3D LUT for converting from log to video space and a set of ASC CDLs from an on-set workflow, and that you are told the CDLs should be applied before rather than after the 3D LUT. In your chain of transforms, include the default look first, followed by the 3D LUT. Apply this file as your viewer transform, and set the appropriate ASC CDL transform for the shot as your defaultLook alias. Now you are able to work on the original log media with your viewer configured to emulate what was seen on set. Furthermore, you can take advantage of the dynamic Look On/Off switch in the viewer to easily toggle the look on and off.

A Complex Color Management Example

Projects often include a variety of media from different sources, and it can be difficult to know what color management to apply. The transforms in the Autodesk Color Management collection have been designed as building blocks to provide maximum flexibility. With an understanding of the concepts presented in this

guide, you will be able to combine these building blocks to solve your color workflow challenges. With that in mind, here is an advanced workflow example.

Suppose that you have a project that was mostly shot on 35mm film, but for various reasons some specific shots used different digital cinema cameras. In addition, there are some rendered 3D CG elements as well as title cards. You need to combine all these images to produce multiple deliverables: DCDM for projection in theaters plus HD video for home Blu-ray.

Choose a Working Color Space

Your first step is to decide on a working color space, unless that decision has already been made for you.

- A scene-linear working space is a good idea, especially for compositing the 3D elements.
- Considering that the deliverables are digital cinema (which uses the P3 primaries for projection) and HD (which uses the Rec. 709 primaries), it makes sense to choose the P3 primaries. They have a larger gamut than Rec. 709, so the DCDM can use all of the colors that are available on a SMPTE reference projector. Furthermore by restricting the working space to this gamut, you reduce the possibility of out-of-gamut colors.
- Many people find the DCI calibration white point too green, and prefer to work with a different creative white point such as D60.

So, a suitable choice for a working space is a scene-linear encoding using the P3 primaries and a white point of D60.

Convert the Inputs

Next, you need to convert all the inputs to this working space:

- The film scans are most likely DPX files using ADX or another Cineon-like encoding. You can use one of the transforms in the film/ directory to convert these to scene-linear ACES on import (see [Color Managing Images from Scanned Film](#) (page 1594) for additional considerations). Looking at the transforms available in the primaries/ directory, there is no direct way to convert from ACES to the P3 primaries. However, it is possible using two steps: by applying ACES_to_CIE-XYZ followed by CIE-XYZ_to_P3-D60. You can export the whole chain of transforms as a single .ctf file for convenience when importing many shots.
- Digital cinema cameras all use different proprietary encodings. Depending on the camera make, model, and lighting settings, use the appropriate transform from the camera/ directory to convert the images to ACES (see [Color Managing Digital Cinema Camera Footage](#) (page 1595)). As with the film footage, you can then convert the images to the P3 primaries by applying ACES_to_CIE-XYZ followed by CIE-XYZ_to_P3-D60 from the primaries/ directory.
- The rendered 3D CG elements are most likely scene-linear images already, but are probably using the sRGB primaries (which are the same as the Rec. 709 primaries). You can convert these images to your working space by applying Rec-709-sRGB_to_CIE-XYZ followed by CIE-XYZ_to_P3-D60 from the primaries/ directory (see [Color Managing Rendered 3D CG Images](#) (page 1596)).
- Suppose that the title cards are sRGB images. To convert them to scene-linear, you need to apply an inverse tone map. One way to do this is to apply inversePhotoMap_gamma_2.4 from the tone-map/ directory (see [Color Managing Video Footage](#) (page 1595)), and then convert the primaries in the same way as for the 3D elements using Rec-709-sRGB_to_CIE-XYZ followed by CIE-XYZ_to_P3-D60 from the primaries/ directory. However because you will be using the ACES RRT tone map for output (more about that coming up), use the sRGB_to_ACES transform followed by ACES_to_CIE-XYZ and CIE-XYZ_to_P3-D60 — this ensures that the original sRGB values are unchanged by the matching combination of inverse tone map for input and tone map for both display and output.

Set Up the View Transform

Now you need to set up your view transform to display these images as you work. Since the working space is scene-referred, you need to use a tone map to convert the images to output-referred values, and of course you should use the same tone map as the final deliverables. For the purpose of this example, suppose that you decide to use the ACES RRT.

To use any of the transforms in the RRT+ODT/ directory, you must first convert to ACES. You can do this using P3-D60_to_CIE-XYZ followed by CIE-XYZ_to_ACES from the primaries/ directory. Finally, you can apply ACES_to_current-monitor from the RRT+ODT/ directory. Chromatic adaptation is built into these transforms to map the D60 white point of the working space to the monitor's white point. Export this chain of transforms as a single .ctf file and set it as your viewing transform.

In addition, you may want to preview on a projector calibrated to the DCI white point. You can first convert to ACES using P3-D60_to_CIE-XYZ followed by CIE-XYZ_to_ACES from the primaries/ directory as above, and then use ACES_to_P3-DCI from the RRT+ODT/ directory. Although the calibration white is DCI, the creative white is D60, so chromatic adaptation is neither necessary nor built-in (see [White Point Conversion](#) (page 1597)).

See [Color Managing Images for Display](#) (page 1592) for more information.

Color Managing the Output

Finally, you need to apply the correct transforms for your deliverables. As for the display, you need to use a tone map to convert from scene-referred to output-referred.

Once again, you can convert from the working space to ACES using P3-D60_to_CIE-XYZ followed by CIE-XYZ_to_ACES from the primaries/ directory. After that:

- For the DCDM, apply ACES_to_DCI-60 from the RRT+ODT/ directory.
- For HD video, apply ACES_to_HD-video from the same directory.

See [Color Managing Images for Output](#) (page 1594) for more information.

Color Transform Files

The color transforms included with Autodesk Color Management are supplied as individual files in CTF format. In addition, Autodesk Color Management can import many third-party LUT and transform formats.

Autodesk Color Transform Collection

The transforms in the Autodesk Color Management collection are CTF files based on the Academy/ASC XML color transform format. They include several categories for different purposes.

The directory location depends on the operating system:

- Windows:

```
C:\ProgramData\Autodesk\Synergy\SynColor\<version>\transforms
```

- Linux:

```
/opt/Autodesk/Synergy/SynColor/<version>/transforms
```

- Mac OS X:

Category	Description
RRT+ODT	Various combinations of a reference rendering transform (RRT) followed by an output device transform (ODT) designed for output from the ACES color space, as well as the corresponding inverse transforms.
bit-depth	Converts between various integer and floating-point value formats.
camera	Converts from various digital-camera native formats to other color spaces such as ACES.
display	Converts colors in a connection space to and from output spaces appropriate for various display devices.
film	Converts scanned-film color spaces to and from ACES, or applies various 1D log/linear conversions.
gamma	Applies or removes various common gamma curves, including those for sRGB and Rec. 709.
interchange	Converts colors in a connection space to and from spaces that are commonly used for file input and output, such as AdobeRGB and sRGB.
levels	Various functions to clamp or adjust color values.
misc	Various transforms that may be useful for debugging or other purposes.
primaries	Converts between linear color spaces that use different primary colors.
tone-map	Converts from scene-linear to video color spaces, and vice versa.
whitepoint	Converts the white point of linear color spaces.

Supported Color Transform File Formats

In addition to the native CTF format, applications that use Autodesk Color Management can read several LUT and transform file formats. When imported, these formats are converted to native operators and can be exported as CTF files.

Supported formats include:

.lut Autodesk legacy 1D LUT.

.3dl Autodesk legacy 3D LUT.

.cdl ASC color decision list.

ASC .cdl files are loaded as ASC_CDL operators. The style used by the color transform operator is determined by the SYNCOLOR_DEFAULT_CDL_STYLE environment variable. This can be one of the following values: v1.2_Fwd, v1.2_Rev, noClampFwd, or noClampRev. If this environment variable is undefined, the default is v1.2_Fwd. For more information about these styles, see [ASC_CDL](#) (page 1634).

When a .cdl file is applied to the display, a Look switch is added that allows you to toggle the transform on and off.

.ccc ASC color correction collection.

The first CDL defined in the file is loaded as an ASC_CDL operator. The style is also determined by the SYNCOLOR_DEFAULT_CDL_STYLE environment variable.

.csp Cinespace

.icc, **.icm**, **.pf** ICC monitor profile. The PCS-to-monitor-RGB transform defined in the profile is loaded.

.cube Iridas Cube

.itx Iridas itx

.look Iridas Look (no mask support)

.m3d, **.mga** Pandora

.spi1d Imageworks 1D LUT

.spi3d Imageworks 3D LUT

.spimtx Imageworks matrix

.vf Nuke

Autodesk CTF File Format Version 1.3

There are a wide variety of colour transform (also known as "LUT") formats used in the media and entertainment industry. This creates workflow problems since you may receive a LUT which is not supported by one or more of the applications you use. Furthermore, most of these LUT formats are based on out-dated technology and lack the quality, flexibility, and metadata needed to meet today's requirements.

To address these problems, the technology committees of the Academy of Motion Picture Arts and Sciences and the American Society of Cinematographers convened a group of experts to design a common transform format that could become an industry standard.

Autodesk has chosen to adopt this format as the native format for our colour management technology and we provide a large collection of transforms in this format with our applications (e.g., to support the Academy Color Encoding System).

This guide provides information about the Academy/ASC format to help you author your own colour transforms. In addition it defines several Autodesk-specific extensions which you may use when authoring colour transforms solely for use in Autodesk applications. All Autodesk extensions are marked with the version in which they were introduced or updated. All other elements and attributes are part of the original Academy/ASC format.

Anatomy of a CTF File

The transform format allows the author to define an arbitrary chain of color operators (also called processing nodes). The set of available operator types includes 1D LUTs, 3D LUTs, matrices, and others defined below. The format is written in XML and is therefore human readable.

Here is an example:

```

[Saturation](#) (page 1640)

[Reference](#) (page 1640) Inherited attributes: id, name, inBitDepth, outBitDepth, bypass attributes: alias, path, basepath

XML Declaration

The XML declaration is optional but recommended. It indicates to the XML parser the version of XML and character encoding used.

If it is present, the XML declaration must be the first line of the file.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
```

ProcessList

The ProcessList element is the root element of a CTF file. It must contain at least one operator element.

Contains

In order:

- [Info](#) (page 1609). Optional, no more than one.
- [Description](#) (page 1611). Optional, any number.
- [InputDescriptor](#) (page 1612). Optional, no more than one.
- [OutputDescriptor](#) (page 1613). Optional, no more than one.

- At least one of [LUT1D](#) (page 1615), [LUT3D](#) (page 1617), [Matrix](#) (page 1619), [Range](#) (page 1623), [Gamma](#) (page 1627), [ExposureContrast](#) (page 1630), or [Reference](#) (page 1640) in any combination in the order in which they are to be applied.

NOTE The `inBitDepth` attribute of each operator must match the `outBitDepth` attribute of the previous operator in the chain. See [Common Operator Attributes](#) (page 1614).

Contained By

- no parent

Attributes

id A unique identifier (required).

name A nickname for the entire color transform (optional). This is used for display and selection in applications that support Autodesk Color Management.

version Indicates the presence of Autodesk extensions to the Academy/ASC XML color transform format. Files with a value higher than that supported by the application are rejected.

inverseOf The `id` attribute from another CTF file. It identifies this transform as the inverse of the other one. This information is useful to the color management system to detect the case where a transform and then its inverse are applied, so the transform pair may be optimized out. It is an Autodesk extension to the Academy/ASC XML color transform format.

Example

```
<ProcessList id="7214fa79-6c42-48b9-b164-3d0c5e543fe0" version="1.2">
  <Description>F65 Raw integer code values to ACES (tungsten
illuminant).</Description>

      0.0600766540 -0.1010185331 1.0409418344
    </Array>
  </Matrix>
</ProcessList>
```

Metadata Elements

The metadata elements provide information about a color transformation that can be displayed in information panels in applications.

Info

The Info element is a container for the Copyright and Release elements.
It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.2.

Contains

In any order:

- [Copyright](#) (page 1609). Optional, no more than one.
- [Release](#) (page 1610). Optional, no more than one.

Contained By

</ProcessList>

```

Operator Elements

The operator elements specify the operations to be applied to the color data. You can have as many as you like in a ProcessList element, in the order in which they are to be applied.

NOTE The inBitDepth attribute of each operator must match the outBitDepth attribute of the previous operator in the chain. See [Common Operator Attributes](#) (page 1614).

Common Operator Attributes

Several attributes are common to all of the color transform operator elements.

id A unique identifier for the element. Optional.

name A friendly name for the element. Optional.

bypass Introduced in version 1.3. Specifies that the operator should not be applied during color processing. Optional. If this attribute exists, its value must be "true". By using this attribute in combination with a [DynamicParameter](#) (page 1642) element that has its param attribute set to "LOOK_SWITCH", you can define operators that will never affect values rendered to file but that can still be toggled on and off for display.

inBitDepth The input color data type expected by the operator. Required.

outBitDepth The output color data type produced by the operator. Required.

NOTE The inBitDepth attribute of each operator must match the outBitDepth attribute of the previous operator in the chain.

Supported Values for inBitDepth and outBitDepth

Value	Meaning
"8i"	8-bit integer
"10i"	10-bit integer

Value	Meaning
"12i"	12-bit integer
"16i"	16-bit integer
"16f"	16-bit floating point (half-float)
"32f"	32-bit floating point (single precision)

About Bit Depth

The values specified for `inBitDepth` and `outBitDepth` attributes do not affect the quantization of color values. All processing is performed using 32-bit floating-point values.

The `inBitDepth` and `outBitDepth` attributes affect only the format of the numbers used in the CTF file, such as the values used in an Array, Matrix, or Range element. For example, if you find it convenient to specify values as integers in the range [0, 1023] then you can use an `inBitDepth` of "10i". You can still specify values outside this range, and those values will be used in the intermediate computations.

LUT1D

The LUT1D element specifies a 1D LUT to apply.

Contains

- [Description](#) (page 1611). Optional, any number.
- [Array \(LUT1D\)](#) (page 1616). Required, one only.
- [DynamicParameter](#) (page 1642). Optional, no more than one. The param attribute must be set to "DEFAULT_LOOK".

NOTE The IndexMap element is not supported. The most efficient way to achieve the same result is to precede the operator with another LUT1D element, or to combine both LUTs into a single one.

Contained By

- [ProcessList](#) (page 1607)

Attributes

id, **name**, **bypass**, **inBitDepth**, **outBitDepth** See [Common Operator Attributes](#) (page 1614).

interpolation Optional. The only currently supported value is "linear".

halfDomain Optional. If this attribute is present, its value must be "true". In this case, the input domain is all possible 16-bit floating-point values, and there must be exactly 65536 entries in the Array element. For example, the unsigned integer 15360 has the same bit-pattern (0011110000000000) as the half-float value 1.0, so the 15360th entry (zero-indexed) in the Array element is the output value corresponding to an input value of 1.0.

rawHalfs Optional. If this attribute is present, its value must be "true". In this case, the values in the array should be 16-bit floating point values expressed as unsigned 16-bit integers representing the equivalent bit

pattern. For example, to represent the value 1.0, you would enter the integer 15360 in the Array element because it has the same bit-pattern. This allows you to specify the exact half-float values you want without relying on conversion from decimal text strings.

Example

1D LUT

```
<ProcessList id="8a52d5fb-a903-4805-8bae-24f7553bfb70" version="1.2">
  <LUT1D inBitDepth="10i" outBitDepth="32f">
    <Array dim="1024 1">
      -0.014279292
      -0.014160193
      -0.014040368
      <!-- 1021 lines omitted -->
    </Array>
  </LUT1D>
</ProcessList>
```

3×1D LUT

```
<ProcessList id="a76dbe2e-e610-49a6-8c3b-5962375a8b4a" version="1.2">
  <LUT1D inBitDepth="16i" outBitDepth="32f">
    <Array dim="2 3">
      -0.092903227 -0.092903227 -0.092903227
      11.798709869 11.798709869 11.798709869
    </Array>
  </LUT1D>
</ProcessList>
```

Array (LUT1D)

The Array element specifies an array of values for a LUT or matrix. When it is contained by a LUT1D element, the format of its contents is different than when it is contained by LUT3D or Matrix elements.

Contains

- A series of numeric values specifying the output values of the LUT. The corresponding input values are implied by the [inBitDepth](#) (page 1614) of the containing element. For integers, the first value corresponds to an input of 0 and the last to an input of $(2^{\text{bitdepth}} - 1)$. For floating-point numbers, the first value corresponds to an input of 0.0 and the last to an input of 1.0. Input values outside these domains are clamped.

The intervals between the input values are uniform and depend on the number of entries. For example, if there are 5 floating-point entries, they correspond to inputs of 0.0, 0.25, 0.5, 0.75, and 1.0.

For a 1D LUT, there is one value per entry which is used for all color channels. For a 3×1D LUT, there are three values per entry specifying the separate R, G, and B output values.

Contained By

- [LUT1D](#) (page 1615)

Attributes

dim Two integers representing the dimensions of the array. The first value is the number of entries in the contents of the Array element. The second value is number of values per entry: 1 for a single value applied to all channels or 3 for for separate values applied to the R, G, and B channels respectively.

The dim attribute is required, and its value must match the number of entries actually present.

Example

1D LUT

```
<ProcessList id="8a52d5fb-a903-4805-8bae-24f7553bfb70" version="1.2">
  <LUT1D inBitDepth="10i" outBitDepth="32f">
    <Array dim="1024 1">
      -0.014279292
      -0.014160193
      -0.014040368
      <!-- 1021 values omitted -->
    </Array>
  </LUT1D>
</ProcessList>
```

3×1D LUT

```
<ProcessList id="a76dbe2e-e610-49a6-8c3b-5962375a8b4a" version="1.2">
  <LUT1D inBitDepth="16i" outBitDepth="32f">
    <Array dim="2 3">
      -0.092903227  -0.092903227  -0.092903227
      11.798709869  11.798709869  11.798709869
    </Array>
  </LUT1D>
</ProcessList>
```

See Also

- [Array \(LUT3D\)](#) (page 1618)
- [Array \(Matrix\)](#) (page 1620)

LUT3D

The LUT3D element specifies a 3D LUT to apply.

Contains

- [Description](#) (page 1611). Optional, any number.
- [Array \(LUT3D\)](#) (page 1618). Required, one only.
- [DynamicParameter](#) (page 1642). Optional, no more than one. The param attribute must be set to "DEFAULT_LOOK".

NOTE The IndexMap element is not supported. The most efficient way to achieve the same result is to precede the operator with a LUT1D element.

Contained By

- [ProcessList](#) (page 1607)

Attributes

id, **name**, **bypass**, **inBitDepth**, **outBitDepth** See [Common Operator Attributes](#) (page 1614).

interpolation Supported values are "trilinear" and "tetrahedral".

This attribute is optional. If it is not specified, the default is "trilinear".

Example

```
<ProcessList id="b5b90615-573b-4959-a838-f35e0e588ac2" version="1.2">
  <LUT3D inBitDepth="32f" interpolation="tetrahedral" outBitDepth="32f">
    <Array dim="48 48 48 3">
      0.000669299 0.000704187 0.000766901
      0.001848371 0.001297010 0.010368987
      0.002599007 0.001144927 0.023227118
    <!-- 48*48*48-3 lines omitted -->
    </Array>
  </LUT3D>
</ProcessList>
```

Array (LUT3D)

The Array element specifies an array of values for a LUT or matrix. When it is contained by a LUT3D element, the format of its contents is different than when it is contained by LUT1D or Matrix elements.

Contains

- A series of numeric values specifying the output values of the LUT. The corresponding input values are implied by the [inBitDepth](#) (page 1614) of the containing element and the number of entries (uniform distribution).

For a 3D LUT, each entry has three values specifying the separate R, G, and B output values. The entries are in order from minimum to maximum with the index of the last column changing fastest and the index of the first column changing slowest. For example, the order of entries for a 2×2×2 cube is:

Entry	R	G	B
1	0	0	0
2	0	0	1
3	0	1	0
4	0	1	1
5	1	0	0
6	1	0	1

Entry	R	G	B
7	1	1	0
8	1	1	1

Contained By

- [LUT3D](#) (page 1617)

Attributes

dim Four integers representing the dimensions of a 3D cube followed by followed by the number of components per entry.

Only 3D LUTs with the same dimension in all three channels are supported, so the first three values must be the same. The fourth value must be 3.

The dim attribute is required, and its value must match the number of entries actually present.

Example

```
<ProcessList id="b5b90615-573b-4959-a838-f35e0e588ac2" version="1.2">
  <LUT3D inBitDepth="32f" interpolation="tetrahedral" outBitDepth="32f">

    </Array>
  </Matrix>
</ProcessList>
```

Array (Matrix)

The Array element specifies an array of values for a LUT or matrix. When it is contained by a Matrix element, the format of its contents is different than when it is contained by LUT1D or LUT3D elements.

Updated

Version 1.3.

Contains

- A series of numeric values specifying the elements of the matrix.

In a Matrix, the values specify the entries of the matrix which are serialized row by row from top to bottom and from left to right. The scaling of the array values depends on the input and output bit-depths. Color values are treated as column vectors for the purpose of multiplication.

The scaling of the array values depends on the input and output bit-depths. For example if the input depth is 10i and the output depth is 12i, then a matrix containing entries of 4095/1023 along the main diagonal and entries of 0 everywhere else is the identity transform.

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} = \begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix}$$

$$R_{out} = a_{11}R_{in} + a_{12}G_{in} + a_{13}B_{in}$$

$$G_{out} = a_{21}R_{in} + a_{22}G_{in} + a_{23}B_{in}$$

$$B_{out} = a_{31}R_{in} + a_{32}G_{in} + a_{33}B_{in}$$

3×3 Matrix Multiplication

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & offset_R \\ a_{21} & a_{22} & a_{23} & offset_G \\ a_{31} & a_{32} & a_{33} & offset_B \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \\ 1.0 \end{bmatrix} = \begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix}$$

$$R_{out} = a_{11}R_{in} + a_{12}G_{in} + a_{13}B_{in} + offset_R$$

$$G_{out} = a_{21}R_{in} + a_{22}G_{in} + a_{23}B_{in} + offset_G$$

$$B_{out} = a_{31}R_{in} + a_{32}G_{in} + a_{33}B_{in} + offset_B$$

3×4 Matrix Multiplication

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \\ A_{in} \end{bmatrix} = \begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \\ A_{out} \end{bmatrix}$$

$$R_{out} = a_{11}R_{in} + a_{12}G_{in} + a_{13}B_{in} + a_{14}A_{in}$$

$$G_{out} = a_{21}R_{in} + a_{22}G_{in} + a_{23}B_{in} + a_{24}A_{in}$$

$$B_{out} = a_{31}R_{in} + a_{32}G_{in} + a_{33}B_{in} + a_{34}A_{in}$$

$$A_{out} = a_{41}R_{in} + a_{42}G_{in} + a_{43}B_{in} + a_{44}A_{in}$$

4×4 Matrix Multiplication

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} & offset_R \\ a_{21} & a_{22} & a_{23} & a_{24} & offset_G \\ a_{31} & a_{32} & a_{33} & a_{34} & offset_B \\ a_{41} & a_{42} & a_{43} & a_{44} & offset_A \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \\ A_{in} \\ 1.0 \end{bmatrix} = \begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \\ A_{out} \end{bmatrix}$$

$$R_{out} = a_{11}R_{in} + a_{12}G_{in} + a_{13}B_{in} + a_{14}A_{in} + offset_R$$

$$G_{out} = a_{21}R_{in} + a_{22}G_{in} + a_{23}B_{in} + a_{24}A_{in} + offset_G$$

$$B_{out} = a_{31}R_{in} + a_{32}G_{in} + a_{33}B_{in} + a_{34}A_{in} + offset_B$$

$$A_{out} = a_{41}R_{in} + a_{42}G_{in} + a_{43}B_{in} + a_{44}A_{in} + offset_A$$

4x5 Matrix Multiplication

Contained By

- [Matrix](#) (page 1619)

Attributes

dim Specifies the size of the matrix and the number of channels to operate on.

Value	Meaning
"3 3 3"	A 3x3 matrix operating on RGB values.
"3 4 3"	A 3x4 matrix operating on RGB values. Introduced in version 1.3.
"4 4 4"	A 4x4 matrix operating on RGBA values. Introduced in version 1.3.
"4 5 4"	A 4x5 matrix operating on RGBA values. Introduced in version 1.3.
"4 4 3"	A 4x4 matrix operating on RGB values. If you use this option, the bottom row of the matrix should be [0 0 0 1]. This option is valid only if the version attribute of the Process-List element is "1.2". For versions 1.3 and later, use "3 4 3" instead.

Example

3x3 Matrix Operating on RGB Values

```
<ProcessList id="af6a6c73-aae9-4be6-8051-a796bc480b1c" version="1.2">
  <Matrix inBitDepth="32f" outBitDepth="32f">

- [Array \(LUT3D\)](#) (page 1618)

Range

The Range element maps the input domain to the output range by scaling and offsetting values.

If a minInValue is present, then minOutValue must also be present and the result is clamped at the low end. Similarly, if maxInValue is present, then maxOutValue must also be present and the result is clamped at the high end. If none of minInValue, minOutValue, maxInValue, or maxOutValue are present, then the Range operator performs only bit-depth conversion.

The scaling of minInValue and maxInValue depends on the input bit-depth, and the scaling of minOutValue and maxOutValue depends the output bit-depth.

If both minimum and maximum values are specified, then the formula for Range is:

$$out = \min \left(\max \left(in \left(\frac{max_{out} - min_{out}}{max_{in} - min_{in}} \right) + min_{out} - min_{in} \left(\frac{max_{out} - min_{out}}{max_{in} - min_{in}} \right), min_{out} \right), max_{out} \right)$$

If only minimum values are specified, the formula is:

$$out = \max \left(in \left(\frac{size(outBitDepth)}{size(inBitDepth)} \right) + min_{out} - min_{in} \left(\frac{size(outBitDepth)}{size(inBitDepth)} \right), min_{out} \right)$$

If only maximum values are specified, the formula is:

$$out = \min \left(in \left(\frac{size(outBitDepth)}{size(inBitDepth)} \right) + max_{out} - max_{in} \left(\frac{size(outBitDepth)}{size(inBitDepth)} \right), max_{out} \right)$$

Where:

$size(int) = 2^{bitDepth} - 1$

$size(float) = 1.0$

Contains

Gamma

The Gamma element applies a gamma correction to color values.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.2.

Contains

- [Description](#) (page 1611). Optional, any number.
- [GammaParams](#) (page 1628). Required, maximum three total.
- [DynamicParameter](#) (page 1642). Optional, no more than one. The param attribute must be set to "DEFAULT_LOOK".

Contained By

- [ProcessList](#) (page 1607)

Attributes

id, name, bypass, inBitDepth, outBitDepth See [Common Operator Attributes](#) (page 1614).

style Specifies the type of power law curve. Required.

NOTE The following equations assume that the input and output bit-depths are floating-point. For integers, the values are normalized to [0.0, 1.0]. In other words, the gamma and offset values stored in the CTF file do not depend on the input and output bit depths.

Value	Meaning
"basicFwd"	Applies the power law with the gamma value specified in the GammaParams element. The GammaParams element must not have an offset attribute. $out = (\max(0, in))^{\gamma}$
"basicRev"	Applies the power law with the inverse of gamma value. The GammaParams element must not have an offset attribute. $out = (\max(0, in))^{\frac{1}{\gamma}}$
"moncurve-Fwd"	Applies a function that has a linear segment near the origin (black) and a power-law segment at higher values. At the junction, the curve is continuous in both value and tangent. This type of curve is used in the Rec. 709, sRGB, and CIE L* equations. The GammaParams element must have an offset attribute.

Value	Meaning
-------	---------

$\gamma = \text{gamma}$ $k = \text{offset}$ $x = \text{in}$ $y = \text{out}$

$$x \leq \frac{k}{\gamma - 1} \quad y = \frac{\gamma - 1}{k} \left(\frac{k\gamma}{(\gamma - 1)(1 + k)} \right)^\gamma x$$

$$x > \frac{k}{\gamma - 1} \quad y = \left(\max \left(0, \left(\frac{x + k}{1 + k} \right) \right) \right)^\gamma$$

"mon-
curveRev"

Applies a function that has a linear segment near the origin (black) and an inverse power-law segment at higher values. The GammaParams element must have an offset attribute.

$\gamma = \text{gamma}$ $k = \text{offset}$ $x = \text{in}$ $y = \text{out}$

$$x \leq \left(\frac{k\gamma}{(\gamma - 1)(1 + k)} \right)^\gamma \quad y = \left(\frac{\gamma - 1}{k} \right)^{\gamma - 1} \left(\frac{1 + k}{\gamma} \right)^\gamma x$$

$$x > \left(\frac{k\gamma}{(\gamma - 1)(1 + k)} \right)^\gamma \quad y = \left(\max(0, x) \right)^{\frac{1}{\gamma}} (1 + k) - k$$

Example

Without Offset

```
<ProcessList id="9e999646-3e76-4374-814c-e4c46c6438de" version="1.2">
  </Matrix>
  <Gamma inBitDepth="32f" outBitDepth="12i" style="basicRev">
    <GammaParams gamma="2.4000000000000000" />
  </Gamma>
</ProcessList>
```

With Offset

```
<ProcessList id="1b86aac2-1fdb-4dd8-bc6b-54f3551b9bd4" version="1.2">
  <Gamma inBitDepth="32f" outBitDepth="32f" style="moncurveFwd">
    <GammaParams gamma="2.6000000000000000" offset="0.050000" />
  </Gamma>
</ProcessList>
```

GammaParams

The GammaParams element defines the gamma value and optional offset for a Gamma element. It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.2.

Contains

No content.

Contained By

- [Gamma](#) (page 1627)

Attributes

channel The color channel to apply gamma correction to. Possible values are "R", "G", and "B". Optional.

If this attribute is not specified, the gamma correction is applied to all channels.

gamma The power value to use. Valid values range from 0.1 to 10.0 inclusive. Required.

offset The offset to use. Valid values range from 10^{-6} to 0.9 inclusive. Optional.

If it is used, the Gamma element's style attribute should be set to "moncurveFwd" or "moncurveRev". Otherwise, the style attribute should be "basicFwd" or "basicRev".

Example

Without Offset

```
<ProcessList id="9e999646-3e76-4374-814c-e4c46c6438de" version="1.2">
  </Matrix>
  <Gamma inBitDepth="32f" outBitDepth="12i" style="basicRev">
    <GammaParams gamma="2.4000000000000000" />
  </Gamma>
</ProcessList>
```

With Offset

```
<ProcessList id="1b86aac2-1fdb-4dd8-bc6b-54f3551b9bd4" version="1.2">
  <Gamma inBitDepth="32f" outBitDepth="32f" style="moncurveFwd">
    <GammaParams gamma="2.6000000000000000" offset="0.050000" />
  </Gamma>
</ProcessList>
```

Separate Channels

```
<ProcessList id="id">
  <Gamma inBitDepth="32f" outBitDepth="10i" style="basicRev">
    <GammaParams channel="R" gamma="2.4" />
    <GammaParams channel="G" gamma="2.35" />
    <GammaParams channel="B" gamma="2.2" />
  </Gamma>
</ProcessList>
```

ExposureContrast

The ExposureContrast element simulates adjusting the exposure of an image, and also modifies the contrast between light and dark colors.

It is an Autodesk extension to the Academy/ASC XML color transform format.

If a color transform is used for display, then depending on the application users can still adjust the exposure and contrast interactively as long as the CTF file contains at least one ExposureContrast element with DynamicParameter sub-elements. In this case, the corresponding parameter values defined in the ECParams sub-element are ignored for display only, and instead the values set in the application are applied at each point in the transform chain that an ExposureContrast element with DynamicParameter sub-elements occurs.

Introduced

Version 1.2.

Contains

- [Description](#) (page 1611). Optional, any number.
- [ECParams](#) (page 1631). Required, one only.
- [DynamicParameter](#) (page 1642). Optional, up to 3. Each param attribute must be set to a different value.

Contained By

- [ProcessList](#) (page 1607)

Attributes

id, name, bypass, inBitDepth, outBitDepth See [Common Operator Attributes](#) (page 1614).

style Declares the input data type. Required.

NOTE The following equations assume that the input and output bit-depths are floating-point. For integers, the values are normalized to [0.0, 1.0]. In other words, the exposure offset, contrast level, and pivot values stored in the CTF file do not depend on the input and output bit depths.

Value	Meaning
"linear"	$out = pivot \times \max\left(0, \frac{2^{exposure} in}{pivot}\right)^{contrast}$
"video"	$out = pivot^{\frac{1}{1.83}} \times \left(\max\left(0, in \times \left(\frac{2^{exposure}}{pivot}\right)^{\frac{1}{1.83}}\right)\right)^{contrast}$
"log"	$out = \left(in + exposure \frac{0.6}{2.046} \log_{10}(2) - \left(\frac{0.6}{2.046} \log_{10}\left(\frac{pivot}{0.9}\right) + \frac{685}{1023}\right)\right)^{contrast} + \left(\frac{0.6}{2.046} \log_{10}\left(\frac{pivot}{0.9}\right) + \frac{685}{1023}\right)$

Example

```
<ProcessList id="561c5aba-8709-477c-8211-7ec4a6fe8820">
  <ExposureContrast inBitDepth="16f" outBitDepth="32f" style="linear">
    <ECPARAMS exposure="0.65" contrast="1.2" pivot="1" />
    <DynamicParameter param="EXPOSURE" />
    <DynamicParameter param="CONTRAST" />
  </ExposureContrast>
</ProcessList>
```

ECPARAMS

The ECPARAMS element specifies the parameters for an ExposureContrast element.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.2.

Contains

No content.

Contained By

- [ExposureContrast](#) (page 1630)

Attributes

exposure A single decimal value representing the exposure offset in stops. A value of 0.0 corresponds to no exposure offset. Required.

contrast A single decimal value representing the contrast level. A value of 1.0 corresponds to no contrast adjustment. Required.

pivot A single decimal value representing the color value used as a pivot for adjusting contrast. A value of 0.18 will pivot around mid-gray. Required.

Example

```
<ProcessList id="561c5aba-8709-477c-8211-7ec4a6fe8820">
  <ExposureContrast inBitDepth="16f" outBitDepth="32f" style="linear">
    <ECPARAMS exposure="0.65" contrast="1.2" pivot="1" />
    <DynamicParameter param="EXPOSURE" />
    <DynamicParameter param="CONTRAST" />
  </ExposureContrast>
</ProcessList>
```

Log

The Log operator applies a logarithmic or anti-logarithmic function to convert between linear and Cineon-style encodings.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.3.

Contains

- [Description](#) (page 1611). Optional, any number.
- [LogParams](#) (page 1633). Required if the style attribute is "logToLin" or "linToLog". There should be one occurrence for values applied to all RGB channels, or three occurrences for different values applied to R, G, and B separately.
- [DynamicParameter](#) (page 1642). Optional, no more than one. The param attribute must be set to "DEFAULT_LOOK".

Contained By

[ProcessList](#) (page 1607)

Attributes

id, **name**, **bypass**, **inBitDepth**, **outBitDepth** See [Common Operator Attributes](#) (page 1614).

style Specifies the formula to use for the conversion. Required.

NOTE The following equations assume that the input and output bit-depths are floating-point. For integers, the values are normalized to [0.0, 1.0]. In other words, the gamma, reference white, reference black, highlight, and shadow values stored in the CTF file do not depend on the input and output bit depths.

In the following equations:

$$\text{FLOAT_MIN} = 1.1754943508222875 \times 10^{-38}$$
$$\text{linearRefBlack} = 10^{\min\left(-0.0001, \frac{(\text{refBlack} - \text{refWhite}) \times 0.002}{\text{gamma}}\right)}$$
$$\text{gain} = \frac{\text{highlight} - \text{shadow}}{1 - \text{linearRefBlack}}$$

Value	Meaning
"log10"	$out = \log_{10}(\max(in, \text{FLOAT_MIN}))$
"log2"	$out = \log_2(\max(in, \text{FLOAT_MIN}))$
"antiLog10"	$out = 10^{in}$
"antiLog2"	$out = 2^{in}$

Value	Meaning
"logToLin"	$relativeExposure = 10^{\frac{(1023 \times in - refWhite) \times 0.002}{gamma}}$ $out = (relativeExposure - linearRefBlack) \times gain + shadow$
"linToLog"	$relativeExposure = linearRefBlack + \frac{in - shadow}{gain}$ $out = \frac{refWhite + \log_{10}(\max(FLOAT_MIN, relativeExposure)) \times \frac{gamma}{0.002}}{1023}$

Example

All Channels

```
<ProcessList id="19510ea6-69a0-4d3d-bc75-d0b36d458f62" name="Log op 1"
version="1.3">
  <Log inBitDepth="16f" outBitDepth="12i" style="linToLog">
    <LogParams gamma="0.6" refWhite="685" refBlack="95" highlight="1.0"
shadow="0.0005"/>
  </Log>
</ProcessList>
```

Separate Channels

```
<ProcessList id="19510ea6-69a0-4d3d-bc75-d0b36d458f62" name="Log op 1"
version="1.3">
  <Log inBitDepth="16f" outBitDepth="12i" style="linToLog">
    <LogParams channel="R" gamma="0.5" refWhite="685" refBlack="95"
highlight="1.0" shadow="0.0005"/>
    <LogParams channel="G" gamma="0.6" refWhite="685" refBlack="95"
highlight="1.0" shadow="0.0005"/>
    <LogParams channel="B" gamma="0.65" refWhite="685" refBlack="95"
highlight="1.0" shadow="0.0005"/>
  </Log>
</ProcessList>
```

LogParams

The LogParams element defines the parameter values used by a Log element.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.3.

Contains

No content.

Contained By

[Log](#) (page 1631)

Attributes

channel Specifies the channel to apply the parameter values to. Possible values are "R", "G", and "B".

Optional. If it is omitted, the values are applied to each of the RGB channels.

gamma Combined film and video gamma (contrast in log space). A typical value is 0.6.

refWhite Value in log space that maps to highlight in linear space. Specified on a 10-bit scale (e.g. 685 is typical).

refBlack Value in log space that maps to shadow in linear space. Specified on a 10-bit scale (e.g. 95 is typical).

highlight Value in linear space that maps to refWhite in log space. Specified on a floating-point scale (e.g. 1.0 is typical). Note that log values above refWhite are not clamped and will map to values above highlight in linear space.

shadow Value in linear space that maps to refBlack in log space. Specified on a floating-point scale (e.g. 0.0 is typical). Note that log values below refBlack are not clamped and will map to values below shadow in linear space (possibly even negative).

Example

All Channels

```
<ProcessList id="19510ea6-69a0-4d3d-bc75-d0b36d458f62" name="Log op 1"
version="1.3">
  <Log inBitDepth="16f" outBitDepth="12i" style="linToLog">
    <LogParams gamma="0.6" refWhite="685" refBlack="95" highlight="1.0"
shadow="0.0005"/>
  </Log>
</ProcessList>
```

Separate Channels

```
<ProcessList id="19510ea6-69a0-4d3d-bc75-d0b36d458f62" name="Log op 1"
version="1.3">
  <Log inBitDepth="16f" outBitDepth="12i" style="linToLog">
    <LogParams channel="R" gamma="0.5" refWhite="685" refBlack="95"
highlight="1.0" shadow="0.0005"/>
    <LogParams channel="G" gamma="0.6" refWhite="685" refBlack="95"
highlight="1.0" shadow="0.0005"/>
    <LogParams channel="B" gamma="0.65" refWhite="685" refBlack="95"
highlight="1.0" shadow="0.0005"/>
  </Log>
</ProcessList>
```

ASC_CDL

The ASC_CDL operator represents a color transform in the American Society of Cinematographers' Color Decision List format (*.ccc or *.cdl).

An ASC CDL transform consists of a slope-offset-power (SOP) function applied individually to each of the RGB channels, followed by a saturation function applied equally to all channels.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.3.

Contains

- [Description](#) (page 1611). Optional, any number.
- [SOPNode](#) (page 1636). Optional, no more than one. If absent, no slope-offset-power function is applied.
- [SatNode](#) (page 1639). Optional, no more than one. If absent, no saturation function is applied.
- [DynamicParameter](#) (page 1642). Optional, no more than one. The param attribute must be set to "DEFAULT_LOOK".

Contained By

- [ProcessList](#) (page 1607)

Attributes

id, name, bypass, inBitDepth, outBitDepth See [Common Operator Attributes](#) (page 1614).

style Determines the formula applied by the operator.

NOTE The equations assume that the input and output bit-depths are floating-point. For integers, the values are normalized to [0.0, 1.0]. In other words, the slope, offset, power, and saturation values stored in the CTF file do not depend on the input and output bit depths.

NOTE The luma weights assume that the image uses the primaries specified by Rec. 709 (for example, HD and sRGB).

Value	Meaning
"v1.2_Fwd"	$out_{SOP} = in_{SAT} = (clamp_{[0,1]}(in \times slope + offset))^{power}$ $luma = 0.2126 \times in_{SAT_R} + 0.7152 \times in_{SAT_G} + 0.0722 \times in_{SAT_B}$ $out = clamp_{[0,1]}(luma + saturation \times (in_{SAT} - luma))$
"v1.2_Rev"	The inverse of "v1.2_Fwd".
"noClampFwd"	The same as "v1.2_Fwd", but without the two clamp functions. If $(in \times slope + offset) < 0$ then no power function is applied.
"noClampRev"	The inverse of "noClampFwd".

Example

```
<ProcessList version="1.3" id="7b42c76a-8c7a-4142-8b6e-1c467084075a">
  <ASC_CDL id="cc01234" inBitDepth="16f" outBitDepth="16f" style="v1.2_Fwd">

    <Description>scene 1 exterior look</Description>
    <SOPNode>
      <Slope>1.000000 1.000000 0.900000</Slope>
      <Offset>-0.030000 -0.020000 0.000000</Offset>
      <Power>1.250000 1.000000 1.000000</Power>
    </SOPNode>
    <SatNode>
      <Saturation>1.700000</Saturation>
    </SatNode>
  </ASC_CDL>
</ProcessList>
```

SOPNode

The SOPNode element defines the slope-offset-power function of an ASC CDL color transform.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.3.

Contains

- [Slope](#) (page 1637). Optional, no more than one. If absent, the default is 1.0 for all channels, that is, no gain is applied.
- [Offset](#) (page 1637). Optional, no more than one. If absent, the default is 0.0 for all channels, that is, no offset is applied.
- [Power](#) (page 1638). Optional, no more than one. If absent, the default is 1.0 for all channels, that is, no gamma is applied.

Contained By

- [ASC_CDL](#) (page 1634)

Attributes

</ProcessList>
```

Reference

The Reference element refers to another CTF file by path or by alias. The external file is imported into the corresponding location of the ProcessList.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Introduced

Version 1.2.

Contains

- [Description](#) (page 1611). Optional, any number.
- [DynamicParameter](#) (page 1642). Optional, no more than one. The param attribute must be set to "DEFAULT_LOOK".

Contained By

- [ProcessList](#) (page 1607)

Attributes

It is necessary to specify either a path or an alias attribute, but not both.

id, name, bypass, inBitDepth, outBitDepth See [Common Operator Attributes](#) (page 1614).

Note that the values specified here override the values in the external file.

alias A short name for the path and file name of another CTF file. The alias must be defined in a [Ref](#) (page 1647) element in the [SynColor configuration file](#) (page 1643). By default, the following aliases are available, and can be changed from the user interface of some applications that support Autodesk Color Management:

- The "graphicsMonitor" alias should refer to the appropriate transform for display on the workstation monitor.
- The "broadcastMonitor" alias should refer to the appropriate transform for display on the broadcast monitor.
- The "currentMonitor" alias gets resolved to either the value of the "graphicsMonitor" alias or the value of the "broadcastMonitor" alias depending on where an image is displayed.
- The "defaultLook" alias should refer to the transform that re-creates the look used on set.

You can create additional aliases as desired.

path The path and file name of another CTF file. The path is relative to basePath if that attribute is defined; otherwise, the path is absolute.

basePath The base location for a relative path.

Value	Meaning
Autodesk	The installation location of the color transforms supplied with Autodesk applications. The exact path is resolved based on the version of Autodesk Color Management used by the running application.
Shared	The shared location for custom color transforms for any application that uses Autodesk Color Management. The location is set in the SharedHome (page 1645) of the SynColor configuration file (page 1643).

Example

```
<ProcessList id="561c5aba-8709-477c-8211-7ec4a6fe8820">
  <Reference basePath="Autodesk" inBitDepth="32f" outBitDepth="32f"
    path="RRT+ODT/ACES_to_CIE-XYZ_v0.1.1.ctf" />
  <Reference alias="graphicsMonitor" inBitDepth="32f" outBitDepth="8i" />
  <Reference inBitDepth="8i" outBitDepth="8i" path="lut1d_example.xml"
    basePath="Shared" />
  <Reference inBitDepth="8i" outBitDepth="8i" path="/zeus/toto/toto.xml"
    />
</ProcessList>
```

DynamicParameter

The DynamicParameter element signals to a compatible application that a parameter is dynamic. If the transform is used for display, the parameter value defined in the CTF file is ignored and the value set in the application is used instead.

It is an Autodesk extension to the Academy/ASC XML color transform format.

Updated

Version 1.3.

Contains

No content.

Contained By

- Any operator element (LOOK_SWITCH)
- [ExposureContrast](#) (page 1630) (EXPOSURE, CONTRAST).

Attributes

param Specifies the parameter that will be overridden by the application when the CTF file is applied to the display.

Value	Meaning
"EXPOSURE"	Allows the exposure value to be overridden when the transform is used for display in applications that support this ability. This value can be used only when the DynamicParameter element is a child of an ExposureContrast (page 1630) element.
"CONTRAST"	Allows the contrast value to be overridden when the transform is used for display in applications that support this ability. This value can be used only when the DynamicParameter element is a child of an ExposureContrast (page 1630) element.
"LOOK_SWITCH"	Allows the operator's effect to be toggled on and off when the transform is used for display in applications that support this ability. This can be used in conjunction with the bypass (page 1614) attribute of the parent element to create operators that will never affect values rendered to file but that can still be toggled on and off for display. Introduced in version 1.3.

Example

```
<ProcessList id="561c5aba-8709-477c-8211-7ec4a6fe8820">  
  <ExposureContrast inBitDepth="16f" outBitDepth="16f" style="linear">  
    <ECParams contrast="1.0000" exposure="0.0000" pivot="0.1800" />  
    <DynamicParameter param="EXPOSURE" /><DynamicParameter  
param="CONTRAST" />  
  </ExposureContrast>  
  <Reference basePath="Autodesk" inBitDepth="16f" outBitDepth="16f"
```

```

path="misc/default_look-ACESproxy.ctf" bypass="true">
  <DynamicParameter param="LOOK_SWITCH" />
</Reference>
<Reference basePath="Autodesk" inBitDepth="16f" outBitDepth="16f"
path="RRT+ODT/ACES_to_CIE-XYZ_v0.1.1.ctf" />
<Reference alias="currentMonitor" inBitDepth="16f" outBitDepth="10i" />
<</ProcessList>

```

Comments

You can include standard XML comments in CTF files.

However if you want the information to appear in the metadata panel of Autodesk applications, you can use [Description](#) (page 1611) elements instead of comments.

XML comments begin with:

```
<!--
```

and end with:

```
-->
```

Comments cannot appear inside tags (between < and >). In addition, comments cannot be nested.

SynColor Configuration File

The SynColor configuration file is an XML file that controls how Autodesk Color Management works for all applications on the same workstation.

Some applications might read this file only on start-up. You may need to restart the application after modifying this file.

The directory location depends on the operating system:

- Windows:

```
C:\ProgramData\Autodesk\Synergy\SynColor\<version>\synColorConfig.xml
```

- Linux:

```
/opt/Autodesk/Synergy/SynColor/<version>/synColorConfig.xml
```

- Mac OS X:

```
/Applications/Autodesk/Synergy/SynColor/<version>/synColorConfig.xml
```

Anatomy of the SynColor Configuration File

This section shows a sample of a SynColor configuration file.

```

<?xml (page 1607) version="1.0" encoding="UTF-8"?>
<SynColorConfig (page 1644) version="1.0">
  <SharedHome (page 1645)
dir="/opt/Autodesk/Synergy/SynColor/Shared/transforms"/>

```

```

<ReferenceTable (page 1646)>
  <Ref (page 1647) alias="broadcastMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/broadcast/CIE-XYZ_to_HD-video.ctf"
/>
  <Ref alias="defaultLook"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/misc/identity.ctf"
/>
  <Ref alias="graphicsMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/Eizo/CIE-XYZ_to_CG245W.ctf"
/>
</ReferenceTable>
</SynColorConfig>

```

SynColorConfig

The SynColorConfig element is the root element of the SynColor configuration file.

Contains

In any order:

- [SharedHome](#) (page 1645). Required, one only.
- [ReferenceTable](#) (page 1646). Required, one only.

Contained By

- no parent

Attributes

version The version of the SynColor configuration file format.

Example

```

<?xml version="1.0" encoding="UTF-8"?>
<SynColorConfig version="1.0">
  <SharedHome dir="/opt/Autodesk/Synergy/SynColor/Shared/transforms"/>
  <ReferenceTable>
    <Ref alias="broadcastMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/broadcast/CIE-XYZ_to_HD-video.ctf"
/>
    <Ref alias="defaultLook"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/misc/identity.ctf"
/>
    <Ref alias="graphicsMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/Eizo/CIE-XYZ_to_CG245W.ctf"
/>
  </ReferenceTable>
</SynColorConfig>

```

AutoConfigure

The AutoConfigure element determines whether certain options get automatically configured when you start an application that supports Autodesk Color Management.

Currently this works only for Autodesk Smoke on Mac OS X.

- [SynColorConfig](#) (page 1644)

Attributes

graphicsMonitor Uses the ICC profile set in your operating system's preferences as the graphicsMonitor alias.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<SynColorConfig version="1.0">
  <AutoConfigure graphicsMonitor="true" />
  <SharedHome dir="/Applications/Autodesk/Synergy/SynColor/Shared/transforms"
  />
  <ReferenceTable>
    <Ref alias="broadcastMonitor"
path="/Applications/Autodesk/Synergy/SynColor/2013.3/transforms/display/broadcast/CIE-XYZ_to_HD-video.ctf"
  />
    <Ref alias="defaultLook"
path="/Applications/Autodesk/Synergy/SynColor/2013.3/transforms/misc/identity.ctf"
  />
    <Ref alias="graphicsMonitor"
path="/Library/ColorSync/Profiles/Displays/Color
LCD-00000610-0000-9CCF-0000-0000042733C0.icc" />
  </ReferenceTable>
</SynColorConfig>
```

SharedHome

The SharedHome element specifies the location of the Shared directory. This is a useful location for storing your own custom transforms that can be used by other applications that use Autodesk Colour Management installed on the same computer.

Some applications allow you to set this value in their preferences.

Contains

- No content.

Contained By

- [SynColorConfig](#) (page 1644)

Attributes

dir Full path to the shared directory. This can be on the local or a remote computer.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<SynColorConfig version="1.0">
  <SharedHome dir="/opt/Autodesk/Synergy/SynColor/Shared/transforms"/>
    <ReferenceTable>
      <Ref alias="broadcastMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/broadcast/CIE-XYZ_to_HD-video.ctf"
/>
      <Ref alias="defaultLook"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/misc/identity.ctf"
/>
      <Ref alias="graphicsMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/Eizo/CIE-XYZ_to_CG245W.ctf"
/>
    </ReferenceTable>
  </SynColorConfig>
```

ReferenceTable

The ReferenceTable element is a container for Ref elements defining aliases, or short names for CTF files.

Contains

- [Ref](#) (page 1647). Optional, any number.

However, if there are no Ref elements to define the following aliases, then some Autodesk-supplied transforms will not work:

- The `graphicsMonitor` alias should set to the appropriate transform for display on the workstation monitor.
- The `broadcastMonitor` alias should set to the appropriate transform for display on the broadcast monitor.
- The `defaultLook` alias should be set to the transform that you are using to re-create the look used on set.

Users can define additional aliases for other transform files as they wish.

Contained By

- [SynColorConfig](#) (page 1644)

Attributes

None.

Example

```
<?xml version="1.0" encoding="UTF-8"?>
<SynColorConfig version="1.0">
  <SharedHome dir="/opt/Autodesk/Synergy/SynColor/Shared/transforms"/>
    <ReferenceTable>
      <Ref alias="broadcastMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/broadcast/CIE-XYZ_to_HD-video.ctf"
/>
      <Ref alias="defaultLook"
```

```

path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/misc/identity.ctf"
/>
    <Ref alias="graphicsMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/Eizo/CIE-XYZ_to_CG245W.ctf"
/>
    </ReferenceTable>
</SynColorConfig>

```

Ref

The Ref element defines an alias for a CTF file so that it can be easily referenced in other CTF files.

Some applications allow users to set certain aliases, like graphicsMonitor, in their preferences.

When an alias is changed, references that use it might not get updated until the application is restarted.

Contains

- No content.

Contained By

- [ReferenceTable](#) (page 1646)

Attributes

alias A unique name for the alias. Required.

path The path and file name of the corresponding CTF file. Required.

basePath A base path that is prefixed to the path attribute value to fully resolve the file or location. Optional.

If this attribute is used, then the path attribute is interpreted as relative to the base path. Otherwise, the path attribute is interpreted as an absolute path.

Example

```

<?xml version="1.0" encoding="UTF-8"?>
<SynColorConfig version="1.0">
    <SharedHome dir="/opt/Autodesk/Synergy/SynColor/Shared/transforms"/>
    <ReferenceTable>
        <Ref alias="broadcastMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/display/broadcast/CIE-XYZ_to_HD-video.ctf"
/>
        <Ref alias="defaultLook"
path="/opt/Autodesk/Synergy/SynColor/2013.3/transforms/misc/identity.ctf"
/>
        <Ref alias="graphicsMonitor"
path="/opt/Autodesk/Synergy/SynColor/2013.1/transforms/display/Eizo/CIE-XYZ_to_CG245W.ctf"/>
    </ReferenceTable>
</SynColorConfig>

```

Tangent Element Control Surface

28

The Tangent Element control surface is designed to improve interactivity when working in Flame Premium. Adding to the colour grading functions for use with Lustre, the Tangent Elements panel supports navigation and interaction with the Workspace, the thumbnails, the reels, the players and the timeline and Timeline FX, as well as the Colour Corrector and the Colour Warper in Flame Premium.

NOTE Because colour grading tasks are particularly well suited for use with the Tangent Element control surface, the Flame Premium Grading application has expanded functionality. For more information, see [Tangent Element Control Surface](#) (page 2425).

Installing the Control Surface

The first time you connect the Tangent Element Control Surface to your Flame Premium station, it automatically connects to your software and populates all the menus.

If the Control Surface does not automatically connect, see the [Tangent Troubleshooting](#) (page 1699) section.

The Modes

The basic Tangent Element workflow is mode based. The panel automatically sets itself to the appropriate mode, based on where you are in the application. Alternatively, you can manually set the panel to the mode of your choice and the application's user interface follows. For example, accessing the Colour Corrector from the user interface automatically sets the panel to the appropriate Colour Corrector mode (Master, Shadows, Midtone, Highlights). And setting the CC Master mode on the panel, opens the Colour Corrector in Master mode in the user interface.

The following modes are supported by the Tangent Element Control Surface in Flame Premium:

Media Panel Focus Mode

This mode focuses on the Media panel and enables you to scrub the selected clip, as well as navigate the current reel within the Media panel, select, scrub and play clips in the players. Additionally, you can perform insert, overwrite and replace edits in the timeline, from the Media panel.

Thumbnail Focus Mode

This mode focuses on the Viewing panel in Thumbnails view and enables you to scrub the selected clip, as well as navigate through and select, scrub and play clips in the players. You can also perform insert, overwrite and replace edits in the timeline.

Reels Focus Mode

This mode focuses on the Viewing panel in Reels view and enables you to scrub the selected clip, as well as navigate the reels and select, scrub and play clips in the players. Additionally, you can perform insert, overwrite and replace edits in the timeline.

Timeline Focus Mode

This mode focuses on the timeline and enables you to navigate the timeline, its layers and tracks. This mode also supports panning and zooming the timeline via the trackball and wheel. In addition to the ability to perform insert, overwrite and replace edits, you can also add Timeline FX and transitions. All of the Timeline FX are supported.

NOTE The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.

Player Modes

When you bring up a player, either using the Tangent panel or from the user interface, the panel enters one of the player modes, based on the selected player. There are four player modes:

- 1Up Player
- Src-Seq Player
- Triptych Player
- Full Screen Player

From the Player modes, you can play and navigate through clips and sequences, drop markers on clips and toggle the different players.

Colour Corrector Modes

These modes focus on the Colour Corrector Timeline FX and enable you to control all of the creative settings within the Colour Corrector, including the Colour Corrector Quick Bar.

NOTE The Colour Corrector Batch node and the Colour Corrector Tool in the Tools tab are not supported.

Colour Warper Mode

This mode focuses on the Colour Warper Timeline FX and enables you to control all of the creative settings within the Colour Warper, including the Colour Warper Quick Bar.

NOTE The Colour Warper Batch node and the Colour Warper Tool in the Tools tab are not supported.

Using the Modules

The Tangent Element Control Surface is composed of four modules.

The layout of the displays of each module mirrors the functions of the knobs/buttons of each module.

KB module (Knobs)

The KB module is a knob-based interface for user input parameters.

The values of each parameter assigned to the knobs can be reset by pressing the knob.

A button: Cycle through the different pages of functions mapped to the module.

B button:

- Alt mode: Press to enable the alternate functions mapped across the entire panel.
- Precise mode: Hold to enable Precise Mode.

NOTE You can press the B button twice and lock Alt mode.

TK module (Trackballs)

The TK module is also an interface for user input parameters. The trackballs and rings provide an intuitive way of precisely modifying parameters and are especially well suited for grading, among other things.

Trackballs: You can modify parameters by spinning the trackballs left / right or up / down based on the current mode.

Rings: You can modify parameters by turning the rings left / right.

The values of the parameters assigned to the trackballs and the rings can be reset by pressing the Reset button above them.

A button: Cycle through the different pages of functions mapped to the module.

B button:

- Alt mode: Press to enable the alternate functions mapped across the entire panel.
- Precise mode: Hold to enable Precise Mode.

NOTE You can press the B button twice and lock Alt mode.

MF module (Multi-Function)

The MF module enables you to select the mode you want to work in and provides a transport section, which allows navigation via the trackball and ring as well.

Trackball: You can modify parameters by spinning the trackball left / right or up / down based on the current mode.

Ring: You can modify parameters by turning the ring left / right.

The values of the parameters assigned to the trackballs and the rings can be reset by pressing the Reset button above them.

A button: Cycle through the different pages of functions mapped to the module.

B button:

- Alt mode: Press to enable the alternate functions mapped across the entire panel.
- Precise mode: Hold to enable Precise Mode.

NOTE You can press the B button twice and lock Alt mode.

Button sequences for alternate functions on the MF module

- **Next Element Button + B Button:** Move the positioner forward to the next keyframe in your timeline.
- **Previous Element Button + B Button:** Move the positioner backward to the previous keyframe in your timeline.
- **Stop Button + Forward Play button:** Move the positioner forward by one frame in your timeline.
- **Stop Button + Backward Play button:** Move the positioner backward by one frame in your timeline.

BT module (Buttons)

The BT module is dedicated to providing quick access to the editing operations and to the Timeline FX.

A button: Cycle through the different pages of functions mapped to the module.

B button:

- Alt mode: Press to enable the alternate functions mapped across the entire panel.
- Precise mode: Hold to enable Precise Mode.

NOTE You can press the B button twice and lock Alt mode.

Control Surface Layouts

Media Panel Focus Layout

Module 3 (MF)

- **MediaPanel:** Enable Media Panel Focus mode.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.

- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Go to 1Up player mode and backward play the currently selected clip.
- **Backward Play + Stop buttons:** Move the clip displayed in the player one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the clip displayed in the player one frame forward.
- **Forward Play button:** Go to 1Up player mode and forward play the currently selected clip.
- **Previous button:** Move the selection in the current reel within the Media panel down by one increment.
- **Next button:** Move the selection in the current reel with in the Media panel up by one increment.

Module 4 (BT)

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.

Thumbnail Focus Layout

Module 3 (MF)

- **Thumbnail:** Enable Thumbnail Focus mode.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Go to full screen player mode and backward play the currently selected clip.
- **Backward Play + Stop buttons:** Move the currently selected thumbnail one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the currently selected thumbnail one frame forward.
- **Forward Play button:** Go to full screen player mode and forward play the currently selected clip.
- **Previous button:** Select the previous thumbnail.
- **Next button:** Select the next thumbnail.

Module 4 (BT)

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.

Reels Focus Layout

Module 3 (MF)

- **Reels:** Enable Reels Focus mode.

- **Up:** Move the selection in the Media panel up by one increment.
- **Down:** Move the selection in the Media panel down by one increment.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Go to the full screen player mode and backward play the currently selected clip.
- **Backward Play + Stop buttons:** Move the currently selected thumbnail one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the currently selected thumbnail one frame forward.
- **Forward Play button:** Go to the full screen player mode and forward play the currently selected clip.
- **Previous button:** Select the previous thumbnail.
- **Next button:** Select the next thumbnail.

Module 4 (BT)

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.

Timeline Focus Layout

Module 3 (MF)

- **Timeline:** Enable Timeline Focus mode.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip/sequence in the timeline backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip/sequence in the timeline backward or forward.
- **Backward Play button:** Go to the 1Up player mode and backward play the currently selected clip.
- **Backward Play + Stop buttons:** Move the timeline positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the timeline positioner one frame forward.
- **Forward Play button:** Go to the 1Up player mode and backward play the currently selected clip.
- **Previous button:** Move the timeline positioner to the previous transition.
- **Next button:** Move the timeline positioner to the next transition.

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
 - **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
 - **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.
 - **BatchFX:** Single press to apply a BatchFX to the currently selected timeline segment(s). You are taken into Batch.
- NOTE** If the selected timeline segment already has a BatchFX applied to it, double pressing the button takes to into Batch for editing.
- **Timewarp:** Single press to apply a Timewarp Timeline FX to the currently selected timeline segment. Double press to enter the Timewarp editor.
 - **Resize:** Single press to apply a Resize Timeline FX to the currently selected timeline segment. Double press to enter the Resize editor.
 - **Text:** Single press to apply a Text Timeline FX to the currently selected timeline segment. Double press to enter the Text editor.
 - **ColourC:** Single press to apply a Colour Corrector Timeline FX to the currently selected timeline segment. Double press to enter the Colour Corrector editor.
- NOTE** The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.
- **ColourW (Alt):** Single press (while holding Alt) to apply a Colour Warper Timeline FX to the currently selected timeline segment. Double press (while holding Alt) to enter the Colour Warper editor.
- NOTE** The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.
- **Spark:** Press to apply a placeholder Spark. Click the Load Spark button (L), with your mouse or pen, to open the Sparks Browser and navigate to the appropriate Spark.
 - **Gmask:** Single press to apply a Gmask Timeline FX to the currently selected timeline segment. Double press to enter the Gmask editor.

- **Blur:** Single press to apply a Blur Timeline FX to the currently selected timeline segment. Double press to enter the Blur editor.
- **Action:** Single press to apply an Action Timeline FX to the currently selected timeline segment(s). Double press to enter the Action editor.

Module 4 (BT) - Page 2 of 2

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.
- **Comp:** Single press to apply a Comp Timeline FX to the currently selected timeline segment. Double press to enter the Comp editor.
- **Flip:** Single press to apply a Flip Timeline FX to the currently selected timeline segment. Double press to enter the Flip editor.
- **Transform:** Single press to apply a Transform Timeline FX to the currently selected timeline segment. Double press to enter the Transform editor.
- **Dissolve:** Single press to apply a Dissolve video transition to the currently selected timeline segment(s). Double press to enter the Dissolve editor.
- **Wipe:** Single press to apply a Wipe video transition to the currently selected timeline segment(s). Double press to enter the Wipe editor.
- **Action:** Single press to apply an Action video transition to the currently selected timeline segment(s). Double press to enter the Action editor.

Player Focus Layouts

1Up Player Focus Layout

Module 3 (MF)

- **Player:** Enable 1Up Player Focus mode. Press again to toggle between Source Player and Sequence Player.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Play the current clip backward.
- **Backward Play + Stop buttons:** Move the player head one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the player head one frame backward.
- **Forward Play button:** Play the current clip backward.
- **Previous button:** Got to the previous transition.
- **Previous button (Alt):** Go to In mark.
- **Next button:** Go to the next transition.
- **Next button (Alt):** Got to Out mark.

Module 4 (BT)

- **Mark In:** Drop an In point marker.
- **Mark:** Drop a navigation marker.
- **Mark Out:** Drop an Out point marker.

Src-Seq Player Focus Layout

Module 3 (MF)

- **Src-Seq:** Enable Src-Seq Player Focus mode. Press again to toggle between Source focus and Sequence focus.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Play the current clip backward.
- **Backward Play + Stop buttons:** Move the player head one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the player head one frame backward.
- **Forward Play button:** Play the current clip backward.
- **Previous button:** Got to the previous transition.
- **Previous button (Alt):** Go to In mark.
- **Next button:** Go to the next transition.
- **Next button (Alt):** Got to Out mark.

Module 4 (BT)

- **Mark In:** Drop an In point marker.
- **Mark:** Drop a navigation marker.
- **Mark Out:** Drop an Out point marker.

Triptych Player Focus Layout

Module 3 (MF)

- **Triptych:** Enable Triptych Player Focus mode. Press again to toggle the Player focus.

- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Play the current clip backward.
- **Backward Play + Stop buttons:** Move the player head one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the player head one frame backward.
- **Forward Play button:** Play the current clip backward.
- **Previous button:** Got to the previous transition.
- **Previous button (Alt):** Go to In mark.
- **Next button:** Go to the next transition.
- **Next button (Alt):** Got to Out mark.

Module 4 (BT)

- **Mark In:** Drop an In point marker.
- **Mark:** Drop a navigation marker.
- **Mark Out:** Drop an Out point marker.

Full Screen Player Focus Layout

Module 3 (MF)

- **FullPlayr:** Enable Full Screen Player Focus mode.
- **QuickScrol (Trackball):** Spin the ball along the X axis to quickly scroll the currently selected clip backward or forward.
- **Scroll (Ring):** Turn the ring to scroll the selected clip backward or forward.
- **Backward Play button:** Play the current clip backward.
- **Backward Play + Stop buttons:** Move the player head one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the player head one frame backward.
- **Forward Play button:** Play the current clip backward.
- **Previous button:** Got to the previous transition.
- **Previous button (Alt):** Go to In mark.
- **Next button:** Go to the next transition.
- **Next button (Alt):** Got to Out mark.

Module 4 (BT)

- **Mark In:** Drop an In point marker.
- **Mark:** Drop a navigation marker.
- **Mark Out:** Drop an Out point marker.

Colour Correction Focus Layouts

Colour Corrector Quick Bar Focus Layout

Module 1 (KB) - Page 1 of 2

- **Hue:** Adjust the hue value across the entire spectrum.
- **Saturation:** Adjust the saturation value across the entire spectrum.
- **Contrast:** Adjust the contrast value across the entire spectrum..
- **R Offset:** Adjust the Red Offset value.
- **R Gamma:** Adjust the Red Gamma value.
- **R Gain:** Adjust the Red Gain value.
- **G Offset:** Adjust the Green Offset value.
- **G Gamma:** Adjust the Green Gamma value.
- **G Gain:** Adjust the Green Gain value.
- **B Offset:** Adjust the Blue Offset value.
- **B Gamma:** Adjust the Blue Gamma value.
- **B Gain:** Adjust the Blue Gain value.

- **Contrast:** Adjust the contrast value across the entire spectrum..
- **R Contrast:** Adjust the Red Contrast value.
- **G Contrast:** Adjust the Green Contrast value.
- **B Contrast:** Adjust the Blue Contrast value.

Module 2 (TK)

- **Offset:** Adjust the Master Offset value.
- **Gamma:** Adjust the Master Gamma value.

- **Gain:** Adjust the Master Gain value.

Module 3 (MF)

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
 - **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
 - **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.
 - **BatchFX:** Single press to apply a BatchFX to the currently selected timeline segment(s). You are taken into Batch.
- NOTE** If the selected timeline segment already has a BatchFX applied to it, double pressing the button takes to into Batch for editing.
- **Timewarp:** Single press to apply a Timewarp Timeline FX to the currently selected timeline segment. Double press to enter the Timewarp editor.
 - **Resize:** Single press to apply a Resize Timeline FX to the currently selected timeline segment. Double press to enter the Resize editor.
 - **Text:** Single press to apply a Text Timeline FX to the currently selected timeline segment. Double press to enter the Text editor.
 - **ColourC:** Single press to apply a Colour Corrector Timeline FX to the currently selected timeline segment. Double press to enter the Colour Corrector editor.
- NOTE** The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.
- **ColourW (Alt):** Single press (while holding Alt) to apply a Colour Warper Timeline FX to the currently selected timeline segment. Double press (while holding Alt) to enter the Colour Warper editor.
- NOTE** The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.
- **Spark:** Press to apply a placeholder Spark. Click the Load Spark button (L), with your mouse or pen, to open the Sparks Browser and navigate to the appropriate Spark.
 - **Gmask:** Single press to apply a Gmask Timeline FX to the currently selected timeline segment. Double press to enter the Gmask editor.

- **Blur:** Single press to apply a Blur Timeline FX to the currently selected timeline segment. Double press to enter the Blur editor.
- **Action:** Single press to apply an Action Timeline FX to the currently selected timeline segment(s). Double press to enter the Action editor.

Module 4 (BT) - Page 2 of 2

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.
- **Comp:** Single press to apply a Comp Timeline FX to the currently selected timeline segment. Double press to enter the Comp editor.
- **Flip:** Single press to apply a Flip Timeline FX to the currently selected timeline segment. Double press to enter the Flip editor.
- **2D Transform:** Single press to apply a 2D Transform Timeline FX to the currently selected timeline segment. Double press to enter the Transform editor.
- **Dissolve:** Single press to apply a Dissolve video transition to the currently selected timeline segment(s). Double press to enter the Dissolve editor.
- **Wipe:** Single press to apply a Wipe video transition to the currently selected timeline segment(s). Double press to enter the Wipe editor.
- **Action:** Single press to apply an Action video transition to the currently selected timeline segment(s). Double press to enter the Action editor.

Colour Corrector Master Focus Layout

Module 1 (KB) - Page 1 of 2

- **Hue:** Adjust the hue value across the entire spectrum.
- **Saturation:** Adjust the saturation value across the entire spectrum.
- **Contrast:** Adjust the contrast value across the entire spectrum.
- **R Offset:** Adjust the Red Offset value.
- **R Gamma:** Adjust the Red Gamma value.
- **R Gain:** Adjust the Red Gain value.
- **G Offset:** Adjust the Green Offset value.
- **G Gamma:** Adjust the Green Gamma value.
- **G Gain:** Adjust the Green Gain value.
- **B Offset:** Adjust the Blue Offset value.
- **B Gamma:** Adjust the Blue Gamma value.
- **B Gain:** Adjust the Blue Gain value.

- **HistMinIn:** Adjust the minimum Black input value.
- **HistMinOut:** Adjust the minimum Black output value.
- **HistMaxIn:** Adjust the minimum White input value.
- **HistMaxOut:** Adjust the minimum White output value.
- **Pivot:** Adjust the Pivot percentage value.
- **Contrast:** Adjust the contrast value across the entire spectrum..
- **R Contrast:** Adjust the Red Contrast value.
- **G Contrast:** Adjust the Green Contrast value.
- **B Contrast:** Adjust the Blue Contrast value.

Module 2 (TK)

- **ShadowClr:** Move the trackball to adjust the colour of the shadows.
- **Mid Clr:** Move the trackball to adjust the colour of the midtones.
- **HighClr:** Move the trackball to adjust the colour of the highlights.
- **Offset:** Turn the ring to adjust the RGB offset value.
- **Gamma:** Turn the ring to adjust the RGB gamma value.
- **Gain:** Turn the ring to adjust the RGB gain value.

Module 3 (MF)

- **Exit:** Exit the current menu.
- **Redo:** Reapply the last operation performed after an Undo operation.
- **Undo:** Undo the last operation performed.
- **Pan (Trackball + Alt):** Spin the ball along the X axis to pan the current shot left and right.
- **Scroll (Ring):** Turn the ring to scroll the current shot backward or forward.
- **Zoom (Ring + Alt):** Turn the ring to zoom the current shot in and out
- **Backward Play button:** Play the current shot backward. Results may vary according to the number of unrendered effects on the shot.
- **Backward Play + Stop buttons:** Move the positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the positioner one frame forward.
- **Forward Play button:** Play the current shot forward. Results may vary according to the number of unrendered effects on the shot.
- **Previous button:** Go to the start of the current segment.
- **Previous button (Alt):** Go to the previous keyframe.
- **Next button:** Go to the end of the current segment.
- **Next button (Alt):** Go to the next keyframe.

- **R Supp:** Adjust the Red suppression value.
- **G Supp:** Adjust the Green suppression value.
- **B Supp:** Adjust the Blue suppression value.
- **C Supp:** Adjust the Cyan suppression value.
- **M Supp:** Adjust the Magenta suppression value.
- **Yw Supp:** Adjust the Yellow suppression value.
- **RstBasics:** Reset the basic Colour Corrector parameter values.
- **RstHisto:** Reset the Histogram values.
- **Rst All:** Reset all parameter values.

Colour Corrector Shadows Focus Layout

Module 1 (KB) - Page 1 of 2

- **Shd Hue:** Adjust the hue value of the shadows.
- **Shd Sat:** Adjust the saturation value of the shadows.
- **ShdCntrst:** Adjust the contrast value of the shadows.
- **R Offset:** Adjust the Red Offset value.
- **R Gamma:** Adjust the Red Gamma value.
- **R Gain:** Adjust the Red Gain value.
- **G Offset:** Adjust the Green Offset value.
- **G Gamma:** Adjust the Green Gamma value.
- **G Gain:** Adjust the Green Gain value.
- **B Offset:** Adjust the Blue Offset value.
- **B Gamma:** Adjust the Blue Gamma value.
- **B Gain:** Adjust the Blue Gain value.

- **HistMinIn:** Adjust the minimum Black input value.
- **HistMinOut:** Adjust the minimum Black output value.
- **HistMaxIn:** Adjust the minimum White input value.
- **HistMaxOut:** Adjust the minimum White output value.
- **Pivot:** Adjust the Pivot percentage value.
- **Contrast:** Adjust the contrast value across the entire spectrum.
- **R Contrast:** Adjust the Red Contrast value.
- **G Contrast:** Adjust the Green Contrast value.
- **B Contrast:** Adjust the Blue Contrast value.

Module 2 (TK)

- **ShadowClr:** Move the trackball to adjust the colour of the shadows.
- **Mid Clr:** Move the trackball to adjust the colour of the midtones.
- **HighClr:** Move the trackball to adjust the colour of the highlights.
- **ShdOffset:** Turn the ring to adjust the shadows offset value.
- **Shd Gamma:** Turn the ring to adjust the shadows gamma value.
- **Shd Gain:** Turn the ring to adjust the shadows gain value.

Module 3 (MF)

- **Exit:** Exit the current menu.
- **Redo:** Reapply the last operation performed after an Undo operation.
- **Undo:** Undo the last operation performed.
- **Pan (Trackball + Alt):** Spin the ball along the X axis to pan the current shot left and right.
- **Scroll (Ring):** Turn the ring to scroll the current shot backward or forward.
- **Zoom (Ring + Alt):** Turn the ring to zoom the current shot in and out
- **Backward Play button:** Play the current shot backward. Results may vary according to the number of unrendered effects on the shot.
- **Backward Play + Stop buttons:** Move the positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the positioner one frame forward.
- **Forward Play button:** Play the current shot forward. Results may vary according to the number of unrendered effects on the shot.
- **Previous button:** Go to the start of the current segment.
- **Previous button (Alt):** Go to the previous keyframe.
- **Next button:** Go to the end of the current segment.
- **Next button (Alt):** Go to the next keyframe.

Module 4 (BT)

- **R Supp:** Adjust the Red suppression value.
- **G Supp:** Adjust the Green suppression value.
- **B Supp:** Adjust the Blue suppression value.
- **C Supp:** Adjust the Cyan suppression value.
- **M Supp:** Adjust the Magenta suppression value.
- **Yw Supp:** Adjust the Yellow suppression value.
- **RstBasics:** Reset the basic Colour Corrector parameter values.
- **RstHisto:** Reset the Histogram values.
- **Rst All:** Reset all parameter values.

Colour Corrector Midtones Focus Layout

Module 1 (KB)

- **Mid Hue:** Adjust the hue value of the midtones.
- **Mid Sat:** Adjust the saturation value of the midtones.
- **MidCntrst:** Adjust the contrast value of the midtones.
- **R Offset:** Adjust the Red Offset value.
- **G Offset:** Adjust the Green Offset value.
- **B Offset:** Adjust the Blue Offset value.
- **R Gamma:** Adjust the Red Gamma value.
- **G Gamma:** Adjust the Green Gamma value.
- **B Gamma:** Adjust the Blue Gamma value.
- **R Gain:** Adjust the Red Gain value.
- **G Gain:** Adjust the Green Gain value.
- **B Gain:** Adjust the Blue Gain value.

- **HistMinIn:** Adjust the minimum Black input value.
- **HistMinOut:** Adjust the minimum Black output value.
- **HistMaxIn:** Adjust the minimum White input value.
- **HistMaxOut:** Adjust the minimum White output value.
- **Pivot:** Adjust the Pivot percentage value.
- **Contrast:** Adjust the contrast value across the entire spectrum..
- **R Contrast:** Adjust the Red Contrast value.
- **G Contrast:** Adjust the Green Contrast value.
- **B Contrast:** Adjust the Blue Contrast value.

Module 2 (TK)

- **ShadowClr:** Move the trackball to adjust the colour of the shadows.
- **Mid Clr:** Move the trackball to adjust the colour of the midtones.
- **HighClr:** Move the trackball to adjust the colour of the highlights.
- **MidOffset:** Turn the ring to adjust the midtones offset value.
- **Mid Gamma:** Turn the ring to adjust the midtones gamma value.
- **Mid Gain:** Turn the ring to adjust the midtones gain value.

Module 3 (MF)

- **Exit:** Exit the current menu.
- **Redo:** Reapply the last operation performed after an Undo operation.
- **Undo:** Undo the last operation performed.
- **Pan (Trackball + Alt):** Spin the ball along the X axis to pan the current shot left and right.
- **Scroll (Ring):** Turn the ring to scroll the current shot backward or forward.
- **Zoom (Ring + Alt):** Turn the ring to zoom the current shot in and out
- **Backward Play button:** Play the current shot backward. Results may vary according to the number of unrendered effects on the shot.
- **Backward Play + Stop buttons:** Move the positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the positioner one frame forward.
- **Forward Play button:** Play the current shot forward. Results may vary according to the number of unrendered effects on the shot.
- **Previous button:** Go to the start of the current segment.
- **Previous button (Alt):** Go to the previous keyframe.
- **Next button:** Go to the end of the current segment.
- **Next button (Alt):** Go to the next keyframe.

Module 4 (BT)

- **R Supp:** Adjust the Red suppression value.
- **G Supp:** Adjust the Green suppression value.
- **B Supp:** Adjust the Blue suppression value.
- **C Supp:** Adjust the Cyan suppression value.
- **M Supp:** Adjust the Magenta suppression value.
- **Yw Supp:** Adjust the Yellow suppression value.
- **RstBasics:** Reset the basic Colour Corrector parameter values.
- **RstHisto:** Reset the Histogram values.
- **Rst All:** Reset all parameter values.

Colour Corrector Highlights Focus Layout

Module 1 (KB) - Page 1 of 2

- **High Hue:** Adjust the hue value of the highlights.
- **High Sat:** Adjust the saturation value of the highlights.
- **HiCntrst:** Adjust the contrast value of the highlights.
- **R Offset:** Adjust the Red Offset value.
- **G Offset:** Adjust the Green Offset value.
- **B Offset:** Adjust the Blue Offset value.
- **R Gamma:** Adjust the Red Gamma value.
- **G Gamma:** Adjust the Green Gamma value.
- **B Gamma:** Adjust the Blue Gamma value.
- **R Gain:** Adjust the Red Gain value.
- **G Gain:** Adjust the Green Gain value.
- **B Gain:** Adjust the Blue Gain value.

- **HistMinIn:** Adjust the minimum Black input value.
- **HistMinOut:** Adjust the minimum Black output value.
- **HistMaxIn:** Adjust the minimum White input value.
- **HistMaxOut:** Adjust the minimum White output value.
- **Pivot:** Adjust the Pivot percentage value.
- **Contrast:** Adjust the contrast value across the entire spectrum..
- **R Contrast:** Adjust the Red Contrast value.
- **G Contrast:** Adjust the Green Contrast value.
- **B Contrast:** Adjust the Blue Contrast value.

Module 2 (TK)

- **ShadowClr:** Move the trackball to adjust the colour of the shadows.
- **Mid Clr:** Move the trackball to adjust the colour of the midtones.
- **HighClr:** Move the trackball to adjust the colour of the highlights.
- **HighOffset:** Turn the ring to adjust the highlights offset value.
- **High Gamma:** Turn the ring to adjust the highlights gamma value.
- **High Gain:** Turn the ring to adjust the highlights gain value.

Module 3 (MF)

- **Exit:** Exit the current menu.
- **Redo:** Reapply the last operation performed after an Undo operation.
- **Undo:** Undo the last operation performed.
- **Pan (Trackball + Alt):** Spin the ball along the X axis to pan the current shot left and right.
- **Scroll (Ring):** Turn the ring to scroll the current shot backward or forward.
- **Zoom (Ring + Alt):** Turn the ring to zoom the current shot in and out
- **Backward Play button:** Play the current shot backward. Results may vary according to the number of unrendered effects on the shot.
- **Backward Play + Stop buttons:** Move the positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the positioner one frame forward.
- **Forward Play button:** Play the current shot forward. Results may vary according to the number of unrendered effects on the shot.
- **Previous button:** Go to the start of the current segment.
- **Previous button (Alt):** Go to the previous keyframe.
- **Next button:** Go to the end of the current segment.
- **Next button (Alt):** Go to the next keyframe.

Module 4 (BT)

- **R Supp:** Adjust the Red suppression value.
- **G Supp:** Adjust the Green suppression value.
- **B Supp:** Adjust the Blue suppression value.
- **C Supp:** Adjust the Cyan suppression value.
- **M Supp:** Adjust the Magenta suppression value.
- **Yw Supp:** Adjust the Yellow suppression value.
- **RstBasics:** Reset the basic Colour Corrector parameter values.
- **RstHisto:** Reset the Histogram values.
- **Rst All:** Reset all parameter values.

Colour Warper QuickBar Focus Layout

Module 1 (KB)

- **Black:** Adjust the black point.
- **Gamma:** Adjust the RGB gamma value.
- **White:** Adjust the white point.
- **Hue:** Adjust the RGB hue value.
- **Saturatio:** Adjust the RGB saturation value.
- **R Gamma:** Adjust the Red Gamma value.
- **G Gamma:** Adjust the Green Gamma value.
- **B Gamma:** Adjust the Blue Gamma value.

Module 3 (MF)

- **Timeline:** Enable Timeline Focus mode.
- **Pan Tmln (Trackball):** Spin the ball along the X axis to zoom the timeline.
- **Zoom Tmln (Trackball + Alt):** Spin the ball along the X axis to pan the the timeline left and right.
- **ScrolTmln (Ring):** Turn the ring to scroll the timeline backward or forward.
- **Backward Play button:** Go to the 1Up player mode and backward play the currently selected clip.
- **Backward Play + Stop buttons:** Move the timeline positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the timeline positioner one frame forward.
- **Forward Play button:** Go to the 1Up player mode and backward play the currently selected clip.
- **Previous button:** Move the timeline positioner to the previous transition.
- **Next button:** Move the timeline positioner to the next transition.

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.
- **BatchFX:** Single press to apply a BatchFX to the currently selected timeline segment(s). You are taken into Batch.

NOTE If the selected timeline segment already has a BatchFX applied to it, double pressing the button takes to into Batch for editing.

- **Timewarp:** Single press to apply a Timewarp Timeline FX to the currently selected timeline segment. Double press to enter the Timewarp editor.
- **Resize:** Single press to apply a Resize Timeline FX to the currently selected timeline segment. Double press to enter the Resize editor.
- **Text:** Single press to apply a Text Timeline FX to the currently selected timeline segment. Double press to enter the Text editor.
- **ColourC:** Single press to apply a Colour Corrector Timeline FX to the currently selected timeline segment. Double press to enter the Colour Corrector editor.

NOTE The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.

- **ColourW (Alt):** Single press (while holding Alt) to apply a Colour Warper Timeline FX to the currently selected timeline segment. Double press (while holding Alt) to enter the Colour Warper editor.

NOTE The Tangent panel only supports the Colour Corrector and Colour Warper Timeline FX editors for input parameters.

- **Spark:** Press to apply a placeholder Spark. Click the Load Spark button (L), with your mouse or pen, to open the Sparks Browser and navigate to the appropriate Spark.
- **Gmask:** Single press to apply a Gmask Timeline FX to the currently selected timeline segment. Double press to enter the Gmask editor.

- **Blur:** Single press to apply a Blur Timeline FX to the currently selected timeline segment. Double press to enter the Blur editor.
- **Action:** Single press to apply an Action Timeline FX to the currently selected timeline segment(s). Double press to enter the Action editor.

Module 4 (BT) - Page 2 of 2

- **Insert:** Perform an insert edit with the selected clip in the active timeline sequence.
- **Overwrite:** Perform an overwrite edit with the selected clip in the active timeline sequence.
- **Replace:** Perform a replace edit with the selected clip in the active timeline sequence.
- **Comp:** Single press to apply a Comp Timeline FX to the currently selected timeline segment. Double press to enter the Comp editor.
- **Flip:** Single press to apply a Flip Timeline FX to the currently selected timeline segment. Double press to enter the Flip editor.
- **2D Transform:** Single press to apply a 2D Transform Timeline FX to the currently selected timeline segment. Double press to enter the Transform editor.
- **Dissolve:** Single press to apply a Dissolve video transition to the currently selected timeline segment(s). Double press to enter the Dissolve editor.
- **Wipe:** Single press to apply a Wipe video transition to the currently selected timeline segment(s). Double press to enter the Wipe editor.
- **Action:** Single press to apply an Action video transition to the currently selected timeline segment(s). Double press to enter the Action editor.

Colour Warper Master Focus Layout

Module 1 (KB)

- **Luma:** Adjust the RGB luma value.
- **Hue:** Adjust the RGB hue value.
- **Saturatio:** Adjust the RGB saturation value.
- **R Gamma:** Adjust the Red Gamma value.
- **G Gamma:** Adjust the Green Gamma value.
- **B Gamma:** Adjust the Blue Gamma value.

Module 2 (TK)

- **ShadowClr:** Move the trackball to adjust the colour of the shadows.
- **Mid Clr:** Move the trackball to adjust the colour of the midtones.
- **HighClr:** Move the trackball to adjust the colour of the highlights.
- **Black:** Adjust the black point.
- **Gamma:** Adjust the RGB gamma value.
- **White:** Adjust the white point.

Module 3 (MF)

- **Exit:** Exit the current menu.
- **Redo:** Reapply the last operation performed after an Undo operation.
- **Undo:** Undo the last operation performed.
- **Pan (Trackball + Alt):** Spin the ball along the X axis to pan the current shot left and right.
- **Scroll (Ring):** Turn the ring to scroll the current shot backward or forward.
- **Zoom (Ring + Alt):** Turn the ring to zoom the current shot in and out
- **Backward Play button:** Play the current shot backward. Results may vary according to the number of unrendered effects on the shot.
- **Backward Play + Stop buttons:** Move the positioner one frame backward.
- **Stop button:** Stop playback.
- **Forward Play + Stop buttons:** Move the positioner one frame forward.
- **Forward Play button:** Play the current shot forward. Results may vary according to the number of unrendered effects on the shot.
- **Previous button:** Go to the start of the current segment.
- **Previous button (Alt):** Go to the previous keyframe.
- **Next button:** Go to the end of the current segment.
- **Next button (Alt):** Go to the next keyframe.

Module 4 (BT)

- **Master:** Adjust the Red suppression value.
- **Selectiv1:** Press to target selective 1.
- **Selectiv2:** Press to target selective 2.
- **Selectiv3:** Press to target selective 3.

Troubleshooting

In the event that one or more of your panel modules are not recognized by Flame Premium, restarting the background service that manages the interactions between Flame Premium and the Tangent Element Control Surface can resolve the issue.

To restart the background service:

- 1 Exit Flame Premium.
- 2 Open a shell on your Linux machine.
- 3 Login as root.
- 4 Type: `/etc/init.d/tangenthub restart`
- 5 Launch Flame Premium.

All of your module panels should now be recognized.

If the above procedure does not resolve the issue, you can manually connect the Control Surface to your software. To do this, you must define each module's unique ID number in the panel-list.xml file within the Flame Premium filesystem for the panel to be recognized.

To manually install the panel:

- 1 Plug and connect the four or five modules (depending on your setup) of your Tangent Element Control Panel to a power outlet and to your USB hub.

- 2 Once the modules are booted up and are displaying the Tangent logo, hit the A button on each module to display its unique ID number.

- 3 On your Linux machine, log in as root and use kEdit to edit the panel-list.xml file:

kedit /var/opt/Tangent/Hub/panel-list.xml

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<TangentWave fileType="PanelList" fileVersion="3.0">
  <Panel type="Element-Mf" number="1" serial="30"/>
  <Panel type="Element-Bt" number="1" serial="68"/>
  <Panel type="Element-Bt" number="2" serial="77"/>
  <Panel type="Element-Kb" number="1" serial="53"/>
  <Panel type="Element-Tk" number="1" serial="13"/>
  <Panel type="Wave"/>
  <Options>
    <DHCP enabled="true"/>
  </Options>
</TangentWave>
```

- 4 Add the corresponding ID numbers to the panel-list.xml file.

NOTE In a four module setup, the line `<Panel type="Element-BT" number="2" serial="00"/>` should be left blank.

- 5 Save the file.

The Tangent Element Control Surface should be now recognized by Flame Premium.

Flame and Smoke Classic Keyboard Shortcuts

NOTE When you press a keyboard shortcut, a white keyboard appears in the lower-right corner of the screen. If a keyboard shortcut becomes stuck at any time, the white keyboard remains until you unstuck the keyboard shortcut by pressing it. Click the white keyboard to display the name of the problematic keyboard shortcut in the message bar.

Determining a Button's Current Keyboard Shortcut

You can determine the keyboard shortcut assigned to a button from anywhere within Flame Premium.

To determine the keyboard shortcut for a button:

- 1 If auto display of tooltips is enabled in the Preferences, hover over the button for which you want to determine the assigned keyboard shortcut. If you have disabled the auto display of tooltips, press and hold **Ctrl+W** and hover over the button.

If a keyboard shortcut exists for the button, it is displayed in the tooltip.

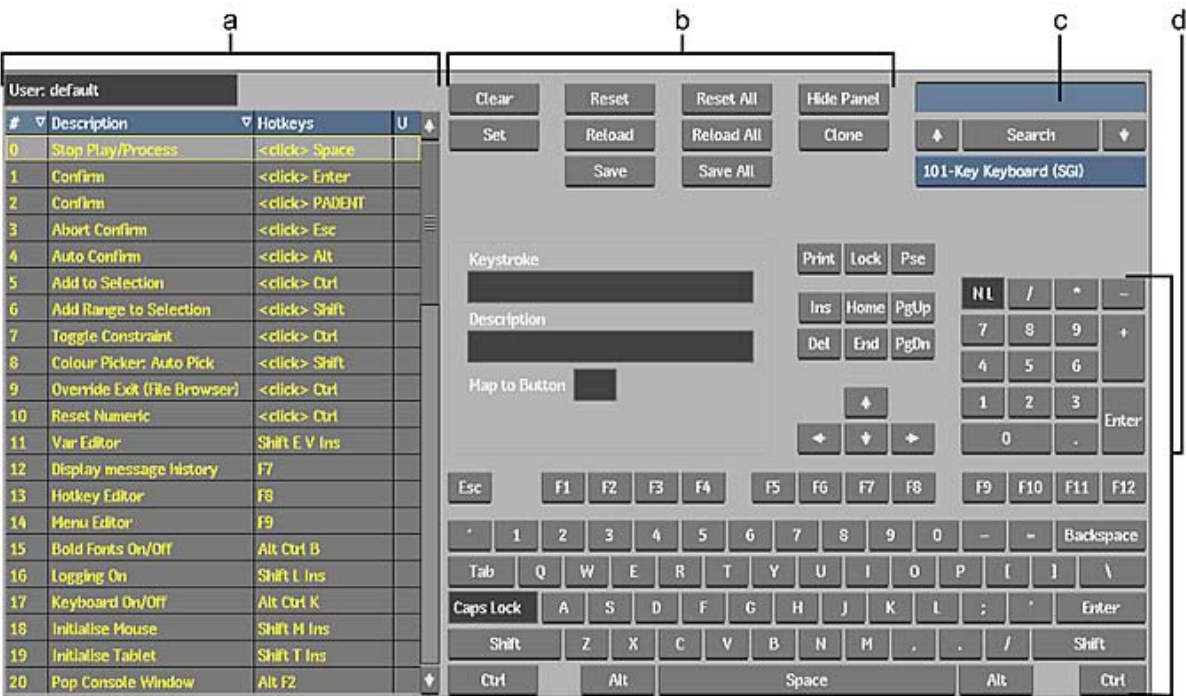

(a) Current keyboard shortcut message

Accessing the Keyboard Shortcut Editor

Use the Keyboard Shortcut Editor to view, modify, and create keyboard shortcuts.

To access the Keyboard Shortcut Editor:

- 1 From the Flame menu, select Keyboard Shortcuts.

(a) Keyboard Shortcut Catalogue (b) Keyboard Shortcut Manager (c) Search Field (d) Keystroke Editor

Keyboard Shortcut Catalogue

A catalogue of keyboard shortcuts is maintained for every user. If the user profile was created in the default home directory, the catalogue is found in `/usr/discreet/user/effects/<user_name>/keyboard shortcut`. If the user profile was created elsewhere, the catalogue is found in `<user home directory>/keyboard shortcut`. The keyboard shortcuts in the keyboard shortcut catalogue are stored in the following formats:

- `default.<component>.butt.keyboard shortcut`
- `default.<component>.func.keyboard shortcut`
- `factory.<component>.butt.keyboard shortcut`
- `factory.<component>.func.keyboard shortcut`

Where:	Means:
<code><component></code>	The module containing the keyboard shortcut.
<code>default</code>	The keystroke that is currently in use.
<code>factory</code>	The Autodesk factory default.

Where:	Means:
<i>butt</i>	A button keyboard shortcut.
<i>func</i>	A non-button function keyboard shortcut.

User-modified keyboard shortcuts are stored in a separate file: *default.<component>.butt.keyboard shortcut.user*. This file is loaded after the system keyboard shortcut file, *default.<component>.butt.keyboard shortcut*. Entries in the user-modified keyboard shortcut file replace the system keyboard shortcut entries, with the exception of cloned keyboard shortcuts, which are duplicated.

Selecting Your Keyboard Type

In the Keyboard Shortcut Editor you can select the type of keyboard you are using to take advantage of extra keys on certain keyboards.

You have the choice of the following keyboards:

When you select your keyboard, the onscreen keyboard is changed to reflect your choice, and entries in the Keyboard Shortcut Catalogue are updated accordingly.

NOTE If a keyboard shortcut is set on a key not available for the keyboard selected, the Keyboard Shortcut Catalogue displays the entry in black.

Searching the Keyboard Shortcut Catalogue

You can search the Keyboard Shortcut catalogue to find keyboard shortcuts whose description match your search criteria.

To search the Keyboard Shortcuts catalogue:

- 1 In the Search field, enter the characters you want to search for.
- 2 Click Search.
The catalogue is searched and the keyboard shortcuts whose description match your search criteria are highlighted.
- 3 If more than one keyboard shortcut is highlighted, use the previous and next buttons located next to the Search field to move through the list of search results.

Changing Keyboard Shortcuts

The Keyboard Shortcut catalogue shows all keyboard shortcuts for your product. Keyboard shortcuts appear in yellow text or in white text in the list:

- Yellow text: identifies shortcuts that are used everywhere in your product.
- White text: identifies keyboard shortcuts that are specific to the area you are in.

To edit a keyboard shortcut:

- 1 From the area where you want to use the new keyboard shortcut, open the Keyboard Shortcut Editor.
- 2 Select the keyboard shortcut in the Keyboard Shortcut catalogue.
The keystroke sequence and its description appear in the Keystroke Editor fields. If you select a map-to-button keyboard shortcut, the word “Yes” appears in the Map-to-Button field.
- 3 Click Clear in the Keyboard Shortcut Manager area to clear the existing keystroke sequence.
- 4 Enter the new keystroke sequence by clicking keys in the Keystroke Editor or by pressing keys on your computer's keyboard.
- 5 Click Set in the Keyboard Shortcut Manager area.
- 6 Click Save to save the changes to the current user's Keyboard Shortcut catalogue.

The edited keyboard shortcut is marked in the catalogue with a “Y” to show that it is user-modified.

# ▾	Description ▾	Hotkeys	Y	Δ
15	Keyboard On/Off	K	Y	
16	Initialize Mouse	Shift M Ins		
17	Initialize Tablet	Shift T Ins		
18	Pop Console Window	Alt F2		

NOTE If you enter a keystroke sequence that is already in use, an error message is displayed.

Cloning Keyboard Shortcuts

You can use Clone to map multiple keystroke sequences to a single button, field, or function using the regular system keyboard. This feature does not provide macro functionality.

To clone a button, field, or function:

- 1 Select a button, field, or function in the Keyboard Shortcut catalogue.
- 2 Click Clone in the Keyboard Shortcut Manager area to create a second entry for this button, field, or function.

A “Y” appears in the Keyboard Shortcut catalogue indicating that the cloned keyboard shortcut is user-modified.

- 3 Activate a control or enter a keystroke sequence on the system keyboard).

NOTE You must enter a keystroke sequence that is not in use. Otherwise, an error message appears.

- 4 Click Set in the Keyboard Shortcut Manager area of the Keyboard Shortcut Editor.
- 5 Click Save to save the changes to the current user catalogue.

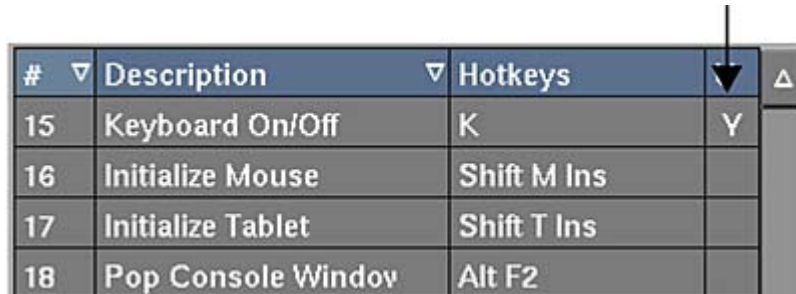

Editing Local Keyboard Shortcuts

Almost every module has its own catalogue of keyboard shortcuts. The keyboard shortcuts listed in white are local keyboard shortcuts, and can be customized to suit your needs without affecting other modules. Modified keyboard shortcuts are saved as a user preference.

To edit a local keyboard shortcut:

- 1 In the module where you want to use the new keyboard shortcuts, access the Keyboard Shortcut Editor (Alt+Ctrl+F8).
- 2 Select the keyboard shortcut in the Keyboard Shortcut catalogue.
The keystroke sequence and its description appear in the Keystroke Editor fields. If you select a map-to-button keyboard shortcut, the word “Yes” appears in the Map-to-Button field.
- 3 Click Clear in the Keyboard Shortcut Manager area to clear the existing keystroke sequence.
- 4 Enter the new keystroke sequence by clicking keys in the Keystroke Editor or by pressing keys on your computer's keyboard.
- 5 Click Set in the Keyboard Shortcut Manager area.
- 6 Click Save to save the changes to the current user's Keyboard Shortcut catalogue.

The edited keyboard shortcut is marked in the catalogue with a “Y” to show that it is user-modified.

# ▾	Description ▾	Hotkeys	Map-to-Button	Δ
15	Keyboard On/Off	K	Y	
16	Initialize Mouse	Shift M Ins		
17	Initialize Tablet	Shift T Ins		
18	Pop Console Window	Alt F2		

NOTE If you enter a keystroke sequence that is already in use, an error message is displayed.

Editing Global and Shared Keyboard Shortcuts

You can edit global and shared keyboard shortcuts wherever the Keyboard Shortcut Editor is available. When you access the Keyboard Shortcut Editor through the Preferences menu, click Global or Shared to view all current global or shared keyboard shortcuts, respectively. In this menu, the names of these keys appear in yellow.

In other modules, the global and shared keyboard shortcuts appear in yellow in the Keyboard Shortcut catalogue. When changing a global or shared keyboard shortcut, you are warned that the change will affect all modules, and are asked to confirm the action.

Mapping a Button to a Keyboard Shortcut

You can create new map-to-button keyboard shortcut. New keyboard shortcuts are saved as a user preference.

The screenshot shows the 'Keyboard Shortcut Editor' window. It has several input fields and buttons. The 'Keystroke' field contains 'Alt'. The 'Description' field contains 'Right -> Left (Button)'. The 'Map to Button' field contains 'YES'. There is a 'Cycle Pop-up' button which is disabled. The 'Value' field contains 'Bool' and the 'Increment' field contains '0'.

To map a button to a keyboard shortcut:

- 1 With the Keyboard Shortcut Editor open, click the menu button for which you want to create the keyboard shortcut.
NOTE If the button you want to click is hidden by the Keyboard Shortcut Editor, click the Hide Panel button.
If the menu button you selected is a map-to-button keyboard shortcut, Yes appears in the Map to Button field, and the name of the menu button appears in the Description field.
- 2 Enter the new keystroke sequence by clicking keys in the Keystroke Editor, your computer's keyboard, or the keys on your pen tablet. The new keystroke appears in the Keystroke field.
- 3 If the menu button is a field, you can set a default value type and increment in the Value Type box and Increment field.
- 4 If the menu button is an option box, you can enable Cycle Pop-up to allow your new keyboard shortcut to cycle through the options each time it is pressed.
- 5 Click Set.
- 6 Click Save to save the changes to the current user's Keyboard Shortcut catalogue.

Keyboard Shortcut Editor Menu Settings

Keyboard Shortcut Manager Area

The screenshot shows a grid of buttons for managing keyboard shortcuts. The buttons are arranged in three rows. The first row contains 'Clear', 'Reset', 'Reset All', and 'Hide Panel'. The second row contains 'Set', 'Reload', 'Reload All', and 'Clone'. The third row contains 'Save' and 'Save All'.

Clear button Clears the contents of the Keystroke field in the Keystroke Editor before you enter a new keystroke sequence.

Set button Sets the contents of the Keystroke field.

Reset button Resets the current local keyboard shortcuts to their default settings.

Reload button Reloads the current catalogue of keyboard shortcuts. This is useful if you made a change but have not yet saved it, and you wish to discard the change.

Save button Saves the current keyboard shortcuts to the Keyboard Shortcut Catalogue of the current user.

Reset All button Resets all keyboard shortcuts to their default settings.

Reload All button Reloads all keyboard shortcuts from the Keyboard Shortcut Catalogue of the current user.

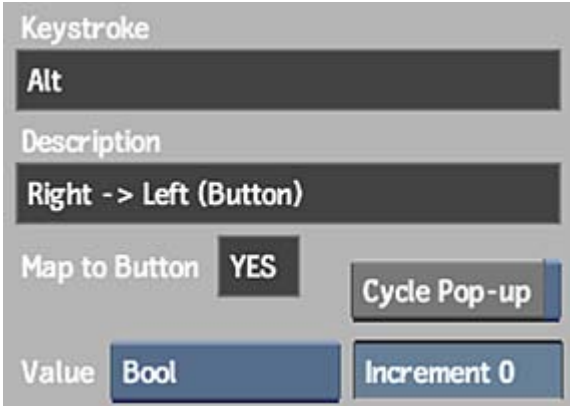

Save All button Saves all keyboard shortcuts to the Keyboard Shortcut Catalogue of the current user.

Hide Panel button Hides the Keyboard Shortcut Editor panel when you want to select a menu button hidden by the panel. The panel reappears when you select a menu button. Alternatively, click in an open area to return to the Keyboard Shortcut Editor panel without selecting anything.

NOTE This button is only available when accessing the Keyboard Shortcut Editor from a module.

Clone button Assigns a regular keyboard keystroke sequence to a single button, field, or function.

Keystroke Editor Section

The screenshot shows a window titled 'Keystroke Editor'. It contains several fields and buttons: a 'Keystroke' field with the text 'Alt', a 'Description' field with the text 'Right -> Left (Button)', a 'Map to Button' field with a 'YES' button, a 'Cycle Pop-up' button, a 'Value' field with a 'Bool' button, and an 'Increment 0' button.

Keystroke field Displays the keystroke sequence. Click keys in the Keystroke Editor or the keyboard to enter a new sequence.

Description field Displays the name of the selected menu button. Non-editable.

Map to Button field Displays whether the selected keyboard shortcut is a map-to-button hot key (a keystroke sequence that is mapped to a button or a field on the current menu). Non-editable.

Value Type box Select a value type for the selected menu button.

Integer Increment field Displays the integer increment for the selected value type. Editable.

Float Increment field Displays the float increment for the selected value type. Editable.

Cycle Pop-up button Enable to allow the new keyboard shortcut to cycle through options for the selected box.

Search Section

Search field Displays the search criteria for the Hot Key Catalogue. Editable.

Search button Performs a search based on the characters in the Search field.

Previous button Selects the previous highlighted item in the search results.

Next button Selects the next highlighted item in the search results.

Miscellaneous Settings

User field Displays the current user that hot keys are saved for. Non-editable.

Keyboard Type box Select the type of keyboard being used to take advantage of extra keys on certain keyboards. See [Selecting Your Keyboard Type](#) (page 1711).

Close button Click to close the Keyboard Shortcut Editor, and return to your previous view.

Setting Flame Premium Preferences

30

Customize your working environment using preferences.

To open the Preferences dialog box:

- 1 Click Flame > Preferences.
- 2 Select the category of preferences you want to modify. The dialog box opens to the tab with the category of preferences you selected.

Audio Preferences

Player

Monitor Sync box Indicates which monitor will have audio sync when you play back a clip (the broadcast monitor or the high-resolution monitor).

Broadcast Delay field Displays the number of frames (-30.00 to 30.00) to delay the audio signal when syncing to the broadcast monitor. Editable.

Hi-Res Delay field Displays the number of frames (-30.00 to 30.00) to delay the audio signal when syncing to the graphics monitor. Editable.

Auto Fade field Displays the amount of time (0 to 10 ms) that a fade is added to the start and end of each audio segment. Use this setting to avoid audible clicks between audio sources. Editable.

Meters

Meter Range field Displays the overall scale for the fader meters. Editable.

Meter Green field Displays the green meter range. Editable.

Meter Yellow field Displays the yellow meter range. Editable.

Meter Step field Displays the step value for the meters. Enter a lower value to view a more detailed meter.

Meter Units box Select whether the meters display digital or analog units.

Tone

Audio Tone box Select the default audio tone.

Reference Level field Displays the reference level for custom audio tones. Editable.

Tracks

Consider Audio Head/Tail button Enable to include audio that extends before or after video when exporting movie files.

Supported Playback Tracks field Displays the number of playback tracks supported by your sound card. Non-editable.

Supported I/O Tracks field Displays the number of I/O tracks supported by your sound card. Non-editable.

Supported Audio Monitoring Field Displays the audio monitoring option supported by your sound card. Non-editable.

Outputs

Output Source field Displays all current outputs. Non-editable.

Output Sampling Rate field Displays the current output sampling rate. Non-editable.

Monitoring Level field Displays the default volume level. Does not effect output. Editable.

Backburner Preferences

Backburner Manager box The hostname of the Backburner Manager system that handles background jobs submitted by the workstation.

Backburner Group box Specifies a server group (a preset group of render nodes) used to process jobs submitted by the application. By default, Backburner Manager assigns a job to all available render nodes capable of processing it. If you have a dedicated group of render nodes for processing jobs, set the value to the name of the render node group. See the Backburner User Guide for information on creating groups.

Burn Job Type box Configure according to the GPU capabilities of the nodes in your background processing network.

- **Software:** none of the nodes in your background processing network is equipped with a GPU. The application will not send jobs that require a GPU to the background processing network, but only jobs that can be processed in software mode (using OSMesa) by the render nodes.
- **GPU Burn:** all the nodes in your background processing network are GPU-enabled. The application will send all jobs to the GPU-equipped nodes in the background processing network, even if some jobs do not specifically require a GPU node. The GPU-equipped render nodes will render jobs that require a GPU, as well as OSMesa jobs. If your background processing network also contains nodes without a GPU, and this setting is used, all jobs are sent only to GPU-equipped render nodes, and the nodes without a GPU are never used.

Burn Priority field Sets the priority for renderings jobs, from 1 (highest priority) to 100 (lowest).

Wire Priority field Sets the priority for transfers from and to this workstation, from 1 (highest priority) to 100 (lowest).

Store Priority field Sets the priority for caching imported media on this workstation, from 1 (highest priority) to 100 (lowest).

Burn Export field Sets the priority for exporting clips from this workstation, from 1 (highest priority) to 100 (lowest).

NOTE Regarding the different priorities, be careful when setting new values or you might end up with a system trying to transfer frames before they are rendered.

Broadcast Monitor Preferences

Broadcast Monitor Preferences

Broadcast Monitor box Select the output device used by the broadcast monitor, or turn it off.

Broadcast Selection box Select what you want to preview on your broadcast monitor (can be changed on-the-fly).

Always Send Grab Area button Enable to display Player or viewport output, including times when neither is in use. Active when the Screen Grab option is selected.

Scale Clip to Fit Monitor button Enable to resize the clip to fit the broadcast monitor. Active when the Show Selected Item option is selected.

Use Ratio button Enable to maintain the original proportions of the clip. Disable to use the monitor ratio. Active when the Show Selected Item option is selected.

Broadcast Multiview Preferences

Viewport Monitoring button Enable to send to the broadcast monitor the content of the viewport displaying the "Monitor" symbol. Disable to use the broadcast monitor as an additional viewport; then use the Broadcast Monitor toolbar to control the broadcast monitor as you would any other viewport.

Hide Broadcast Toolbar button Enable to hide the Broadcast Monitor toolbar. By default, the toolbar is displayed in the top-right corner of the graphics monitor. Spacebar+Click to move the Broadcast Monitor toolbar.

Image Data Type Preferences

Image Data Type box Select the type of image data you are displaying in the broadcast monitor. Your selection determines the type of transformation that is applied to the clip to modify the contrast. It is disabled if the Follow button is enabled.

Bypass button Enable to deactivate the image data type display settings in the broadcast monitor.

Broadcast LUT Preferences

Use 3D LUT in Monitor button Enable to apply a 3D LUT from the 3D LUT list to the broadcast monitor.

3D LUT List box Displays the list of 3D LUTs that you imported in the LUT tab.

Broadcast Overlay Preferences

Broadcast Overlay box Select the overlays displayed on the broadcast monitor. "Off" for no letterbox or reference overlay, "Letterbox" for aspect ratio and letterbox guides, "All" for letterbox and all reference overlay elements.

Broadcast Stereo

Broadcast Stereo box Displays the current stereoscopic display option.

General Preferences

Project Information

Project Framerate field Displays the framerate that corresponds with the current project's default resolution. Non-editable.

Incoming Sync

Incoming Sync field Displays the timing of the sync received by the workstation. Non-editable.

Timecode

Display Dual Timecodes button Enable to display both 29.97 and 23.97 fps timecode on the timeline and in the Player. This allows you to monitor which transitions will fall on jitter frames when 2:3 insertion is applied.

Dual TC: 23.97->29.97 fps NDF/DF box Select whether to view the 29.97 fps timecode in the Dual Timecode display as either drop frame or non-drop frame.

Drop Frame Reference Timecode field Displays the point at which the 29.97 fps material is in sync with the 23.97 fps material. Editable.

Drop Frame Bump Mode box Select a translation mode for invalid calculator entries.

Player

Source Time Mode box Select to display the timecode, keycode, or frame number of the source clip in the Player.

Auto-Toggle Player button Enable to open the Player automatically when you press the keyboard shortcuts for playback.

Display Sequence Viewer button Enable to display the currently selected sequence as a thumbnail with a red border in the Thumbnail view. When disabled, the selected sequence does not appear Thumbnail view.

Jog / Shuttle on Drag button Enable to shuttle a clip in the Player when jogging. The further from the center of the clip that the cursor is placed and dragged, the faster the shuttling.

Auto-Toggle Trim View button Enable to automatically display the Trim View when double-clicking a timeline cut, or when double-clicking a timeline segment with Slip or Slide mode selected.

Untitled Clip Name

Untitled Clip Name box Select an option to rename untitled clips to make it easier to distinguish multiple Untitled clips.

Rendered Clip Name

Rendered Clip Name box Select whether to add an acronym indicating the area of the software your clip was rendered from as a prefix or suffix to a rendered clip name, if a setup name does not already exist for the clip.

Stereo Naming

Left Eye field Displays the token used to identify left eye media in a stereo clip split or exported. Editable.

Right Eye field Displays the token used to identify right eye media in a stereo clip split or exported. Editable.

Animation

Default Interpolation box Select the default interpolation type for the channel editor.

Default Extrapolation box Select the default extrapolation type for the channel editor.

Audio Gain Animation

Default Audio Interpolation box Select the default audio interpolation type for the channel editor.

Autosave

Soft Save field Displays the time delay for a soft autosave. A small red icon appears indicating a two-second delay before a soft autosave occurs (allowing for a cancellation with any movement in the application). Editable.

Hard Save field Displays the time delay for a hard autosave. A hard autosave occurs at the specified time regardless of user intervention. Editable.

Tools Save field Displays the time delay for an autosave when you are using a tool that you accessed from the Tools tab. Editable.

Help Location

Help Location button Displays the location of the product help. By default, the product help is available online. You must have an internet connection to view it. You can download and install the help locally from the Autodesk website.

Browse Help button Opens a browser window. Select the folder that contains the help that you downloaded from the Autodesk website.

Reset Help button Resets the help location to the default.

Help Location field Displays the location of the help.

Setups

Scale Setups button Enable to scale setups when loading that were created in a resolution different from that of the current project.

Image Data Type

Image Data Type box Select a default image type setting.

Undo

Clear Buffer button Removes clips from the undo buffer and frees up disk space on the framestore

Undo Level field Displays how many levels of information are saved to the undo buffer. Editable.

Clip Select

Ignore Scan Format button Enable to disregard scan mode mismatches.

Background Tasks

Update field Displays a value, in seconds, for the wait time to update the Backburner Queue. Editable.

Default Rendering Options

Rendering Display Select whether to display all frames as they are rendered or to allow the display of all frames with potential tearing.

Render box Select whether you want to include history and/or Burn when rendering.

Keep History Mode box Select whether Sources or Intermediates and Sources appear on the workspace when working with clip history.

Shared Libraries

Shared Libraries Refresh Rate field Displays the frequency at which the application refreshes the contents of Shared Libraries. Editable.

Shared Libraries Lock Timeout field Displays how long an inactive shared folder remains available for writing. Editable.

Media Library

Protect from Editing button Enable to protect all of the contents in the Media Library from editing. To work on media in a protected Media Library, you must bring it to a Batch or Desktop folder in the Media panel.

Input Devices Preferences

Pointer

Tablet Model field Displays the model of the currently installed tablet. Non-editable.

Pointer Reset button Returns all pointer preferences to their default values.

Threshold Test button Assesses the sensitivity of the pen interactively. Press the pen on the button and a sliding grey bar in the message bar displays the response to the amount of pressure applied.

Pressure Threshold field Displays the amount of pressure that you want to apply when using the pen. Use a higher value to decrease the sensitivity of the pen (more pressure required).

Use Mouse Cursor button When using a tablet, enable to use mouse cursors instead of tablet cursors.

Trackball Pressure button Enable to allow the trackballs to respond to changes in the pressure applied when using a stylus.

Tablet Margins

Proportional Margins button Enable to change the four margin controls proportionally.

Top Margin Control field Displays a percentage value to adjust the top boundary of the active area on the tablet. Editable.

Bottom Margin Control field Displays a percentage value to adjust the bottom boundary of the active area on the tablet. Editable.

Left Margin Control field Displays a percentage value to adjust the left boundary of the active area on the tablet. Editable.

Right Margin Control field Displays a percentage value to adjust the right boundary of the active area on the tablet. Editable.

LUT Preferences

1D LUT/3D LUT and Colour Transform list Displays the list of imported 1D LUTs or 3D LUTs and Colour Transforms in separate tabs. See [Making 1D LUTs Available for Display](#) (page 1576) and [Making 3D LUTs and Colour Transforms Available for Display](#) (page 1576).

LUT Type box Select whether you want to define a gamma function or import a 1D LUT file in the highlighted row and assign the corresponding keyboard shortcut.

Import button Opens the Import LUT browser. Navigate to the 1D LUT file to import, and select it to load it into the list. This button is available when the LUT Type box is set to LUT File.

Value field Displays the gamma value. This field is available when the LUT Type box is set to Gamma.

Select button Apply the highlighted gamma or 1D LUT to all displayed images. See [Applying 1D LUTs to the Monitor](#) (page 1577).

Import button Opens the Import LUT browser. Navigate to the 3D LUT or Colour Transform file to import, and select it to load it to the 3D LUT and Colour Transform list.

Reset button Removes the highlighted item from the list.

Reset All button Removes all LUTs and Colour Transforms from the current list.

Shared Directory Displays the file path to the shared colour transforms directory. This is a useful location for storing custom transforms that can be used by other applications that use Autodesk Colour Management.

Browse Browse to select a different shared directory for color transforms. The path you select is used by all compatible applications on the same workstation.

Default Reset the shared directory to its installation default.

Broadcast Monitor Transform Specifies the colour transform that is used when the broadcastMonitor alias is referenced inside another transform. See [Configuring the Colour Transform Aliases](#) (page 1576).

Default Reset the Broadcast Monitor Transform to its installation default.

Browse Browse to select a different colour transform for the broadcastMonitor alias.

Graphics Monitor Transform Specifies the colour transform that is used when the graphicsMonitor alias is referenced inside another transform. See [Configuring the Colour Transform Aliases](#) (page 1576).

Browse Browse to select a different colour transform for the graphicsMonitor alias.

Default Look Transform Specifies the colour transform that is used when the defaultLook alias is referenced inside another transform. See [Configuring the Colour Transform Aliases](#) (page 1576).

Clear Sets the value of the defaultLook alias to the identity transform, which has no effect on colour values.

Browse Browse to select a different colour transform for the defaultLook alias.

Storage Preferences

Space Calculation

Space Calculation options Choose to display all available frames in the message bar, all available and purgeable frames in the message bar, or to purge frames before making a space calculation.

Volume Statistics button Lists the number of frames, proxies, and audio sources stored in the clip libraries, and main work area of each project.

Video Framestore Estimate button Displays the estimated amount of space left on the video framestore.

Framestore

Test Disks button Displays the number of frames read per second; the number of seconds required to read a single frame; and the amount of data, in megabytes, read per second.

Local Gateway

Restart button Restarts the local Wiretap Gateway service, which must be running for you to import and export media. Use this button when troubleshooting failing import or export processes.

Temporary Libraries

Clear All button Click to delete temporary libraries from the current project. Do not use if background operations are running. Use the Background Tasks monitor to ensure all tasks are done before using.

Temporary libraries are used by background tasks, and are usually automatically deleted by Flame Premium. But it can happen that they are not deleted correctly, build up over time and tax your storage. Clearing these libraries recovers that lost space. This is a safe operation unless background operations are running: wait for them to complete before clearing the temporary libraries.

Support Preferences

Upload Config Info Only button Click to upload only configuration information to Autodesk Customer Support. Use only if instructed by Autodesk Customer Support.

Upload Config Info and Logs button Click to upload pertinent configuration information and system logs to Autodesk Customer Support. Use only if instructed by Autodesk Customer Support.

Max Logged Days field Displays the number of logged days of information to be uploaded to Autodesk Customer Support. Editable.

Case ID field Enter the Case ID number given to you by Autodesk Customer Support so that it is included in the uploaded information.

Timeline Preferences

Editing

Default Timecode field Displays the default start timecode value for new items overwritten or inserted into a timeline sequence. Editable.

Merge Tracks Mode box Select how a timeline will be flattened when merging tracks.

Select:	To merge tracks by:
Simple Track Merge	Hard committing all soft transitions. Cut points between elements are preserved; clip handles are not.
Complex Track Merge	Hard committing soft transitions but creating separate elements with clip handles for each.
Committed Track Merge	Preserving editable soft transitions and clip handles.

Auto Timewarp button Enable when performing a four-point edit if you do not want to timewarp the frames from the source clip. When disabled, a four-point edit is treated as a three-point edit.

When you specify the number of frames in the sequence clip for the four-point edit, the same number of frames is used in the source clip. The source clip selection begins at the in point. If the source is shorter or longer than the number of frames specified in the sequence clip, a timewarp is applied to the source clip in order to match the duration of the sequence clip.

Framerate Converter button Enable to format the source clip to the correct destination framerate by applying a video timewarp to the source clip.

Snap Includes Marks button Enable to snap to timeline marks.

Snap With Positioner button Enable to snap segments to the positioner.

Display Phantom Marks button Enable to turn on phantom marks on the timeline and source clip. Phantom marks indicate the result of a 4-point edit regardless of whether you have marks set.

Containers

Uncontain options box Select whether new tracks and versions are added or overwritten when a container segment is uncontained.

Contain Timewarped Edits button Enable to preserve the edits in a fit-to-fill four-point edit. The incoming clip is contained and a timewarp is applied to the container instead of the clip.

Segment Display

Handles box Select an option for displaying heads and tails on segments in the timeline.

Navigation

Frame Positioner box Select whether to snap the timeline positioner frame-to-frame, or on a sub-frame basis (one-tenth of a frame).

Autoscroll field Displays the speed at which the timeline scrolls. Editable.

Scroll During Playback button Enable to scroll the timeline during playback, keeping the frame positioner visible.

Scroll Past First Frame button Enable to allow the positioner to move before frame one.

Transitions

Dissolve Duration field Drag left or right, or enter a value to set the default duration for dissolves.

Transition Alignment box Sets the default alignment for dissolves, wipes, axis, and custom transitions.

Curve Type box Select Bezier or linear as the default curve type for dissolves.

Rendering

Timeline Effects Render Mode box Select the render mode when a Timeline FX is added to a clip.

Timewarp Render Mode box Select the default rendering mode for timewarps created in the timeline.

Transitions Render Mode box Select a default rendering mode for transitions created in the timeline.

Timeline Effects Rendering box Select whether to render an entire track first, then the next track (Track Based Render), or to render all tracks frame-by-frame (Frame Based Render).

Timeline FX / Batch FX Preferences

Batch FX

Interactive Max field Displays the number of seconds that the system uses to attempt a render when previewing the effect. Editable.

Add Comp On Matte Output button Enable to have a Comp timeline effect automatically added to the timeline when a matte is output from the output node to the timeline.

Always Load Nodes button Enable to automatically load all FX nodes into memory when a setup is loaded. Disable to load nodes when entering an FX level.

Clear Rendered Memory button Enable to automatically clear an FX node (and all nodes in setups nested within the clip) from memory when its output is rendered.

Batch FX Mode

Head Media option box Select how to interpret missing information before a clip.

Gap Media option box Select how to interpret missing information during a clip.

Tail Media option box Select how to interpret missing information after a clip.

Batch FX Automatic Nodes Copy

Automatic Nodes Copy box Select whether FX nodes are never copied into memory, always copied, copied when there is an Action node in the setup, or copied in a partially rendered setup.

Timeline Timewarp

Interpolation Option box Select an interpolation option for your interlaced timewarp.

Use Last Speed button Enable to apply the last timewarp speed to future timewarps.

Timewarp Speed Display box Select whether timewarp speed is displayed as a percentage (%) or in frames per second (fps).

Timewarp Sample Option box Select whether the speed of the timewarp is set in relation to the speed at the beginning, middle, or end of the timing curve for each frame or field. You can also change the Timewarp Sample option in the Timewarp Editor to override this selection.

Timeline Resize

Fit Method box Select a fit option for clips that must be resized when they are added to the timeline because their resolution is different from the project.

Resize Quality box Select a sampling algorithm for clips that must be resized when they are added to the timeline.

Keep Aspect button Enable to maintain the aspect ratio of clips that are resized when you add the to the timeline.

Viewport Settings

Default Viewport box Select whether to use a 1-Up or 2-Up view as the default Batch FX view. You can also change the viewport layout from within Batch FX.

Batch FX Cache Life Span

Cache Life Span field Displays the number of days that Batch FX clips are cached. Editable.

Batch Cache Life Span

Cache Life Span field Displays the number of days that Batch clips are cached. Editable.

Batch Read File Node

Absolute Frame Offset button Enable to allow all clips imported with a Read File node in Batch to automatically use the start frame of the clip.

Batch Snapshot

Also Save Batch File button Enable to save a Batch setup file when saving a Batch Snapshot.

User Interface Preferences

Colour

Background field Displays the background brightness value. Editable

Brightness field Displays the brightness of interface elements such as buttons and fields. Editable.

Contrast field Displays the contrast of interface elements such as buttons and fields. Editable.

On-Screen Widgets

On-screen Keyboard button Enable to have the on-screen keyboard appear when you enter text in a field.

Calculator Placement box Select where the calculator appears when you click in a numeric field.

Display

Clip Information box Select to display frames or timecodes in frame marking controls, the timebar, segments, and the fields below the timeline.

Bold Font button Enable bold fonts on buttons.

Drag Transparency field Displays the transparency level of clips while dragging. Editable.

Auto Key Button Look

Auto Key look box Select whether to apply a Classic (grey) or Coloured (yellow) look to the Auto Key button.

Thumbnail View

Snap to Grid button Enable to snap thumbnails to a grid. The grid becomes visible when this button is enabled.

Grid Size field Enter a value in pixels for the size of the boxes that make the grid.

Thumbnail Height field Enter a default value in pixels for the height of thumbnails displayed in the Thumbnail view. All new thumbnails are generated at this height. Existing ones are unchanged.

Tooltips

Auto Display button Enable to automatically display tooltips. If disabled, you can still display tooltips for selected buttons using the keyboard shortcut Ctrl+W.

Hover field Displays the amount of time you must position the mouse over the object before the tooltip displays (in seconds). Editable.

Duration field Displays the amount of time that the tooltip is visible (in seconds). Editable.

Reels

Friction field Displays a value that represents how much the reels scroll after you release your mouse/pen. Increase the value to limit the amount the reel scrolls after you release the mouse/pen.

Reels Orientation box Select a horizontal or vertical orientation for the reels.

Reverse button Enable to reverse the order that clips appear on the reels.

Clip Spacing field Enter a value to control the padding between clips on the reels.

Number of Default Reels field Enter a value for the default number of reels that appear in the Reels view.

Broadcast Display button Enable or disable Broadcast Monitor Display.

Gestural Workflow

Swipe Bars button Click to enable swipe bars that you can use to switch views in different areas of your product.

Layout Selection Overlay button Click to enable the menu overlay in the Timeline view. You can use the menu overlay to change what is displayed in the Timeline view.

Gateway Clip Description

31

The Gateway .clip is an XML structured file that describes at least the following information.

- Physical location of files, and additional metadata information, such as timecode and keycode
- Clip versions

NOTE This documents to use notation as close as possible to DTD definitions.

- xml-element?: zero or one instance of xml-element;
- xml-element+: at least one instance of xml-element;
- xml-element*: any number of instances of xml-element;
- #cdata: a placeholder for data described in the xml-element description, usually a string of any valid characters;

clip

The <clip> element defines the top-level data structure. The minimum elements required to create a valid <clip> are:

- <tracks>
- <versions>

Attribute	Description	Data Type	Al- lowed Values	Attribute is...
type	The data type of the element.	character data	clip	Required
version	Version of the xml element.	integer	3	Required

Attribute	Description	Data Type	Allowed Values	Attribute is...
uid	Optional unique identifier. When used, <code>uid</code> must be a unique ID within the <code>.clip</code> file.	ID	any	Implied

Children

handler?, [name](#) (page 1734)?, sourceName?, startTimeCode?, [duration](#) (page 1732)?, editRate?, [dropMode](#) (page 1731)?, [userData](#) (page 1740)?, [comment](#) (page 1730)?, [tracks](#) (page 1740), [versions](#) (page 1742)

comment

The `<comment>` contains an unparsed string. Use it to store comments.

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	string	Implied
version	Version of the xml element.	unsigned integer	3	Implied

Child Element

#cdata

Found in...

[<clip>](#) (page 1729), [<track>](#) (page 1739), [<version>](#) (page 1741)

Example

Flame displays `<name>` (with `<clip>` as immediate parent) in Batch as the clip name in the Batch setup. But `<name>` as child of `<track>` is used as the name of the channel.

nbTicks

The `nbTicks` element is the number of samples that make up the media. It is a 64-bit integer.

This number divided by the value of the `<rate>` element defines the duration of the media.

The `nbTicks` element has no attributes.

Children

#cdata

Found in...

[<duration>](#) (page 1732)

numerator

The `<numerator>` element must be an insigned integer. It expresses, when divided by the `<denominator>` element, a frame rate.

The <numerator> element has no attributes.

Children

#cdata

Found in...

[rate](#) (page 1736), [sampleRate](#) (page 1737)

path

The <path> element is the path to the media. The path can be relative or absolute. You can also use range brackets for file sequences.

```
/dir/clip.mp4
/dir/fileSequence/dpxSequence.[0-99].dpx
```

NOTE Regarding files sequence and padding in the <path> element: The Gateway reconstructs a sequence as indicated by brackets. dpxSequence.[1-99].dpx indicates to the Gateway there are 99 dpx files named dpxSequence.1.dpx to dpxSequence.99.dpx. It can also manage padding. dpxSequence.[001-099].dpx is read as a sequence of 99 files named dpxSequence.001.dpx to dpxSequence.099.dpx.

In a Smoke and Flame context, use the subFeedId attribute to pair up paths and create stereo spans.

```
<path subFeedId="Left">/dir/stereoClip.Left.[0-99].dpx</path>
<path subFeedId="Right">/dir/stereoClip.Right.[0-99].dpx</path>
```

The actual use and interpretation of the subFeedId attribute is left to the client application.

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	path	Implied
version	Version of the xml element.	unsigned integer	3	Implied
subFeedId	Use this attribute to further identify the type of feed. In a Smoke or Flame context, you create stereo pairs by using the "Left" and "Right" values.	character data	any	Implied

[](#) (page 1737)

rate

Frame rate of the media. If no frame rate is specified, it is up to the application to decide on the frame rate to use.

Use `numerator/denominator` elements to express as a fraction frame rates that use decimals; this provides more precision. The following expresses a frame rate of 23.976 fps.

```
<rate type="time">
  <numerator>24000</numerator>
  <denominator>1001</denominator>
</rate>
```

To express frame rates that use integers, use the short-hand notation without child-elements but only a single integer.

```
<rate type="time">25</rate>
```

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	rate	Implied

Attribute	Description	Data Type	Allowed Values	Attribute is...
version	Version of the xml element.	unsigned integer	3	Implied

Children

([numerator](#) (page 1734), [denominator](#) (page 1731)) | #cdata

NOTE #cdata must be an unsigned integer.

sampleRate

The `<sampleRate>` element describes the frames per second rate of the media described by the `<feed>` element. If no frame rate is specified, it is up to the application to decide on the frame rate to use.

Use numerator/denominator elements to express as a fraction frame rates using decimals. Use an integer for other cases. The following expresses a frame rate of 23.976 fps.

```
<sampleRate type="time">
  <numerator>24000</numerator>
  <denominator>1001</denominator>
</sampleRate>
```

To express a frame rate using an unsigned integer, use the short-hand notation without child-elements but only a single integer.

```
<sampleRate type="time">25</sampleRate>
```

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	rate	Required
version	Version of the xml element.	unsigned integer	3	Implied

([numerator](#) (page 1734), [denominator](#) (page 1731)) | #cdata

span

The `` element contains media that make up all or parts of the `<feed>`. A `` element describes its duration and the path to the physical media files. A `<feed>` made up of multiple `` elements means that multiple media files/sequences make up that one `<feed>`. The order in which each `` element is listed is the order in which they are read to rebuild the sequence.

All media referenced in a `` must have homogeneous properties (same codec, compression, format, length, rate...). To mix types of media in a .clip, use different `<track>` elements.

A `` with a `<duration>` but no `<path>` is the definition of a gap.

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	span	Implied
version	Version of the xml element.	unsigned integer	3	Implied

Found in...

[<tracks>](#) (page 1740)

tracks

The container for all the track elements making up the current .clip file.

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	tracks	Implied
version	Version of the xml element.	unsigned integer	3	Implied

Children

[track](#) (page 1739)+

Found in...

[<clip>](#) (page 1729)

trackType

The type of media described in the track element. `<trackType>` must match the type of media later referenced by the feeds elements.

The `<trackType>` element has no attributes.

Allowed values for `<trackType>`:

- video
- audio

Children

#cdata

Found in...

[<track>](#) (page 1739)

userData

`<userData>` is dictionary object that stores client-defined elements, passed directly to the client application by the Gateway.

Here is an simple example of a `<userData>` structure used to store the name and version of the source application that created the .clip.

```
<userData type="dict">
  <appName type="string">Flame</appName>
```

```
<appVersion type="int16">2012</appVersion>
</userData>
```

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	dict	Required
version	Version of the xml element.	unsigned integer	3	Implied

Children

#undefined

No children elements are defined for the `<userData>` element since its data structure is undefined; each child element created by the client must define its data type using the `type` attribute. The allowed data types are listed below.

Data Type	Defined Values
Integer (bound or unbound)	int, int8, int16, int32, int64
Unsigned integer (bound or unbound)	uint, uint8, uint16, uint32, uint64
Floating point	float, double
Boolean	bool
String	string

Found in...

[<clip>](#) (page 1729), [<feed>](#) (page 1732), [](#) (page 1737), [<version>](#) (page 1741)

version

The `<version>` element contains metadata for a clip version, and lists an existing version using its `uid` attribute.

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	version	Implied
version	Version of the xml element.	unsigned integer	3	Implied

Attribute	Description	Data Type	Allowed Values	Attribute is...
uid	Defines which <feed> of each <track> to use, based on matching vuid.	IDREF	Any vuid defined in a <feed>. Each uid must be unique across <version> elements.	Required

Children

Found in...

[<versions>](#) (page 1742)

versions

The <versions> element lists two things: the available versions of a clip, and the version currently in use.

Different versions of a track are described by different <feed> elements each identified with a unique vuid attribute. In a Gateway clip XML, a specific version of a clip is defined as all the <feed> elements sharing the same vuid attribute across different <track> elements.

The <version> element describes and lists the available versions, while the currentVersion attribute defines which <version> element is the current one. The client application that reads the .clip is not required to currentVersion; it only serves as a flag put there by the creator.

Consider the following, simplified example.

```
<tracks>
  <track uid="track1">
    <feeds>
      <feed vuid="v1" uid="t1f1"/>
      <feed vuid="v3" uid="t1f2"/> <!-- version 3 of the track, version 2 was never
created -->
    </feeds>
  </track>
  <track uid="track2">
    <feeds>
      <feed vuid="v1" uid="t2f1"/>
      <feed vuid="v2" uid="t2f2"/>
      <feed vuid="v3" uid="t2f3"/>
    </feeds>
  </track>
</tracks>
```

And you have the following <versions> structure.

```
<versions currentVersion="v2">
  <version uid="v1"/>
  <version uid="v2"/>
```

```
<version uid="v3"/>
</versions>
```

You now have a clip that can display the following:

- Version 1: track1 using feed t1f1 and track2 using t2f1;
- Version 2: track2 using t2f2 only(there is no `vuid` in track1 matching "v2");
- Version 3: track1 using feed t1f3 and track2 using t2f3;

And in this example, the client application should display the version 2 of the clip because `currentVersion=2`.

Attribute	Description	Data Type	Allowed Values	Attribute is...
type	The data type of the element.	character data	versions	Implied
version	Version of the xml element.	unsigned integer	3	Implied
currentVersion	Defines the current version of the clip, as set by the client application that created the file. The client application is expected to view this version as the most up-to-date. If not defined, the Gateway considers the last <code><version></code> element defined in the file as the current version.	IDREF	any existing one <code>uid</code> from an enclosed <code><version></code> element.	Implied

Children

[version](#) (page 1741)+

Found in...

[<clip>](#) (page 1729)

Creating a Simple Gateway Clip

A simple Gateway clip contains one video track. It has no versioning and no setup information; it is the simplest case, and is a nice, practical, exercise.

Solution

Use the simplest form of .clip you can create: one video track, no audio. The following is the minimal structure required to to have a valid Gateway clip.

```
<?xml version="1.0" encoding="UTF-8"?>
<clip type="clip" version=3>
  <tracks>
    <track uid="client-defined unique identifier">
      <trackType>video</trackType>
      <feeds currentVersion="the <feed> vuid">
        <feed vuid="client defined" uid="client-defined unique identifier">
```

```

        <spans>
          <span>
            <duration>number of samples in the media
sequence</duration>
            <path>path the media sequence</path>
          </span>
        </spans>
      </feed>
    </feeds>
  </track>
</tracks>
<versions currentVersion="one of the <version> uid">
  <version uid="the currentVersion of <feeds>"/>
</versions>
</clip>

```

NOTE Regarding files sequence and padding in the `<path>` element: The Gateway reconstructs a sequence as indicated by brackets. `dpxSequence.[1-99].dpx` indicates to the Gateway there are 99 dpx files named `dpxSequence.1.dpx` to `dpxSequence.99.dpx`. It can also manage padding. `dpxSequence.[001-099].dpx` is read as a sequence of 99 files named `dpxSequence.001.dpx` to `dpxSequence.099.dpx`.

Example and Discussion

Here is a commented .clip file. It does contain additional elements than the bare minimum, so as to play nicely with Smoke, Flame, or Lustre applications.

```

<?xml version="1.0" encoding="UTF-8"?>
<clip type="clip" version=3>
  <name type="string">NoVersionNoSetup</name>
  <tracks>
    <track uid="1b22da75-33e5-4dbe-80d0-7ed680a8b2b7">
      <trackType>video</trackType>
      <duration type="time">
        <rate type="rate">
          <numerator>30000</numerator>
          <denominator>1001</denominator>
        </rate>
        <nbTicks>26</nbTicks>
        <dropMode>NDF</dropMode>
      </duration>
      <name type="string">ClipNoVersionNoSetup</name>
      <feeds currentVersion="0">
        <feed vuid="0" uid="track1Feed1">
          <spans>
            <span>
              <duration>26</duration>
              <path>/var/tmp/UltimateFlick.[001-026].dpx</path>
            </span>
          </spans>
        </feed>
      </feeds>
    </track>
  </tracks>
  <versions currentVersion="0">
    <version uid="0">

```

```

        <creationDate>2010/12/14 11:54:06</creationDate>
      </version>
    </versions>
  </clip>

```

NOTE If you compare this to the .clip structure described before, you will notice the use of user-defined elements such as `<userData>`. Both are optional. For example, Flame uses the following child of `<clip>`:

```

  <userData type="dict">
    <appName type="string">Flame</appName>
    <appVersion type="string">2012</appVersion>
  </userData>

```

This is used by Flame to determine the software and version used to create the .clip. But the Gateway ignores all `<userData>`: it is up to the client application to determine what to do with it.

Comments

```
<clip type="clip" version=3>
```

The `<clip>` element has two required attributes, with fixed values: `type="clip"` and `version=3`.

```
<name type="string">NoVersionNoSetup</name>
```

`<name>` is optional, but the client application uses it as the name of the clip. Note here that `type="string"` is mandatory so that the Gateway knows how to pass it to the client application.

```
<track uid="1b22da75-33e5-4dbe-80d0-7ed680a8b2b7">
```

Since this example has only one video track (or layer), there is only one `<track>` element.

The uid used here is a UUID, but it can be something as simple as "1", as long as it is unique accross `<track>` elements.

```
<trackType>video</trackType>
```

video is one of two allowed values in the `<trackType>` context, the other being audio. You must have a defined `<trackType>` for each `<track>`.

```

  <duration type="time">
    <rate type="rate">
      <numerator>30000</numerator>
      <denominator>1001</denominator>
    </rate>
    <nbTicks>26</nbTicks>
    <dropMode>NDF</dropMode>
  </duration>

```

`<duration>` defines the duration of the track, using the formula `<rate>/<nbTicks>`.

The `<rate>` element used here is the best definition of the 29.97 fps frame rate. This avoids rounding errors. Of course, if the frame rate is an integer such as 24 fps, use the simplified structure `<rate>24</rate>`.

And since 29.97 fps can be drop frame or non-drop frame, we have to define `<dropMode>`.

```
<name type="string">ClipNoVersionNoSetup</name>
```

Again, `<name>` is optional here, but Flame uses it as the name of the track.

```
<feeds currentVersion="0">
```

`currentVersion` refers to the vuid of the enclosed `<feed>`.

```
<feed vuid="0" uid="track1Feed1">
```

A feed forms a version of a track, identified with by its `vuid`.

As shown here (track1Feed1), a `<feed uid=>` can be any sort of value, as long as it is unique across all the `<feed>` elements.

```
<spans>
```

The `<spans>` element exists because you can have multiple spans. Such is the case with media cartridges that split clips into 2GB files.

```
<span>
  <duration>26</duration>
  <path>/var/tmp/UltimateFlick.[001-026].dpx</path>
</span>
```

Because we have 26 dpx files, and because we want to use them all, `<duration>` is set at 26. To use less of it, we can specify a lower value.

When linking to streaming media, `<duration>` becomes the number of samples to use.

```
<versions currentVersion="0">
  <version uid="0">
    <creationDate>2010/12/14 11:54:06</creationDate>
  </version>
</versions>
</clip>
```

Every `.clip` has at least one version, defined using a `<version>` element. `currentVersion` refers to an existing `uid` from a `<version>`. The `uid` must be an existing `vuid`.

`<creationDate>` is not parsed by the Gateway, only passed to the client application.

Lustre Workflow

It is a good idea to read this chapter thoroughly to understand how the workflow of a typical colour grading project corresponds to working in Lustre. The first section in this chapter describes the image processing order—the order in which modifications are applied to a shot. Each subsequent section summarizes a significant stage in a colour grading project and provides cross-references to sections containing procedural information.

This workflow is presented as a linear process. However, due to the flexibility and unpredictability of the creative process, it is unlikely that you will go through the stages in the order presented—often different stages are worked on simultaneously and some stages are revisited several times.

Image Processing Pipeline

In Lustre, image processing order is pre-determined—the order in which you perform image processing tasks does not change the order in which they are processed. You can perform these tasks on different stations simultaneously and get the same results. For example, if you apply an input LUT to a shot from a Lustre Station, it will be processed before the colour grading effects created on the Master Station are processed, regardless of the order in which you apply them.

Colour grading may occur at the beginning, the end, or the beginning and end of the post-production process. In Lustre, the order in which you create image processing effects parallels the different stages in the post-production process. Each task corresponds to a menu.

The image processing is as follows:

- 1 The application of a CDL from the CDL menu.
- 2 The application of input LUTs from the Input LUT menu.
- 3 Initial primary colour grading from the Grading menu (with the Input button enabled).
- 4 RGB and Hue curves colour grading from the Curves menu.
- 5 Secondary colour grading from the Secondaries menu.
- 6 Sparks® plugin effects from the Effects menu.
- 7 RGB curves colour grading from the Curves menu.

- 8 Final primary colour grading from the Primary menu (with the Output button enabled).
- 9 The application of output LUTs from the Render | Output menu.

NOTE Dust removal operations are processed separately. Shots where artefacts have been removed are not updated in other menus until you render.

Setting Up Users and Projects

At the beginning of every project, you specify the location of your footage, set up user profiles, the project, project parameters (such as logarithmic or linear colour space), and the scenes that contain the reel or scene footage that you are going to work on. During each session, you then select a user profile and project so that you can save metadata for your grades. See [Project Management](#) (page 1765).

Monitor Calibration

At the beginning of a project, and throughout, you should calibrate the monitors for all stations to ensure the proper display of your footage. Calibrate the monitors according to the colour space (logarithmic or linear) and footage you are using. See [Monitor Calibration](#) (page 1892).

Applying Print LUTs

For film print simulation, you can apply Print LUTs, which are updated regularly by your film lab. See [Applying LUTs for Viewing \(Print LUTs\)](#) (page 1899).

Editing

Once you store your media and resources into the appropriate directories, you can edit the footage to the timeline in preparation for colour grading. Procedures for editing footage may include:

- Browsing footage and bringing it to the timeline. See [Loading Clips to the Library](#) (page 1917).
- Assembling EDLs in the timeline. See [Working with EDL, ALE, and Cutlist Files](#) (page 1935).
- Editing shots in a multi-layer Timeline. See [Editing in the Timeline](#) (page 1979).
- Capturing footage from a VTR. See [Capturing Material](#) (page 2305).
- Performing basic gestural edits such as trimming, slipping, and sliding shots, as well as creating dissolves. See [Editing](#) (page 1954).

Rendering Proxies

For projects that use large files (such as 2K Cineon® files), you should render half-resolution (1K) proxies of all the shots in the timeline before you begin colour grading. Proxies are used to reduce processing time when interaction is slow, such as when you apply several secondaries to a shot. See [Generating and Viewing Proxies](#) (page 2271).

Removing Dust

You can remove dust and other artefacts from your shots at any time in the project workflow. However, it is recommended that you remove dust early in the project so that the colourist can work with clean shots and you have time to do more than one dust removal pass on the footage.

Dust removal metadata is saved separately from other colour grading data. This makes it possible to remove dust on Lustre Stations while developing the colour grade on the Master Station. The same applies if using more than one Lustre HD Station. You can then replace dusty shots with clean ones without affecting the colour grade. See [Removing Dust](#) (page 2041).

Repositioning Shots

Once your footage is organized in the timeline, you can reposition shots that need the viewable area adjusted. For example, reposition shots that come from a wide-screen film format and are going to video. See [Repositioning Images](#) (page 2059).

Applying Input LUTs

With your footage organized and prepared for creative work, you are ready to apply any necessary input LUTs before you begin colour grading. Apply an input LUT to a shot when you need to remap colour values in the entire shot. Procedures for applying input LUTs include:

- Applying an existing input LUT to create a particular look (such as a KODAK™ film stock look). See [Applying an Existing Input LUT](#) (page 2072).
- Creating an input LUT to convert logarithmic data to linear data when working with film footage in Linear mode. See [Linear Mode: Creating Conversion LUTs](#) (page 2073).

Colour Grading

Lustre is primarily a colour grading application. Project setup, editing, and basic image processing are all procedures that you perform in preparation for creating a convincing colour grade.

Colour grading procedures include:

- Performing primary colour grading to change the overall colour look of each shot used in a series of shots, scene, or entire project. See [Primary Colour Grading](#) (page 2101).
- Modifying RGB and Hue curves to colour grade specific ranges of colour without using keys. See [Colour Grading Secondaries](#) (page 2131).
- Performing secondary colour grading to specific ranges of colour or areas in an image through keys and geometries. See [Colour Grading Secondaries](#) (page 2131).
- Generating keys for secondary colour grading. See [Creating a Secondary by Keying a Range of Colours](#) (page 2159).
- Creating and tracking geometries for secondary colour grading. See [About Geometries](#) (page 2134) and [Animating the Point Tracker](#) (page 2187).

Using Sparks

While colour grading your shots, you can load Autodesk Sparks® plugins to create additional image processing effects such as a blur or a glow. Sparks are applied on a shot-by-shot basis. See [Creating Lustre Sparks Effects](#) (page 2199).

Animating Colour Effects

At various times, you may want to animate a colour grading parameter to enhance the colour look, ambience, or to make a static shot more dynamic. You can animate most parameters using the Animation controls. See [Animation](#) (page 2214).

Outputting the Result

At the end of a project, you output the final version of your grade. You may also want to output your grade in the middle of a project to preview the colour grade or show it to your client. Outputting procedures may include:

- Applying a Log to Lin conversion LUT. See [Setting Colour Space Options](#) (page 2269).
- Rendering a print of the final grade. See [Rendering](#) (page 2258).
- Outputting rendered files to a VTR or any other device. See [Playing Out to a VTR](#) (page 2321).

Interoperability Workflows in Lustre

Interoperability allows for Creative Finishing applications, on the same or on different workstations, to share clips and sequences (timelines).

To obtain a sequence, the Lustre artist simply browses the remote project's project folders, and drags and drops the Smoke/Flame sequence to the Lustre Storyboard. Grading proceeds as usual. Once done, Lustre renders its results back to the project's defined render destination (i.e Lustre Shared Library or any location on the Media List). Within the context of Source Grading, this process leaves all Timeline FX, transitions and metadata intact.

Conceptually, this is the simplest scenario. However, the interoperability features give you a high level of flexibility, whereas you can send your sequence to and back from any of the Creative Finishing applications at any point of the finishing process.

About Source Grading and Sequence Grading

There are two ways you can use Autodesk Lustre to grade media coming from Autodesk Smoke and Autodesk Flame, depending on the project you're working on and the requirements of your facility:

- You may want to work in parallel of the editorial process and grade the sources as the editorial decisions are being made (Source Grading).
- You may want to perform the colour grading at the end of your project, once the online editing, visual effects and titling are complete (Sequence Grading).

Source Grading Workflow

- 1 Assemble your sequence in Smoke/Flame.

- 2 Save your sequence to the Lustre shared Library.
- 3 Import your sequence into Lustre, with the Source Grading option enabled. Your multilayer sequence is imported into Lustre and the source media is displayed. You can grade your sources in context, taking into account the editorial decisions to date.
- 4 Grade your sequence sources.
- 5 Render the graded sequence in Lustre.
- 6 Open the graded sequence in Smoke/Flame for further enhancements.

Sequence Grading Workflow

- 1 Assemble your sequence in Smoke/Flame.
- 2 Render your sequence in Smoke/Flame and save it to the Lustre Shared Library.
- 3 Import your sequence into Lustre, with the Source Grading option disabled. Your multilayer sequence is imported into Lustre and all effects and unsupported transitions are committed.
- 4 Grade your sequence.
- 5 Render the graded sequence in Lustre.
- 6 Import the rendered sequence into Smoke/Flame or export the final media from Lustre.

Basic Interoperability Workflow

The setup of your interoperability project depends on whether you have Smoke/Flame and Lustre installed on separate workstations or whether you have them installed on the same workstation, as in Flame Premium.

To set up an interoperability project on standalone Smoke/Flame and Lustre workstations:

- 1 Create your projects in Smoke/Flame and Lustre.
- 2 Set your Scans and Renders paths in Lustre to correspond with your Smoke/Flame projects.

See:

[Project Menu Settings](#) (page 2374)

[Setting Up the Lustre Wiretap Project](#) (page 2373)

To set up an interoperability project with Smoke/Flame and Lustre on the same workstation, as in Flame Premium:

- 1 Create your project in Flame Premium as usual.

Smoke/Flame create a Lustre project and a shared library named Lustre in your project that Lustre renders back to by default.

NOTE Creating a Flame Premium project automatically creates a Lustre project. However, creating a Lustre project does not create a Flame Premium project.

Important Source Grading Considerations

To use the interoperability features between different Creative Finishing applications and workstations, you must be running the same version of Wiretap Server on each workstation.

File Path Translation

File path translation ensures that different workstations running different operating systems are able to convert file paths from other operating systems to a file path in their native file structure. This ensures compatibility between Linux, Mac OSX and Windows workstations in a collaborative workflow, as the different workstations send and receive commands to exchange media to and from shared storage.

Shared Storage in a Workgroup Environment

Before performing finishing and grading in a shared project from multiple workstations, using a shared storage (NAS/SAN), you must configure the following files:

- **Init.config:** located in: /usr/autodesk/lusterpremium_2013.1/
- **wiretap_path_translation_db.xml:** located in: /usr/discreet/wiretap/current/cfg/

Init.config

To make sure Lustre is able to read media files from its direct connection to a shared storage, you must edit the PathTranslationTable portion of the init.config file, as follows:

```
<PathTranslationTable>
<PathTranslation src="172.16.129.101@wtg:/Volumes/QASAN01"
dst="localhost@wtg:/QASAN01"/>
```

This example translates a Mac Wiretap Gateway mountpoint to its corresponding Linux Lustre mountpoint, which allows Lustre to read the media from its own storage mount point, rather than from the remote workstation.

wiretap_path_translation_db.xml

It is possible to render media files on a shared storage and write the sequence and clips metadata in the Smoke / Flame Premium Media Library or Shared Folder (Wiretap Render). If the shared volume does not have the same mount point on the two workstations, you must add the corresponding mount points to the wiretap_path_translation_db.xml file, as follows:

Add the corresponding mount points:

```
<map src_os="Linux" src_path="/QASAN01" dst_os="MacOSX" dst_path="/Volumes/QASAN01"
/>
<map src_os="MacOSX" src_path="/Volumes/QASAN01" dst_os="Linux" dst_path="/QASAN01"
/>
```

Save the file and restart Stone+Wire

Performing a Wiretap render writes the files and the generated clips and sequence(s) that will reference the translated path.

NOTE

- Lustre is able to read & write to any folder in a Workspace that is not Read-Only.
- Flame Premium Batch Snapshots cannot be accessed in Lustre.

BatchFX

You must render BatchFX segments and BatchFX on gaps prior to importing the sequence into Lustre.

- Rendered effects are seen as source media by Lustre and can be graded along with the rest of the sources.
- Unrendered BatchFX are displayed as black frames in Lustre.

NOTE Rendered BatchFX segments in Lustre do not display the BatchFX icon. And the BatchFX icon is not displayed on the BatchFX timeline segments in Smoke/Flame after being rendered in Lustre.

Transitions

All transitions are preserved by Lustre.

- Only dissolves (with or without animation) are displayed.
- Action and Wipe transitions are displayed as dissolves. The original Wipe/Action transitions are preserved in Lustre and are recreated in Smoke/Flame upon reimport. A special icon is displayed in the timeline in Lustre whenever Action and Wipe transitions occur.

Action Transition in Smoke/Flame (Image courtesy of EVN PRODUCTIONS)

Action Transition displayed as a dissolve in Lustre (Image courtesy of EVN Productions)

Custom Transitions

Custom transitions are rendered media and appear as a clip in Lustre. This clip is maintained in Smoke/Flame when you reload the sequence after it is rendered in Lustre. It is recommended to create your custom transitions after the source media has been graded and replaced in Smoke/Flame.

Custom Transition in Smoke/Flame (Image courtesy of EVN PRODUCTIONS)

Custom transition in Lustre

Custom transition in Smoke/Flame after render from Lustre

Timeline FX

Timeline FX are preserved in Lustre. Lustre retains the Timeline FX metadata and displays the source clip rather than the result clip of the Timeline FX. Timeline segments with Timeline FX are displayed in the Lustre sequence with a Timeline FX icon. The Timeline FX are reapplied in Smoke/Flame when you reload the sequence. The following Timeline FX are supported:

- TimeWarp
- Resize
- Text
- Colour Correct
- Spark
- GMask
- Action
- Stereo Toolbox

- Flip
- Colour Warper
- Blur
- 2D Transform
- Composition parameters
- Format options
- Pre-processing parameters
- Containers
- Matte Containers

Note: Format Options and Pre-Processing parameters are only available in Lustre on clips for which the media is not cached.

Adjustment layers are supported like any other Timeline FX. However, they are not displayed when scrubbing or playing back in Lustre and cannot be graded. The original adjustment layer is restored in Smoke/Flame when you reload the sequence after it has been rendered in Lustre.

- If there is media under the adjustment layer, that media is displayed in the viewport.
- If there is no media under the adjustment layer, a red "X" is displayed in the viewport.

NOTE In the case of a soft timewarp that is not long enough to cover the duration of the segment (for example, a slow-motion effect), Lustre preserves the duration of the segment but displays a red X on missing frames. This is normal because you are grading the sources, which are not being affected by the timewarp animation curve.

Containers and Matte Containers

Containers and matte containers created in Smoke/Flame are preserved in Lustre.

TIP

- To add a matte to the first frame of a source clip in a matte container/multi-channel clip in Lustre, press Ctrl and drag and drop the matte to the container.
- To insert the matte at the first frame of the In point of the timeline segment, press Ctrl+Alt and drag and drop the matte to the container.

See:

[About Containers](#) (page 1985)

[About Matte Containers](#) (page 1987)

[Adding a Matte to a Matte Container](#) (page 1988)

[Selecting a Matte to Grade Secondary Layers](#) (page 1989)

Multi-channel Clips

Multi-channel clips created in the Lustre sequence are recreated as matte containers in Smoke/Flame.

See:

[About Multi-channel Clips](#) (page 1990)

Saving a Sequence for Grading in Lustre

To save a sequence for grading in Lustre (Source Grading Workflow):

- 1 Render your BatchFX.
- 2 Save your sequence to the Lustre shared library.

To save a sequence for grading in Lustre (Sequence Grading Workflow):

- 1 Render your entire sequence.
- 2 Save your sequence to the Lustre shared library.

Importing the Sequence from Smoke/Flame

To import a sequence from Smoke/Flame:

- 1 Open the Editing/Browse menu in Lustre.
- 2 Determine whether you want to work using the Source Grading or the Sequence Grading workflow. If you are working in the Source Grading workflow, enable Source Grading. If you are working in the Sequence Grading workflow, disable Source Grading.

- 3 Navigate to the folder that contains the sequence you want to import.
- 4 Drag your sequence directly from the file browser to the storyboard area.
- 5 Your sequence and its sources are added to the library. You are now ready to grade.

NOTE

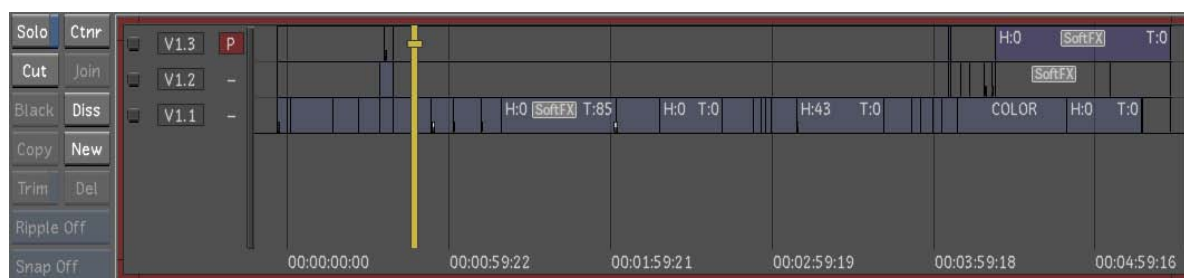

- If you import an unrendered sequence without enabling Source Grading, Lustre looks for the processed Timeline FX segments in the sequence rather than the source clips and displays black frames on unrendered effects. This also applies to relink media. If you relink media to an unrendered sequence without enabling Source Grading, Lustre looks for the processed Timeline FX segments in the sequence rather than the source clips and displays a red X on unrendered effects.
 - The behavior in Lustre has not changed when importing with Timelines Only disabled, even if Source Grading is enabled. The one sequence version of the sequence sources will be imported as before.
-

Displaying and Editing the Sequence in Lustre

It is not recommended to make editorial changes in Lustre to clips with Timeline FX or transitions. Editing clips with Timeline FX or transitions may cause unexpected results when you open the sequence in Smoke/Flame.

To display the Smoke/Flame sequence for editing in Lustre, it is recommended to use the Colour/Timeline menu. Some editorial functions are locked in this menu to prevent any accidental editorial changes.

All editorial changes you make in Lustre are supported in Smoke/Flame.

See:

[Timeline Menu](#) (page 1975) for a complete list of supported editing operations in Lustre.

Rendering and Exporting in Lustre

Rendering Back to Smoke/Flame

There are two ways to render your sequence back to Smoke/Flame from Lustre:

- Rendering to the shared Lustre Library
- Rendering to a shared storage location

Rendering to the Lustre Shared Library

When rendering to a Wiretap location from Lustre, you are rendering to a Smoke/Flame standard file system. To render to a Smoke/Flame standard file system, you must set your Renders paths to refer to a Wiretap server path (A destination folder on the Smoke/Flame standard file system. The Lustre shared library is the recommended destination).

NOTE You can create Shared Libraries and folders in the Media Library of the Smoke/Flame projects directly from Lustre and use it as a rendering destination from Lustre.

For example:

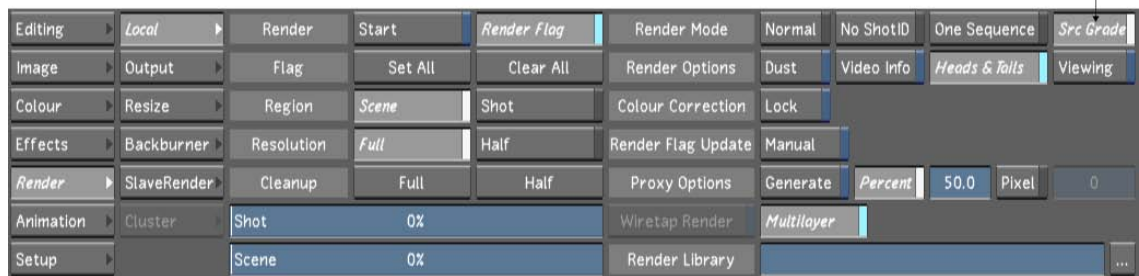

oshawa@wt:/stonefs7/Hatched_Project/Lustre

The resulting rendered media is located on your standard file system and is managed by Smoke/Flame.

NOTE By default, Flame Premium configures the Lustre project to render to a Smoke/Flame library.

To render to the Lustre shared folder:

- 1 Access the Project Settings, in the Setup/Settings menu.
- 2 Make sure your Renders Home paths are set correctly. For example: oshawa@wt:/stonefs7/Hatched_Project/Lustre.
- 3 Access the Render/Local menu in Lustre.
- 4 Enable the Src Grade render mode.

- 5 (Optional) Enable the Heads & Tails option.
- 6 Click Start.

Rendering to a Shared Storage Location

If you want Lustre to render back to shared storage, such as a SAN or a NAS, your Renders paths must refer to a storage path outside your standard file system.

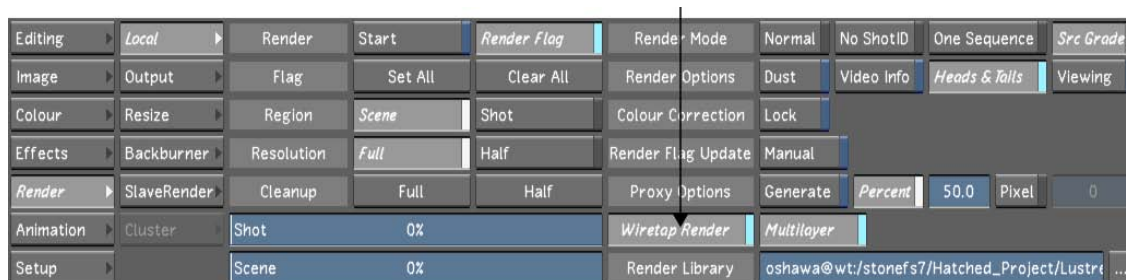

For example:

/mnt/SAN01/Hatched_Project

The resulting media is rendered to a location on your SAN/NAS while the metadata is sent to the Wiretap server. The resulting sequence is seen as soft-imported in Smoke/Flame . This media is not managed by Smoke/Flame.

To render to a shared storage location:

- 1 Access the Project Settings, in the Setup/Settings menu.
- 2 Make sure your Renders Home paths are set correctly. For example: /mnt/SAN01/Hatched_Project.
- 3 Access the Render/Local menu in Lustre.
- 4 Enable the Src Grade render mode.
- 5 (Optional) Enable the Heads & Tails option.
- 6 Define the Wiretap location to which you want Lustre to save the metadata in the Render Library field.
- 7 Enable the Wiretap Render option.

8 Click Start.

NOTE

- You can define the Wiretap location for the metadata permanently for your project in the Project Settings Network Rendering tab, in the Render Library field.
- Re-rendering the same sequence from Lustre replaces the media on the shared storage. If you make changes to your grades and re-render the sequence, all Smoke/Flame sequences using the same media are updated with the new rendered sources.
- If you are using workstations running different operating systems within your interoperability workflow (Smoke for Mac OSX, Lustre on Microsoft Windows, Linux) and want to render to a shared storage location, you must configure your Wiretap Path Translation file, as each operating system (Mac, Windows, Linux) has a different path to the same location.

See [Autodesk Flame Premium Install Guides](#)

Outputting the Final Version from Lustre

There are two ways to output your final version from Lustre:

- Rendering the final version from Lustre as one sequence in an uncompressed format to a location outside the Standard fs.
- Exporting the final version from Lustre to a compressed format to a location outside of the Standard fs.

Rendering the Final Version from Lustre

Depending on the state of your sequence at the point where you decide to perform your grading in Lustre, or the nature of your project, you may want to render the final version of your project from Lustre.

To do this, you must set your Lustre Renders paths to point to a location outside of the Smoke/Flame Standard fs.

- 1 Access the Project Settings, in the Setup/Settings menu.
- 2 Make sure your Renders Home paths are set correctly. For example: mnt/StorageMedia/Renders.
- 3 Access the Render/Local menu in Lustre.
- 4 Enable the One Sequence render mode.
- 5 (Optional) Access the Render/Output menu.
- 6 (Optional) Disable Same format as scans and select an output format.
- 7 In the Render/Local menu, Press Start.

Lustre renders your timeline as one sequence at the specified destination.

Exporting the Final Version from Lustre

Depending on the state of your sequence at the point where you decide to perform your grading in Lustre, or the nature of your project, you may want to export the final version of your project from Lustre to a compressed format. This is done through the Render/Export menu.

NOTE Your sequence must be rendered prior to exporting.

- 1 Render your project in One Sequence mode.
- 2 In the Render/Export menu, create a new Export version. See Export Versions.
- 3 Set the Media Origin field to One Sequence Renders.
- 4 Set the Region field to Scene to export all shots.
- 5 If the sequence has audio media and that you want to be included in the export, enable the Video & Audio option.
- 6 Set the Video File Format and the Compression type for your audio and video or select a profile, if available.
- 7 Define the File Name using tokens or an actual alphanumeric filename.
- 8 Define the Export Destination.
- 9 Save your Export Version.
- 10 Click Export.

Advanced Interoperability Workflows

RED Media Interoperability Workflow

When importing RED footage in Flame Premium, you can transcode the media prior to import. The transcode settings determine the resolution, bit depth, colour settings, etc. of the media created from your R3D files. If you choose to soft-import your media (i.e. linking to the media from its original location), you are able to access the media at any of the resolutions supported by its debayer in Lustre, after importing the timeline. This can be helpful for grading, where a high level of detail can sometimes be critical.

To illustrate this workflow, we are importing an FCP xml file and soft-importing its associated RED sources for conforming in Smoke. We then import the Flame Premium sequence in Lustre, where we can modify the media's transcode settings to perform our grading tasks on the full resolution footage. Once done, we render the sequence back to Smoke for further enhancement.

We are assuming that you have already created your Flame Premium and Lustre projects and that the Lustre library has already been generated.

Importing RED footage to Flame Premium

- 1 Click the Conform tab.
- 2 From the contextual menu, select Load new FCP XML / AAF.
- 3 Navigate to the location of the RED footage (with xml) to soft-import.

You can apply resize settings and apply a LUT on import from the Transcode menu. See

■ [Transcode Resize Options](#) (page 1929)

■ [LUT Options Settings](#) (page 1926)

NOTE If you are accessing media that was imported to a Smoke/Flame system with the Cache Source Media option enabled, that media is no longer considered Gateway media. It is seen by Lustre as managed media and hence the LUT and Resize on import options are not available. To work around this, you can perform a Flush Cache Media operation in Smoke / Flame, prior to importing in Lustre.

If you want to change the transcode settings of your media, you can do so from the File I/O menu under the Media Browser prior to importing. If you don't make any changes, the media is imported with the camera settings.

- 4 Select the FPC XML and click Import.

Smoke finds the sources and reassembles the sequence.

Your sequence is now available in Flame Premium for editing. Once you are satisfied with the sequence and are ready for grading in Lustre, save it to a library and exit Smoke.

See [Saving a Sequence for Grading in Lustre](#) (page 1756).

Accessing the Flame Premium sequence for grading in Lustre

Because we are working with soft-imported RED footage, once the Flame Premium sequence is imported into Lustre, you can modify the transcode settings set in Flame Premium and access the footage at up to full resolution for grading.

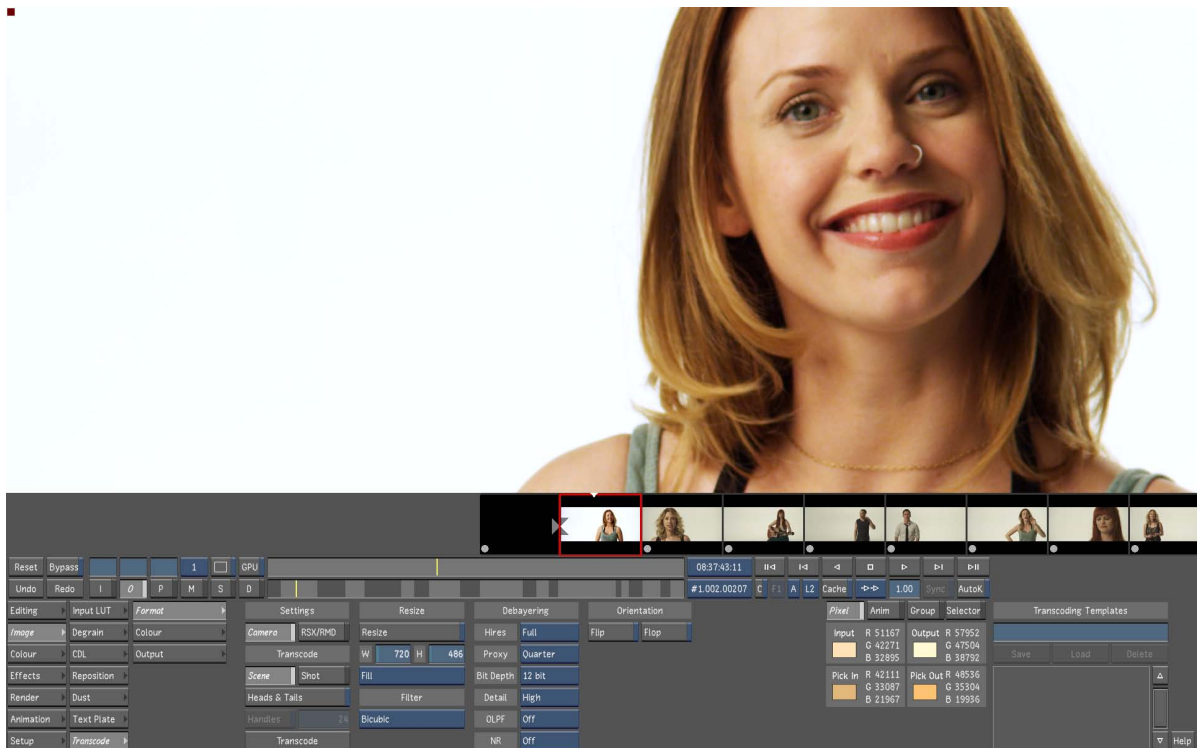

To access the Flame Premium sequence from Lustre

- 1 Access the Editing/Browse menu.
- 2 Navigate to your Flame Premium project.
- 3 Enable Source Grading.
- 4 Drag & drop the Flame Premium sequence onto the storyboard.

The sequence and its associated sources are automatically added to the Library.

Modifying the Flame Premium transcode settings

Access the Image/Transcode menu. You can modify any of the transcode settings that you like; one of which being the debayering settings. Changing the debayering settings will enable you to work at any of the resolutions supported by the debayer: a higher resolution for greater detail or a lower resolution for more responsiveness. The resolution of the media is immediately updated in the viewport and you are ready to grade your sources.

Footage taken from "Other People's Children", courtesy of Golden Films.

Once you are happy with your grades, you have a few options:

Option 1

Render the sequence back to Flame Premium for further enhancement. Lustré creates new (graded) sources and a new sequence (containing all the metadata from the original sequence). The format of the footage is no longer RED media. Instead the sources are in uncompressed RGB, on the Flame Premium Standard fs.

See [Rendering and Exporting in Lustré](#) (page 1757).

Option 2

Render the final version from Lustré as one sequence in an uncompressed format to a location outside the Standard fs.

See [Rendering and Exporting in Lustré](#) (page 1757).

For more details on rendering media in Lustré, see [About Rendering in Lustré](#) (page 2258).

Option 3

Export the final version from Lustré to a compressed format to a location outside of the Standard fs.

NOTE The sequence must be rendered prior to exporting.

See [Rendering and Exporting in Lustré](#) (page 1757).

For more details on exporting media from Lustré, see [Background Media Export](#) (page 2284).

ProRes Interoperability Workflow

It is possible to import and export ProRes footage to and from Autodesk Smoke, Flame and Lustre applications. To accomplish this, you must have access to a Mac computer running Autodesk Backburner (which is automatically installed if you are running Smoke on the Mac computer).

For information on installing Backburner, see the [Autodesk Flame Premium Install Guides](#).

This workflow demonstrates how to import ProRes footage from a Final Cut Pro .xml into Smoke and send the conformed sequence to Lustre for grading in Source Grading mode. We then export the graded ProRes sources from Lustre to relink them with the original Smoke sequence, preserving all metadata and soft effects.

Importing the ProRes footage and sequence into Smoke/Flame

To import a ProRes sequence into Smoke/Flame

- 1 Click the Conform tab.
- 2 From the contextual menu, select Load new FCP XML / AAF.
- 3 Navigate to the Mac computer with the ProRes media (with xml) on your local network.
- 4 Select the FPC XML.
- 5 Enable Consolidate on Import (recommended).
- 6 Set your Max Handles (recommended).

- 7 Click Import.

The sequence is now open in your Flame Premium workspace.

Once you are ready to grade the source files, save your sequence to the Lustre shared library.

Then, launch Lustre, navigate to the project where you saved your sequence, enable Source Grading and drag and drop the sequence to the storyboard. Your sources and the sequence are automatically imported to your Library. You are ready to grade your sources.

Once you are satisfied with your grades, you have a few options:

Option 1

Render the sequence back to Smoke/Flame for further enhancement. Lustre creates new (graded) sources and a new sequence (containing all the metadata from the original sequence). The format of the footage is no longer ProRes media. Instead the sources are in uncompressed RGB, on the Smoke/Flame Standard fs.

See [Rendering and Exporting in Lustre](#) (page 1757).

Option 2

Render the final version from Lustre as one sequence in an uncompressed format to a location outside the Standard fs.

See [Rendering and Exporting in Lustre](#) (page 1757).

For more details on rendering media in Lustre, see [About Rendering in Lustre](#) (page 2258).

Option 3

Export the final version from Lustre to a compressed format to a location outside of the Standard fs.

NOTE The sequence must be rendered prior to exporting.

See [Rendering and Exporting in Lustre](#) (page 1757).

For more details on exporting media from Lustre, see [Background Media Export](#) (page 2284).

Option 4 (Linux Only)

Export the graded sources from Lustre to the ProRes format and relink the graded sources back to the original Smoke/Flame sequence, for further enhancement.

NOTE The sequence must be rendered prior to exporting.

Exporting the Graded Sources from Lustre to the ProRes Format (Linux Only)

After having rendered the sequence in Lustre, you can set up a Source Grade export.

- 1 Access the Render / Export menu.
- 2 Set your export destination. This must be a Mac computer running Backburner. The Backburner manager.host file must be edited to have the Flame Premium or Lustre Linux system as the Backburner manager.

To edit the manager.host file

- 1 From a shell, login as root.
- 2 Navigate to /usr/discreet/backburner/cfg/manager.host.
- 3 Open the file for editing with a text editor.
- 4 By default, the backburner manager is set to localhost. Change this to the name or IP address of your Flame Premium or Lustre Linux workstation.
- 5 Save the file and exit.

NOTE If the backburner manager is set to localhost in the manager.host file on your mac, this workflow will not work. You will get error messages when trying to export.

- 3 In the Render / Export menu, select Source Grade Renders, under Media Origin.
- 4 Select Video & Audio, under the Region buttons.
- 5 Select QuickTime under Video File Format.
- 6 Select one of the ProRes codecs under Compression.
- 7 Press Export.

Footage taken from "Face Divided", courtesy of Red Truck Productions.

Lustre begins exporting the media.

NOTE If the sequence is not rendered, Lustre automatically starts a render before exporting.

Updating the Sequence with the Graded Sources

Once the media is exported:

- 1 Launch Smoke/Flame.
- 2 Click the MediaHub tab.
- 3 Navigate to the folder containing exported ProRes sources.
- 4 Drag the folder to the Media Library in the Media panel.
- 5 Still in the MediaHub, navigate to the folder containing your original sequence and drag it to the Media Library in the Media panel.
- 6 Click the Timeline tab.
- 7 Select the original sequence you just copied to the Media Library in the Media panel.
This displays the sequence with all of its sources unlinked.
- 8 Click the Conform tab.
The list of unlinked media is displayed on top of the sequence.
- 9 Select the folder containing your exported ProRes sources.
- 10 From the contextual menu, select **Conform ► Set As Search Location**.
Your sources are found. A green check mark appears next to the matched sources.
- 11 Click Link Matched Sources.
Your original sequence is assembled with the new graded ProRes sources, with all its original metadata intact.

You can now continue refining your graded sequence. This workflow can be repeated as many times as you wish. When you are happy with your sequence, you can render or export it to the format of your choice.

Project Management

Project Management is definition of project and user settings to customize the colour grading environment.

In Lustre, a project uses the following hierarchy:

- **Project:** Generally speaking, a Lustre project corresponds to a large work effort such as a film. A project contains all the information regarding the location of:
 - Project data files
 - Original footage
 - Rendered files
- **Scene:** A scene contains the Libraries, the Scene-based Grade Bin and degraigned material within the project.
- **Library:** The library contains the source clips, cuts, grades, audio and related metadata.
- **Cut:** A group of shots that get rendered.
- **Grade:** The operations performed on a cut.

In addition, a project also contains information about the users accessing the project, and their preferences. Lustre saves the preferences of each user of a project at the end of every work session. The saved settings are restored when the user logs back on.

To prepare a project for colour grading:

- 1 (Optional) Before running Lustre for the first time, configure the *init.config* file. See [Configuring System Settings](#) (page 1766).
- 2 Create and set up the project. See [Project Configuration](#) (page 1776).
- 3 Create and set up the users for the project. See [User Configuration](#) (page 1801).
- 4 Create scenes. See [Working With Scenes](#) (page 1815).
- 5 Organize the footage in cuts. See [Managing Cuts](#) (page 1819).
- 6 Create grades. See [Creating a Grade Version for a Cut](#) (page 1822)

Incinerator-Specific Project Management Configuration

Lustre with Incinerator® in-line processing uses the same project management concepts. The only difference is that in order to use Incinerator on the Lustre workstation, the Scans and Render Home paths must point to the Gigabit Ethernet (GigE) Browsed® IP address of the Lustre Media Server. In the Lustre Project menu, you can set the Project Home path to use the nfs mount of the media server. For further information on project management configuration in Incinerator, refer to the *Autodesk Incinerator Installation and User Guide*.

Configuring System Settings

When Lustre is installed, it is pre configured with the default system-level settings. These system-level settings are found in the *init.config* file.

You can define these settings manually if you like or you may want to view the *init.config* file for troubleshooting purposes.

To configure/view the system settings:

- 1 Open the *init.config* file in a text editor. The location of the file depends on the workstation's operating system.

Operating System:	Location:
Windows	C:\Program Files\Autodesk\<Lustre_version>
Linux	/usr/autodesk/<Lustre_version>

- 2 Edit the *init.config* file as required to define:
 - BrowseD.
 - Wiretap® and Wiretap Gateway server
 - Calibration settings
 - Autodesk Control Panel
 - Lustre ShotReactor
 - Backburner™
 - Internal keywords
 - DPX keycode emulsion list
- 3 Save your changes and exit the text editor.

Lustre Software, Project, and User Configuration Files

Configuration File Overview

The configuration files define all the necessary settings your software needs to recognize various hardware and software settings on the Master Station and on the dedicated render station.

The following is a list of the Lustre configuration files.

Configuration file	Lustre Standalone Location	Flame Premium Grading Location	Description
<i>init.config</i>	<i>/usr/autodesk/lustre <version>/</i>	<i>/usr/autodesk/lustre <version>/</i>	This file stores system settings as well as Wiretap servers, Lustre ShotReactor settings, and film stock information.
<i>login.config</i>	<i>/usr/autodesk/lustre <version>/</i>	<i>/usr/autodesk/lustre <version>/</i>	This file records the last user and last project used so at the next session, the user and project login defaults will reflect these values.
<i>project.config</i>	<i>/usr/autodesk/projects/<project>/project.config</i>	<i>/usr/discreet/projects/<project>/project.config</i>	This file stores project-level information including project settings, calibration, rendering, engineering, and Backburner and Wiretap settings specific to the project.
<i>user.config</i>	<i>/usr/autodesk/users/<user>/user.config</i>	<i>/usr/discreet/users/grading/<user>/user.config</i>	This file stores user settings specific to a particular user, such as Autosave, printer light, GUI background/gain/gamma.
<i><user>Context.config</i>	<i>/usr/autodesk/projects/<project>/<user>Context.config</i>	<i>/usr/discreet/projects/<project>/<user>Context.config</i>	This file stores several settings relevant to the context of a particular user working on a particular project. The purpose of storing context-specific information is that there are some parameter settings that, by their nature, are more likely to be needed in the next session, but that are not configurable in the Project Management pages.

System Settings

You can configure the system settings manually in the *init.config* file. If these system settings are not configured, Lustre uses the default system settings. The following table describes the relevant system settings that can be configured.

NOTE All keyword values are case-sensitive.

Parameter	Data type	Default	Function
<Locations>			
<MainProjectHome>	String		Location of the Project configuration settings folder.
<MainUserHome>	String		Location of the User configuration settings folder.
<GlobalGradeBinHome>	String		Defines the location of the global Grade bin.
<LutHome>	String	[LUSTRE_HOME]/lut	Defines the location of the LUTs. NOTE If you are configuring a remote ShotReactor system, and [LUSTRE_HOME] is located on a mounted network drive, make sure you use the full UNC path of the network folder instead of the mapped drive letter.
<PresetsHome>	String	[LUSTRE_HOME]/presets	Defines the location of the presets. NOTE If you are configuring a remote ShotReactor system, and [LUSTRE_HOME] is located on a mounted network drive, make sure you use the full UNC path of the network folder instead of the mapped drive letter.
<PluginsHome>	String	[LUSTRE_HOME]/plugins	Defines the location of the plug-ins. NOTE If you are configuring a remote ShotReactor system, and [LUSTRE_HOME] is located on a mounted network drive, make sure you use the full UNC path of the network folder instead of the mapped drive letter.

Parameter	Data type	Default	Function
<TemplatesHome>	String	[LUSTRE_HOME]/templates	Defines the location of the templates. NOTE If you are configuring a remote ShotReactor system, and [LUSTRE_HOME] is located on a mounted network drive, make sure you use the full UNC path of the network folder instead of the mapped drive letter.
<Help>			
<HelpWebBased state>	String	On	Defines the location of the Lustre Help that is opened by the Help button and shortcut. Lustre Help is web-based by default.
<HelpLocalPath>	String		Defines the default location for Lustre Help when it is installed locally.
<Browser>			
<HideFolder> (within <MediaBrowseHideFoldersGroup>)	String	degrain_cache,original,matte,marry_grade, and 128x96	Hides the degrain cache, original, matte, marry_grade, and 128x96 folders from the file browser. NOTE You can hide any additional folder by adding the folder name to the list.
<Wiretap>			
<ServerAuto>	State	On	Specifies whether Lustre automatically scans for Wiretap servers.
<WiretapServer> (within <WiretapServer Group>)	String	0.0.0.0	The IP address or DNS host name for a specific Wiretap server. If one or more <WiretapServer> keywords are set to valid Wiretap server addresses, Lustre lists the content of these servers in the browser before the results of the auto scan. If <ServerAuto> is set to OFF, only the specified Wiretap servers are listed in the browser.
<WiretapGatewayServer> (within <WiretapGatewayServer Group>)	String	0.0.0.0	The IP address or DNS host name for a specific Wiretap Gateway server.

Parameter	Data type	Default	Function
<PathTranslation> (within <PathTranslationTable>)	String	0.0.0.0	Allows you to map hostnames to IP addresses, as well as to define path translation rules.
<NTSCImageAspectRatio>	Float	1.333333333333	Applies the correct aspect ratio to NTSC resolution footage rendered to the Wiretap server, but not imported from the Wiretap server.
<PALImageAsepectRatio>	Float	1.333333333333	Applies the correct aspect ratio to PAL resolution footage rendered to the Wiretap server, but not imported from the Wiretap server.
<MonitoringAndCalibration>			
<DisplayType>	Enumerated (abstract data)	LCD	Specifies the monitor display type (e.g., LCD or CRT).
<Calibration_Steps>	Integer	10	Specifies the number of monitor calibration steps performed.
<ControlSurface>			
<AutodeskPanels>	State	On	When ON, this keyword enables the Autodesk Control Surface (ACS). When OFF, Lustre enables the Tangent CP100 control surface (if applicable). You must also set the path for the control surface rules file in the Panel Setup File field.
<PanelIDs>		function="0" grading="0" navigation="0"	The ID numbers for the Function, Navigation, and Grading panels of the ACS. You must manually configure these keywords. If your control surface is a Tangent CP100, Lustre does not use these keywords.
<PanelIPTags>		function="101" grading="100" navigation="102"	
<Browsed>			

Parameter	Data type	Default	Function
<Port>	Integer	1055	All computers on the <i>BrowseD</i> network must use the same port to communicate. NOTE For Linux over IP, set the port value to 1044.
<Username>	String	root	Administrative user on the <i>BrowseD</i> server.
<Password>	String	xxx	Password for the administrative user. NOTE To encrypt the password, set the attribute <code>toEncrypt</code> to <code>yes</code> . The next time the application starts, the password string is encrypted in the configuration file.
<UseInfi>	State	Off	Switch to ON if the networking protocol to use with <i>BrowseD</i> is the InfiniBand.
<ReadCacheBuffer Num>	Integer	0	
<ReadCacheThread Num>	Integer	0	
<BrowsedServer> (within <BrowsedServer Group>)	String	0.0.0.0	Defines the IP address or DNS host name for a specific <i>BrowseD</i> server.
<ShotReactor>			
<HostName>	String		The IP address or DNS host name for a specific ShotReactor machine.
<Timeout>	Integer	5000	Sets the timeout duration (in milliseconds) of the automatic ShotReactor detection.
<Backburner>			
<Hostname>	String	localhost	The IP address or DNS host name for a specific Backburner Manager machine.
<Transcode>			
<Transcode>	String	localhost	The IP address or DNS host name for a specific WT Gateway that will be used to create and access the transcoded media.

Parameter	Data type	Default	Function
<MatchCustomGroup>			
<MatchCustom>	Name	"AliasName" type="s"	Specifies the XML metadata field to be used by the Custom match option selected from the Browse menu. "s" represents string.
<MatchCustom>	Name	"DPXTimeCode" type="tc"	"tc" represents timecode.
<MatchCustom>	Name	"DPXkeycode" type="kk"	"kk" represents keycode.
<MatchCustom>	Name	"DPXTapeNAME" type="s"	"s" represents string.
<MatchCustom>	Name	"EDLReelName" type="s"	"s" represents string.
<MatchCustom>	Name	"DL_EDLClip_name" type="s"	"s" represents string.
<MatchCustom>	Name	"DL_edlFrameID" type="i"	"i" represents integer.
<MatchCustom>	Name	"DLEDL_startTC" type="tc"	"tc" represents timecode.
<AVIO>			
<PayoutHighSpeed>	State	Off	When OFF, it refreshes the Player as you are performing a payout. When ON, the Player is no longer refreshed and therefore the performance of the payout improves.
<WTTFirstSDLeadIn Correction>	Integer	1	Sets the delay for the SD first lead-in.
<WTTSubsequentSD LeadInCorrection>	Integer	2	Delays all the lead-ins following the SD first shot.
<WTTSDLeadIn Increment>	Integer	0	Corrects the delay after the SD third shot.
<WTTFirstHDLedIn Correction>	Integer	0	Sets the delay for the HD first lead-in.
<WTTSubsequentHD LeadInCorrection>	Integer	0	Delays all the lead-ins following the HD first shot.

Parameter	Data type	Default	Function
<WTHDLeadIn Increment>	Integer	0	Corrects the delay after the HD third shot.
<VtrTCTD>	Integer	10	<p>The TimeCode Transition Delay specifies the number of milliseconds the application waits before asking for timecode from the VTR. The default value of 10 ms works for most decks. For HDCAM-SR decks use the following values:</p> <ul style="list-style-type: none"> ■ 14, for 1080/59i/60 or 720/50/59/60 ■ 21 for other timings
<Miscellaneous>			
<DPXHeaderOffsetCheck>	State	On	<p>When this keyword is enabled, Lustre reads the DPX / Cineon® file header of each frame in a sequence. This is useful when using DPX/Cineon files that have a different media offset within the same sequence of files. When disabled, Lustre reads only the first frame header of a sequence.</p> <p>WARNING Turning this keyword on can alter playback performance.</p>
<DisablePanScan Frame>	State	On	
<NVidiaSDISync>	State	Off	
<NVidiaPlayoutDelay>	Integer	0	
<BlockSize>	Integer	2048	
<AudioResyncTime>	Float	-1	
<LoadingSetup>	Integer	0	
<EnableKeycode Sending>	Enumerated (abstract data)	Off	
<LoginGUIGain>	Float	1.0	
<LoginGUIGamma>	Float	1.0	
<ClusterPlayDelay>	Integer	0	Available for Incinerator® only.

Parameter	Data type	Default	Function
<ClusterSmooth Playback>	State	Off	Available for Incinerator only.
<ChangeCutOffset>	State	On	<p>Allows the change cut or match grade feature to preserve the keyframe animations based on therecord timecode whenever a shothas been replaced or moved within a timeline.</p> <p>NOTE Be sure to enable only the Record button within the Match Option when performing a change cut or match grade.</p>
<AnimCopy_UsingTrimOffset_Off>	State	On	<p>"On" enables the first animation key-frame to load on the first frame of the shot.</p> <p>"Off" enables the first keyframe to be loaded according to the source frame number (and thus load with the offset).</p>
<PreallocEnable>	State	Off	Allows Burn rendering from a Lustre Windows workstation to use CXFS SAN preallocation.
<FirstFrameNumber>	Integer	On	
<StartShotFrameNumber>	Integer	On	
<DefaultDelivvablePanScanFilter>	Enumerated (abstract data)	Fast	<p>Possible values are:</p> <ul style="list-style-type: none"> ■ Fast (Lanczos2 filter) ■ Quality (Lanczos2 filter) ■ Custom (BSpline filter)
<RenderNaming> See Render Naming Settings (page 1793)			
<NormalMode>	String		Normal render mode file path and token based naming convention.
<NoShotIdMode>	String		No Shot Id render mode file path and token based naming convention.
<OneSeqMode>	String		One Sequence render mode file path and token based naming convention.
<SrcGradeMode>	String		Source Grade render mode file path and token based naming convention.

Parameter	Data type	Default	Function
<StereoNormalMode>	String		Stereoscopic Normal render mode file path and token based naming convention.
<StereoNoShotIdMode>	String		Stereoscopic No Shot Id render mode file path and token based naming convention.
<StereoOneSeqMode>	String		Stereoscopic One Sequence render mode file path and token based naming convention.
<StereoSrcGradeMode>	String		Stereoscopic Source Grade render mode file path and token based naming convention.
<NormalPadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the Normal render mode.
<NoShotIdPadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the No Shot Id render mode.
<OneSeqPadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the One Sequence render mode.
<SrcGradePadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the Source Grade render mode.
<StereoNormalPadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the Steroscopic Normal render mode.
<StereoNoShotIdPadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the Stereoscopic No Shot Id render mode.
<StereoOneSeqPadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the Stereoscopic One Sequence render mode.

Parameter	Data type	Default	Function
<StereoSrcGradePadding>	String		Defines the padding of the file name (the number of digits used for file numbering) for the Stereoscopic Source Grade render mode.
<Debug>			
<DumpDLEDLPath>	String		Path to place the contents of a DLEDL when it is loaded in the timeline or Shot bin.
<DumpWiretapCreate Clip>	State	Off	When ON, the attributes of a Wiretap clip are placed into a log file each time a clip is created on a Wiretap server. The file <i>WiretapClipDump.log</i> is located in the Lustre home folder. Use this keyword for debugging only.
<FilmTypeGroup>			
<FilmType>	Name		Various film types for AGFA, Kodak™, Eastman, and Fuji emulsions. It defines the relationship between the DPX film emulsion code and the DPX film code number.

Project Configuration

Projects are a means of organizing work performed in Lustre, as well as the directories where the original footage and rendered files are stored. A project typically corresponds to an entire creative piece, such as a film or commercial.

All the work you do in Lustre is non-destructive. Operations performed on the footage are saved as metadata, separate from the original footage. A render permanently applies operations to a copy of the original footage.

When creating a project, you specify a main project directory—known as *Project Home*—in which all metadata files for the project are stored. You can store footage and render files in sub-directories of the Project Home or in another location. If you store footage and renders outside the Project Home, you must specify the location when you define the project.

NOTE Before creating a project, you must have a good idea of how you will structure your data directories. See [Recommended Directory Structure for Projects](#) (page 1780).

You can configure the following default settings for your project:

- Project
- Calibration
- Rendering
- Render Naming

NOTE Render Naming Settings are exclusive to Lustre 2012 Extension 1.

- Engineering
- Network Rendering

Select:	To configure:
Project	The name and location of the project. See Project Settings (page 1784).
Calibration	Default system calibration settings and define the default LUTs for a project. See Calibration Settings (page 1787).
Rendering	Default rendering settings for a project. See Rendering Settings (page 1789).
Render Naming	Default render naming settings for a project. See Render Naming Settings (page 1793).
Engineering	Default video and graphics settings for a project. See Engineering Settings (page 1795).
Network Rendering	Default Backburner/Burn®, Lustre ShotReactor, and Wiretap directory paths and settings for a project. See Network Rendering Settings (page 1799).

About Project Defaults and Session Settings

When configuring your project settings in Lustre, you can configure some parameters as project defaults and others as user defaults. The parameters that are configurable as project defaults become the default settings each time a project is loaded, regardless of the logged in user. However, if you make changes in the Lustre application that affect the default settings and then save these changes to a grade file, the default settings will be overridden the next time you load the project.

While logged in, the user can override some of the project default settings, such as Render Mode in the Local menu. However, these overrides only last for the duration of the session. Restarting the application resets the settings to the values set at project creation.

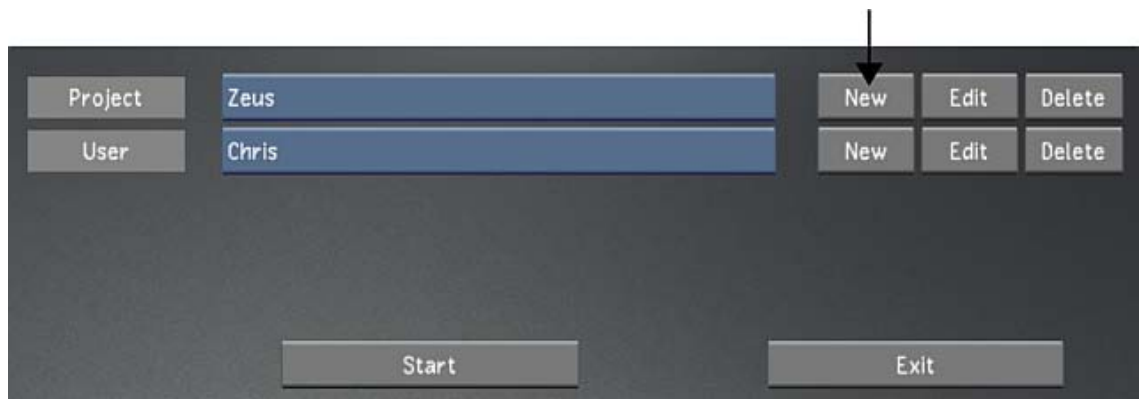

Creating a Project

Creating a Lustre project is the first step to prepare Lustre for a new colour grading project. You can use templates to accelerate project setup. See [Working with Templates](#) (page 1838).

NOTE You can create multiple projects with the same Project Home. This allows you to work on a project with different settings while sharing the same scenes, cuts, and grades.

To create a new project:

- 1 Do one of the following:
 - From the Lustre splash screen, click New in the Project group.
 - From the Main menu, click Setup, then Settings, and then click New in the Project group.

NOTE If you have a template named *default*, then its settings will be loaded automatically.

- 2 Configure the project. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).
- 3 To save the settings of the new project, click Save Project.
- 4 Click Exit Project.

To create a project based on an existing project:

- 1 Do one of the following:
 - From the Lustre splash screen, select the baseline project, and then click Edit in the Project group.
 - From the Main menu, click Setup, and then Settings. Select the baseline project, and then click Edit in the Project group.

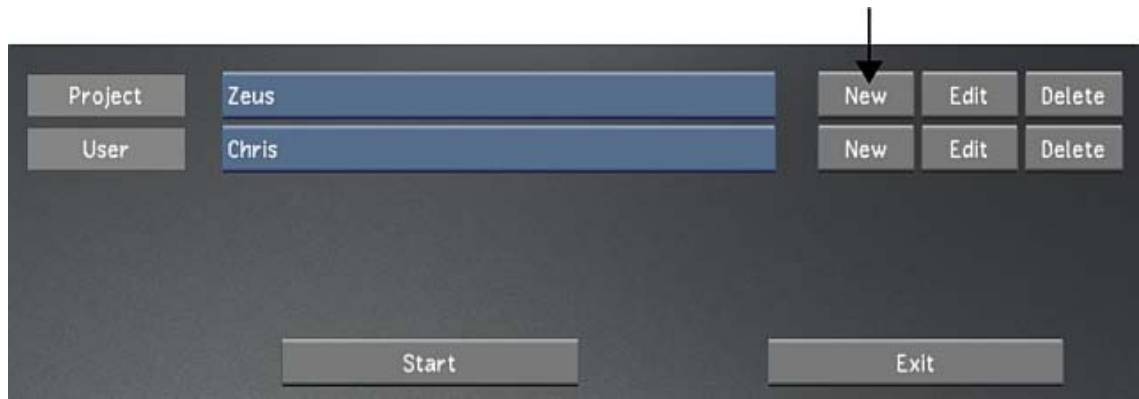

- 2 In the Project Name field, enter a new name for the new project, or you will overwrite the original project's settings with the new settings.
- 3 Configure the project. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).
- 4 To save the settings for the project, click Save Project.
- 5 Click Exit Project.

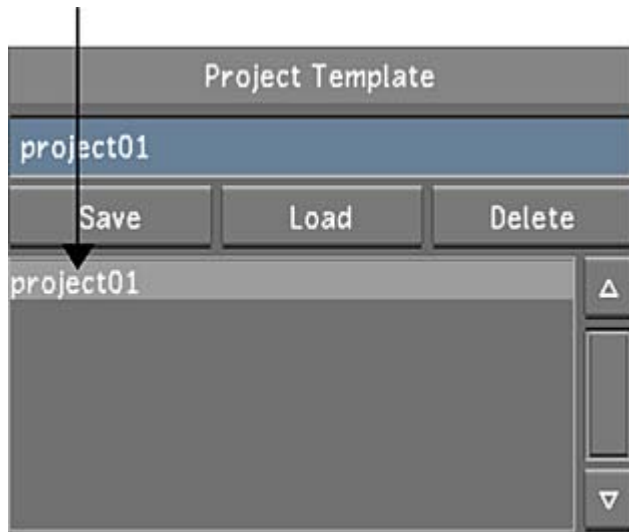

To create a new project using a template:

- 1 Do one of the following:
 - From the Lustre splash screen, click New in the Project group.
 - From the Main menu, click Setup, then Settings, and then click New in the Project group.

NOTE If you have a template named "default", then its settings will be loaded when you click New.

- 2 From the Project Template list, select a template. See [Creating a Project Template](#) (page 1838).

- 3 Click Load.
The template's settings are now loaded.
- 4 Configure the project. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).
- 5 To save the settings for the project, click Save Project.
- 6 Click Exit Project.

Editing an Existing Project

While working on a project, you can edit some of its default settings.

To edit the settings of a project:

- 1 Do one of the following:
 - From the Main menu, click Setup, and then Settings. Select the project to edit, and then click Edit in the Project group.
 - From the Lustre splash screen, select the project to edit, and then click Edit in the Project group.

- 2 Configure the project. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).
- 3 To save the settings for the project, click Save Project.
- 4 Click Exit Project.

Recommended Directory Structure for Projects

The following files can be stored per scene in the Project Home directory, or they can be stored in separate directories, as decided within the project settings. See [Project Settings](#) (page 1784).

- Original footage, both full and half resolution
- Render files, both full and half resolution
- Audio
- Grade files
- Grade Bin
- Cached degrained frames
- Library: this new folder contains all the metadata created in the scene.

Project Name	Project1	
Project Home	/Storage/AllProjects/Project1	...
Scans Full Home	/Storage/AllProjects/Project1/Scans_Full	...
Scans Half Home	/Storage/AllProjects/Project1/Scans_Half	...
Renders Full Home	/Storage/AllProjects/Project1/Renders_Full	...
Renders Half Home	/Storage/AllProjects/Project1/Renders_Half	...
Project Grade Bin	/Storage/AllProjects/Project1/GradeBin	...
Degrain Cache	/Storage/AllProjects/Project1/cache	...

Example of file directory structure configuration in the Project menu

When directories are not located in Project Home, they can be located on another drive, mount point, or even on a remote SAN or file server. Select the location that best suits your hardware configuration. For example, if you work on one project at a time, you may have enough space to store all footage on the Master

Station. If you are working on multiple projects, you may not have the required space on the Master Station; in this case, you could store your full scans and render files on a large remote server, and store the half-resolution scans locally.

NOTE If configuring Lustre on an Autodesk Incinerator® high-speed network, see [Incinerator-Specific Project Management Configuration](#) (page 1766).

Configuring File Locations in Project Home

When project data is stored in Project Home, the following structure is recommended during product configuration. In this example, the Project Home is defined in Windows as the *H:* drive, whereas in the Linux version it is usually defined as the */mnt/md0/* mount point.

Directory for:	Windows Folder:	Linux Directory:
Project Home	<i>H:\<project name></i>	<i>/mnt/md0/<project_name></i>
Scans	<i>H:\<project name>\<scene name>\<scans folder></i>	<i>/mnt/md0/<project_name>/<scene_name>/<scans_directory></i>
Renders	<i>H:\<project name>\<scene name>\<renders folder></i>	<i>/mnt/md0/<project_name>/<scene_name>/<renders_directory></i>
Grade bin	<i>H:\<project name>\<scene name>\<grade bin folder></i>	<i>/mnt/md0/<project_name>/<scene_name>/<grade_bin_directory></i>
Degrain cache	<i>H:\<project name>\<scene name>\<degrain cache folder></i>	<i>/mnt/md0/<project_name>/<scene_name>/<degrain_cache_directory></i>

Configuring Project Sub-directories

Once you configure file locations for your project files, you must create the sub-directories for your scans manually. Lustre generates many sub-directories automatically for specific types of file.

When you create a scene in your project, Lustre generates directories for these scenes in the project directory. Alternatively, you can manually create the scene's directory and Lustre will recognize it as an existing scene directory if you later define scenes with the exact names you gave to the directories. See [Working With Scenes](#) (page 1815).

Lustre stores all project metadata in sub-directories of the project directory. The metadata is saved per scene, each scene having its sub-directory. The sub-directory is created automatically and is named *Library*.

The render directories related to the scenes are created automatically by Lustre. The directory structure differs depending on the Render Place option specified when rendering. See [Specifying the Destination for Local Render Files](#) (page 2263).

In the following table, the Project Home is defined in Windows as the *H:* drive, whereas in the Linux version it is usually defined as the */mnt/md0/* mount point.

Directory for:	Windows Folder:	Linux Directory:
Scene	<i>H:\<project name>\<scene name></i>	<i>/mnt/md0/<project_name>/<scene_name></i>
Library	<i>H:\<project name>\<scene name>\Library</i>	<i>/mnt/md0/<project_name>/<scene_name>/Library</i>
Scans sub-directories associated with a shot	<i>H:\<project name>\<scene name>\<scans folder>\<shot name></i>	<i>/mnt/md0/.../<scans_directory>/<shot_name></i>
Scans at half- and full-resolution footage, which should both be at this level, in different directories. The directory name must include the scan resolution. Example: <i>2048x1556</i> . If you generate proxies in Lustre, the proxies directory is created automatically.	<i>H:\<project name>\<scene name>\<scans folder>\<shot name>\<resolution></i>	<i>/mnt/md0/.../<scans_directory>/<shot_name>/<resolution></i>
Degrain cache	<i>H:\<project name>\<scene name>\<degrain cache folder>\<resolution>\degrain_cache</i>	<i>/mnt/md0/<project_name>/<scene_name>/<degrain_cache_directory>/<resolution>/degrain_cache</i>
Degrain cache (when saved with Scans)	<i>H:\<project name>\<scene name>\<scans folder>\<shot name>\<resolution>\degrain_cache</i>	<i>/mnt/md0/.../<scans_directory>/<shot_name>/<resolution>/degrain_cache</i>
Renders	<i>H:\<project name>\<scene name>\<render mode></i>	<i>/mnt/md0/<project_name>/<scene_name>/<render mode></i>

Configuring File Locations Separately from Project Home

To have the scanned footage and renders stored on a separate storage location, the Scans Full Home and the Renders Full Home must be explicitly defined as a separate location. On Windows, an example of this separate location could be a shared folder coming from a remote file server, and mapped to the local drive *G:* under the *films\myfilm* folder. On Linux, a corresponding example would be a directory exported from a remote file server, and mounted on the */mnt/fileservers/* NFS mount point under the *films/myfilm* directory.

Directory:	Windows Folder:	Linux Directory:
Project Name	<i>H:\<project name></i>	<i>/mnt/md0/<project_name></i>
Scene	<i>H:\<project name>\<scene name></i>	<i>/mnt/md0/<project_name>/<scene_name></i>

Directory:	Windows Folder:	Linux Directory:
Library	<i>H:\<project name>\<scene name>\Library</i>	<i>/mnt/md0/<project_name>/<scene_name>/ Library</i>
Where you create sub-directories to store original footage	<i>G:\films\myfilm\<scans folder></i>	<i>/mnt/fileserver/ films/myfilm/<scans_directory></i>
Where Lustre creates sub-directories for render files	<i>G:\films\myfilm\grd</i>	<i>/mnt/fileserver/ films/myfilm/grd</i>

NOTE If you decide to store half-resolution scans in a different location from the originals, the project directory structure must be identical in both locations and must include the root directory of the project. For example, if the Project Home is defined as *V:\Data\Lustre_project\My_movie*, the Scans Full Home could be defined as *W:\mnt\San\Lustre_project\My_movie* and the Scans Half Home could be *X:\Lustre_project\My_movie*.

The following table shows the sub-directory structure that CEV_ProdName_CEV creates for renders. The structure differs depending on the Render Place option specified when rendering. See [Specifying the Destination for Local Render Files](#) (page 2263). For the sake of simplicity, in this table, *G:\...* represents *G:\films\myfilm*, and */mnt/fileserver/.../* represents */mnt/fileserver/films/myfilm* as shown in the first table in this section.

Directory:	Windows Folder:	Linux Directory:
Where sub-directories of the renders are located.	<i>G:\...\<render mode>\</i>	<i>/mnt/fileserver/.../<render mode></i>

Browsing for Paths

Instead of typing the path, you can browse for paths using the path browser.

To browse for paths:

- 1 Display the path browser by clicking '...'.

- 2 Using the path browser, navigate the directory structure to reach the desired directory. The selected path is automatically displayed in the path field.
- 3 To exit the browser, click Enter.

Using Environment Variables

You can use your operating system's environment variables to define all or a portion of a path. In Lustre, if you choose to use environment variables, enclose the variable name inside diamond brackets. For example, the Project Home field might be:

<HOME>\Projects\Zeus

Using the [PROJECT_NAME] and [USER_NAME] Variables

You can also use [PROJECT_NAME] and [USER_NAME] in your paths. You do not need to define these variables as they are predefined. The value of [PROJECT_NAME] is always the value you assign to Project Name in the Project settings page of Project Management. Likewise, the value of [USER_NAME] is always the value you assign to User Name in the Display & Interface settings page of User Management.

NOTE Both the [PROJECT_NAME] and [USER_NAME] variables require opening and closing square brackets.

The following graphic shows the use of both types of variables.

Project Name	New_Project	
Project Home	/John/Projects/[PROJECT_NAME]	...
Scans Full Home	/John/Scans	...
Scans Half Home	/John/Scans	...
Renders Full Home	/John/Projects/[PROJECT_NAME]	...
Renders Half Home	/John/Projects/[PROJECT_NAME]	...
Project Grade Bin	/John/Projects/[PROJECT_NAME]	...
Degrain Cache	/John/Projects/[PROJECT_NAME]	...

Project Configuration Settings

Project Settings

Use the Project settings to define:

- The Project Name
- The Project Home directory
- The Scans Home directory
- The Renders Home directory
- The Transcode Home directory
- The architecture

- The scan type
- The frame rate
- The proxy size
- The pixel ratio
- The Stereoscopy state
- The RED Timecode

For the project's directory structure, follow the guidelines described in [Recommended Directory Structure for Projects](#) (page 1780). When entering a directory path, you can use the path browser. See [Browsing for Paths](#) (page 1783).

Project Name	Project_1	
Project Home	/Storage/AllProjects/Project_1	...
Scans Full Home	/Storage/AllProjects/Project_1/Scans_Full	...
Scans Half Home	/Storage/AllProjects/Project_1/Scans_Half	...
Renders Full Home	/Storage/AllProjects/Project_1/Renders_Full	...
Renders Half Home	/Storage/AllProjects/Project_1/Renders_Half	...
Transcode Hires Home	[TRANSCODE_HOST]@wtg:[SCANS_FULL]	...
Transcode Proxy Home	[TRANSCODE_HOST]@wtg:[SCANS_HALF]	...

The screenshot shows the Project Settings dialog box with the following sections and controls:

- Architecture:** Logarithmic
- Output Colour Space:** Logarithmic
- RED Timecode:** Primary, Startup Grade Load, Project Based
- Project Template:** Save, Load, Delete buttons, and a list of templates: 1080i_25, 1080i_2997, 1080psf_2397, 1080psf_24, 1080psf_25, 2K_Linear, 2K_Linear_stereo.
- Scan Type:** Progressive
- Frame Rate:** 23.97, 24 (selected), 25, 29.97, DF, 24 (selected)
- Proxy Width:** Percent (selected), 50
- Pixel Ratio:** 1.00
- Stereoscopy:** (slider)

Labels in the image point to the following controls:

- (a)** Points to the Percent/Pixel option box.
- (b)** Points to the Drop Frame button (DF).
- (c)** Points to the Frame Rate field (24).
- (d)** Points to the Pixel Ratio slider.

(a) Percent/Pixel option box **(b)** Drop Frame button **(c)** Frame Rate field **(d)** Pixel Ratio slider

Project Name field Enter the name of the project.

Project Home field Enter, or browse to, the location of the main project directory.

Scans Full Home field Enter, or browse to, the location of the scanned footage directory.

Scans Half Home field Enter, or browse to, the location of the proxy footage directory.

Renders Full Home field Enter, or browse to, the location of the render directory for renders of (full resolution) footage.

Renders Half Home field Enter, or browse to, the location of the render directory for renders of proxy footage.

Architecture option box Toggle to set the default grading architecture and colour space while working in Lustre to logarithmic or linear.

Scan Type option box Toggle to set the default scan type.

Frame Rate buttons Enable the default frame rate for the project's timeline and editing tools.

Drop Frame button Enable when your shot contains drop frames. For the majority, this button is greyed-out since most of the default frame rates do not support drop frames. This button becomes available when you select a frame rate that supports drop frames (e.g., you have selected 29.97 or you have entered a personal frame rate within the frame rate field).

Frame Rate field Displays the selected default frame rate or you can enter your own frame rate within the field.

Output Colour Space option box Toggle to set the default colour space architecture when rendering to logarithmic or linear.

Percent/Pixel option box Toggle to set whether Lustre will determine the proxy width as a percentage of the original footage, or as a fixed number of pixels.

Proxy Width slider Use to define the default proxy width. Whether it is a percentage or a number of pixels is defined by the Percent/Pixel option box.

Pixel Ratio button Enable to configure the default aspect ratio.

Pixel Ratio slider Sets the default aspect ratio. Available if Pixel Ratio is enabled.

Stereoscopy button Enable to work on a stereoscopic project.

RED Timecode option box Select which RED media timecode to transcode. Note that when conforming an EDL, overriding the timecode data of the clips with a different timecode track will prevent relinking in the Autodesk Visual Effects and Finishing applications. For more information about RED media and transcoding, see [Transcode Options](#) (page 1921).

Select:	To:
Primary	Select either the Time of Day or Edgecode timecode. Only select this option if you know which timecode has been set as the primary.
Time of Day	Establish a timecode field that is set by the internal clock from the RED camera.
Edgecode	Establish a timecode field that is set by the camera operator.

Startup Grade Load option box Select the grade loading behavior at startup. Options are:

- **Project Based:** Loads the last grade used in the project.
- **User Based:** Loads the last grade used by the current user.
- **Never Load:** Does not load a grade at startup.

Project Template field Enter the name of a project template you wish to create in this field before clicking Save.

Save button Click to save the project settings of the current project to the template named in the Project Template field. Use to create a new template or to update an existing template.

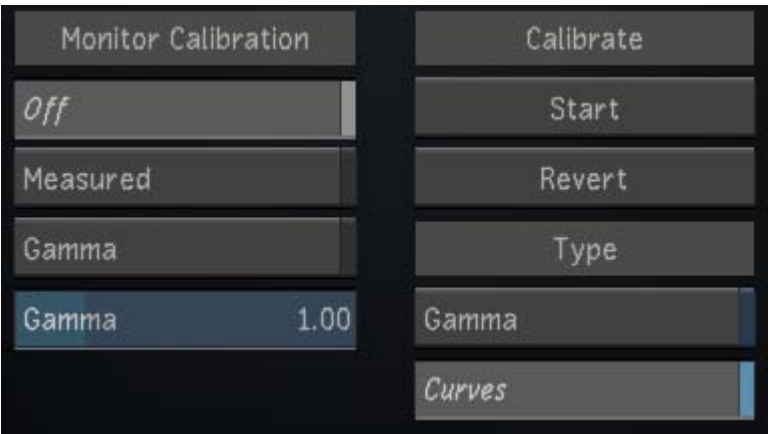

Load button Click to load a project template after you select a template in the Template Name list.

Delete button Click to delete a project template after you select a template in the Template Name list.

Template Name list Select an existing project template from this list before loading or deleting the selected template. See [Working with Templates](#) (page 1838).

Calibration Settings

Use the Calibration settings to configure default system calibration settings and to define the default LUTs for a project.

Off button Enable to disable all monitor calibration settings.

Measured button Enable to apply configured monitor calibration settings.

Gamma button Enable to adjust the monitor's gamma level manually (without the use of an external colourimeter).

Gamma slider Use to increase or decrease the default gamma.

Start button Click to begin the calibration. See [Monitor Calibration](#) (page 1892).

Revert button Click to revert back to the previous automatic calibration.

Gamma button Enable to set the calibration type to 'Gamma'.

Curves button Enable to set the calibration type to 'Curves'.

Print LUT buttons Enable one of the LUT 1, 2, or 3 buttons, then select a displayed print LUT to perform a quick comparison among three LUTs. For example, to designate a LUT as Print LUT 1, enable LUT 1 and select one of the displayed print LUTs. Repeat this for LUT 2 and 3.

LUT Type menu Select the type of Print LUT: **1D Lut**, **3D Lut**, or **Colour Transform**. See [Applying LUTs for Viewing \(Print LUTs\)](#) (page 1899).

Print LUT list Select a print LUT from each list after you enable one of the Print LUT buttons. You can import a LUT into the list. See [Importing a LUT File](#) (page 2070).

Custom button Enable to select a custom input LUT (an input LUT other than the Log-to-Lin LUT). See [Input LUTs](#) (page 2069).

NOTE If you enable Custom, make sure you also select a custom LUT in the Input LUT list.

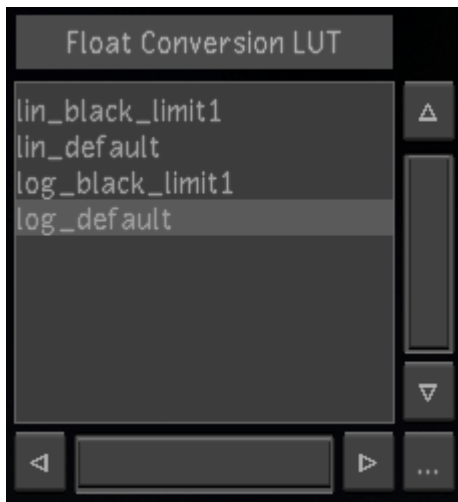

Log>Lin button Enable to configure Lustre to perform a logarithmic-to-linear conversion on shots as they are dragged into the timeline or when assembling an EDL. See [Input LUTs](#) (page 2069).

Input LUT list Select a custom input LUT from this list to configure Lustre to use this LUT when:

- Dragging a shot from the Library or Browser to the timeline, or
- Assembling an EDL

You can import a LUT into the list. See [Importing a LUT File](#) (page 2070).

NOTE To select a custom input LUT, enable the Custom button.

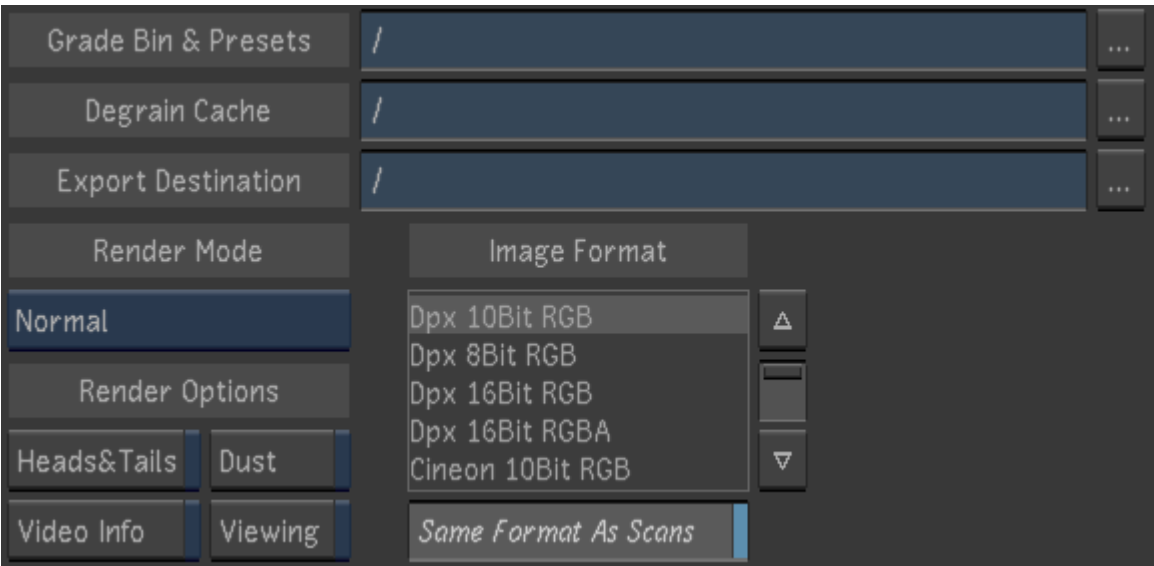

Float Conversion LUT list Select a LUT to convert the OpenEXR 16-bit float data to 16-bit integer Lustre internal format. You can import a LUT into the LUT list. See [Importing a LUT File](#) (page 2070).

Rendering Settings

Use the Rendering settings to:

- The Grade Bin & Presets directory.
- The Degrain Cache directory.
- The Export Destination directory.
- The Render Mode.
- The Render Options.
- The Image (Output) format.
- The Marry grade settings.
- The Dust settings.
- The Degrain settings.
- The Proxy Generation filters.
- The Reposition filter.
- The Output Lut.

Project Grade Bin field Enter, or browse to, the location of the grade files for the current project.

Degrain Cache field Enter, or browse to, the location of the user-defined cache location for degrained frames. When there is no access to the Scan directories, and the Degrain File Location option box in the Rendering menu is set to Saved with Scan, cached frames are saved in this location. See [Rendering Settings](#) (page 1789).

NOTE Verify that the cache location supports the bandwidth you require for the project.

Export Destination field Enter, or browse to, the location to export to.

Render Mode Set the default render option.

Select:	To have:
Normal	Each shot of a cut rendered to a separate directory, with a Unique ID, under the render path specified in the project.
No Shot ID	Each shot in the cut rendered to a separate directory under the render path specified in the project.
One Sequence	Shots rendered into one directory as a single sequence of renamed images.
Src Grade	Individually-graded shots rendered to their own UID (unique ID) folder in the Renders Home location. This option is mostly used in the Interoperability workflow.

Heads & Tails Enable to set the project's default to render shots with head and tail frames.

Dust Enable to set the project's default to render shots with dust metadata.

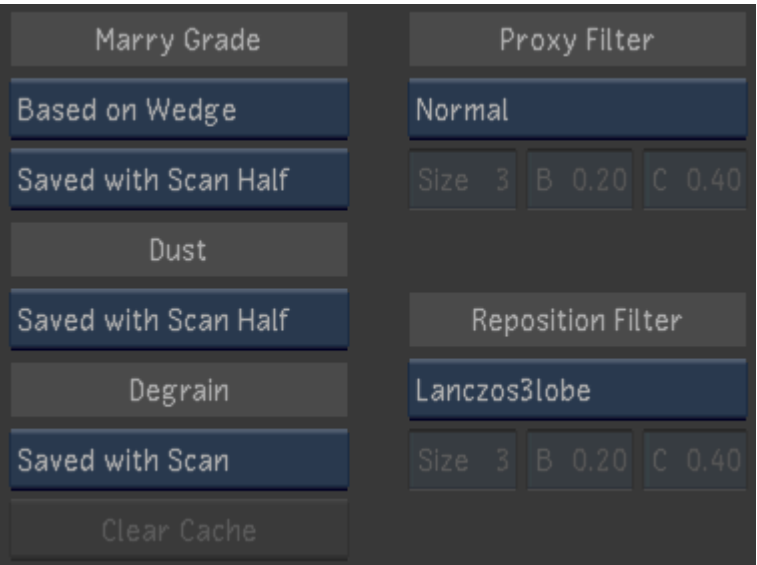

Video Info Enable to set the project's default to burn in the timecode into the render.

Viewing Select to render viewing LUT; however, it renders 8-bit BMP files. Use this option when you want to render the image displayed in the monitor.

Image Format list Select the default format of the media to be rendered from this list.

Same Format As Scans Enable to render media in the same format as the source media.

NOTE If you apply a colour transform that converts between integer and floating-point data or vice versa in the Transcode menu, you should disable Same Format As Scans and specify the output format manually.

Marry Grade Format option box Toggle to specify the default marry grade format. For more information about the marry grade formats, see [Saving and Loading Marry Grades](#) (page 1830).

Select:	To:
Based on Wedge	Save marry grade files based on the wedge number, defined by the first and last frame in the shot's frame range.
Based on UID	Save marry grade files based on their unique identifiers.

Marry Grade File Location option box Toggle to specify the location where marry grade files are saved. Marry grades are saved in resolution-specific directories.

Select:	To save marry grade files to a resolution-specific directory:
Saved with Scan Full	Under the Scans Full Home directory.
Saved with Scan Half	Under the Scans Half Home directory.

Dust File Location option box Toggle to specify the location where Lustre saves dust files. Dust files are saved in resolution-specific directories.

Select:	To save dust files to a resolution-specific directory:
Saved with Scan Full	Under the Scans Full Home directory.
Saved with Scan Half	Under the Scans Half Home directory.

Degrain File Location option box Toggle to specify the location for caching degrained frames.

Select:	To save cached frames:
Saved with Scan	In the Scans directories.
Saved in Degrain Cache	In the user-defined Degrain Cache directory.

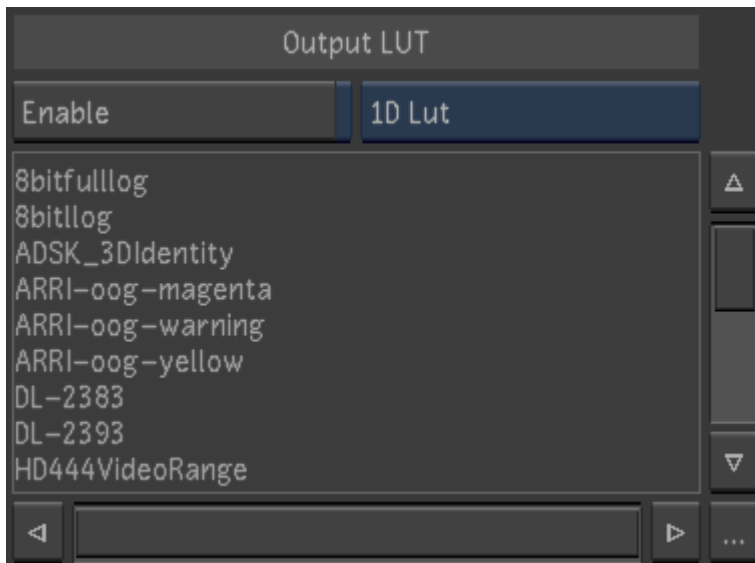

Clear Cache Click to delete all files in the degrain file cache. This button is disabled when the Degrain File Location option box is set to Saved with Scan.

Proxy Filter Select the default filter to use when creating a proxy.

Select:	To use as default:
Normal	An average filter if the resolution of the proxy is half, and to use a Sync filter if the resolution of the proxy is full.
CatmullRom	The CatmullRom proxy generation filter when creating proxies.
Lanczos	The Lanczos proxy generation filter when creating proxies.
Sinc	The Sinc proxy generation filter when creating proxies.
Mitchell	The Mitchell proxy generation filter when creating proxies. Use the sliders below to define the filter settings.

Reposition Filter Select the reposition filter to use by default when creating proxies.

Select:	To use as default:
Normal	An Average filter if the resolution of the proxy is half, and to use a Sync filter if the resolution of the proxy is full.
CatmullRom	The CatmullRom reposition filter.
Lanczos3lobe	The Lanczos3lobe reposition filter.
Mitchell	The Mitchell reposition filter. Use the sliders below to define the filter settings.

Enable button Apply the output LUT or colour transform when rendering.

Output LUT Type option Choose 1D LUT, 3D LUT, or Colour Transform.

Output LUT list Select a default output LUT or color transform to use when rendering from this list, or click the Browse (...) button at the lower right to select a file.

Render Naming Settings

Use the Render Naming Settings to configure the token based folder structure and naming conventions of rendered media. These settings are included in any project templates you create.

The project is provided with default path structures for each render mode based in the RenderNaming section of the init.config file. You can customize the folder structure and naming conventions of your renders by modifying the fields in the new Render Naming menu in the Project settings.

If you modify a render naming path for a new grade, and you load a previous grade that has a different rendering path for the same render mode, Lustre will be able to link the grade to its previously saved render path. The render naming paths are saved in the file called <grade name>.renderinfo.

Modes	Standard Render	Stereoscopic Render	Padding
Normal	[RENDERS_HOME]/Normal/[SCENE]/[GRADE_NAME]/[REEL_NAME]/[RESOLUTION]/[UID]_[ORIGINAL_FILENAME]_[GRADE_NAME]		.x06d
No ShotID	[RENDERS_HOME]/NoShotID/[SCENE]/[GRADE_NAME]/[REEL_NAME]/[RESOLUTION]/[ORIGINAL_FILENAME]_[GRADE_NAME]		.x06d
One Seq	[RENDERS_HOME]/OneSequence/[SCENE]/[GRADE_NAME]/[RESOLUTION]/		.x06d
Src Grade	[RENDERS_HOME]/SrcGrade/[SCENE]/[GRADE_NAME]/[REEL_NAME]/[RESOLUTION]/[UID]_[ORIGINAL_FILENAME]_[GRADE_NAME]		.x06d

Standard Render Button Select to set standard (monoscopic) rendering.

Stereoscopic Render Button Select to set stereoscopic rendering.

Normal Field The location and naming convention for Normal renders.

No ShotID Field The location and naming convention for No ShotID renders (individually rendered shots).

One Seq Field The location and naming convention for One Sequence renders.

Src Grade Field The location and naming convention for Source Grading renders.

Padding Field Defines the padding of the file name (the number of digits used for file numbering) for each render mode. For example: `<NormalPadding string=".%06d" />` will generate a six digit file like this: `filename.123456.dpx`.

NOTE It is possible to create a file with only a frame index (no filename), by removing the "." in the Padding Field. This is the default padding value of the One Sequence render mode.

The following tokens can be used for rendering:

- [PROJECT_NAME]: Name of the current project.
- [PROJECT_HOME]: Home folder of the project.
- [SCANS_HOME]: Location of the scans home according to the current Full or Half resolution view at the time of render.
- [SCANS_FULL_HOME]: Location of the full resolution scans.
- [SCANS_HALF_HOME]: Location of the proxy resolution scans.
- [RENDERS_HOME]: Location of the renders home according to the current Full or Half resolution view at the time of render.
- [RENDERS_FULL_HOME]: Location of the full resolution renders.
- [RENDERS_HALF_HOME]: Location of the proxy resolution renders.
- [SCENE]: Current scene name.
- [USER]: Current user.
- [RESOLUTION]: Output resolution, i.e. 1920x1080.
- [REEL_NAME]: Reel/tape name of the source clip.
- [STEREO_LAYER]: Left or Right.
- [GRADE_NAME]: Grade name (i.e grd01).
- [GRADE_NOTE]: Text data entered by user and displayed between the grade name and cut --> grd01 FinalGrade [cut01], "FinalGrade" is the grade note.
- [CUT]: Name of the cut.
- [UID]: Shot-based Unique ID.
- [ORIGINAL_FILENAME]: The original file name of the source clip (minus the extension), like "12345_clip.0000001.dpx", "12345_clip" is the file name.
- [ORIGINAL_PATH]: The original path and file name of the source clip (including the extension). Use this token to replace the source footage when rendering.

NOTE

When using the [ORIGINAL_PATH] token, the padding field is not available as the original file padding is used.

When rendering to a Wiretap destination, ie. `<wiretap_server>@wt:/stonefs...`, the clip names are not affected by the Render Naming convention. However, the naming of the Media files will be affected if the Wiretap Render option is enabled (i.e. media files in this case are written to a shared location as unmanaged media).

Avoid using spaces in the names you choose for your folders. Use underscores instead.

You must include the brackets when adding or modifying a token.

Grade-based Render Location

Each grade saves the current render naming path associated with its render mode every time you start a new render, submit a render job to Burn or ShotReactor. This means if you modify a render naming path for a new grade, and you load a previous grade that has a different rendering path for the same render mode,

Lustre will be able to link the grade to its previously saved render path. The render naming paths are saved in a file called <grade name>.render<render mode>, according to the selected render mode. For example:

- grd01.renderNormal
- grd01.renderNoShotId
- grd01.renderOneSequence
- grd01.renderSourceGrade

Modifying the Render Naming

If you type an invalid token and press enter (or select another path field), Lustre will highlight the invalid token to warn you about the error.

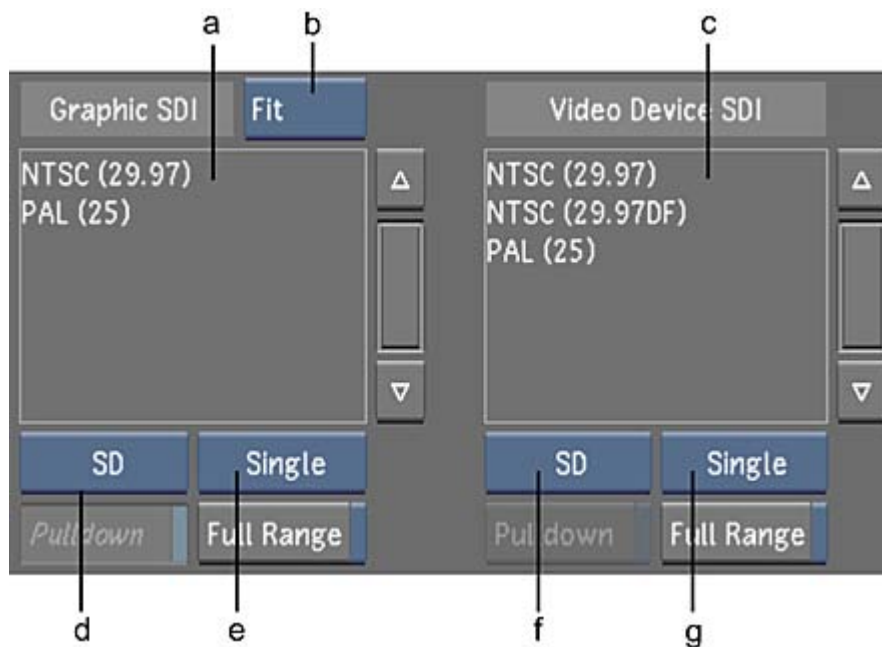

```
[RENDERS_HOME]/Normal/[SCENE]/[GRADE_NAME]/[REEL_NAME]/[RESOLUTION]/[UID]_[ORIGINAL_FILENAME].[GRADE]
```

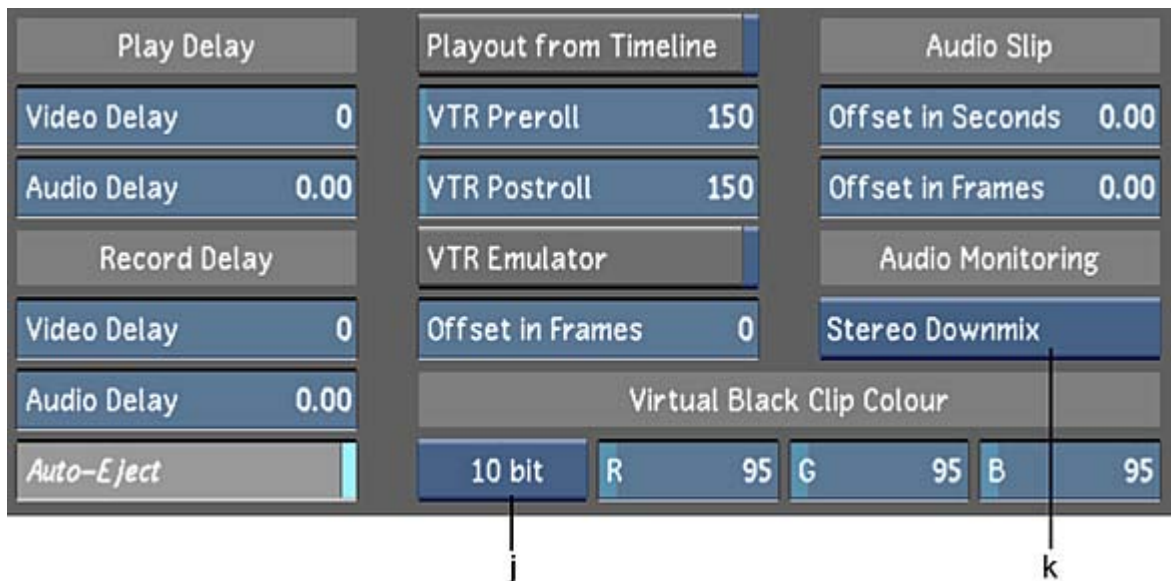

Also, after modifying a render location field, if you want to revert to the default location defined in the init.config, press the CTRL key and click on the field you want to reset.

Engineering Settings

Use the Engineering settings to configure:

- Video device SDI settings
- Graphic SDI settings
- Sync mode settings
- Video capture and playout settings
- Audio capture and playback settings
- Virtual black clip colour

(a) Graphic SDI Raster list (b) Graphic SDI Display option box (c) Video Device SDI Raster list (d) Graphic SDI Format option box (e) Graphic SDI Link Type option box (f) Video Device SDI Format option box (g) Video Device SDI Link Type option box (h) Audio File Type option box (i) Audio Sampling Rate/Bit Depth option box (j) Bit Depth option box (k) Audio Monitoring option box

Graphic SDI Display option box Allows you to select how you would like to display your video on the Graphic SDI output. Cycle through the list to select one of the options.

Select:	To:
Fit	Enlarge the image as much as possible while preserving the aspect ratio at the SDI out (graphics card).

Select:	To:
Fit W	Fit the image to the width of the monitor at the SDI out.
Fit H	Fit the image to the height of the monitor at the SDI out.
Stretch	Fit the image to the dimensions of the monitor by adjusting the aspect ratio at the SDI out (graphics card).
Center	Center the image without zooming at the SDI out (graphics card).

Graphic SDI Raster list Select one of the graphics rasters to set the default format for the graphic card's SDI output.

Graphic SDI Format option box Toggle to display, in the Rasters list, rasters using the selected resolution format.

Graphic SDI Link Type option box Toggle to display, in the Rasters list, rasters using the selected link.

Graphic SDI Pulldown button Enable to configure Lustre to add a pulldown frame when outputting through the Graphic SDI. See [About 3:2 Pulldown](#) (page 2338).

Graphic SDI Full Range button Enable to configure Lustre to use the full range of YUV and RGB when outputting to the Video device SDI. When this button is disabled, Lustre uses the Normal mapping matrix for the configured video raster.

Video Device SDI Raster list Select one of the video rasters to set the default video resolution for the video device's SDI.

NOTE You must choose a video device SDI raster with the same frame rate as the graphic SDI output raster. Otherwise, the video raster will not be enabled in the application.

Video Device SDI Format option box Toggle to display, in the Rasters list, rasters using the selected footage format.

Video Device SDI Link Type option box Toggle to display, in the Rasters list, rasters using the selected link.

Video Device SDI Pulldown button Enable to configure Lustre to add a pulldown frame when outputting through the video device SDI. See [About 3:2 Pulldown](#) (page 2338).

Video Device SDI Full Range button Enable to configure Lustre to use the full range of YUV and RGB when outputting to the Video device SDI. When this button is disabled, Lustre uses the Normal mapping matrix for the configured video raster.

Sync Mode list Select one of the sync mode options from this list.

Select:	To:
InternalSync	Set the sync mode to a free running internal sync (SD and HD).
ExternalSync	Genlock to analog sync connected to the sync input (SD only).
TrilevelSync	Genlock to trilevel sync connected to the sync input (HD only).

Horizontal Delay slider Use to define the number of pixels by which the horizontal sync output is delayed in relation to the incoming sync. The step interval is half a pixel for SDTV devices and two pixels for HDTV devices. The maximum delay is one line length.

Vertical Delay slider Use to define the number of pixels by which the vertical sync output is delayed in relation to the incoming sync. The step interval is +/- 1 field for SDTV devices and +/- 8 line pixels for HDTV devices. The maximum delay is one line length.

Video Capture Format list Select a video capture format to define Lustre's video capture format to a specific file type, colour space, and bit depth.

Select:	To configure Lustre to capture only:
Dpx 10Bit RGB	DPX files with an RGB colour space at a bit depth of 10 bits.
Tiff 8Bit RGB	TIFF files with an RGB colour space at a bit depth of 8 bits.

Audio File Type option box Choose whether to save audio captured from a VTR/ATR, or imported from Wiretap as a Wave (.WAV) or AIFF (.AIF) file.

Audio Sampling Rate/Bit Depth option box Select to capture the audio tracks at a sampling rate of 48 kilohertz (kHz) and a bit depth of 16-bit, or 48 kHz and a bit depth of 24-bit.

Single File Capture button When enabled, all the selected audio tracks are saved in a single file. When disabled, each audio track is saved as an individual file. This option is not available when you are importing audio from Wiretap.

Video Delay (Play) slider Define the default number of video frames to add before the start of the shot when capturing from the VTR.

Audio Delay (Play) slider Define the default number of audio frames to add before the start of the shot when capturing from the VTR.

Video Delay (Record) slider Define the default number of video frames to add before the start of the shot when recording to the VTR.

Audio Delay (Record) slider Define the default number of audio frames to add before the start of the shot when recording to the VTR.

Auto-Eject button Enable to set the project's default to automatically eject the tape during EDL capture.

Playout from Timeline button Enable to set the project's default to play out from the Output view. If this button is disabled, the playout to tape function plays out rendered material only.

VTR Preroll slider Define the time (in seconds) allowed for the VTR to run up to speed and stabilize to perform an edit.

VTR Postroll slider Define the time (in seconds) allowed for the VTR to roll after an edit.

VTR Emulator button Enable to set the project to emulate a VTR.

VTR Emulator Offset in Frames slider Define the default number of frames you wish to offset the Start Timecode from the timeline.

Offset in Seconds slider Define the default number of seconds you wish to offset the audio. See [Offsetting the Audio File](#) (page 2353).

Offset in Frames slider Define the default number of frames you wish to offset the audio. See [Offsetting the Audio File](#) (page 2353).

Audio Monitoring option box Toggle to select a monitoring option to make sure your playback settings correspond to your audio configuration. See [Audio Monitoring Options](#) (page 2352).

Select:	Audio Device:	When:
Stereo Downmix	DVS or AJA	There are only two audio tracks that are supported on the audio monitoring device. All the odd numbered tracks (e.g., 1, 3, 5, etc.) go through port 1 and all the even numbered tracks go through port 2.
4-Track Downmix	DVS or AJA	There are only four audio tracks that are supported on the audio monitoring device.
8 Tracks	DVS only	There are up to eight tracks and each track is supported on the audio monitoring device.
8-Track Downmix	AJA only	There are only eight tracks that are supported on the audio monitoring device.
16 Tracks	AJA only	There are up to 16 tracks and each track is supported on the audio monitoring device.

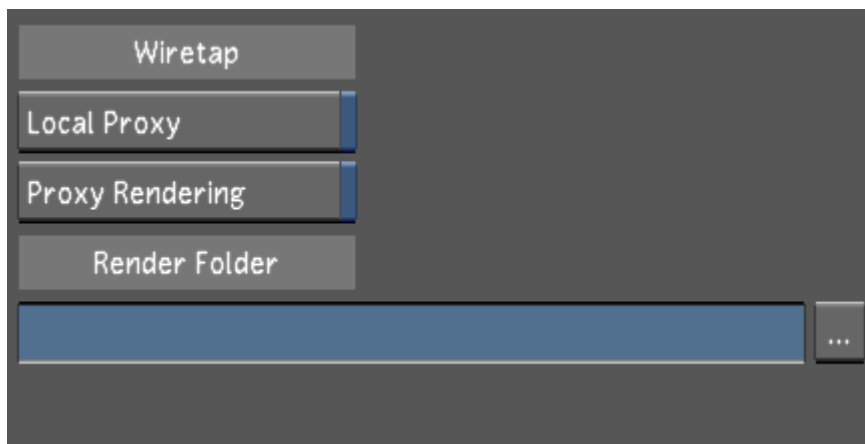

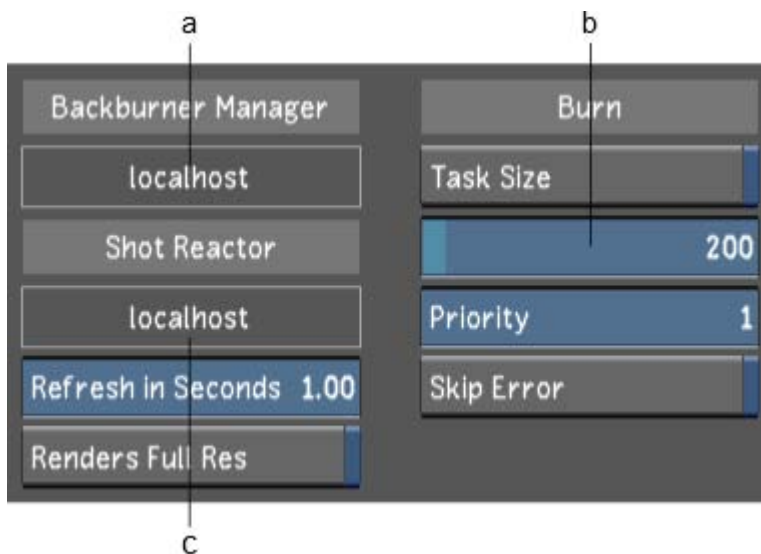

Bit Depth option box Toggle to select the default bit depth of virtual colour clips in your project. Possible values are 8, 10 (default), and 16 bit.

RGB sliders Define the default colour of virtual colour clips in this project.

Network Rendering Settings

Use the Network Rendering settings to configure default Backburner/Burn, Lustre ShotReactor, and Wiretap directory paths and settings for a project.

Configuration	<i>Burn</i>	Shot Reactor	From Project
Project Home	/		...
Scans Full Home	/		...
Scans Half Home	/		...
Renders Full Home	/		...
Renders Half Home	/		...

(a) Backburner Manager host field (b) Task Size slider (c) ShotReactor host field

Burn button Enable to display Burn render path.

ShotReactor button Enable to display ShotReactor render path. See [Network Rendering Settings](#) (page 1799).

From Project button Click to copy project paths to Burn or ShotReactor.

Project Home field The location of the main project directory.

Scans Full Home field The location of the high-resolution (full) scans directory.

Scans Half Home field The location of the proxy (half) scans directory.

Renders Full Home field The location of the high-resolution renders directory.

Renders Half Home field The location of the half-resolution renders directory.

Backburner Manager Host field The IP address or host name of the Backburner Manager node. This address is read from the *init.config* file.

ShotReactor Host field The IP address or host name of the ShotReactor host. This address is read from the *init.config* file.

Refresh in Seconds slider Use to define the default number of seconds allowed to elapse before the ShotReactor progress indicator is updated.

Renders Full Res button Enable to set the default to render high resolution media when working in Proxy mode and using ShotReactor.

Task Size button Enable to configure the size of the task (in number of frames) sent to individual Burn render nodes.

Task Size slider Use to define the number of frames in each task sent to the render nodes.

NOTE You must first enable the Task Size button before configuring the size of the task with the slider.

Priority slider Use to define the default priority of a Burn task.

Skip Error button Enable to configure Lustre to skip errors when performing remote renders with Burn.

Local Proxy button Enable to generate and view, in the Half Resolution Player, the proxies Lustre creates for Wiretap media. Disable to see the proxies located on the Wiretap server.

Proxy Rendering button Enable to automatically generate proxies when you render a hires timeline to the Wiretap server according to the project's Proxy Options. This makes it efficient to load clips in a Visual Effects and Finishing application as you no longer have to generate proxies first.

Render Library field Set the Wiretap location on a Visual Effects and Finishing system where Lustre creates soft-import links for the rendered shots. See [Browsing for Paths](#) (page 1783).

WARNING For publish metadata to be sent to the Render Library path, the Wiretap Render button must be enabled in the Render > Local menu before you render your project.

User Configuration

In Lustre, using user configuration, you can:

- Create a new user profile.
- Create a new user from an existing user profile.
- Create a new user from an existing user template.
- Edit the settings of an existing user profile.

Your options are:

Select:	To configure:
Display & Interface	The default display and interface settings for this user. See Display & Interface Settings (page 1805).
System & Menu	The system, match grade, assemble, and playout settings for this user. See System & Menu Settings (page 1807).
Tools	Keyframe interpolation, animation, dust, and colour isolation settings for this user. See Tools Settings (page 1811).

About User Defaults and Session Settings

When configuring your project settings in Lustre, you can configure some parameters as project defaults and others as user defaults. The parameters that are configurable as user defaults become the default settings each time that user logs in and loads a project. However, if you make changes in the Lustre application that

affect the default settings and then save these changes to a grade file, the default settings will be overridden the next time you load the project.

While logged in, the user can override some of the user default settings. However, these overrides only last for the duration of the session. Restarting the application resets the settings to the values set at user creation.

Setting Context Parameters

When a user logs into a particular project in Lustre for the first time, Lustre creates the `<user>context.config` file, where `<user>` represents the user name associated with a user profile. The context file is found in the `C:\project\<project name>` folder in Windows and the `usr/autodesk/project/<project_name>/` directory in Linux. The context parameters include some attributes not defined in the Project or the User Management pages. They are saved and reloaded each time the context (same user and same project) applies. Contextual settings include:

- Last scene
- Last grade
- Viewing options
- Timeline settings
- Crop value
- Audio file
- State of the surface control
- Stereo sync state

Context parameters are stored in the `<user>Context.config` file. For information, see the *Autodesk Lustre Software Installation Guide*.

NOTE The `Context.config` file can be deleted by holding **Shift** and clicking the User Delete button.

NOTE It is recommended that you verify your user-level and project-level parameters in the User and Project configuration menus, prior to starting a project. See [User Configuration](#) (page 1801) and [Project Configuration](#) (page 1776).

Creating a User Profile

The user settings menu allows you to customize your settings so they are used whenever you enter the Lustre application. The settings are broken down into three groups: Display & Interface, System & Menu, and Tools.

Use templates to accelerate user creation. See [Working with Templates](#) (page 1838).

To create a new user:

- 1 Do one of the following:
 - From the Lustre splash screen, click New in the User group.
 - From the Main menu, click Setup, then Settings, and then click New in the User group.

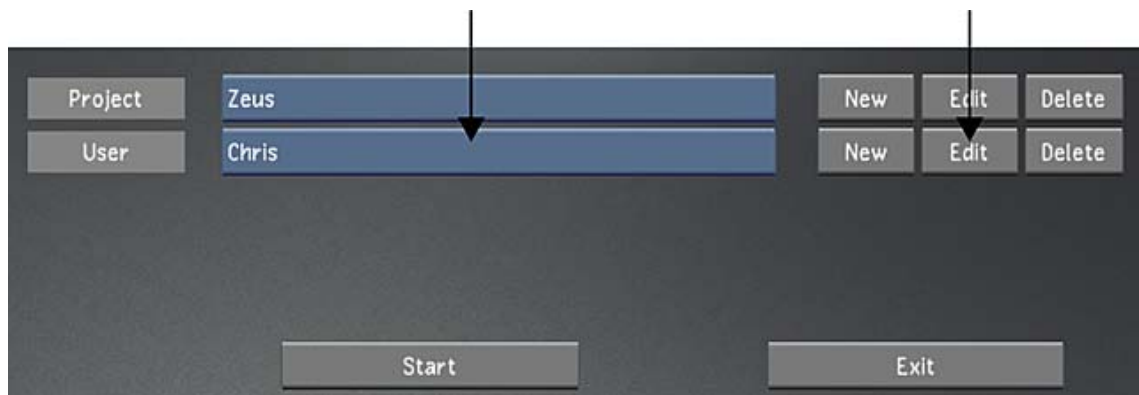

NOTE If you have a template named *default*, then its settings will be loaded automatically.

- 2 Configure the new user. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 3 To save the settings for the user, click Save User.
- 4 Click Exit User.

To create a new user from an existing user:

- 1 Do one of the following:
 - From the Lustre splash screen, select the baseline user, and then click Edit in the User group.
 - From the Main menu, click Setup, and then Settings. Select the baseline user, and then click Edit in the User group.

- 2 In the Project Name field, enter a name for the new project, or you will overwrite the original project's settings with the new settings.
- 3 Configure the new user. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 4 To save the settings for the user, click Save User.
- 5 Click Exit User.

To create a new user using a template:

- 1 Do one of the following:
 - From the Lustre splash screen, click New in the User group. If there is a template named *default*, it will load automatically.

NOTE If you have a template named *default*, then its settings will be loaded automatically.

- From the Main menu, click Setup, then Settings, and then click New in the User group.

- 2 From the User Template list, select the template to use. See [Creating a User Template](#) (page 1842).

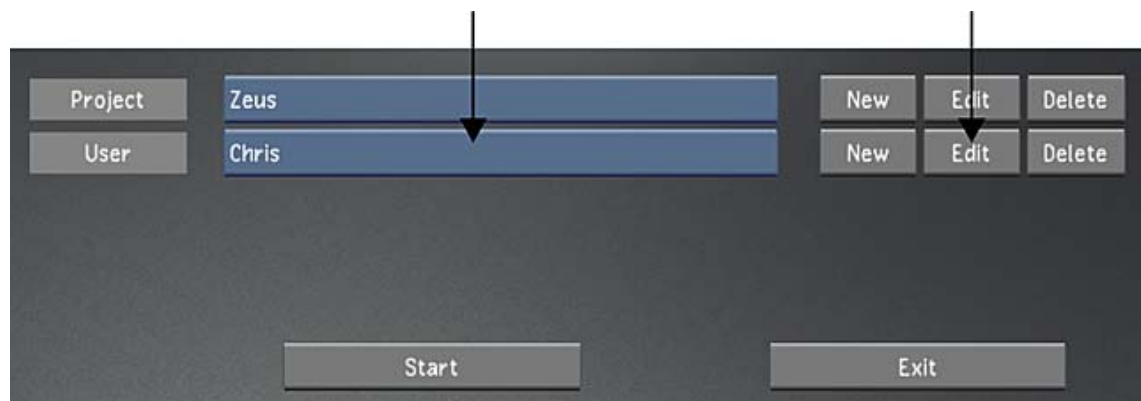

- 3 Click Load.
The template settings are now loaded.
- 4 Configure the new user. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 5 To save the settings for the user, click Save User.
- 6 Click Exit User.

Editing an Existing User

The editing feature allows you to change the settings of an existing user profile.

To edit user settings:

- 1 Do one of the following:
 - From the Lustre splash screen, select the user, and then click Edit in the User group.
 - From the Main menu, click Setup, and then Settings. Select the user, and then click Edit in the User group.

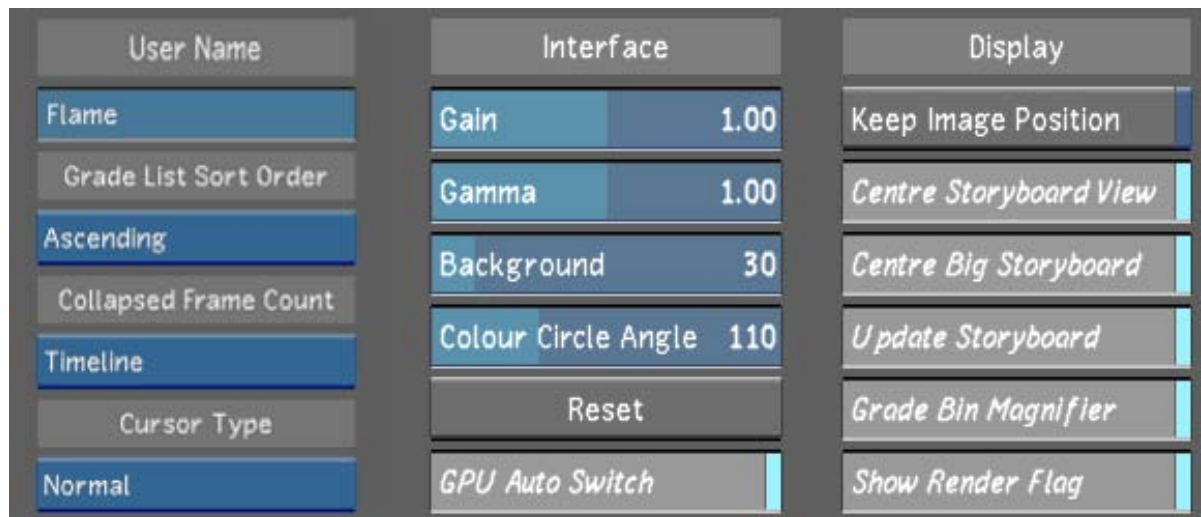

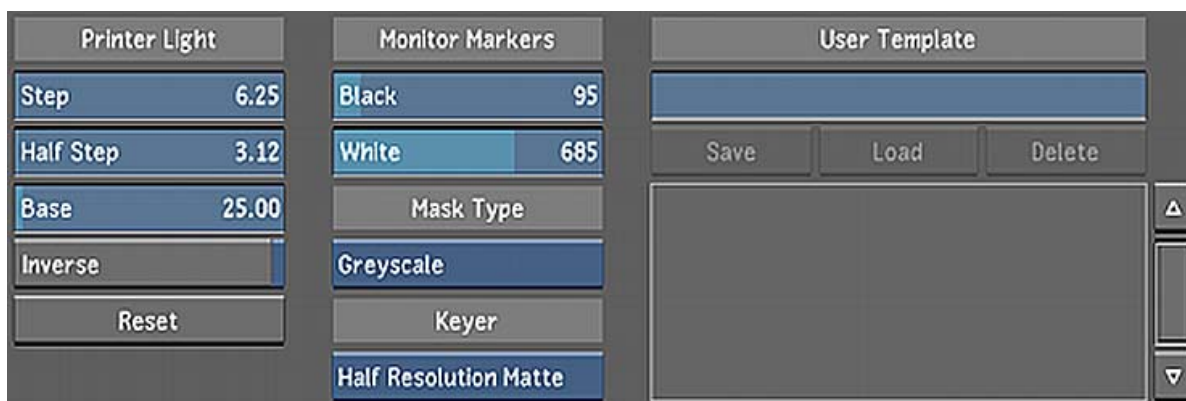

- 2 Edit the user settings. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 3 To save the edits, click Save User.
- 4 Click Exit User.

User Configuration Settings

Display & Interface Settings

Use the Display & Interface Settings page to configure the default display and interface settings for this user.

User Name field Enter your user name in this field. This name appears in the list of users after the user profile is saved.

Grade List Sort Order Define the sort order of the Grade List. Options are:

- Ascending: From grade 001 and up (this is the default option).
- Descending: From the last grade to grade 001.

Collapsed Frame Count Define the numbering of the counter used when working in Collapse mode. Options are:

- Timeline: Displays the counter numbering (record timecode / frame count / feet+frame) relative to the current uncollapsed timeline. This is the default option when creating a new user.
- Collapsed: Displays the continuous counter numbering (record timecode / frame count / feet+frame), based on the record timecode of the first selected shot. Frame counters start at frame 1. This is the default option used in previous versions.

Cursor Type option box Use to select cursor type.

Select:	Cursor:
Normal	Displays the default yellow crosshair cursor.
Micro	Displays a yellow dot as cursor.
Transparent	Displays a transparent cursor.

Gain slider Use to adjust the white point value in the user interface.

Gamma slider Use to increase or decrease the gamma setting in the user interface.

Background slider Use to increase or decrease the background grey settings in the user interface.

Colour Circle Angle slider Use to modify the colour circle angle of the grading colour wheels.

Reset button (Interface group) Use to revert the gain, gamma, background, and colour circle angle back to their default settings.

GPU Auto Switch Automatically disable the GPU processing when using features not supported by the GPU.

Keep Image Position button Enable to maintain the image position in the display when you access the Player. When disabled, the image centres itself in the Player when you hide the user interface.

Centre Storyboard View button Enable to centre the selected shot in the Storyboard.

Centre Big Storyboard button Enable to centre the selected shot when you are viewing the Storyboard in the large Storyboard view.

Update Storyboard button Enable to automatically update the Storyboard thumbnails whenever you make changes to your shot.

Grade Bin Magnifier button Enable to magnify the thumbnail in the Grade bin when the mouse cursor is over a storage container.

Show Render Flag button Enable to display the render flag in the upper-left corner of the screen.

Step slider Use to set the value for one lab light.

Half Step slider Use to change the value for half a lab light.

Base slider Sets the default value for your printer light settings (i.e. red, green, blue (RGB) values).

Inverse button Enable this button in the Printer Light group to invert the printer light density mode.

Reset button (Printer Light group) Click to revert the step, half step, base, and inverse settings to their default value.

Black slider Defines the values of the lines set in the histogram and waveform monitor for black.

White slider Defines the values of the lines set in the histogram and waveform monitor for white.

Mask Type option box Defines the default display mode for the F11 hotkey and the Matte (M) button in the View mode panel.

Select:	To display mattes:
Greyscale	In Greyscale mode. This Mask Type is referred to as Matte view.
Overlay	In Overlay mode. The matte is displayed in its original colour and the unselected region of the matte is overlaid with a uniform colour. This Mask Type is referred to as Secondary view.

Keyer Matte Resolution option box Select the default Keyer matte resolution. Your options are:

- Full Resolution Matte
- Half Resolution Matte

User Template field Enter the name for the template you are creating. See [Working with Templates](#) (page 1838).

Save button Click this button to save the user settings to the template named in the User Template field.

Load button Loads the user template selected in the User Template list.

Delete button Deletes the user template you have selected in the User Template list.

User Template list Displays a list of all the user templates which have been created for Lustre.

System & Menu Settings

Use the System & Menu Settings page to configure the backup options, change shot settings, assemble options, match options, playout settings and background render user preference as well as the panel setup file and the user grade bin and presets directory for this user.

Autosave		History	
Autosave (min)	10	Backup	
Scene Consistency		Change Shot	
AutoCheck		None	
Auto Reparse		Keep Current Grade	
Print View Reparse		Editing While Grading	
Message History		Next Shot Navigation	
Max Messages	100	Go to Next Shot	

Assemble		Match Options	
Auto Cleanup		UID	Source
Auto Match		Record	Custom
Match Grade		EDLReelName FolderReelName DPXReelName DPXKeyCodeStart DPXKeyCodeEnd DLEDClipName DLEDOrigin	
To Layer	Dissolve		
Use Reel Name			
Use DPX Reel			

Playout		Shot Reactor		Burn	
Bars Length		Online			
00:00:05:00		New Job	Start Next	Degrain Only	
Black Length		Degrain Only			
00:00:05:00				Open Home At Start	
Grade Bin & Presets	/usr/discreet/user/grading/[USER_NAME]			...	
Panel Setup File	/usr/discreet/user/grading/[USER_NAME]/acs.rules			...	
Tangent Setup Folder	/usr/discreet/user/grading/[USER_NAME]/precise			... Alt-Precise	

Autosave slider Use to define, in minutes, the frequency with which Lustre automatically saves a backup of the grade and cut you are working on.

Scene Consistency option box Toggle to verify inconsistencies in the file metadata when loading.

Select:	To:
AutoCheck	Check the cut files when loading to look for inconsistencies in the metadata. Results are printed out to the console window.
AutoRepair	Perform the same task as above but additionally, to repair all inconsistencies.
None	Disable the Scene Consistency function in Lustre.

Auto Reparse button Enable to force Lustre to reparse the project structure and source material at start-up.

Print View Reparse button Enable to have Lustre reparse the project structure and source material in Print View.

Message History slider Use to define the number of system messages which Lustre will save in its message history.

NOTE Message History is exclusive to Lustre 2012 Extension 1.

History button Enable to create a history file for each grade whenever you save the grade. Any subsequent grade that you save will also save the cut and grade files to a unique <grdxx_bak> backup directory, which is automatically created in the current scene's library sub-directory in the Project Home location. The backup directory name has the same name as the grade.

Backup button Enable to save a copy of the current grade metadata on the system disk. If you save over your current grade, or save a new grade, a backup copy of all the grade metadata from your current grade is saved in a folder named *backup* that is automatically created in the default location where Lustre is installed (C:\Program Files\Autodesk\Lustre<version> for Windows or usr/autodesk/lustre_<version> for Linux).

NOTE When History is enabled along with Backup, all the cut and grade files from the history backup will also be saved in the system *backup* folder.

Change Shot option box Toggle to define the change operation settings.

Select:	To:
Do	Force a Do operation after moving to another shot.
DoAndClearUndo	Force a Do operation and delete the undo buffer after moving to another shot.
None	Do nothing when moving to another shot.
ClearUndo	Delete the undo buffer after moving to another shot.

Keep Current Grade button Enable to configure Lustre not to remove a current grade from memory when loading a scene.

Editing While Grading button Enable to make editing hotkeys available when you are in the colour grading menus.

Auto Cleanup button Enable to automatically perform cleanup during an EDL assembly. When Lustre performs an EDL cleanup, it arranges EDL events according to record timecode and deletes problematic events. For example, if an EDL has two events with conflicting timecodes, the event with the lower number is deleted during cleanup.

Auto Match button Enable to automatically match EDL event timecodes to available shot timecodes in the Library during assembly.

Match Grade button Enable to apply the current grade settings to a new assembled timeline without having to create a new cut file and use the Change Cut option.

To Layer button Enable to assemble a cut to a new layer above the existing layer(s) in the currently loaded cut.

Dissolve button Enable to include all dissolves in the EDL. If this button is disabled, dissolves are not part of a timeline after the EDL assembly.

Use DPX Reel button Enable to match the EDL reel name to the reel name in the DPX header during an EDL assembly.

UID button Enable to configure matching to be based on the shot's unique ID during EDL assembly.

Source button Enable to configure the matching to be based on the source data, such as a shot's source timecode, during an EDL assembly.

Record button Enable to configure the matching to be based on the record data, such as an EDL's record timecode, during an EDL assembly.

Custom button Enable to use one of the cut file's metadata as matching criteria during EDL assembly.

XML Tag Options list Select one of the cut file's metadata from this list to use as a matching criteria during an EDL assembly. You must enable the Custom button before performing this operation.

Bars Length slider Use the slider to define the default minimum colour bars length when recording in Record mode.

Black Length slider Use the slider to define the default black length time when recording in Record mode.

ShotReactor Online button Enable to automatically enable Lustre ShotReactor when starting Lustre.

ShotReactor Job Priority toggle Set the ShotReactor job priority. Set to Start Next, to place ShotReactor renders next in the queue. Set to Start Last, to place ShotReactor renders at the end of the queue.

ShotReactor Degrain Only button Enable to set the default state of the Degrain Only button in the Render / ShotReactor menu. When this option is enabled, the shot will be rendered with only the Degrain data applied.

Burn Degrain Only button Enable to set the default state of the Degrain Only button in the Render/ Backburner menu. When this option is enabled, the shot will be rendered with only the Degrain data applied.

Open Home At Start button Enable to set the file browser to display the contents of your project's Scans Full directory at start-up.

User Grade Bin & Presets Home field Enter, or browse to, the location of the grade files and presets for the current user. The default path for these files is the User folder of the application. For information about defining paths, see [Browsing for Paths](#) (page 1783).

Panel Setup File field Enter, or browse to, the location of the control panel rules file. The default path for this file is the User folder of the application. For information about defining paths, see [Browsing for Paths](#) (page 1783).

Tangent Setup Folder field Enter, or browse to, the location of the Tangent panel setup folder. The default path for this file is the User folder of the application. For information about defining paths, see [Browsing for Paths](#) (page 1783).

Tools Settings

Use the Tools Settings page to configure keyframe, animation, dissolve, dust, colour isolation and reference image settings for this user.

Keyframe Interpolation	Animation	Dissolve
All Tools	ACS Animation System	Duration 24
Bezier	Shot Based AutoK	Orientation
Primary Tools	AutoK Resets To Shot	Centred
Linear	Hide Inactive Curves	Curve Type
	Autoscroll Playback	Dissolve
Grade Mode Navigation	Hide Inactive Tangents	Interpolation Mode
Keep Current	Lock Keyframe move	Hermite

Dissolve	Dust	Colour Isolation Options	
Duration 24	Contrast 10	Key-in Options	Default keyer
Orientation	Grow 0	Log to lin	Diamond
Centred	Soft Edge 66	Soften 0	Diamond Defaults
Curve Type	Load Dust Data		Softness Scale 1.00
Dissolve			
Interpolation Mode	Reference Image		
Hermite			

Tracker Options	
Tracker Box	Reference Box
Size 40	Size 80

All Tools option box

Toggle to select the default keyframe interpolation mode for all tools, except the input and output primary grading.

NOTE The settings in the All Tools sub-group do not affect tools in the Colour > Grading menu.

Select:	
Linear	Select to use a linear default interpolation for all tools. The linear interpolation joins keyframes with a straight line. This affects all parameters (other than the input and output primary grading) in the Colour menu.
Bezier	Select to make the default interpolation for all tools to be Bezier. The bezier interpolation produces a smooth curve with a smooth transition between keyframes and each keyframe on the curve has tangent handles. This affects all parameters (other than the input and output primary grading) that are in the Colour menu.
Constant	Select to use a constant default interpolation for all tools. Constant interpolation produces a square curve. This affects all parameters (other than the input and output primary grading) in the Colour menu.
Hermite	Enable to make the default interpolation for all tools Hermite. Hermite interpolation produces a smooth curve with a smooth transition between keyframes. This affects all parameters (other than the input and output primary grading) in the Colour menu.

Primary Tools option box

Toggle to select the default keyframe interpolation mode for all primary grading tools.

Select:	
Linear	Select to use a linear default interpolation for all primary grading tools. The linear interpolation joins keyframes with a straight line. This affects all parameters within the Colour menu for input and output primary grading.
Bezier	Select to make the default interpolation for primary grading tools to be Bezier. The bezier interpolation produces a smooth curve with a smooth transition between keyframes and each keyframe on the curve has tangent handles. This affects all parameters within the Colour menu for input and output primary grading.
Constant	Select to use a constant default interpolation for all tools. Constant interpolation produces a square curve. This affects all parameters within the Colour menu for input and output primary grading.
Hermite	Select to make the default interpolation for primary grading tools Hermite. The hermite interpolation produces a smooth curve with a smooth transition between keyframes. This affects all parameters within the Colour menu for input and output primary grading.

Grade Mode Navigation You can enable the Keep Current button to preserve the current grading stage of shots (Primary, Secondary, etc.) as you navigate. This means that when you navigate back to a shot, the last grading stage is automatically recalled.

ACS Animation System button Enable to have Lustre mimic the behavior of the ACS panel when animating from the user interface. Using the ACS Panel, Lustre automatically updates the first keyframe in your timeline

whenever a keyed parameter is modified before the first keyframe or the last keyframe in your timeline
whenever a keyed parameter is modified after the last keyframe.

Shot Based Auto Key button Enable to activate the Auto-key button on a shot basis rather than having AutoKey active for all the shots.

Hide Inactive Curves button Enable to hide animation curves that are not in use. Hiding inactive curves can make it easier for you to manage your keyframes and modify your animations.

Autoscroll Playback button Enable to configure Lustre's default behaviour to scroll automatically when the positioner plays off the edge of the Channel Editor or Timeline.

Hide Inactive Tangents button Enable to hide tangent handles for keyframes that are not selected.

Lock Keyframe move button Enable to allow only vertical movement when dragging a keyframe.

NOTE You can temporarily override locked movement by holding down the Shift key and dragging the keyframe horizontally. If you want to move the keyframe without any restrictions, disable the Lock Keyframe Movement button.

Duration Slider Use to set the default duration, in frames, of dissolves.

Orientation option box Toggle to select Centered, From Cut or Up To Cut as the default orientation of dissolves.

Curve Type option box Toggle to select Dissolve or Blend as the default curve type for dissolves.

Interpolation Mode option box Toggle to select Constant, Linear, Hermite or Bezier as the default interpolation mode for dissolves.

Contrast slider Use to set the amount of contrast used to find dust during automatic analysis. Low contrast values cause the algorithm to accept low colour value differences between corresponding pixels on the current, previous, and next frames. Therefore, low values result in more complete removal of the artefact. However, if the contrast is set lower than actually needed, adjacent pixels are modified more than actually required to remove the dust.

Grow slider Use to control the number of pixels around the pixels detected by Lustre.

Soft Edge slider Use to soften the stroke of the pixels specified by the Grow slider in order to replicate a natural paint stroke.

Load Dust Data button Enable to load the dust removal metadata after you have already loaded the grade.

Reference Image field Enter, or browse to, the path of the reference image. Then, you can press **Shift+K** to load the image into the single file system for reference and then view the image by pressing **L**. For information about defining paths, see [Browsing for Paths](#) (page 1783).

Log to Lin button Enable to apply colour transformation prior to keyer input processing.

Soften slider Use to reduce image grain and noise and to keep edges intact prior to keyer input processing.

Default keyer option box Toggle to select the Diamond Keyer or the HLS Keyer as the default keyer in the secondary menu.

NOTE The default keyer setting only applies to ungraded shots and unused secondaries. A loaded grade file has priority over this setting. This means that the keyer that was used to grade a shot or modify a secondary is the keyer that will be displayed.

Softness Scale slider Use to adjust the scale of the Softness Diamond on the hue cube for the Diamond Keyer.

Tracker Options Define the default size of Tracker and Reference boxes.

Tracker Box slider Use to define the default size of Tracker boxes.

Reference Box slider Use to define the default size Reference boxes.

Loading Users and Projects

After creating a project and defining users, you can start using it. You do so by loading a project and selecting a user profile. This can be done from the Lustre splash screen, or from an already started session.

NOTE When you are already in a Lustre session, you can change both the user and the project independently.

To load a project from the Lustre splash screen:

- 1 Select a project in the Project list.

- 2 Select a user in the User list.

- 3 Click Start.

To load a project or a user during a Lustre session:

- 1 From the Main menu, click Setup, and then Settings.
- 2 (Optional) To load a project, select a project in the Project list and click Load in the Project group.

- 3 (Optional) To load a user, select a user in the User list and click Load in the User group.

- 4 Leave the Settings menu to start working on the loaded project using the loaded user profile.

Working With Scenes

A scene is used to organize your libraries within a given project. A scene called "default" is automatically created with every new project. You can create as many scenes as needed per project.

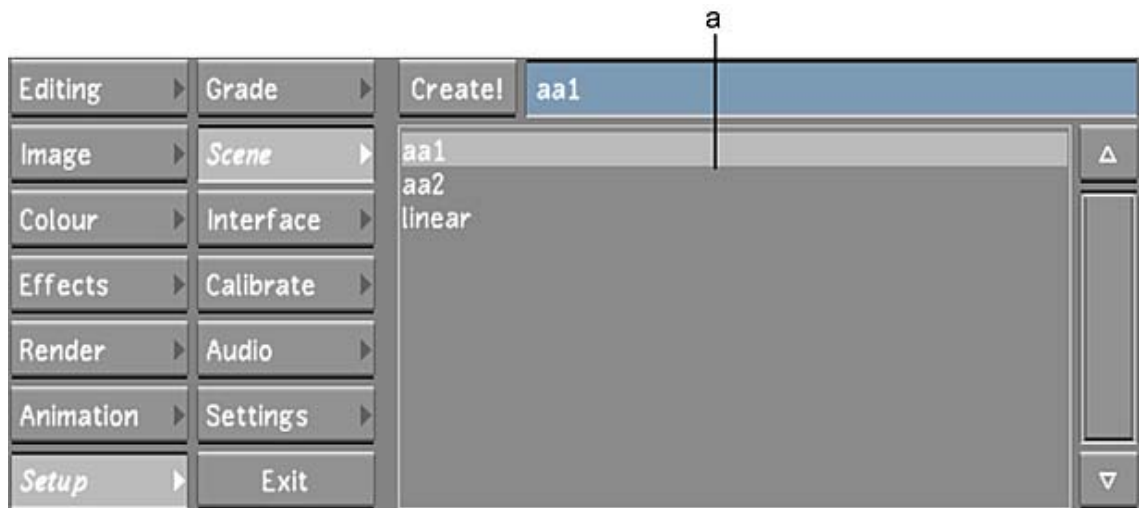

Each Scene folder contains the following folders:

- Audio
- Grade Bin
- Library: this contains all the metadata such as cuts and grades files.

For example, the grade metadata is stored in a file named *grdxx.grade*, where *xx* is the number of the grade file, and the cut metadata is in a file named *cutname.cut*, where *cutname* is the name of the cut.

To create a scene:

- 1 In the Main menu, click Setup, and then click Scene.
The Scene menu appears.

(a) Scene list

- 2 Enter a name for the new scene in the Create Scene field. If there is already a name in the Create Scene field, delete it and then enter the new name. This does not affect the existing scene.

NOTE You can create a scene with the name of an existing sub-directory of the Project Home; in this case, Lustre recognizes the directory as a scene and places the required scene metadata directory inside it.

- 3 Click Create.

The new scene is added to the Scene list. It is highlighted in grey, indicating it is the currently selected scene.

Selecting Scenes

When you select a scene, you gain access to the metadata associated with the scene such as cuts, grade files, the scene-based presets and grade bin, EDLs and audio. Once you select a scene, you then select the grade you want to work on from a list of those associated with the scene. The grade and its associated cut will then be loaded.

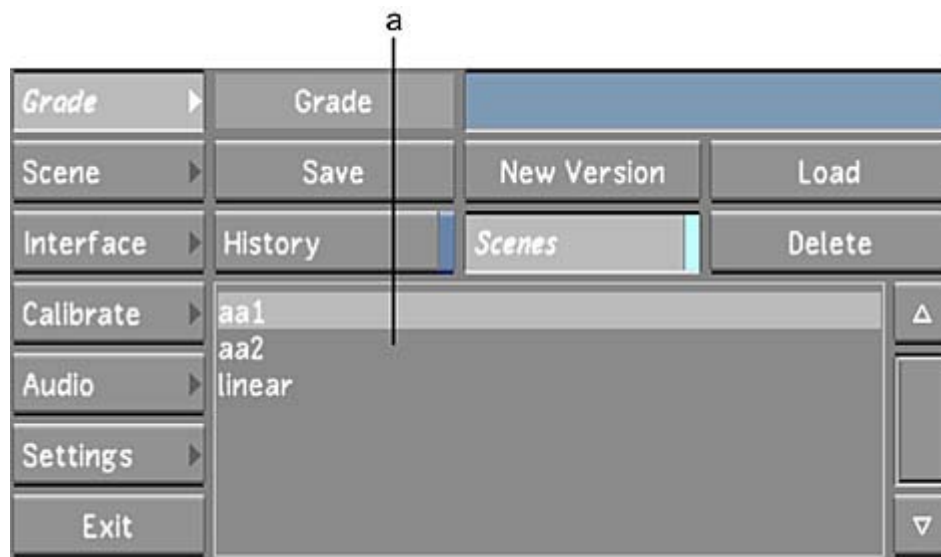

You can select a scene from either the Scene or Grade menu.

To select a scene from the Scene menu:

- 1 In the Main menu, click Setup, and then click Scene.
The Scene menu appears.
- 2 In the Scene list, click a scene to select it.
It is highlighted in grey, indicating it is the selected scene.

To select a scene in the Grade menu:

- 1 In the Main menu, click Setup, and then click Grade.
The Grade menu appears.

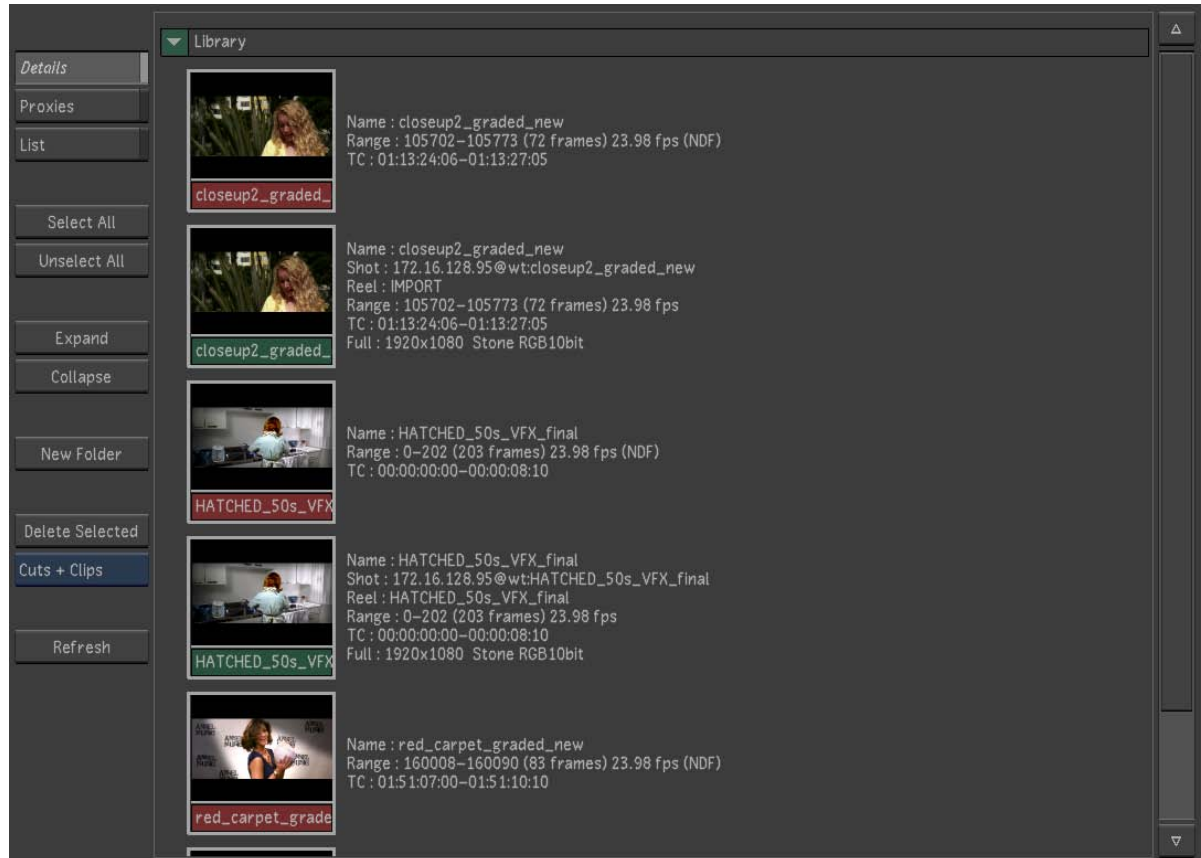

(a) Scene list

- 2 Enable Scenes.
A list of scenes created in the current project appears.
- 3 In the Scene list, click the scene to select it.
It is highlighted in grey, indicating it is the selected scene.

Working with Cuts and Grades

When you create a project, a default scene is automatically created. Within each scene is a Library which contains your source clips (.clip) and timelines or cuts (.cut). A cut is automatically created when importing a Wiretap timeline or assembling an EDL. With source clips imported from the Library, you must create the cut manually.

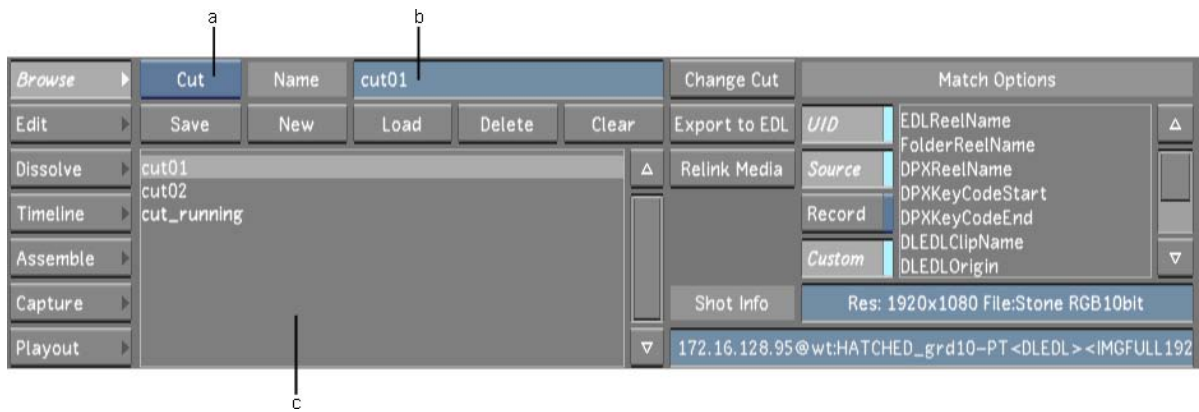

Footage courtesy of EVN PRODUCTIONS

Source clips have green labels; Timelines (or cuts) have red labels.

NOTE Grades are not displayed in the Library because they are managed separately.

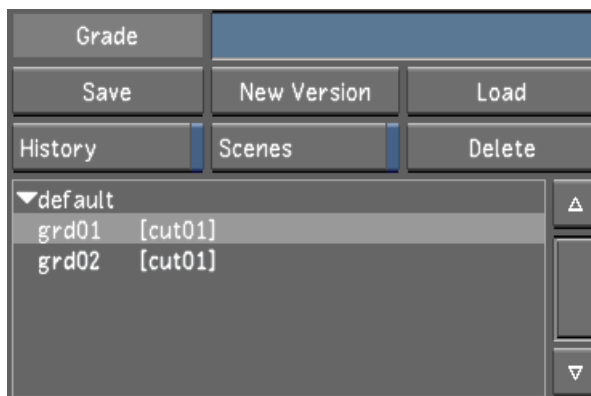

The Browse menu gives you access to all the tools you need to create and manage cuts and change lists. A cut contains edited shots in a timeline, as well as any modifications to the shots such as transcoding, transition effects or Timeline FX metadata from Wiretap.

A change list applies to a specific cut and contains information about how the contents of a cut has changed. When you apply a change list to its parent cut, the cut is modified to match the change list. Change lists are described in [Using Change Lists](#) (page 1821)

As soon as you have created or imported a cut, you need to create an associated grade to contain all the grading information.

A grade is always linked to the cut, but the metadata contained in the grade file is independent of the cut. You can, for example, edit the cut, reorder the shots or add cross-fades, and the grade will not be affected. The grade data for a particular shot will still be linked to it after editing.

When you save the grade, any modifications made to each shot in the associated cut are saved to a grade metadata file. This file is named *grdxx.grade*, where *xx* is the number of the grade file. In addition, any changes made in the Dust menu are saved to a dust metadata file and changes made to the cut (such as trims or dissolves) are saved to the cut metadata file when the grade is saved.

Usually, you save the grade for an entire cut. In some circumstances, it can also be useful to save the grade of an individual shot. See [Saving and Loading Marry Grades](#) (page 1830)

Cardinal rules:

- You can have multiple versions of cuts, but each cut should have an associated grade.
- You can create multiple grade versions that reference the same cut.
- A cut can exist without a grade, but **a grade cannot exist without a cut**, therefore we do not recommend ever deleting a cut still referenced by a grade. This results in the grade still being displayed in the list, without you being able to use it.
- You cannot move a cut to a different folder in the Library once a grade is associated with it, as this will break the link between the cut and the grade.

Managing Cuts

Use the tools in the Browse menu to manage your cuts. You can load, save, change, and delete cuts from this menu.

Cut	Name	cut01		
Save	New	Load	Delete	Clear

The New button is used for creating new cuts from scratch, or creating a new timeline based from an existing cut. When you create a new cut or cut version, you always need to provide a new name for the cut in the Cut name field.

The Save button is used to overwrite an existing cut.

Creating a New Cut

When you create a new scene, you have an empty timeline. Unless you are assembling from an EDL or importing a Wiretap timeline, you must manually create a new cut.

The Save button is for saving editorial changes to a currently loaded cut.

If you want to create a new cut, you will need to click New.

To create a new cut:

- 1 Click Editing, and then click Browse to display the Browse menu.
- 2 Drag source clips from the Browser or Library and drop into the Storyboard or Timeline.
- 3 Enter the name for the new cut in the Cut Name field.
- 4 Click New.

A new cut is created. The name given to the cut appears in the Cut Name list.

To create a new cut version or to save a cut with a new name:

- 1 Click Editing, and then click Browse to display the Browse menu.
- 2 Display the Cut Name list by selecting Cut from the Cut/Change List.
- 3 Select an existing cut from the Cut Name list and click Load.
- 4 Enter the name for the new cut in the Cut Name field.
- 5 Click New.

A new cut is created from the current timeline. The new name given to the cut appears in the Cut Name list.

NOTE It is important to create an associated grade version for the cut, see [Creating a Grade Version for a Cut](#) (page 1822).

Saving a Cut

The most recent changes to a cut are not saved automatically. You explicitly save your cut in the Browse menu, although you can set up a regular autosave interval.

To save a cut:

- 1 Click Editing, and then click Browse to display the Browse menu.
- 2 Click Save.

The cut is saved.

Loading a Cut

You can load an existing cut to resume editorial work on a previously saved timeline.

To load a Cut:

- 1 Click Editing, and then click Browse to display the Browse menu.
- 2 Display the Cut Name list by selecting Cut from the Cut/Change List option box.
- 3 Select the cut in the Cut Name list, and then click Load.

The selected cut is loaded into the timeline.

NOTE You can also load a cut by dragging a Timeline from the Library and dropping into the Storyboard or the timeline.

Clearing a Cut

You can clear the current cut when you no longer need it.

To clear a cut:

- 1 Click Editing, and then click Browse to display the Browse menu.
- 2 Click Clear.
- 3 Click Confirm.

The cut is cleared from the storyboard and the timeline.

Deleting a Cut

You can delete a cut when you no longer need it.

IMPORTANT Do not delete a cut if it has an associated grade file. The grade is dependent upon its cut.

To delete a cut:

- 1 Click Editing, and then click Browse to display the Browse menu.
- 2 Display the Cut Name list by selecting Cut from the Cut/Change List option box.
- 3 In the Cut Name list, select the cut you want to delete.
- 4 Click Delete.
- 5 Click Confirm.

The cut is deleted.

NOTE You can also delete a cut from the Library by selecting the cut thumbnail and clicking 'Delete'.

Using Change Lists

A change list tracks editorial changes to the shots and layers that make up a cut. You use a change list when you want to save changes to a cut without overwriting the cut file. Using this process you can review changes in a cut prior to saving the cut file itself.

The change list tracks the following types of changes:

- Addition/Removal of shots to the cut
- Addition/Removal of layers to the cut
- Rearrangement of shots
- Replacement of shots

A change list always maintains a relationship with the cut from which it is created (the parent cut). You can apply a change list only to its parent cut.

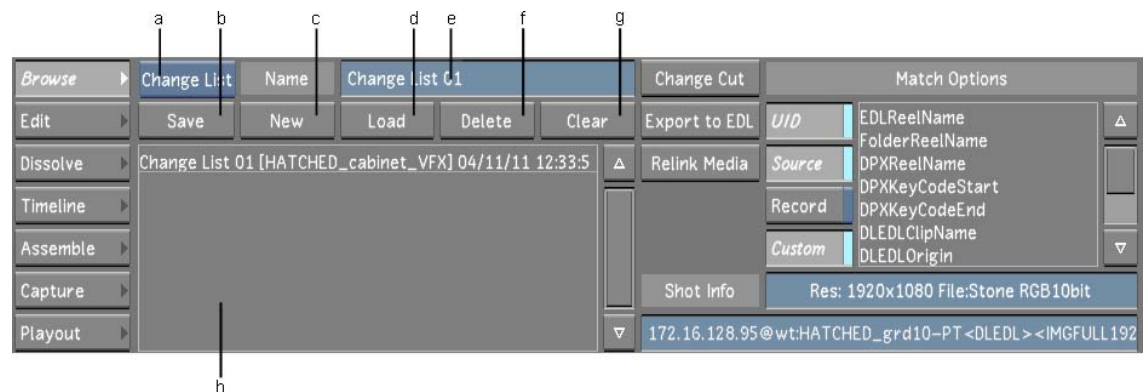

Creating a Change List

After making modifications to the shots in a cut, you can create a change list to save the changes.

To create a change list:

- 1 After modifying the shots in your cut, click Editing, and then click Browse to display the Browse menu.
- 2 Select Change List from the Cut/Change List option box.

The Change List controls appear.

(a) Cut/Change List option box (b) Save button (c) New button (d) Load button (e) Change List Name field (f) Delete button (g) Clear button (h) Change List Name list

- 3 Type a name for the change list in the Change List Name field.
- 4 Click New.

A change list is created. You can see the name of the parent cut in parentheses next to the change list name.

Loading a Change List

You apply the changes stored in a change list to the cut from which the change list was created. This cut is the parent cut.

After you have loaded a change list to its cut, you can continue making changes and save them as a second change list. This second change list contains the changes in the first change list, so should you need to reload all the changes to the parent cut, you do not need to reload the first change list.

To load a change list:

- 1 Load the parent cut to which you want to apply the changes.
 - 2 Select Change List from the Cut/Change List option box.
 - 3 Select the change list in the Change List Name list.
 - 4 Click Load.
- The changes stored in the change list are applied to the parent cut.

Deleting a Change List

You can delete a change list when you no longer need it.

To delete a change list:

- 1 Click Editing, and then click Browse to display the Browse menu.
 - 2 Display the Change List Name list by selecting Change List from the Cut/Change List option box.
 - 3 In the Change List Name list, select the change list you want to delete.
 - 4 Click Delete.
- The change list is deleted.

Managing Grades

Though grades are managed separately from their associated cuts, a grade is dependent upon a cut. You cannot create a grade file without an associated cut.

NOTE Using the Change Cut feature, you can apply a grade to a different cut that contains some or all of the same shots. The grade will be applied to the common shots in the new cut.

See [Changing a Cut](#) (page 1824).

Creating a Grade Version for a Cut

Save the grade to store the grading data on a specific cut. Grades are named using sequential numbers, but you can optionally add a text name to the number.

NOTE You cannot create a grade if a cut is not loaded since a grade needs to always be linked to a cut.

To create a grade for a cut:

- 1 Create or load a cut for which you want to save a grade. See [Managing Cuts](#) (page 1819).
- 2 Work on the grade as needed.
- 3 In the Main menu, click Setup, and then click Grade.

The Grade menu appears.

- 4 In the Grade menu, do one of the following:
 - Click New Version to save the new grade version as a binary file.
 - Hold down `Ctrl` and click New Version to save the grade version as an XML file.
- 5 (Optional) Type a name for the grade in the Grade field and press Enter.

The grade appears in the Grade list under the current scene. It is given a sequential number. If you gave it a name, that name appears in addition to the number. The name of the associated cut appears in brackets to the right of the grade name.

Saving a Grade

When you save a grade by clicking the Save button under the Grade name field in the Setup/Grade menu, the changes are saved by overwriting the currently loaded grade.

IMPORTANT If you have a cut loaded without an associated grade, clicking Save will create grade called "default". If you want to create an actual grade version number, ie. `grd01`, you need to click New Version.

To Save Changes to an Existing Grade:

- 1 In the Main menu, click Setup, and then click Grade. The Grade menu appears.
- 2 Make sure the grade you want to save is loaded.
- 3 Do one of the following:
 - Click Save to save the grade as a binary file.
 - Hold down `Ctrl` and click Save to save the grade as an XML file.

The current settings are saved to the existing grade version.

Loading Grades for a Cut

When you start a work session in Lustre, switch scenes in a project, or want to revert to an older version of a grade, you can select the required grade and load it. This loads both the grade and its associated cut.

WARNING You must save the currently loaded grade before switching to another grade, or you will lose any changes you have made to it.

To load a grade:

- 1 In the Main menu, click Setup, and then click Grade.
The Grade menu appears.
- 2 Click the grade you want to load.
The grade is highlighted in the list.
- 3 Do one of the following:
 - Click Load to load a grade file in binary format.
 - Hold down the `Ctrl` key and click Load to load a grade file in XML format (the XML suffix follows the grade name).

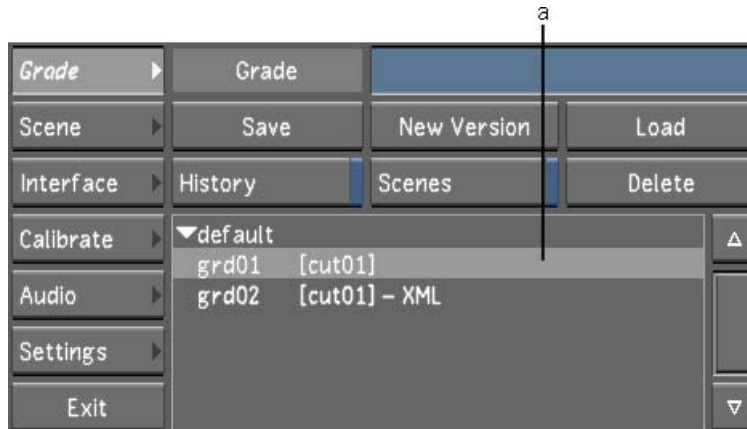

The grade and associated cut are loaded.

Deleting Grades

You can delete grades that you no longer need.

To delete a grade:

- 1 In the Main menu, click Setup, and then click Grade.
The Grade menu appears.

(a) Grade list

- 2 Display and select the grade you want to delete in the Grade list.
It is highlighted in light grey. You do not have to load it.
- 3 Click Confirm.

Changing a Cut

The Change Cut tool allows you to apply the grade settings from the current cut to the new cut you are loading. Flags, notes and Group settings are carried over when you perform a Change Cut.

For example, assume you create a grade with a cut file. You then receive a new EDL and create a new cut from it. This new cut is similar to the first one because it uses many of the same shots, so you would like to use the grade settings that are already done to prevent manually reloading individual grade settings. You load the grade with the original cut, and then change to the new assembled cut. The grade settings that were in the original cut are transferred to the shots that correspond to the Match Options (described below).

The grade is applied to the new cut based on the Match Options (i.e., UID, Source, Record, and Custom). You can base the match on one or multiple options.

NOTE Though the Custom option is enabled by default, nothing is initially selected from the Custom list.

Select:	To:
UID	Match the unique ID of the shots in the original cut to the new cut.
Source	Match the tape/reel name, source ID, and source timecode of the original cut to the new cut.
Record	Match the record timecode of the original cut to the new cut.
Custom	Match the original cut to the new cut based on the keyword that is selected in the custom list.

If the Custom option is enabled, there is a list of keywords to which you can associate the custom option.

Select:	To:
EDLReelName	Match the reel name of the EDL.
FolderReelName	Match the folder reel name.
DPXReelName	Match the DPX reel name.
DPXKeyCodeStart	Match the DPX header keycode start.
DPXKeyCodeEnd	Match the DPX header keycode end.
DLEDLClipName	Match the clip name of the shot coming from the Wiretap server.
DLEDLOrigin	Match the image import path and file name of the timeline coming from the Wiretap server.
DLEDLSourceId	Match the media source's unique ID of the timeline coming from the Wiretap server.

Select:	To:
DLEDLSegmentId	Match the segment's unique ID of the timeline coming from the Wiretap server.
DLEDLStartTc	Match the start source timecode of the timeline coming from the Wiretap server.
EDLComment	Match the unique comment that is applied to the original cut from another application.

The more match options that are enabled, the easier it is to complete an accurate change cut. For example, if you enable UID, Source, and Custom, the same shot can be in the timeline numerous times and the grade will be matched according to the shot's unique ID, tape/reel name, source ID, source timecode, and the custom option you have selected.

Lustre can also apply grading to a new cut on a shot-to-shot (and layer-to-layer) basis, regardless of any matching criteria. This is similar to a direct transfer of grading, depending upon the location of the shots within the timeline. To apply this type of change cut, disable all of the Match Option buttons.

For example, if the original cut is a single layer with two shots, the grade is applied to the new cut's first two shots (if there are more than two shots), even though there is no matching criteria between the shots in the original and new cut.

On a multi-layered cut, if there are two layers of shots in the original cut, the grade is applied to the first two layers of the new cut, on a shot-to-shot basis, even if the new cut has more than two layers. Note that within a multi-layered timeline, the grading is applied to the bottom layer first.

NOTE An alternative to the procedure below is the Match Grade feature. It allows you to apply current grade settings to a new assembled timeline without having to first create a cut file and then apply the Change Cut option. See [Match Grade](#) (page 1944).

To apply a grade with Change Cut:

- 1 Make sure a graded cut is already loaded into the timeline.
- 2 Click Editing, and then click Browse to display the Browse menu.
- 3 Display the Cut Name list by selecting Cut from the Cut/Change List option box.
- 4 Select the cut you want to change the grading to in the Cut Name list.
- 5 Enable the match options you want applied to the change cut.
- 6 Click Change Cut.

The new cut is loaded with the grade settings from the old cut. The storyboard, if displayed, reflects the changes in the following manner:

- Thumbnails of shots to which grading decisions were applied from a Change Cut are updated with the new grade.
- Thumbnails of shots to which grading decisions were applied from a Change Cut, based on partial matching are updated with the new grade and display the Partial Match Flag (orange flag).
- Thumbnails of shots to which grading decisions were not applied from a Change Cut are shown with the Failed Match (red flag). This is due to non-matching criteria or to new shots having been added to the sequence that require grading.

When working with a multi-layer timeline, and Solo mode is disabled, the layers are flattened and only the grade settings from the shots that are visible in the Storyboard are applied to the new cut. When working with a multi-layer timeline and Solo mode is enabled, only the grade settings from the active layer are applied to the new cut. If the new cut has multiple layers, then the grade setting is applied to each layer.

- 7 Click Setup, and then click Grade to display the Grade menu.

- 8 Click New Version to save the grade with the newly associated cut.

Partial Matching for Change Cut

When performing a Change Cut, Lustre uses the various Match options to transfer grading decisions from one cut to another. By default, Strict Matching is enabled and the criteria have to match exactly. In some visual effects workflows however, it happens that file names differ between editorial versions even though they're comprised of the same shots. For these cases, you can perform partial matching using the Custom Match option and disabling Strict matching. For example:

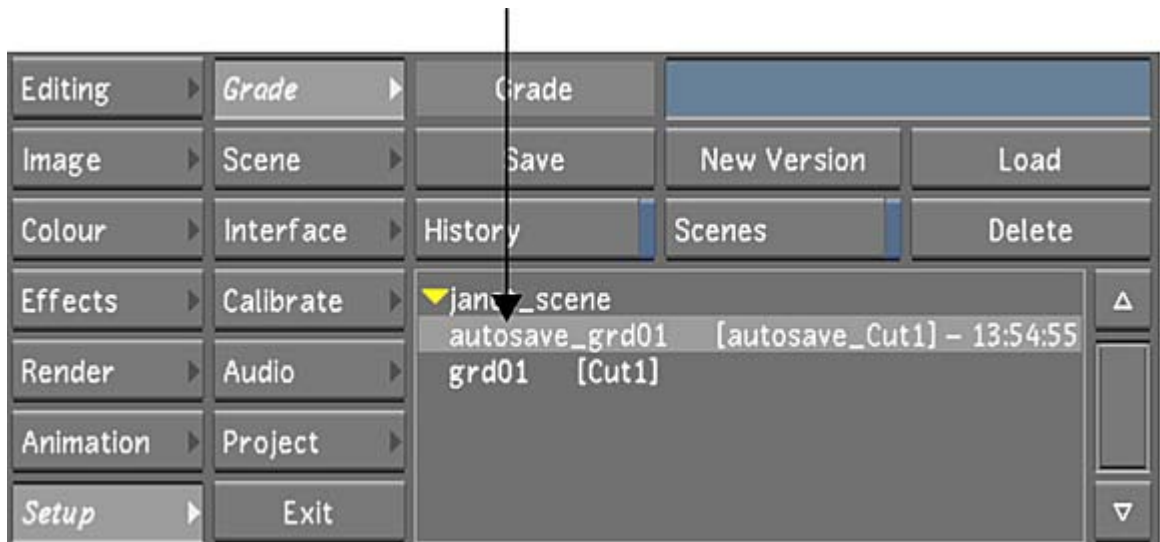

- The original sequence name is seq1_shot1_version1, while the updated sequence name is seq1_shot1_version2.
- The Change Cut is performed based on a Custom / DLEDL Clip name.

The Match is based on partial criteria, and the Partial Match Flag is displayed in the Storyboard.

Autosave Grades and Cuts

The Autosave feature ensures that the current grade and cut from the scene you are working on are backed up at specified time intervals. Only one grade and one cut per scene can be backed up. To enable the Autosave feature, enter an interval in the Autosave field of the System & Menu tab. See [System & Menu Settings](#) (page 1807).

When you are using Autosave, a snapshot of the current grade and cut appears in the Grade list. The word 'autosave_' is added to the beginning of the grade and cut name and a time stamp of the autosave is added to the end.

NOTE The autosave information in the Grade list is not updated according to the Autosave time interval, therefore, you need to press **Ctrl+R** to refresh the information.

A snapshot of the grade, cut, and all their associated files is captured in the Library folder.

There are certain scenarios where an Autosave is performed before its scheduled time interval. These scenarios include the following:

- After you generate proxies

- When you create a new grade (after performing a change cut or restoring an autosaved grade or cut)

Autosave is suspended if you perform a change cut. See [Applying a Grade to a Cut](#) (page 1824). If a change cut is performed, you need to load a grade, save a grade, or create a new grade for the Autosave to reactivate.

To restore an autosaved grade and cut:

- 1 In the Main menu, click Setup, and then Grade.

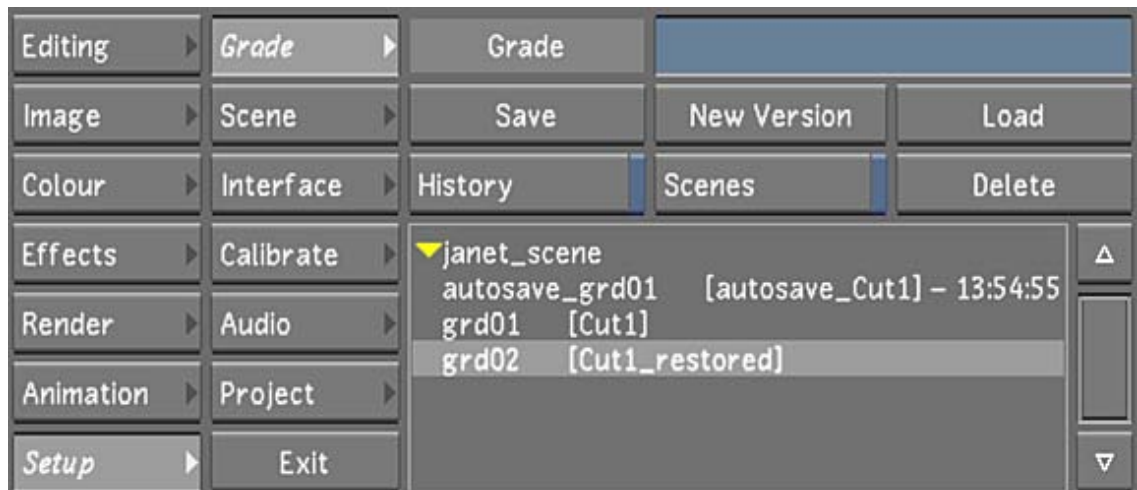

- 2 Press **Ctrl+R** to make sure the most current autosave information is displayed in the Grade list.
- 3 Select the autosaved grade and cut.
- 4 Click Load.

NOTE The autosaved version of the cut file appears in the cut name list (e.g., *autosave_Cut1*).

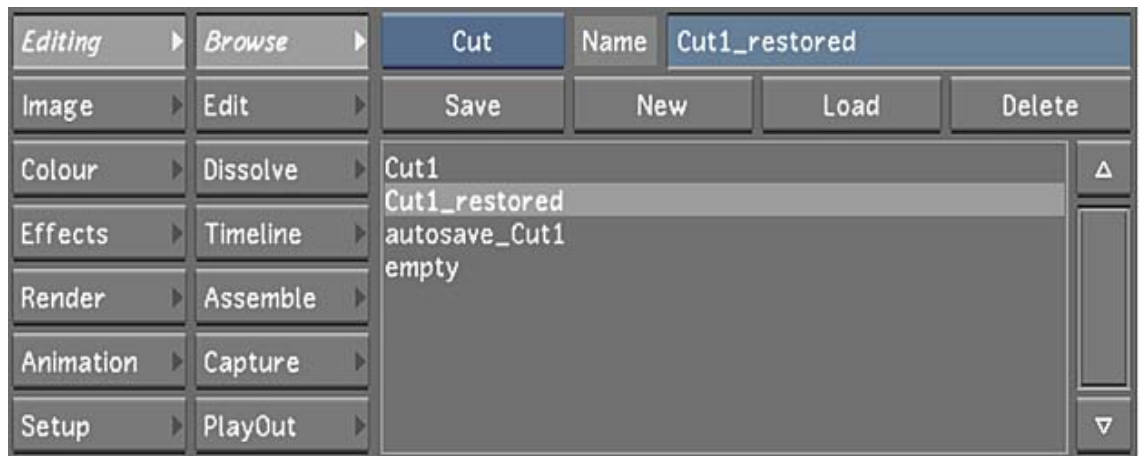

- 5 Click New Version.

NOTE You cannot click Save because you cannot overwrite a loaded Autosave cut and grade.

A new grade is saved and associated with the restored cut.

For the cut file, the existing cut file name is used and *_restored* is added to the end of the name to differentiate the original cut from the one that is restored by using Autosave.

NOTE If you are working with Autosave and multiple grades, you need to use the Grade History list for a list of all the backup grades.

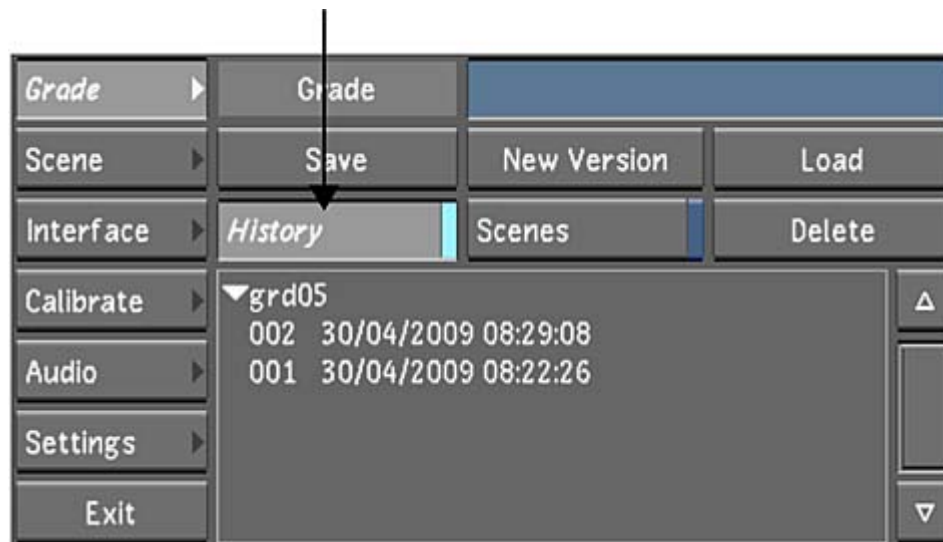

Loading Backup Copies of a Grade

As you save a grade, you can have Lustre save a copy of it each time you click Save. These copies are then available in case you need to revert to a previous version. The date and time of the save is provided to help you identify the version you want to load.

NOTE To save backup copies of grades, you need to first enable the History button when configuring the user. See [System & Menu Settings](#) (page 1807).

To revert to a backup copy of a grade:

- 1 Make sure the grade for which you want a backup copy is loaded. See [Loading Grades for a Cut](#) (page 1823).
- 2 In the Grade menu, click History.

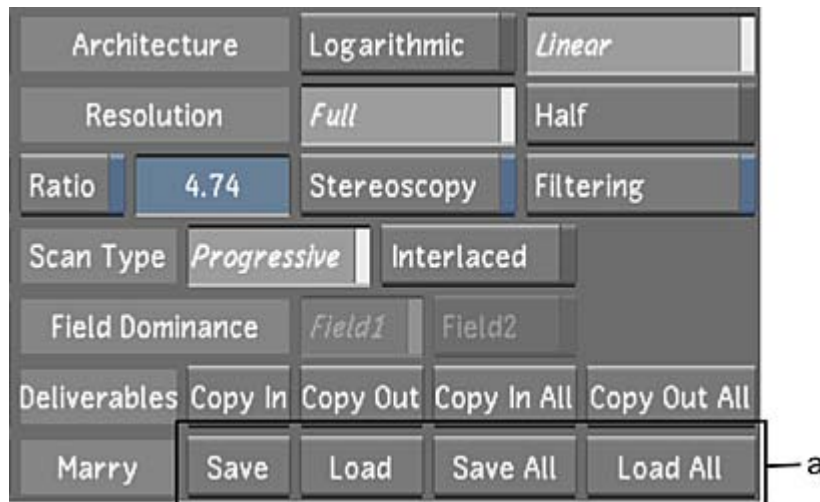

The Grade History list appears. This is a list of backup copies of the currently loaded grade.

- Click the backup version you want to load.
The backup grade is loaded.

Saving and Loading Marry Grades

When you save a grade using the Marry controls, the colour grading metadata is saved separately from the regular grade file. Marry grade files are saved in the same location as the original shots (except for shots imported from Wiretap or the Wiretap Gateway). Marry grade files can also be saved and loaded with the Marry Grade bin thumbnails and Grade view. See [Using the Marry Grade Bin](#) (page 1866).

(a) Marry controls

Marry Grade bin

You can save an individual grade for the current shot or grades for all the shots in the timeline. Similarly, you can load the grade back to the current shot or to all shots in the timeline. One situation where Marry grade files can be useful is if you start your project working on a rough cut of a scene, and later are given the final EDL for the scene. You can save the grades created for particular shots on the rough cut and apply them to shots on the final cut.

Marry grade files can be created with any type of content and are saved along with the original scans files. Marry grades created from Wiretap or Wiretap Gateway media are stored under a local *wt* folder under the Scans Full Home or Scans Half Home.

Marry grade files are saved as binary files by default. You can also save the grading metadata as an XML file.

NOTE You can load Marry grade files from previous versions of Lustre that are in text format. They will be automatically converted into binary files.

The folders in which Marry grade files are saved are named based on the unique identifier (UID) or wedge number of the shot. When you use the Scene Detect function to splice a larger shot into individual shots, each scene-detected shot is also assigned a unique identifier (UID). A shot is also assigned a wedge number, which is a range based on the first and last frame in the shot. A wedge number is also associated to shots that are spliced manually.

NOTE You can find the UID for each shot in the cut file located in your scene's Library folder.

When configuring the Marry Grade panel, select Based on Wedge or Based on UID in the Marry Grade File Location option box. See [Rendering Settings](#) (page 1789).

To save the grade of one or all shots in a cut:

- 1 Click Setup, then click Grade to display the Grade menu.
- 2 If you are saving the grade for one shot, navigate to that shot. See [Navigating through Shots](#) (page 2018).
- 3 Using the Marry controls, do one of the following:
 - Click Save to save the grade for the current shot as a binary file.
 - Click Save All or hold Shift and click Save under the Marry Grade bin to save individual grades for each shot in the cut.
 - Hold down the `Ctrl` key and click either Save or Save All to save the grade(s) in XML format.

To load the grade of one or all shots in a cut:

NOTE To load grades using the Marry controls, the shots in the two cuts must point to the same original footage. If you want to apply the grade of one shot to a different shot, use the Grade bin. See [Using Grade Bins](#) (page 1865).

- 1 Load any cut containing one or more shots for which individual grades have been saved.
- 2 If you are loading the grade of one shot, navigate to the shot.
- 3 Using the Marry controls, do one of the following:
 - Click Load or double-click the appropriate thumbnail in the Marry Grade bin to load the grade of the current shot.
 - Click Load All or hold Shift and double-click the appropriate thumbnail in the Marry Grade bin to load the grades for all shots in the cut.

The grades are loaded to the shots. If the cut contains shots for which no individual grades were saved, those shots are unchanged.

Setting Logarithmic or Linear Mode

Use the Colour Space Architecture options to select between the two basic colour grading modes — Logarithmic and Linear — for use on the project. These modes configure the system and set certain user interface options specific to the mode.

Generally speaking, a project should consist entirely of either Logarithmic or Linear files. For example, film-based projects are usually graded in Logarithmic mode, while video-based projects are usually graded in Linear mode. You should set the architecture to the mode you are planning to work in. If some source files are different from the mode you want to work in, you can convert them before using them. For example, if you are working in Linear mode, and you have a few Logarithmic files, you can convert them to Linear

after bringing them into Lustre. To convert a shot from Logarithmic to Linear and vice versa, use the Input LUT menu. See [About LUTs](#) (page 2069).

The colour space architecture can be set differently per grade, which may be useful in some circumstances, but typically you should set the architecture for the entire project before beginning. Once you start working on your shots, you should not change the architecture as this affects the images and may create unwanted results.

NOTE The colour space setting for rendering also affects images. See [Setting Colour Space Options](#) (page 2269).

Colour Grading Toolset Differences

The colour grading toolset varies depending on if you are in Linear or Logarithmic mode:

- When the colour space is set to Linear, the controls in the Grading menu are customized to reflect the workflow typically used on a video-based project. When set to Logarithmic, the controls reflect the workflow of a film-based project. See [Primary Colour Grading](#) (page 2101).
- Printer lights only appear in Logarithmic mode. See [Adjusting Printer Lights for Primary Grading](#) (page 2104).
- In the Input LUT menu, the controls for creating a Logarithmic to Linear conversion LUT are only available in Linear mode. See [Linear Mode: Creating Conversion LUTs](#) (page 2073).

To set or modify the colour space architecture for the project:

- 1 In the Grade menu, enable Logarithmic or Linear.

See [Project Configuration Settings](#) (page 1784)

Saving Timeline RGB Offsets

You can save the grade for the entire timeline in a file called *primary.txt*. This file is similar to the *.dsc* file, except that the information is timeline-based as opposed to folder-based and cannot be loaded back into Lustre. The benefit of saving timeline RGB offsets is that you can exchange primary grading data with other systems.

The following is an example of what the *primary.txt* file looks like:

GRAO 2

46928774000050 <HOME>/2k/dpx/2048x1556/008_%05d.dpx -64.457 80.586 -16.129

46928774000052 <HOME>/2k/dpx/2048x1556/009_%05d.dpx*-52.922 84.429 -31.507

To save the grade for the timeline:

- 1 Press Shift+G.

The *primary.txt* file is generated in the Lustre export directory, e.g. *C:\Program Files\Autodesk\Lustre<version>\export* on Windows, and */usr/autodesk/lustre<version>/export* on Linux.

The Shift+G hotkey has another function. In addition to saving the primary grading data for the timeline, the hotkey automatically runs batch scripts. This could be used, for example, by a facility to convert the grading data to a LUT or third-party Color Decision List (CDL).

To automatically run a batch script:

- 1 Create a batch script called *primexport.bat*.

- 2 Place *primexport.bat* in the *C:\Program Files\Autodesk\Lustre<version>\export* directory on Windows, and */usr/autodesk/lustre<version>/export* on Linux.
- 3 Press **Shift+G**.
Lustre saves the primary offset RGB values for the timeline in the *primary.txt* file, and automatically runs the batch script.

Setting the Resolution

You can work on the full-resolution version of shots or proxies. Using proxies speeds up interaction and playback of shots containing many effects.

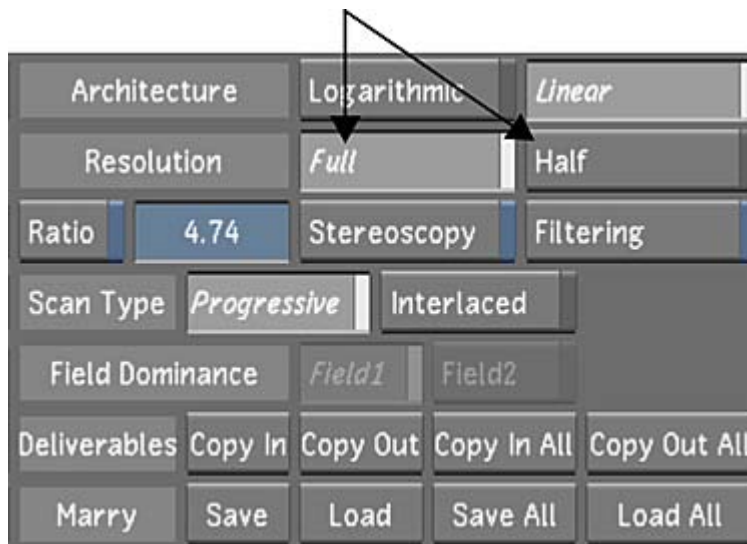

You can switch between full and half resolution at any time. Generating and displaying proxies does not affect your original footage in any way. The resolution is independent of the grade metadata and is therefore completely non-destructive to your work. Metadata is applied to footage only when you render it. You specify the resolution you want for the render files at the time you render.

To display proxies, you must first generate them within Lustre or create them outside Lustre and place them in the project directory structure. If you opt to work on proxies, it is recommended that you generate them as soon as the cut is created so that they will be immediately available for use. See [Generating and Viewing Proxies](#) (page 2271) and [Recommended Directory Structure for Projects](#) (page 1780).

To set the resolution:

- 1 In the Grade menu, enable Full or Half resolution.

TIP You can also use the **F9** hotkey or the **1 / 1/2** button in the View mode panel.

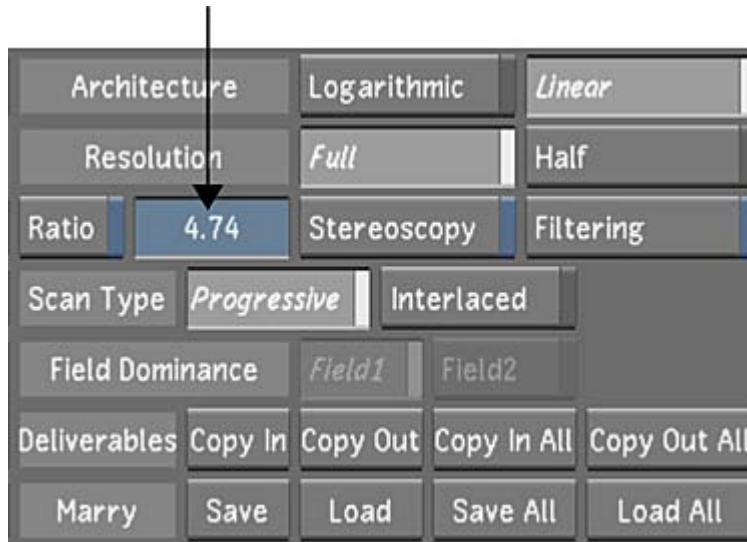

Setting the Aspect Ratio

You can set the display aspect ratio for shots in the project. When you change the aspect ratio, the shots are stretched accordingly.

To set the project aspect ratio:

- 1 In the Grade menu, enable Ratio.
- 2 Enter the aspect ratio in the Ratio field.

The shots are stretched to fit in the specified aspect ratio.

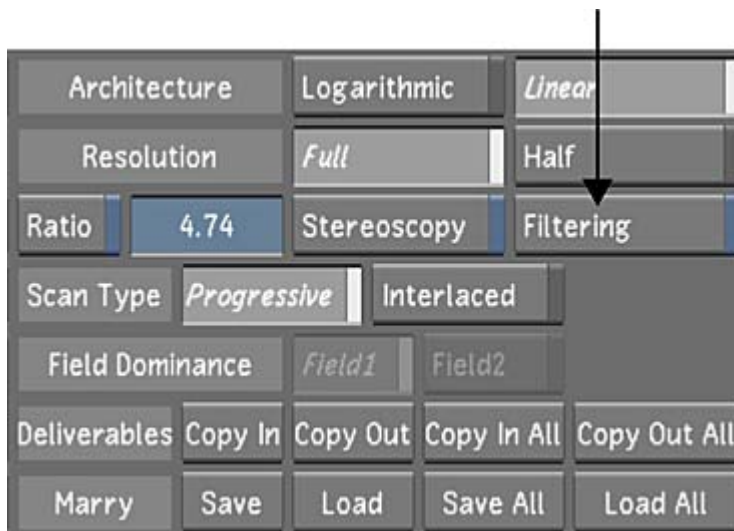

Setting the Filtering

The Filtering option allows you to soften your shot so when you zoom in, the pixels are not as sharp or obvious.

If the Filtering option is enabled during playout with GPU acceleration, the filtered image will be played out to tape.

NOTE The Filtering option should be disabled when you want to isolate the colour of a pixel so it can be used with the HLS and Diamond Keyers.

To enable the filtering option, access the Grade menu and enable the Filtering button.

Setting Up the User Interface

Use the controls in the Interface menu to set the appearance of the user interface to your liking. For example, you can set the user interface to suit the room lighting conditions as well as control the display of a matte overlay by adjusting the opacity and RGB parameters of the unselected region of the matte. From the Interface menu, you can also add an overlay, such as a logo, to your cut.

To access the Interface menu:

- 1 In the Main menu, click Setup, and then click Interface.
The Interface menu appears.

(a) Gain slider (b) Matte Overlay (c) Gamma slider (d) Background slider (e) Colour Circle slider (f) Overlays field (g) Update Storyboard button

The Interface menu is made up of the following elements.

Background field Sets the shade of grey of the area surrounding the player window.

Gamma field Sets the brightness of the midtones of the menu area. The gamma primarily affects the grey areas of the menu, such as button backgrounds.

Gain field Sets the overall brightness of the menu area. The gain primarily affects lighter areas of the menu, such as text.

Colour Circle field Sets the position of colours in the colour wheels found in the Grading menu. The default rotation degree is 110.

Reset button Resets all parameters in this menu to the default values.

Overlay list Includes a list of all files that can be applied as an overlay. See [Applying Overlays](#) (page 1836).

Update Storyboard button Enables and disables the option to automatically update the storyboard thumbnails as you make changes to the shots within your timeline. See [Updating the Storyboard Thumbnails](#) (page 2023).

Matte Overlay Settings

When you perform secondary colour grading, whether with a geometry, a key, or an external matte, it is important to see what part of the image is being affected by the matte. The Matte Overlay feature displays the matte in its original colour, while overlaying the unselected region of the matte with a uniform colour, allowing you to see the precise area of your image that will be colour corrected.

Opacity Sets the opacity of the unselected region of the matte between fully transparent (0) and fully opaque (1).

RGB Set the intensity of the red, blue, and green colours for the unselected region of the matte.

Reset button Resets the Matte Overlay parameters to default values.

You can modify the Matte Overlay settings at any time when you are performing secondary colour grading without affecting the image output. See [Adjusting the Colour and Opacity of a Matte Overlay](#) (page 2149).

NOTE Matte Overlay settings are saved per user; therefore, any changes are saved to the current user profile.

Applying Overlays

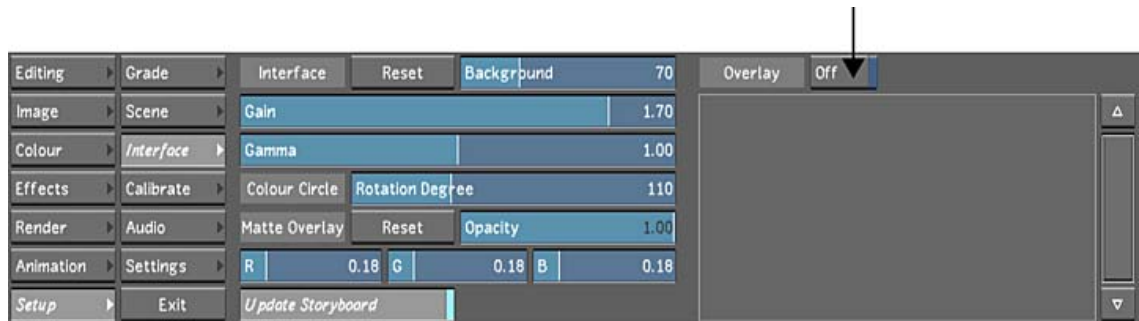

Use this feature to apply an overlay to your cut. For example, you can add a logo to every frame. An overlay consists of a single uncompressed RGBA, TIFF, or SGI® file containing alpha channel information. The white areas of the file are viewable in the cut.

To make files available for use as overlays:

- 1 Exit Lustre.
- 2 Navigate to the Lustre directory by doing one of the following:
 - If using the Windows version of Lustre, in Windows Explorer, go to *C:\Program Files\Autodesk\Lustre<version>*, where *C* is the drive where Lustre is installed.
 - If using the Linux version of Lustre, type:
cd /usr/autodesk/lustre<version>
- 3 Create a directory called *overlay*. To do this in Linux, type:
mkdir overlay
- 4 Place any files you want to use as overlays in this directory. To do this in Linux, type:
cp / <path>/<filename>/usr/autodesk/lustre<version>/overlay
- 5 Restart Lustre.

To apply an overlay to a cut:

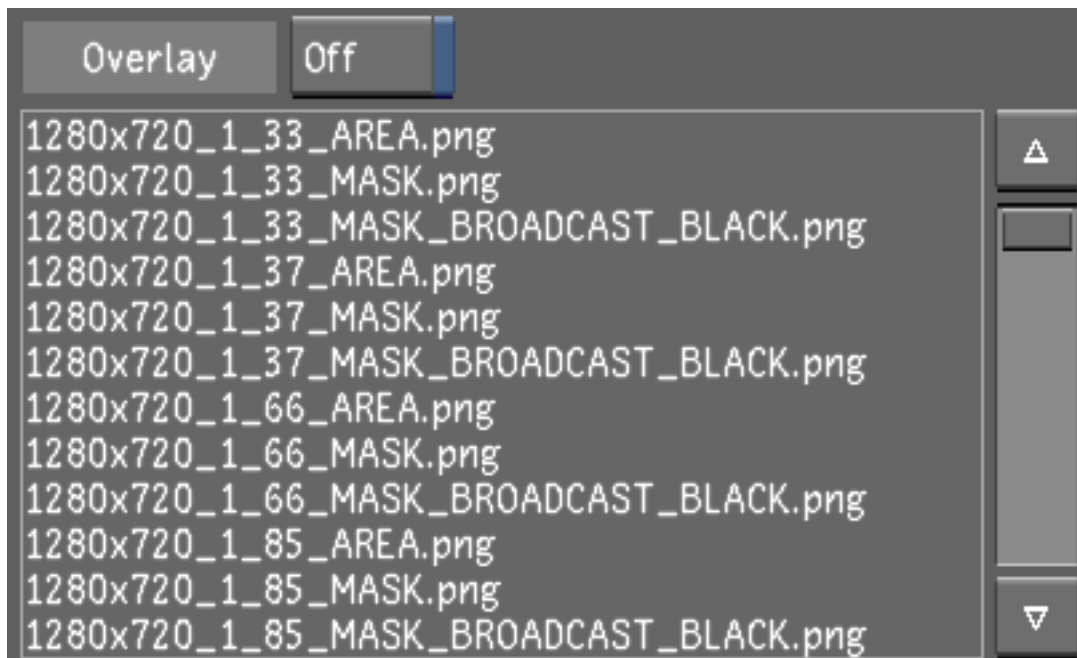

- 1 Load the cut to which you want to apply an overlay. See [Managing Cuts](#) (page 1819).
- 2 In the Main menu, click Setup, and then click Interface.
The files in the *overlay* directory appear in the Overlay list.
- 3 Click the overlay file that you want to apply.
It is highlighted.
- 4 Enable On/Off.

The overlay is applied to the cut.

Overlay Presets

In the Setup / Interface menu, you can select an overlay from a list of overlay presets to apply to your media. You can use these overlays for play out to VTR.

The following overlay presets are available:

- **Area:** White outline showing the framing of the selected resolution and aspect ratio.
- **Safe:** White outline showing the full image area, the safe action and the safe title.

- **Mask:** Black mask showing the framing of the selected resolution and aspect ratio.
- **Mask Broadcast:** Use this mask when you want to playout the full video signal of the grade to VTR, using the Full Range playout option.

Overlays are available for the following resolutions:

- NTSC (720x486)
- PAL (720x576)
- 1280x720
- 1920x1080
- 2048x1556

NOTE Overlays are not saved with the grade file. They are a user interface attribute that is saved with the session. Overlays cannot be rendered to files.

See [VTR Playout and Full Range Video Signal](#) (page 1838).

VTR Playout and Full Range Video Signal

You can play out grades from Lustre to VTR, using the full video range (0 to 255 in 8-bit and 0 to 1024 in 10-bit). To do so, select the Full Range playout option. In this mode, the black and white levels are remapped to the full video range. Make sure the following settings are in place prior to output to VTR:

- In the Project Management / Engineering tab, set the Virtual Black Clip Color to RGB 16-16-16 (for 8-bit) or 64-64-64 (for 10-bit). This creates a legal black video signal for black media.
- If your timeline contains one or multiple gaps on video layer 1, make sure to replace these segments with virtual black. Alternatively, if your timeline contains so many gaps as to render the substitution impractical, insert a video layer underneath the first video layer and insert a virtual black clip spanning the length of the timeline.
- To use letterbox on your playout, use one of the Broadcast Black overlays provided instead of using Image / Reposition or Render / Resize. These Broadcast Black overlays have a black video level that, when remapped, is set to legal black video level.

Working with Templates

Use templates to define re-usable presets for future projects or users.

Creating a Project Template

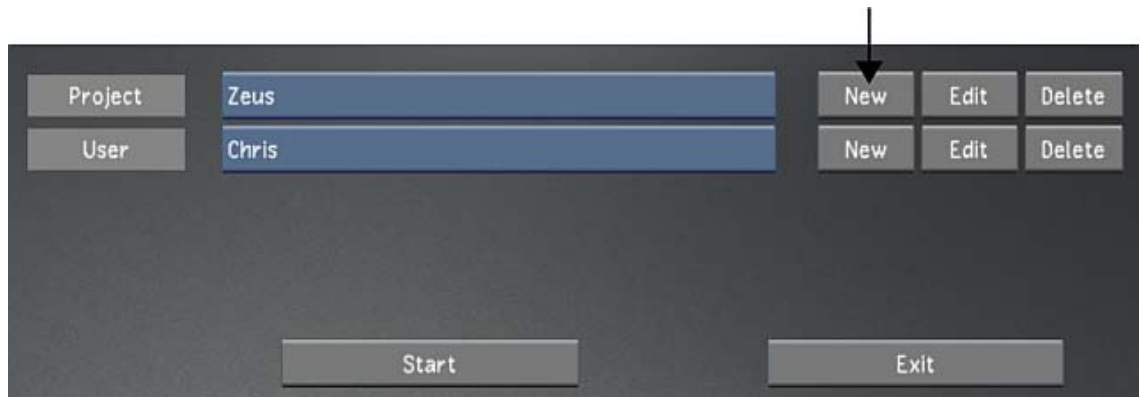

When you are choosing your project settings, you can create a template for your future projects.

From the Project Template group, within the Project settings page, you can complete the following:

- Create a new project template.
- Create a new project template from an existing project.
- Create a new project template from an existing project template.

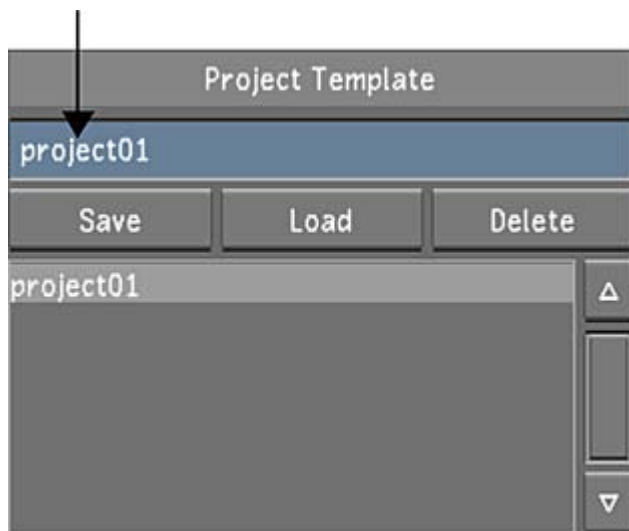

To create a new project template:

- 1 Do one of the following:
 - From the Main menu, click Setup, then Settings, and then click New in the Project group.
 - From the Lustre splash screen, click New in the Project group.

NOTE If you have a template named *default*, then its settings will be loaded automatically.

- 2 Configure the settings for the template. Use Reset to reset all settings, from every menu, to their defaults.
- 3 When you are done editing the settings, click Project, and enter a project name in the Project Template field. See [Project Configuration](#) (page 1776).

- 4 In the Project Template group, click Save.
- 5 To exit, click Exit Project.

To create a new project template from an existing project:

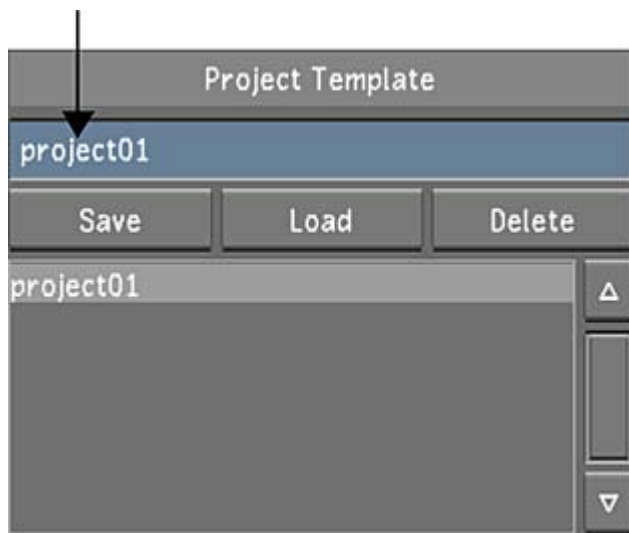

- 1 Do one of the following:
 - From the Main menu, click Setup, and then Settings. In the Project group, select the baseline project, and then click Edit.
 - From the Lustre splash screen, select the baseline project, and then click Edit in the Project group.

- 2 Configure the project. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).

WARNING Rename the new project, or you will overwrite the original project's settings with the new settings.

- 3 Click Project and enter a name in the Project Template field.

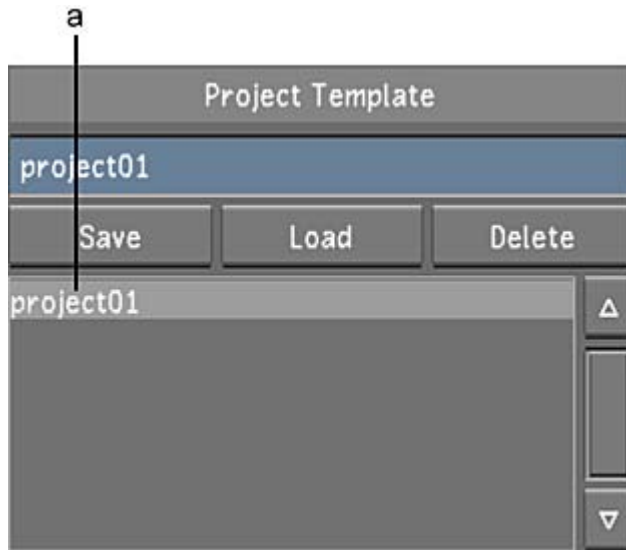

- 4 To save the template, click Save in the Project Template group.
- 5 Click Exit Project.

To create a new project template from an existing project template:

- 1 Do one of the following:
 - From the Main menu, click Setup, and then Settings. Select the project to edit, and then click Edit in the Project group.
 - From the Lustre splash screen, select the project to edit, and then click Edit in the Project group.

- 2 From the Project Template list, select a template.

(a) Project Template list

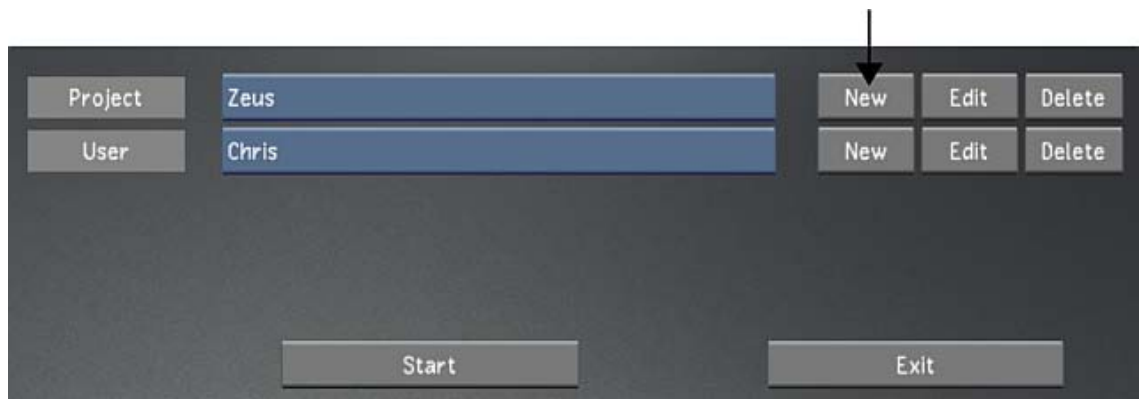

- 3 Click Load.
 - 4 In the Project Template field, enter a new template name, and then click Save.
- WARNING** Rename the new template, or you will overwrite the original template with the new settings.
- 5 Configure the template. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).
 - 6 To save the template, click Save in the Project Template group.
 - 7 Click Exit Project.

Editing a Project Template

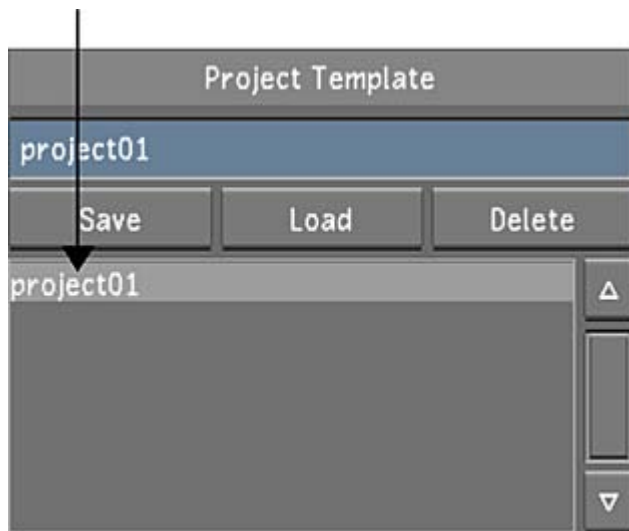

As you create project after project, there may come a time when you need to change a few of the settings and you do not want to create an entire new template. You can accomplish this by using the edit feature.

To edit a project template:

- 1 Do one of the following:
 - From the Main menu, click Setup, then Settings, and then click New in the Project group.
 - From the Lustre splash screen, click New in the Project group.

- 2 From the Project Template list, select the template to edit.

- 3 Click Load.
- 4 Configure the template. Use Reset to reset all settings, from every menu, to their defaults. See [Project Configuration](#) (page 1776).
- 5 To save the template, click Save in the Project Template group.
- 6 Click Exit Project.

Creating a User Template

When creating a user, you can save the setup as a template for other users.

From the User Template section in the Display & Interface settings, you can do the following:

- Create a new user template.
- Create a new user template from an existing user profile.
- Create a new user template from an existing user template.

To create a new user template:

- 1 Do one of the following:
 - From the Main menu, click Setup, then Settings, and then click New in the User group.
 - From the Lustre splash screen, click New in the User group.

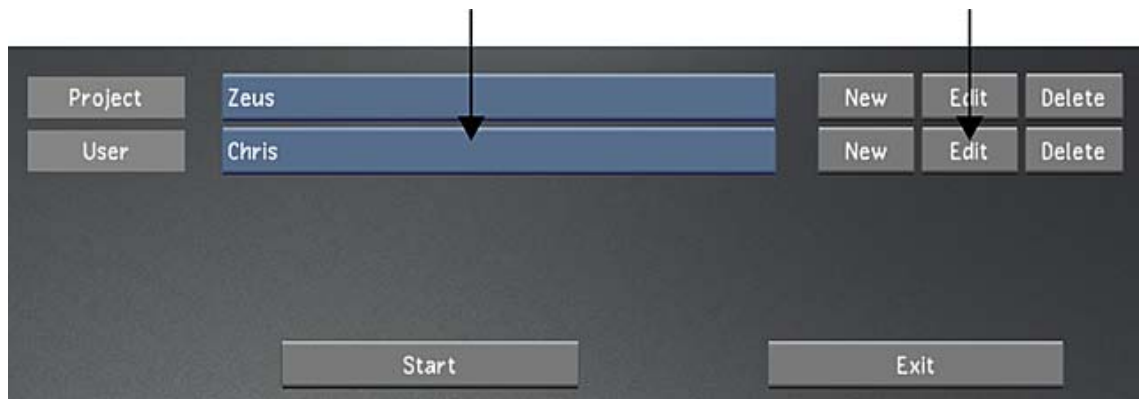

- 2 Configure the new user. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 3 Click Display & Interface, and enter a name in the User Template field.

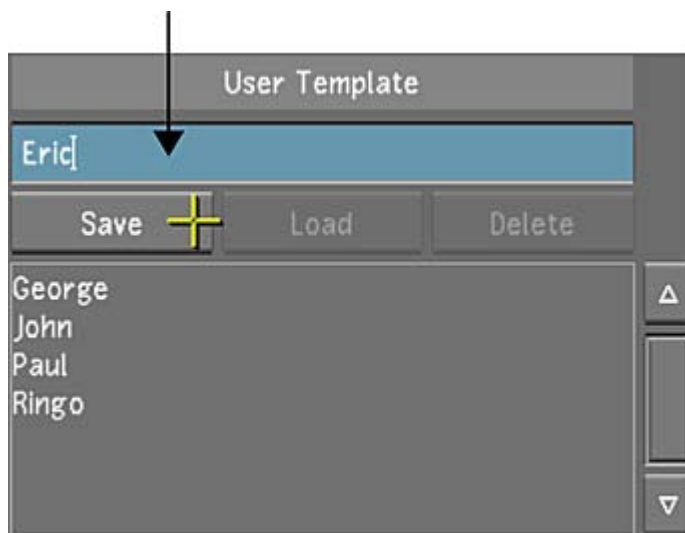

- 4 To save the template, click Save in the User Template group.
- 5 Click Exit User.

To create a user template from an existing user profile:

- 1 Do one of the following:
 - From the Main menu, click Setup, and then Settings. Select the baseline user, and then click Edit in the User group.
 - From the Lustre splash screen, select the baseline user, and then click Edit in the User group.

- 2 Configure the new template. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 3 Click Display & Interface and enter a new name in the User Template field.

- 4 To save the template, click Save in the User Template group.
- 5 Click Exit User.

To create a new user template from an existing user template:

- 1 Do one of the following:
 - From the Main menu, click Setup, then Settings, and then click New in the User group.
 - From the Lustre splash screen, click New in the User group.

- 2 From the User Template list, select the template to use as baseline.

- 3 Click Load.
 - 4 In the User Template field, enter a new template name, and then click Save.
- WARNING** Rename the new template, or you will overwrite the original template with the new settings.
- 5 Configure the template. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
 - 6 From the User Template list, select the new template.
 - 7 To save the template, click Save in the User Template group.
 - 8 Click Exit User.

Editing a User Template

The template editing feature is available for you to make minor changes to existing templates as they are needed.

To edit a user template:

- 1 Do one of the following:
 - From the Main menu, click Setup, then Settings, and then click New in the User group.
 - From the Lustre splash screen, click New in the User group.

- 2 In the User Template group, select the user template to edit.

- 3 Click Load.
- 4 Configure the template. Use Reset to reset all settings, from every menu, to their defaults. See [User Configuration](#) (page 1801).
- 5 To save the template, click Save in the User Template group.
- 6 Click Exit User.

Basics

This chapter introduces basic functionality for Lustre. It provides an overview of the user interface and control surfaces, and explains global features such as undo/redo and the Grade bin.

Starting and Exiting Lustre

To start Lustre, use any of the standard methods for opening an application in Windows or Linux.

To start Lustre:

- 1 Start the application by double-clicking the desktop icon, or by doing one of the following:
 - If using the Windows version of Lustre, select Start | Programs | Autodesk | lustre from the Windows task bar.

- If using the Linux version of Lustre, it is recommended to log into the Lustre environment. If you open a Linux shell, it will automatically place you in the Lustre directory:

/usr/Autodesk/<lustre version>/

Next, start Lustre. Type:

./lustre to start the Lustre application.

Lustre starts with all the settings you used when you last exited. For example, it loads the project, cut, and grade you were working with and places the positioner on the frame you were on.

NOTE If Lustre cannot find a license, the Flex LM® wizard appears, requesting the location of the license file.

To exit Lustre:

- 1 In the Main menu, click Setup.
- 2 Click Exit and confirm.

TIP You can also exit the application by pressing SHIFT + Insert.

Understanding the Lustre User Interface

The Lustre user interface is divided into four main sections.

Footage courtesy of EVN PRODUCTIONS (a) Player display controls (b) Player (c) Storyboard (d) Menu

Most sections display different kinds of information, depending on user preferences and the action being performed.

The Player

This section of the user interface is generally used for viewing the currently selected shot in the Storyboard. However, you can also use it to:

- Display the Library and file browser in order to select footage to add to the Storyboard. See [Browsing for Footage](#) (page 1901).
- View and modify EDL details. See [Working with EDL, ALE, and Cutlist Files](#) (page 1935).
- Display Colour menus. See [Displaying Colour Menus in the Player](#) (page 2085).
- Monitor capture progress. See [Capturing Material](#) (page 2305).

The Storyboard

Use the Storyboard to select shots, arrange shots, navigate through shots, and isolate certain types of shots. Using hotkeys, you can also copy grades to shots via the Storyboard. See [Navigating through Shots](#) (page 2018) and [Storyboard Viewing Options](#) (page 2022).

Player Display Controls

Below the Storyboard, there are controls for:

- Resetting the current menu. See [Resetting Parameters](#) (page 1849).
- Bypassing the current menu. See [Bypassing Menu Parameters](#) (page 1850).
- Undoing and redoing actions. See [Undoing and Redoing Actions](#) (page 1850).
- Setting play and view options for shots. See [Playing, Viewing, and Sorting Shots](#) (page 2011).
- Adjusting printer light settings. These display only when a Colour menu is active. See [Adjusting Printer Lights for Primary Grading](#) (page 2104).
- Setting keyframes automatically. See [Animating Reposition Values](#) (page 2067) and [Animating with Keyframes](#) (page 2219).

The Menu Section

The menu section in Lustre is organized from left to right. The first column of buttons are the main menus. Clicking a main menu displays its sub-menu buttons in the next column. Clicking a sub-menu displays its functions in the central part of the menu. Menu functionality is addressed by other chapters in this guide.

On the right side of the menu are features that, for the most part, are globally applicable. These features include:

- The Notes window. See [Assigning Notes to Shots](#) (page 1852).
- The Flags system. See [Flagging Shots](#) (page 1853).
- Grouping functionality. See [Creating Shot Groups](#) (page 1855).
- The Selector. See [Copying Parameters with the Selector](#) (page 1860).
- The standard Lustre calculator. See [Assigning Values With the Standard Lustre Calculator](#) (page 1864).
- The Grade bin. See [Using Grade Bins](#) (page 1865).

Working with Control Surfaces

Lustre supports the Tangent Element control surface, the Tangent CP100 control surface and the Autodesk control surface (ACS). All three control surfaces improve interactivity when colour grading film and video footage, and allow you to accomplish many of the tasks you do in the Lustre user interface.

See [About the Tangent Element Control Surface](#) (page 2425)

See [The Tangent CP100 Control Surface](#) (page 2533)

See [The Autodesk Control Surface](#) (page 2468)

Resetting Parameters

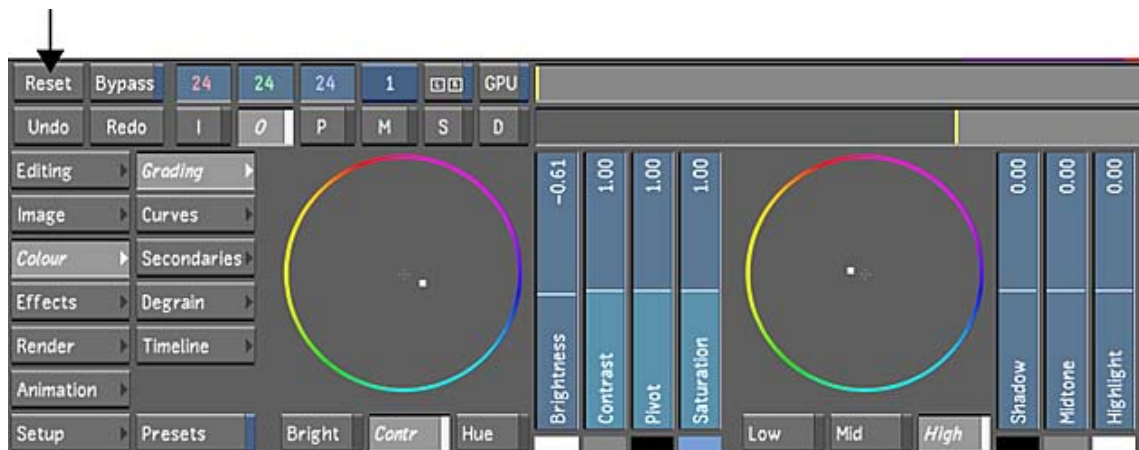

You can reset parameters on a shot-by-shot basis. You can either reset a parameter, reset all parameters in a menu, or reset a shot to its original state.

To reset a parameter:

- 1 After making a change to a parameter, hold down the **Ctrl** key and then click the parameter (field, graph, or option).
The parameter is reset.

To reset all parameters for a menu:

- 1 Select the shot you want to reset.
- 2 Access the menu you want to reset.
- 3 Click Reset, and then confirm.

The menu is reset.

To reset a single shot to its original state:

- 1 Select the shot that you want to reset.
- 2 Press the **R** key twice.

TIP You can also double-click an unused storage container in the Grade bin to remove any grade or repositioning from the selected shot.

The shot is reset to its original state.

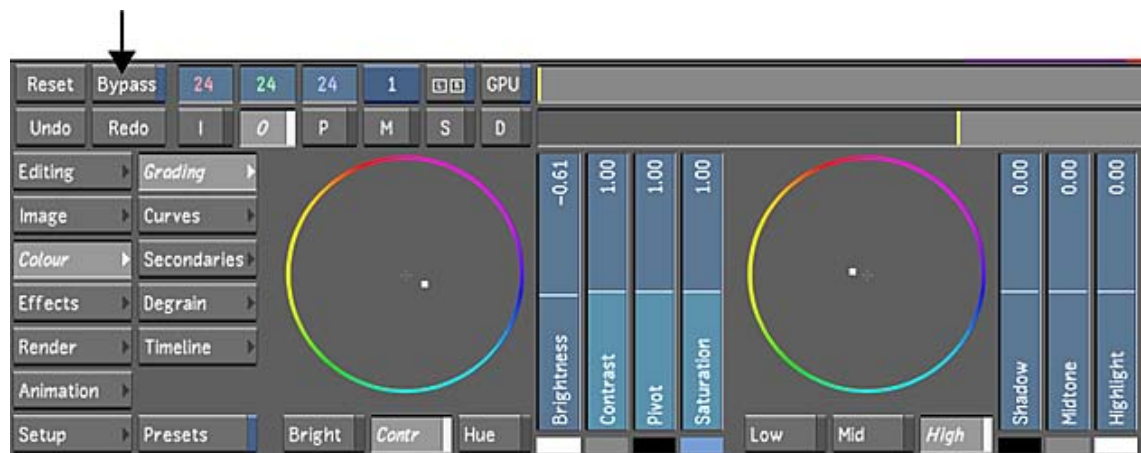

Bypassing Menu Parameters

You can bypass the parameters of a single menu or all menus to view a shot as if the menu or menus had not been modified. Do this when you want to compare the original shot to the modified shot. Bypassing differs from resetting in that you can toggle Bypass on and off, whereas you have to undo a reset operation to return to the previous state. By toggling Bypass off and on, you can easily compare the original shot to the modified one. You can bypass the following menus either singly or simultaneously:

- Grading
- Curves
- Secondaries
- Effects

To bypass menu settings:

- 1 Load the selected modified shot into the Player.
- 2 To bypass a single menu's parameters, click Bypass.

- 3 To bypass all menu parameters, do one of the following:
 - Shift-click Bypass.
 - Press Shift+B.

Changes made to the current menu are temporarily turned off.

- 4 Enable Bypass again to turn the menu back on.

In a stereoscopic project, you can use the Bypass feature on the Left Eye and Right Eye layers. See [Bypassing Menu Parameters of an Eye](#) (page 2258).

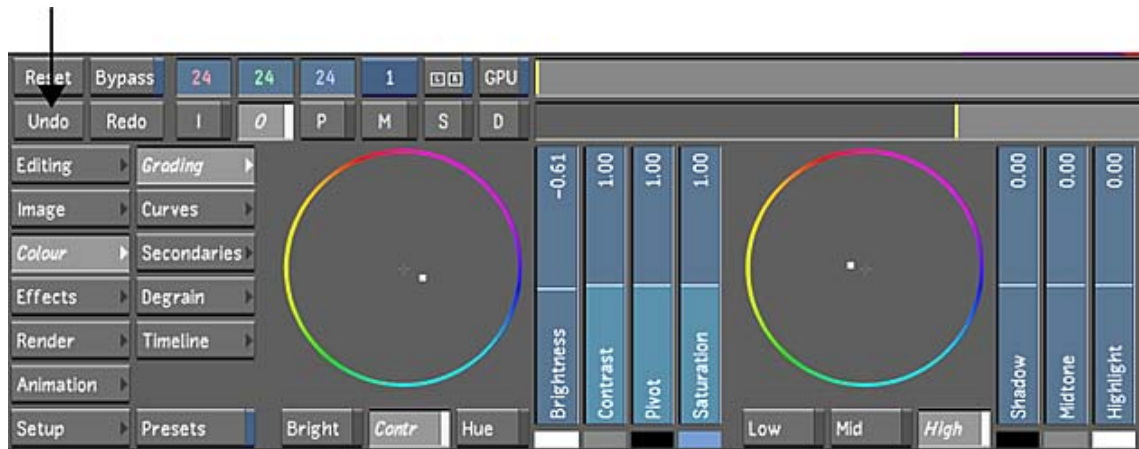

Undoing and Redoing Actions

Each shot in Lustre has its own undo and redo history.

You can undo most operations in Lustre. You can use Redo immediately after undoing an operation.

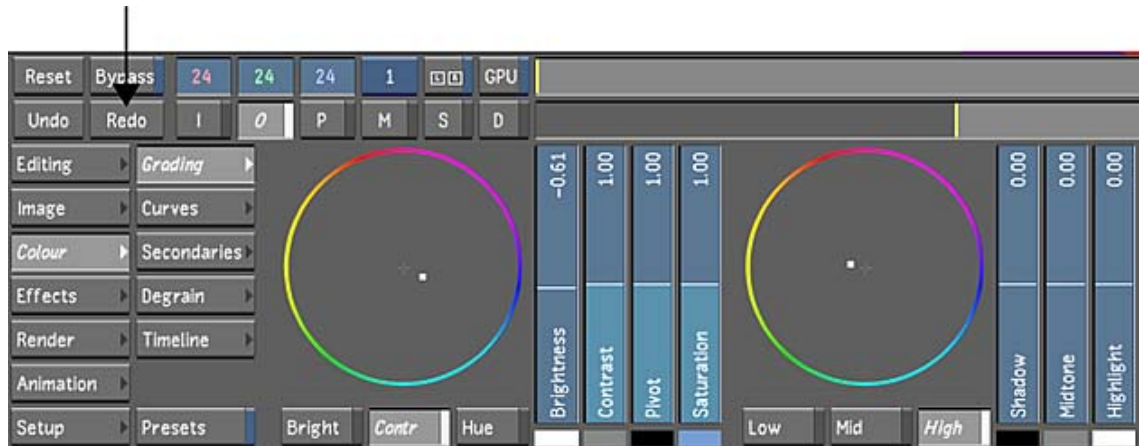

To undo an operation:

- 1 After performing an operation that you want to undo, click Undo.

To redo an operation:

- 1 After undoing an operation, click Redo.

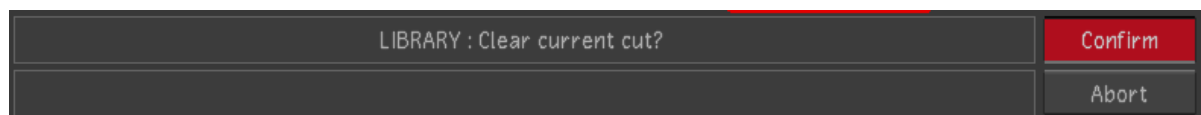

Confirming and Cancelling Actions

There are several operations in Lustre that must be confirmed before they begin. For example, when rendering, capturing, playing out, or deleting material, you must first confirm the action.

When you launch an action that must be confirmed, the Message Bar will show a message asking you to confirm or cancel the action and a red Confirm button along with a grey Abort button will appear to the right of the Message Bar. Click the appropriate button to confirm or abort the action.

NOTE The Message Bar is exclusive to Lustre 2012 Extension 1. In prior versions of Lustre, there is simply a Confirm button.

TIP You can also click anywhere in the grey area of the menu to cancel the action.

Assigning Notes to Shots

The Notes window is available from almost every menu and allows you to enter unlimited wrapping text pertaining to the current shot. Notes are retained as you jump from one shot to another, and saved when you save the grade.

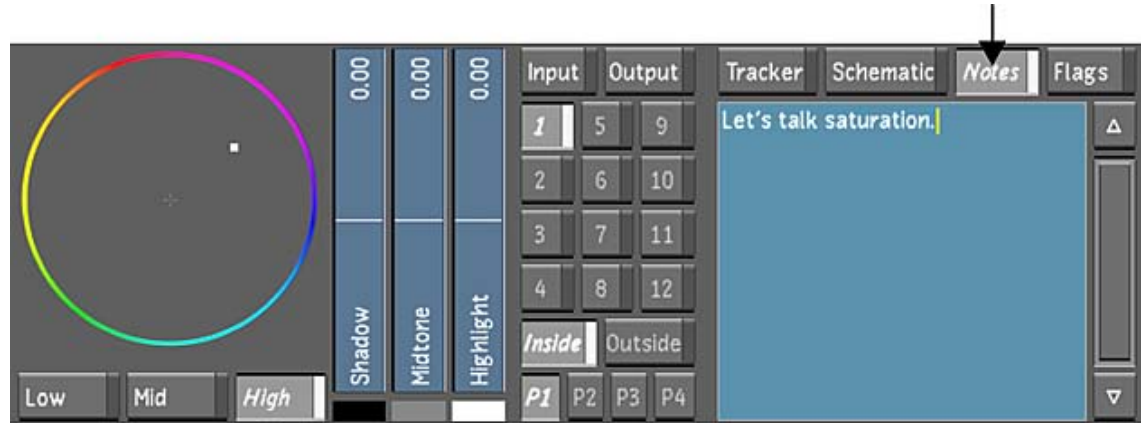

Notes are saved to an .XML file in the scene's *Library* directory. The file is identifiable by a *.desc.xml* extension. You can open the DESC file in a text editor to view and make changes that will be reflected in Lustre the next time you load the grade. This could be useful if, for example, you wanted to review the notes for each shot between grading sessions. You would copy the file to a laptop, and then copy it back to the scene's *Library* directory if any changes were made. See [XML in Lustre](#) (page 2409).

When activating the On-Screen View mode (Ctrl+W), the notes you added to the shot are displayed alongside the shot name.

When editing the DESC file, only the Notes field should be changed. Editing any other field could produce unexpected results.

To use the Notes window:

- 1 Enable the Notes button.

This displays the Notes window below the Notes button.
You can use any of the following standard text editor functions when drafting notes.

Press:	To:
cursor arrows	Move up, down, left or right.
Ctrl+A	Select all text.
Backspace, Delete	Delete text.
Home	Jump to the start of the current line.
Ctrl+Home	Jump to the start of the text.
End	Jump to the end of the current line.
Ctrl+End	Jump to the end of the text.

Press:	To:
Page Up	Jump one text screen up.
Page Down	Jump one text screen down.
Shift+cursor arrow or left mouse button-drag	Select text.
Ctrl+A	Select all text.
Enter	Add an empty line.
Esc or click outside the text editor	Disable the text editor.

NOTE Lustre hot keys are not functional while the Notes text editor is enabled.

- 2 Save the scene's notes by saving the grade. See [Creating a Grade Version for a Cut](#) (page 1822).

Flagging Shots

The flag system is accessible from almost any menu and allows you to enable and disable flags, create and delete flags, and copy flag states to one or more shots.

NOTE When in the timeline or the colourist's timeline, the flag system is always displayed to the right of the timeline canvas.

System flags are available by default for all shots. There are five types.

Render Flags the shots to be rendered.

Changed Indicates whether or not the current shot has been modified since the last save.

Locked Locks the current shot to prevent modifications. The shot's locked status is also indicated by the word Locked that spans the three printer light fields.

Shot Priority Assigns priority to the current shot in the timeline. See [Shot Priority](#) (page 2003).

Notes Denotes whether notes exist against the current shot. Unlike the other system flags, the Notes flag cannot be turned on or off. Instead, its state is automatically updated depending on the contents of the Notes window. The Notes flag is set only when content is added to the Notes window. See [Assigning Notes to Shots](#) (page 1852).

CDL Indicates whether or not CDL data is applied to the current shot.

(a) Flags list (b) Flag controls

To access the Flags window:

- 1 Enable the Flags button.
This displays the flags for the current shot.

To enable or disable a flag:

- 1 Right-click the flag row.
When the flag is enabled, the flag name is in colour and its circle is filled.

(a) Enabled flag (b) Disabled flag

TIP To select a flag without enabling or disabling it, left-click the flag row.

Custom Flags

Apart from the five system flags, you can also create your own custom flags. When creating a custom flag, you must adhere to the following:

- You cannot rename a system flag, nor can you assign the name of a system flag to a custom flag.
- Spaces are not supported in the naming convention. It is recommended that underscores be used instead of spaces when you are working on either Linux or Windows.

Custom flags are saved to the *custom.flags* file in the Lustre version folder. Consequently, the custom flags are applied globally on all projects. After you create a custom flag, newly created grades save the *custom.flags* data to the *grdXX.desc.xml* file in the project's *Library* folder.

To create a custom flag:

- 1 Click New under the Flags window.
A new flag is added to the bottom of the list.
- 2 To rename the custom flag, middle-click it and enter a new name.

To delete a custom flag:

- 1 Select the flag and click Delete under the Flags window.
NOTE System flags cannot be deleted. When deleting custom flags, only one can be selected at a time.

To copy a custom flag's state to all shots:

- 1 Select the Custom flag (the selected flag will be highlighted).
- 2 Click Set All in the Flag controls.

To copy a custom flag's state to one or more shots:

- 1 Select the Custom flag (the selected flag will be highlighted).
- 2 Select the shots in the Storyboard or Multi-Layer Timeline by doing one of the following:
 - Right-click the shots you wish to flag in the Storyboard.
In the Storyboard, the borders of the selected shots will turn aqua in colour.
 - Select the shots you wish to flag in the Multi-Layer Timeline. See [Selecting Elements](#) (page 1980).
In the Multi-Layer Timeline, the selected shots will turn yellow in colour.
 - Create a shot group, then select the group. See [Creating Shot Groups](#) (page 1855).
- 3 Click Set Sel.

Creating Shot Groups

You can group shots together. This is useful, for example, when you have a series of exterior shots and a series of interior shots in the Storyboard. You can define a group for the exterior shots and another group for the interior shots. When you want to adjust parameters for the exterior shots, you select that group. Then, when you want to work on the interior shots, you select the Interior Shots group. Each time you select a different group, the selected shots in the Storyboard change.

In addition to being able to group shots, you can also define what parameters are relevant for the group. In the Exterior Shots group example, you may want to group Primary colour and Effects, but not Secondary

colour. This allows you to perform primary colour grading on all shots in the group, but secondary colour grading is applied only to the current shot.

If, at any point, you need to apply changes to a parameter defined as part of a group, but you want the changes to apply to the current shot only, use Solo. This function temporarily isolates the shot for modification—your changes are not applied to other shots in the group.

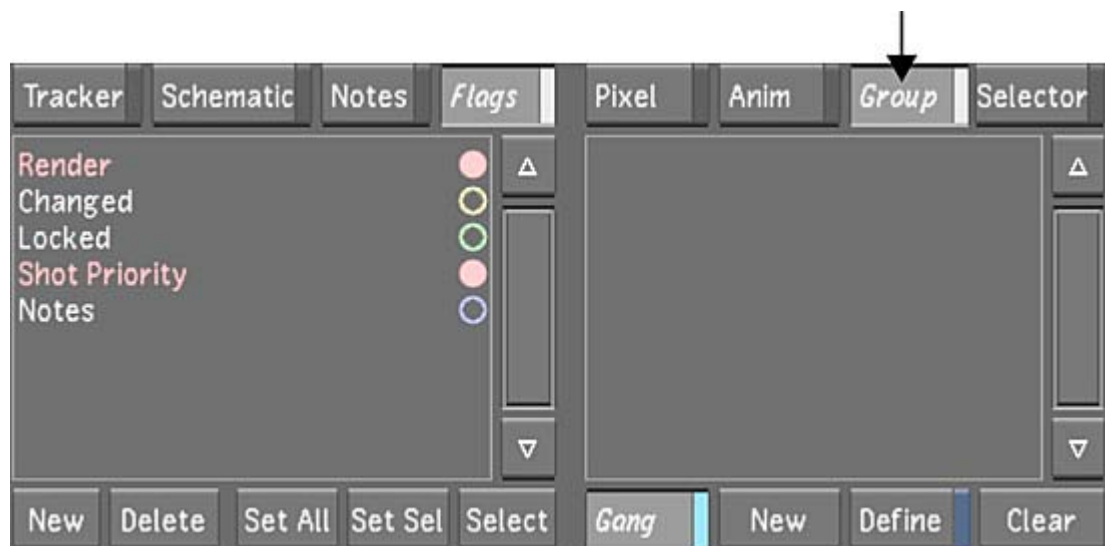

Grouping Shots

Use the Group tool to select shots to group and the parameters to include with the grouping. Any change made to one shot in the group propagates to the other shots in the group, provided that the changes are to parameters that have been included in the group.

Changes made to grouped shots are relative, not absolute. For example, if a non-grouped shot's printer light values are 25, 25, 25 and a new setup is loaded in which the printer light values are 37, 28, 10, then the shot's printer light values will be changed to 37, 28, 10. On the other hand, if the shot were part of a group, the new printer light values would be added, resulting in printer light values of 62, 53, 35. When in group mode, values are added to all the grouped shots, even those that have already been colour corrected.

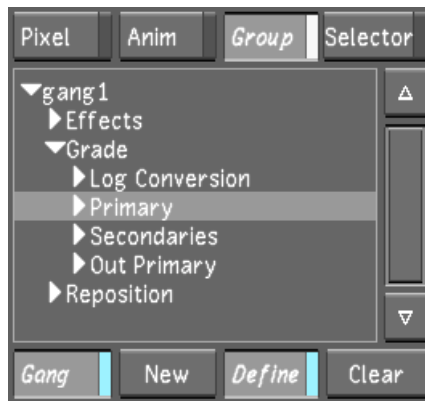

To create a shot group:

- 1 Click Group.

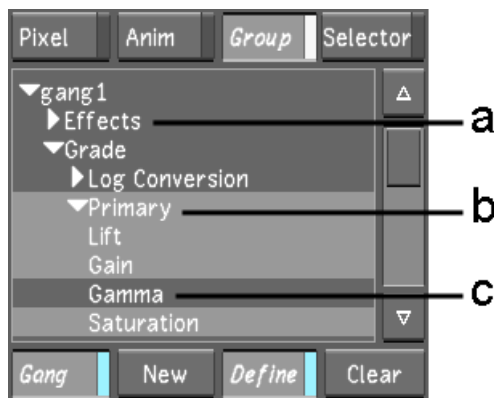

NOTE You can access the Group button from any menu except the Animation menu.

- 2 Click New.
A new group called gang1 is created.
- 3 Enable Define.
This allows you to add shots to the shot group and select the parameters that are applied to the grouping.

- 4 Right-click shots in the Storyboard to add them to the group.
Grouped shots are highlighted with a yellow border.
- 5 Select the channels in the list for the parameters that you want to apply to the group:
 - To select all channels in a directory, select the directory.
 - To select a subset of the channels in a directory, click the arrow to the left of the directory to expand the directory, and then select the channels.
 - To deselect a directory or a channel, click it.

(a) Deselected directory (b) Selected expanded directory (c) Selected channel

- 6 When you have finished setting up the group, disable Define.
- 7 You can name the group by middle-clicking the group and entering a new name.

NOTE Spaces are not supported in naming conventions. It is recommended that underscores be used instead of spaces when working on either Linux or Windows.
- 8 You can delete a group by selecting it and pressing `Delete`, while the cursor is placed over the group menu.
- 9 You can activate split view with grouped shots by right-clicking the group.

Applying Changes to Grouped Shots

After you group shots, changes made to one shot are applied to all other shots in the group.

To apply changes to all shots in a group:

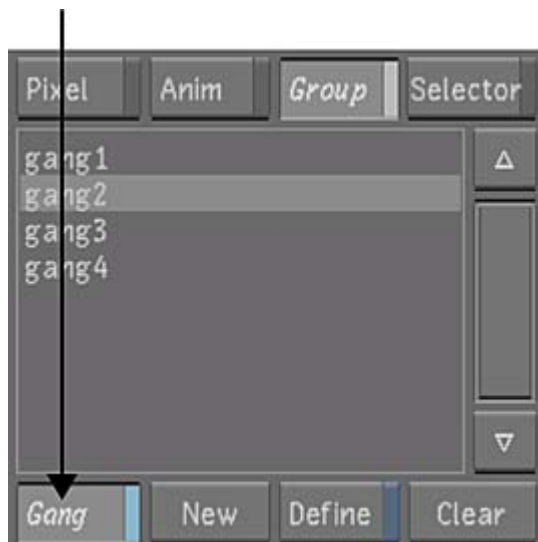

- 1 Click Group.

- 2 Select the group to which you want to make changes.

The grouped shots are selected in the Storyboard.

- 3 Enable the Solo/Gang button.

The Solo button turns to a Gang button and the grouped shots are outlined in yellow.

- 4 Select one of the grouped shots and make modifications to it.

NOTE You can also apply a grade to one of the shots.

The changes are applied to all the other grouped shots.

Soloing Shots

Use Solo to temporarily disable grouping for a shot.

When Solo mode is enabled, you can only modify the current shot. You can copy grades (drag and drop from the Selector or from the Grade bin) only to the current shot. It is possible to copy a grade from any shot to the current shot.

In Solo mode, the outline around the ganged shots is grey.

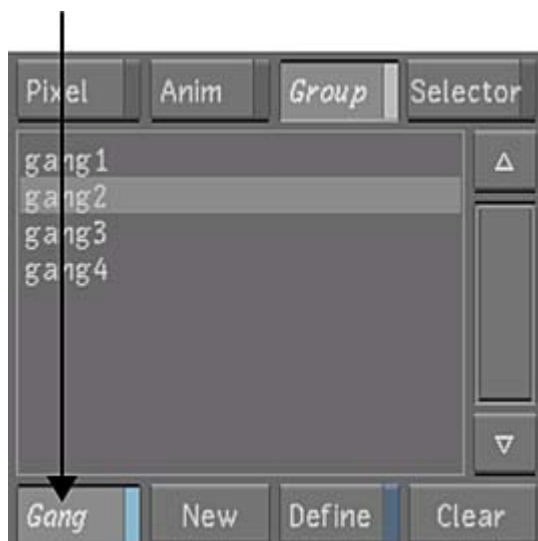

- Group (Gang mode): all shots from the gang can be modified.
- Group (Solo mode): only the current shot can be modified.

To solo shots in a group:

- 1 Click Group.
- 2 Select the group with the shot you want to solo.

- 3 In the Storyboard, select the shot to which you want to make changes.
- 4 Disable the Solo/Gang button.

The Gang button turns to a Solo button.

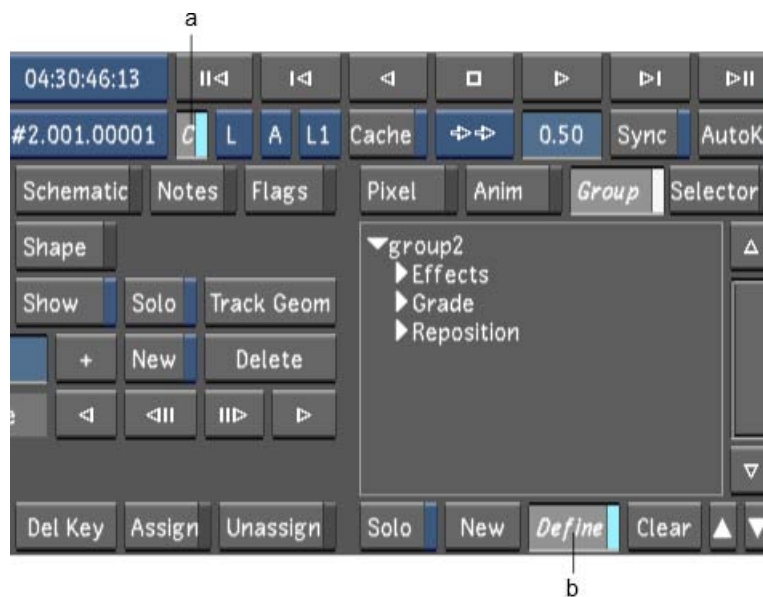

- 5 Make the changes to the shot.
The changes affect the soloed shot only.

- 6 Enable the Solo/Gang button to turn off solo.
Any changes made to the shot are now applied to all grouped shots.

Reordering Shots in a Collapsed Group

You can select multiple shots within a group and collapse the selection to view only the selected shots in the Storyboard. When displaying a collapsed group in the Storyboard, you are able to reorder the shots in the storyboard, without making editorial changes to the sequence. This is useful when you have certain types of shots (interior, exterior, close-up shots of an actor, for example), that you want to view together for grading.

- 1 Create a Group. See [Grouping Shots](#) (page 1856).
- 2 Select the shots you want to include in the collapsed Group, by right-clicking them in the Storyboard.
- 3 Enable the Collapse button.

(a) Collapse button (b) Define button

- 4 Enable the Define button.
You can now reorder the shots by dragging and dropping them within the collapsed Group.
- 5 Grade the grouped shots.
- 6 Disable the Collapsed button.
The reordered shots are returned to their original location in the sequence.

Copying Parameters with the Selector

Use the Selector to copy channel parameters from the current shot to other selected shots in the cut. This feature is useful when you have a series of shots that need to have a similar grade applied to them, for example, shots that are too dark. You can adjust the brightness for the current shot, select all the shots, and then copy the grade setting to all other selected shots. For more information about using the Selector to copy grading information in the Multi-Layer Timeline, see [Copying Grading Information in the Colourist Timeline](#) (page 2098).

You can also use this feature to copy keyer information. For example, if you blurred a shot and adjusted its hue with the HLS Keyer, you can choose to copy only the hue change to the other selected shots; or, if you modified the tolerance and softness of a shot with the Diamond Keyer, you can choose to copy only the tolerance change to another selected shot.

You can copy the following parameters between shots using the Selector:

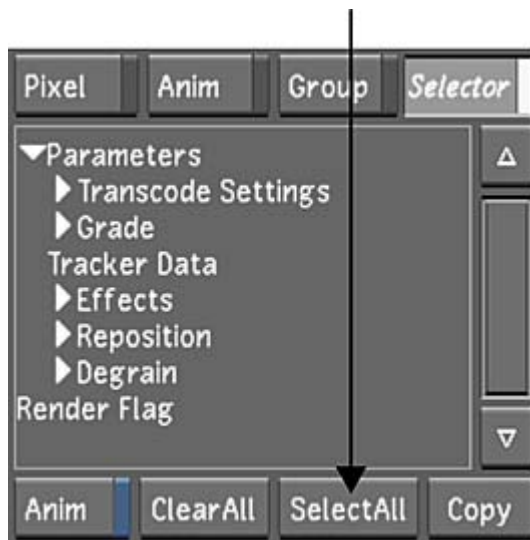

- Colour grading
- Input LUT (1D LUTs and 3D LUTs) selections
- CDL values
- Transcode Settings
- HDRx Settings (ARRIRAW, RED)
- Repositioning values
- Tracker data
- Effects
- Degrain settings
- Render flag settings
- Look Settings (ARRIRAW)

To copy channel parameters from the current shot to selected shots:

- 1 Click Selector.

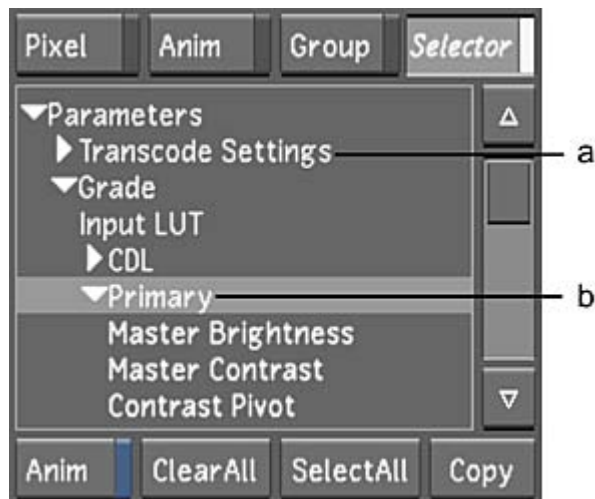

- 2 Select your target shots by completing one of the following:
 - To select your shots one at a time in the Storyboard, right-click specific shots in the Storyboard.
 - To select your shots one at a time in the Timeline, left-click specific shots in the Timeline.
 - To select all the shots in the Storyboard or the Timeline, click SelectAll in the Selector.

The target shots are highlighted in aqua.

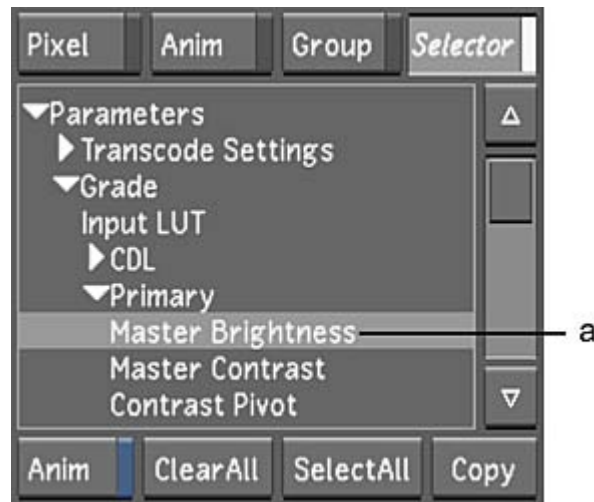

- 3 Click the shot from which you want to copy parameters.
- 4 Specify what parameters to copy by selecting their channels in the Selector channel list:
 - To select all the channels in a directory, select the directory.

(a) Collapsed directory **(b)** Expanded directory

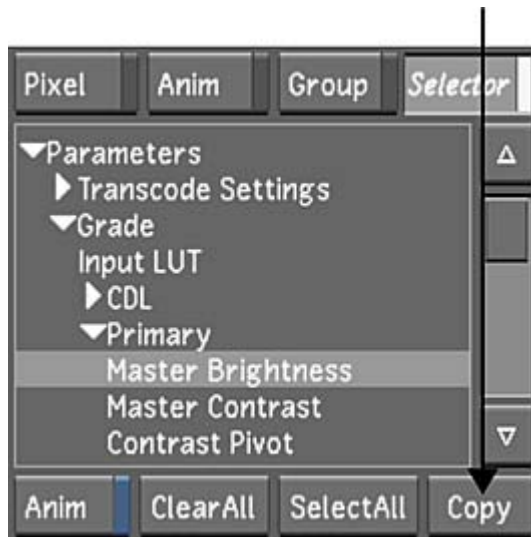

Selected channels are highlighted.

- To select specific channels in a directory, expand the directory and select any of its channels.

(a) Selected channel

- 5 Click Copy.

The parameters for the selected channel are copied to the selected shots.

Copying and Pasting Grading Parameters Between Grading Stages

You can copy or move grading parameters between the Input, Output and any of the Secondary stages with the following key strokes:

- To copy the parameters from one of the grading tabs (Colour/Grading, Colour/Curves or Colour/Secondaries) of the current grading stage (Input, Secondary or Output), to another stage, hold **CTRL** and click the destination stage (Input, Secondary or Output).
- To copy the parameters of all the grading tabs (Colour/Grading, Colour/Curves and Colour/Secondaries) of the current grading stage (Input, Secondary or Output), to another stage, hold **SHIFT** and click the destination stage (Input, Secondary or Output).
- To move the parameters of all the grading tabs (Colour/Grading, Colour/Curves and Colour/Secondaries) of the current grading stage (Input, Secondary or Output), hold **SHIFT + CTRL** and select the destination stage (Input, Secondary or Output). The source stage is reset to the initial values.

- To copy the parameters as defined by the Selector of the currently selected stage (Colour/Grading, Colour/Curves or Colour/Secondaries), hold **ALT** and select the destination stage (Input, Secondary or Output).

See:

[Primary Colour Grading](#) (page 2101)

[Secondary Colour Grading](#) (page 2126)

Assigning Values With the Standard Lustre Calculator

Use the standard Lustre calculator to assign values to sliders and certain fields. You can display the calculator by right-clicking any of the following user interface elements.

Sliders Adjust the value of the currently selected slider.

Zoom field Adjusts the zoom value of the currently selected shot.

Printer Lights Adjust the value of the colour wheel via the printer lights. The calculator displays only after you have already left-clicked in a printer light to display colour wheel values instead of the printer lights. Then, when you right-click a colour wheel value, the calculator appears.

NOTE When you right-click in the timeline Information field, the timecode calculator is displayed. The timecode calculator is used primarily for navigating the timeline. See [Navigating With the Timecode Calculator](#) (page 2021).

(a) Active slider (b) Calculator

NOTE The calculator's default value is always zero.

The calculator features a numeric keypad and buttons for performing standard operations such as addition, subtraction, multiplication, and division. To enter numbers, you can click the calculator buttons, or press the keyboard's number keys or numeric keypad.

It is also possible to assign a negative value to a slider with the calculator.

To assign a negative value to a slider with the calculator:

- 1 Right-click a slider to display the calculator.
- 2 Type '-' on the keyboard.
- 3 Use the calculator to enter the value.

WARNING You must enter the complete number (e.g., 0.654 and not .654).

- 4 Press **Enter**.

The following hotkeys can be used with the calculator.

Press:	To:
Backspace	Erase the last digit in the calculator's numeric field.
Delete	Reset the calculator's numeric field to zero.
Page Down	Change the sign of the value in the calculator's numeric field.
Up cursor arrow	Add the current calculator value to the slider or field value.
Down cursor arrow	Subtract the current calculator value from the slider or field value.
Enter or click the calculator's active numeric field	Calculate the value, apply it, and close the calculator.
Enter or click the calculator's = (equals) button	Calculate the value and display the result without applying it.
Ctrl+Enter or right-click the calculator's = (equals) button	Calculate the value, display the result, and apply it.
Esc or click outside the calculator	Close the calculator and leave the slider or field value unchanged.

Using Grade Bins

Store shot settings to a Grade bin when you need grades for future reference. Intermediary grades are useful when you want to experiment with different looks. Grades are saved on a shot-by-shot basis and contain all shot and animation settings.

The location of grade files determine how they can be shared between users scenes, and projects.

Grade bin type:	Contains:
Global	Grades saved for use between all users and projects on the current workstation.
Project	Grades saved for the current project only.
Scene	Grades saved for the current scene only.
User	Grades saved for the current user only.
Quick	Grades saved in a user-defined folder. See Defining the Quick Folder (page 1881).
Marry	Grades saved as Marry grade files. See Using the Marry Grade Bin (page 1866).

TIP Place the cursor anywhere outside the file browser or expanded Grade bin, and press `Shift++` to cycle through the display of different types of Grade bins.

You can also use Grade bin thumbnails as reference images. See [Viewing Reference Images](#) (page 2013).

Using the Marry Grade Bin

Unlike the other Grade bins, which are used to apply grading to any shot(s) in a given timeline, a Marry Grade bin is shot-specific. Each shot in the cut has its own dedicated Grade bin for its Marry grade files. For example, if a cut is composed of three shots, three Marry Grade bins exist, although the only visible Marry Grade bin is the one for the current shot. This allows you to save multiple Marry grades to the same shot.

Marry Grade file information is also displayed in the Grade view. Marry grade files are saved with their source media files (Marry grade files for media imported from Wiretap and Wiretap Gateway are saved with local links to the shots). Enable the Marry button under the file browser to navigate to the file folder in which Marry grades are located. See [Using the Expanded Grade Bin](#) (page 1873).

You can also use the Marry grade controls in the Setup > Grade menu to save Marry grade files into the Marry Grade bin. See [Saving and Loading Marry Grades](#) (page 1830).

Saving Grades

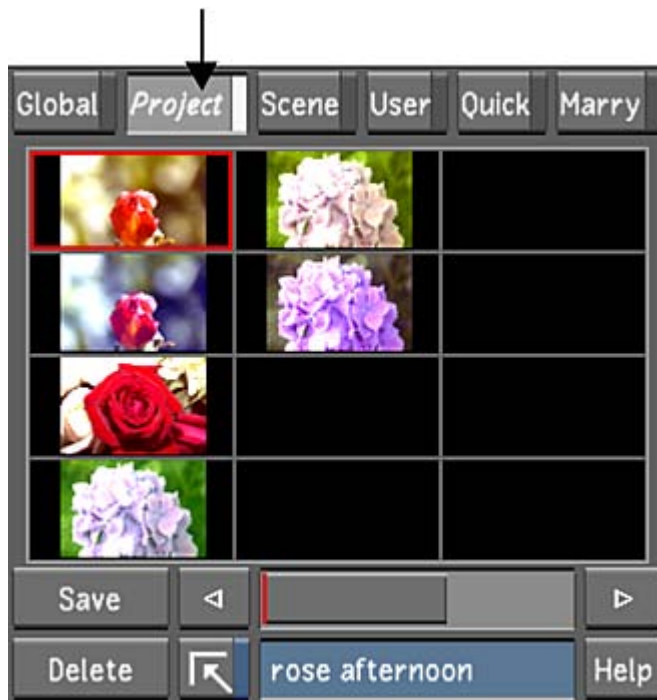

You can save grades to the Grade bin. When you save grades, all the settings are saved with a high-resolution PNG image and a thumbnail for identification. By saving your shot settings to the appropriate Grade bin, you can save your shot settings globally, to a predefined folder, or limit them to a user, scene, or project. You can also save them with your shots as Marry grade files.

If you save grades to a global, project, scene or user Grade bin, each selected grade is saved in a separate storage container, starting from the selected container and proceeding column by column and left to right.

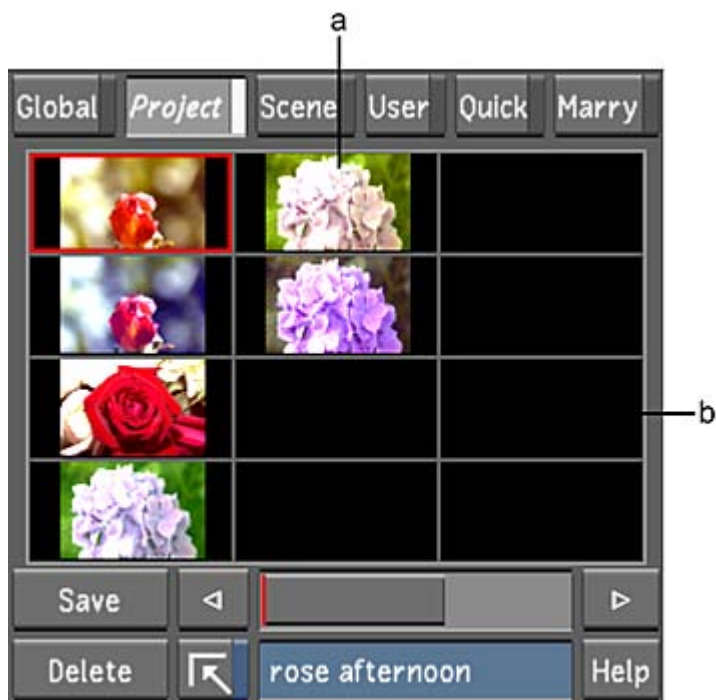

If you save grades to a Marry Grade bin, each selected grade is saved in a separate storage container in the current container position (highlighted in red) in the Grade bin for the shot.

To save a grade to a Grade bin:

- 1 Select the Grade bin you want to use (for example, the Grade bin for the current project).

- 2 (Optional) Scroll to the area of the Grade bin you want to use. To scroll through a Grade bin, middle-click and drag right or left, or use the horizontal slider located immediately below the Grade bin. The red line in the slider indicates the current position.
- 3 Do one of the following:
 - To create a grade, select an unused storage container.
 - To update a grade with modified settings, select the storage container of the grade you want to update.

(a) Used storage container (b) Unused storage container

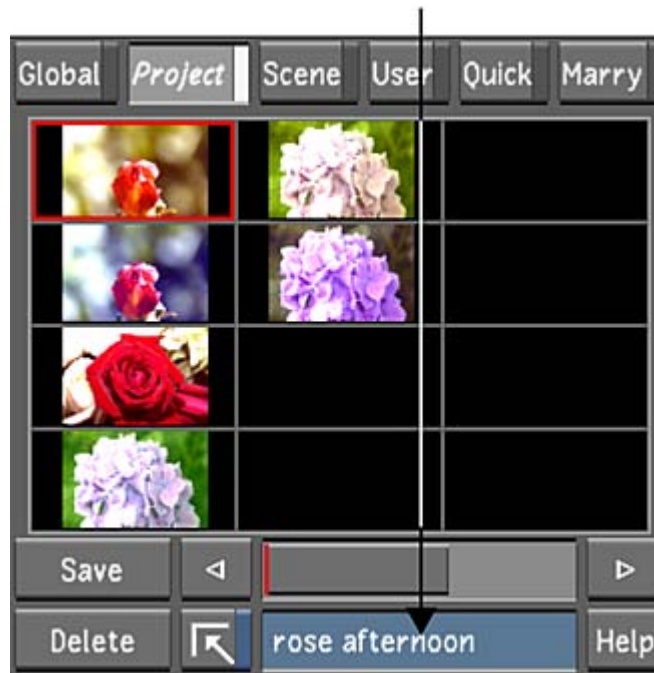

NOTE When you add a grade to a container in the last column of the Grade bin, three new columns are automatically added to the right. You can add an unlimited number of grades.

- 4 Click Save.

The settings from the current shot in the timeline are saved to the Grade Bin and a thumbnail of the current frame appears in the Grade bin.

TIP You can use the thumbnail as a reference image while you work on another shot. See [Viewing Reference Images](#) (page 2013).

- 5 (Optional) Enter a name or comment in the Note field and press **Enter**.

To save grading information from several shots to the Grade bin:

- 1 Do one of the following:
 - To choose grades for specific shots, use the Storyboard or the Multi-Layer Timeline to select the shots whose grading information you wish to save to the Grade bin. For more information about selecting elements in the Multi-Layer Timeline, refer to [Selecting Elements](#) (page 1980).
 - To choose all shots in the timeline, leave all shots unselected.
- 2 In the Grade bin, select the storage container where you wish to save your grade.
- 3 Hold down the **Shift** key while pressing the Save button.

WARNING Storage containers with existing grading information will be overwritten. If you are saving to storage containers that already have grading information, Lustre prompts you to confirm you want to overwrite these grades.

- 4 If you are saving to storage containers that already have grading information, confirm or cancel the action when Lustre prompts you to confirm the action.
The selected grades are saved to the Grade bin.

Applying Grades to Shots

You can apply grades to one or multiple shots in the Storyboard or timeline. Apply intermediary grades to your shots when you want to experiment with different looks. You can control which saved settings you want to apply—all the settings from the intermediary grade, only those selected in the Selector, or only those in the current menu.

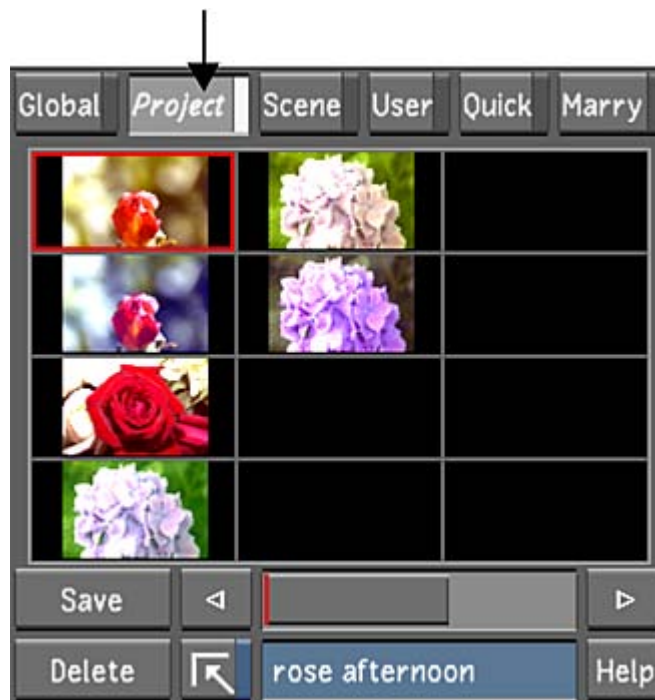

To load intermediary grades from a Grade bin:

- 1 In the Storyboard, select the shots to which you want to apply an intermediary grade.

TIP You can select multiple shots by right-clicking them in the Storyboard. You can also create groups of shots. See [Selecting Shots in the Storyboard](#) (page 2024) and [Creating Shot Groups](#) (page 1855).

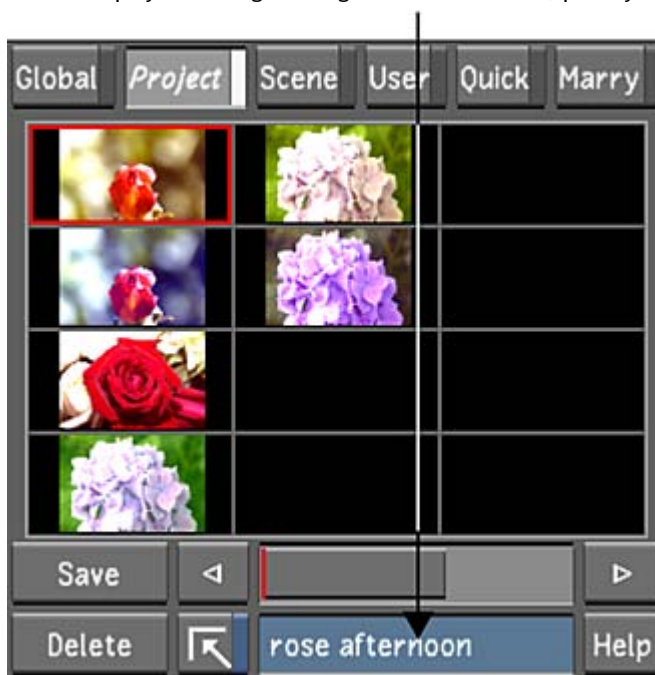

- 2 Select the Grade bin you want to use.

NOTE If you select the Marry Grade bin, each shot that you select will be loaded with the corresponding Marry grades for that specific shot. See [Using the Marry Grade Bin](#) (page 1866).

TIP To display an enlarged image of the thumbnail, place your mouse cursor over a thumbnail without clicking.

3 Do one of the following:

Double-click a shot's thumbnail

- To load all the settings in the grade to the current shot only.

TIP Double-click an unused storage container in the Grade bin to reset selected shots to their default settings.

Press Shift and double-click a shot's thumbnail

- To load all the settings in the grade to selected shots.

Press Ctrl and double-click a shot's thumbnail

- To load the grade settings to the current shot only from the current menu only. For example, if the Grading menu is displayed, the saved settings from the Grading menu are applied.

Press Ctrl+Shift and double-click a shot's thumbnail

- To load the grade settings to selected shots from the current menu only. For example, if the Grading menu is displayed, the saved settings from the Grading menu are applied.

Press Alt and double-click a shot's thumbnail

- To load the grade settings that are selected in the Selector to the current shot only. See [Copying Parameters with the Selector](#) (page 1860).

Press Alt+Shift and double-click a shot's thumbnail

- To load the grade settings that are chosen in the Selector to a selection of shots. See [Copying Parameters with the Selector](#) (page 1860).

The grade is applied. In the Player, the image is updated to reflect the current settings.

TIP To revert to the previous settings, click Undo.

Within the Storyboard view, you can drag and drop the grading from one shot to another. You can reapply the grading in one or more different shots without having to drop it in the Grade bin first.

To drag and drop the grade from one shot to another:

- 1 Do one of the following:
 - Hold down **Ctrl+Shift** and drag and drop to copy grades to multiple destinations.
 - Hold down **Ctrl+Alt** and drag and drop to use the Selector to copy grades to a single destination.
 - Hold down **Ctrl+Shift+Alt** and drag and drop to use the Selector to copy grades to multiple destinations.

Moving Grades

You can reorganize the Grade bin by moving grades from one storage container to another. You can also drag a Grade bin to the file browser or expanded Grade bin in the Grade view. See [Moving Grade Files Between Grade Bins](#) (page 1881).

Deleting Grades

You can delete grades one at a time, or delete all grades from the Grade bin simultaneously.

To delete grades from a Grade bin one at a time:

- 1 Select the Grade bin from which you want to delete grades. The name of the selected thumbnail appears in the Note field.

- 2 The Message Bar will show a message asking you to confirm or cancel the action and a red Confirm button along with a grey Abort button will appear to the right of the Message Bar. Click the appropriate button to confirm or abort the action.

NOTE The Message Bar is exclusive to Lustre 2012 Extension 1. In prior versions of Lustre, there is simply a Confirm button.

You can delete saved grades from the Grade Bin without needing to confirm, by using the Ctrl+Delete keyboard shortcut.

To delete all grades from the Grade bin simultaneously:

- 1 Select the Grade bin from which you want to delete grades.

- 2 Hold down **Shift** while clicking **Delete**.

The Message Bar will show a message asking you to confirm or cancel the action and a red **Confirm** button along with a grey **Abort** button will appear to the right of the Message Bar. Click the appropriate button to confirm or abort the action.

NOTE The Message Bar is exclusive to Lustre 2012 Extension 1. In prior versions of Lustre, there is simply a **Confirm** button.

Using the Expanded Grade Bin

Use the expanded Grade bin to locate and display grade files. You can manage intermediary grade files at the global, project, scene, or user level, and Marry grade files at the shot-based level. You can also define a custom folder and bookmark it for quick access.

In addition to move, copy, and delete operations, you can create new folders, enable a player to view grades and shots, and work in different views to view grade files.

Accessing the File Browser

Use the file browser to locate grade data and load it into the Grade bin.

To access the file browser:

- 1 In the Grade bin, click the **Expand** button.

Footage courtesy of EVN PRODUCTIONS

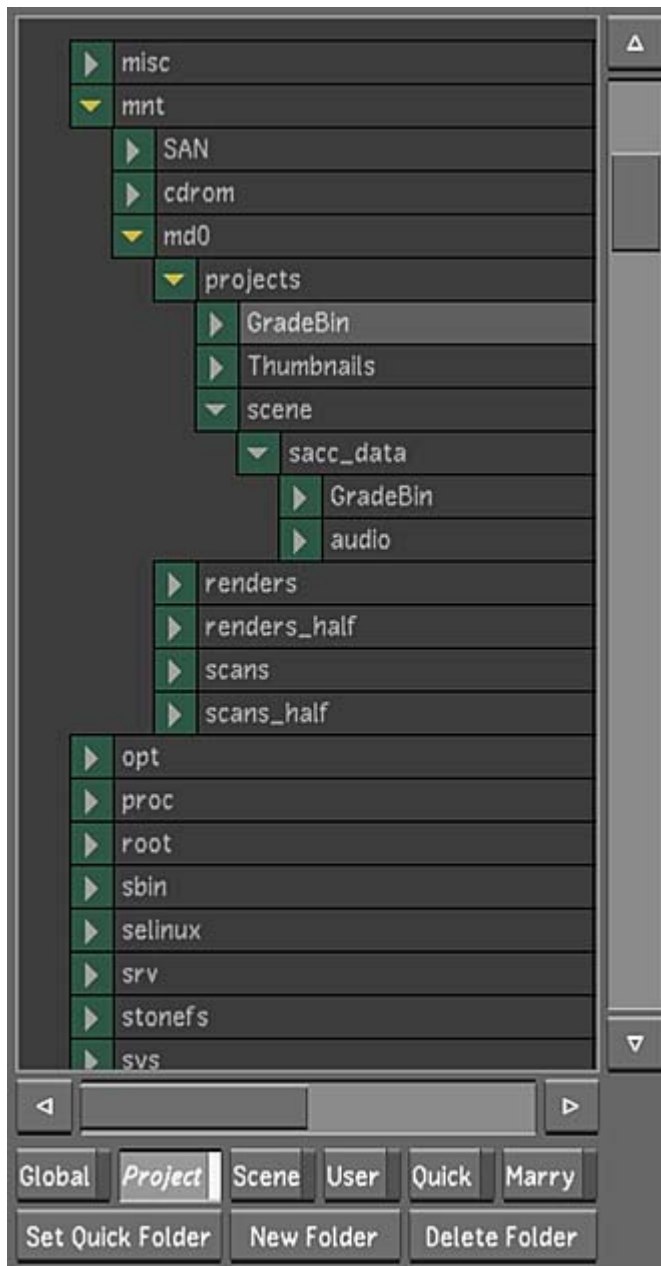

The Grade view appears.

Image courtesy of EVN PRODUCTIONS (a) File browser (b) Expanded Grade bin (c) Player

When you are in the Grade view, the work area is divided into multiple areas.

File browser Use to locate grade data and display it in the expanded Grade bin.

Click:	To:
Global	Display the location of the global Grade bin folder and its contents.
Project	Display the location of the project Grade bin folder and its contents.
Scene	Display the location of the scene Grade bin folder and its contents.
User	Display the location of the user Grade bin folder and its contents.
Quick	Display the location of the folder selected with the Set Quick Folder option.

Click:	To:
Marry	Display the location of a Marry Grade bin folder and its contents. See Using the Marry Grade Bin (page 1866).
Set Quick Folder	Set the currently selected folder in the File Browser as the Quick Folder.
New Folder	Create a new folder under the currently selected folder. Enter a new name. Rename the folder at any time by right-clicking it and entering a new name (the global, scene, project, and user directories, cannot be renamed).
Delete Folder	<p>Delete the currently selected folder (for which you have deletion permissions enabled). The Message Bar will show a message asking you to confirm or cancel the action and a red Confirm button along with a grey Abort button will appear to the right of the Message Bar. Click the appropriate button to confirm or abort the action.</p> <hr/> <p>NOTE The Message Bar is exclusive to Lustre 2012 Extension 1. In prior versions of Lustre, there is simply a Confirm button.</p> <hr/>

TIP Place the cursor over the file browser or expanded Grade bin, and press `Shift++` to cycle through the display of different expanded Grade bins.

Expanded Grade bin Use to display and organize the grade files.

Footage courtesy of EVN PRODUCTIONS

Player Use to display selected shots and grade files.

Footage courtesy of EVN PRODUCTIONS

Click:	To:
Grade	Display the current grade selected in the expanded Grade bin.
Timeline	Display the current shot selected in the Timeline or Storyboard.

NOTE When in Timeline mode, the Player displays the shot from the timeline with its current grade applied to it, which is not necessarily the grade selected in the Expanded Grade Bin.

Defining the Quick Folder

You can use the file browser to select any folder and define it as a location in which you want to store grade files. Once you have stored the location of this folder, you can quickly display and select it in the file browser, and use the Quick buttons to display its contents in the Grade bin and expanded Grade bin.

To set the Quick folder:

- 1 Navigate to the folder you want to set as your Quick folder.
- 2 Click the name of the folder to select it.
- 3 Click Set Quick Folder.

Loading Grade Files from the Expanded Grade Bin

Once you locate your Grade bin folder in the file browser and display its contents in the expanded Grade bin, you can move grade files into the Grade bin storage containers. Grade files in the expanded Grade bin are pointers to the actual files on the file system. You can view information about the grade files in expanded Grade bin.

Moving Grade Files Between Grade Bins

In addition to moving grade files from the expanded Grade bin to a storage container, you can use drag-and-drop operations to move and copy between the expanded Grade bin, Grade bin storage containers, and file browser.

NOTE To copy a grade file from one location to another, hold down `Ctrl` as you drag files from the source Grade bin to its destination.

Drag from:	Drop in:
Expanded Grade bin	<ul style="list-style-type: none">■ A folder in the file browser■ A Grade bin storage container
Grade bin storage container	<ul style="list-style-type: none">■ Another Grade bin storage container■ An expanded Grade bin■ A folder in the file browser
File browser	Illegal operation: Using a drag-and-drop operation, the file browser can only have a grade file moved or copied to it.

Applying Grade Files to Shots in a Cut

You can select grade files in the expanded Grade bin and apply them to a shot in the Storyboard or Timeline.

To apply grade files from the expanded Grade bin to a shot:

- 1 Do one of the following:
 - In the Proxies or Details view, click the grade file.
 - In the List view, click the grade name.

The cursor picks up the grade file. If you click more than one grade file, only the first grade file will be applied.

- 2 Move the cursor to the Storyboard or Timeline.

If the shot is moved to the Storyboard, an orange highlight appears around the selected shot.

- 3 Click to drop the grade file on the shot.

TIP Double-click an unused storage container in the Grade bin to reset selected shots to their default settings.

Deleting Grades From the Expanded Grade Bin

You can delete all or selected grade files from the expanded Grade bin.

NOTE Deleting grade files from the expanded Grade bin does not delete grade data from the Storyboard.

To delete selected grade files from the expanded Grade bin:

- 1 Select the grade files you want to delete.
- 2 Click Delete Selected, and then confirm the action.

All the selected grade files are deleted.

To delete all grade files from the expanded Grade bin:

- 1 Click Delete All.
- 2 The Message Bar will show a message asking you to confirm or cancel the action and a red Confirm button and a grey Abort button will appear to the right of the Message Bar. Click the appropriate button to commence or cancel the action.

All the grade files are deleted.

Grading Presets

From the Grade Bin's Global folder, you can access various grading presets that provide different looks you can use as a starting point for your grades.

The grading presets are organized into seven categories:

- **Color Filters:** 15 color filters, such as Color Temperature Blue, Color Temperature Orange, Cool, Warm, Sepia, etc.
- **Diffusion Filters:** 21 diffusion filters, such as Center Focus, Diffusion, Blur, Fog, etc.
- **Film:** 24 presets emulating film lab processing and film stock, such as xProcess, Bleach Bypass, 2 Strips, 3 Strips, Very Old Film, etc.
- **Grad Filters:** 8 gradient filters, such as Blur, Green, Red, Amber, etc.
- **Image:** 28 image manipulation presets, such as Flip, Flip, Flip/Flop, Sharpen, Negative, Overexposed, Noise, etc.
- **Looks:** 38 look types, such as Day For Night, Film Noir, Expressionism, 8mm, Atomic Blast, etc.
- **Vignette:** 16 circle and rectangle vignettes with various highlight and blur values.

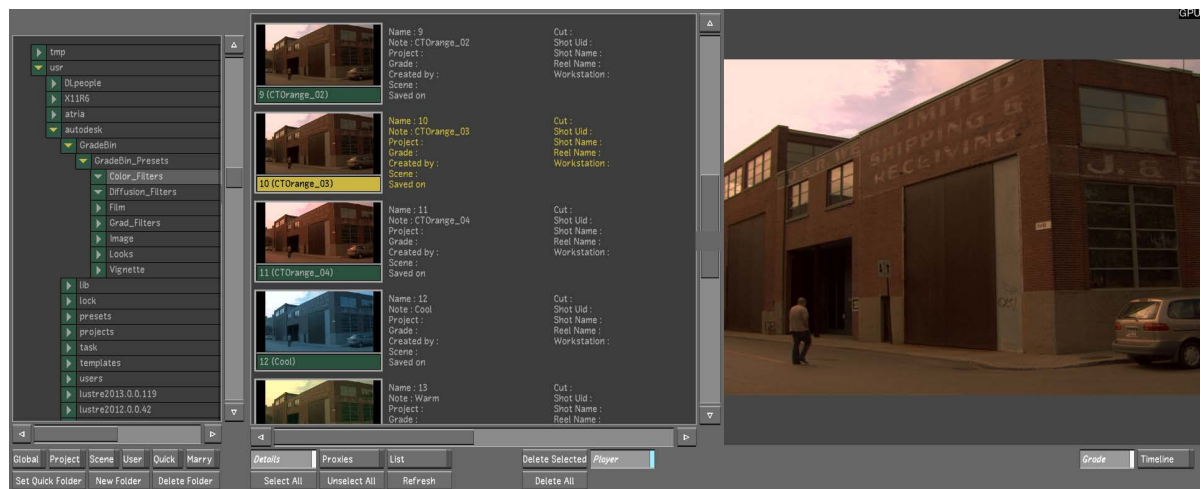

For the complete list of grading presets, see [Grading Presets List](#) (page 1884).

Accessing the Grading Presets

The grading presets are located in the Global Grade Bin folder, in a sub-folder named GradeBin_Presets.

To access the grading presets:

- 1 Navigate to the Global Grade Bin folder with the Expanded Grade Bin and expand the GradeBin_Presets folder to see the different preset categories, listed above.
- 2 Select a preset folder to see a thumbnail representation of the preset in the Expanded Grade Bin.
- 3 Double-click on the name of a preset thumbnail to see the preset in the Expanded Grade Bin Player.

TIP You can also preview the selected preset on the currently selected shot in the storyboard by selecting Timeline rather than Grade in the Expanded Grade Bin Player.

Using the Grading Presets

To use the grading presets, first copy them to either the Global, Project, Scene or User Grade Bin.

To copy grading presets to the Grade Bin:

- 1 Hold the Ctrl key on the keyboard.
- 2 Select one or more grading presets from the Expanded Grade Bin.
- 3 Drag & drop the grading presets to the Grade Bin of your choice (Global, Project, Scene, User).

The selected grading presets are now displayed in the Grade Bin.

To apply a grading preset to a shot:

- 1 Select the shot you want to apply the grading preset to in the Storyboard.
- 2 Double-click on the grading preset in the Grade Bin.

The grading preset is applied to the selected shot.

To edit a preset:

- 1 Apply the grading preset to the selected shot.
- 2 Modify the parameters.
- 3 Press the Save button at the bottom left of the Grade Bin, if you want to save the modified preset.

NOTE You can also load the entire contents of a Grade Bin Presets sub folder (Color_Filters, Diffusion_Filters, Film, etc.) by assigning it as a Grade Bin Quick Folder. However, this creates a symbolic link from the Grade Bin to the location of the grading presets. It does not copy them. This means that if you modify and save a modified grading preset, you are overwriting the original.

See [Accessing the File Browser](#) (page 1873).

See [Applying Grades to Shots](#) (page 1869).

Grading Presets List

The following tables list the complete grading presets available in Lustre. Some presets include multiple variations.

Color Filter Presets:	Description:
Clear	Resets the grading parameters.
CTBlue (01 to 04)	Color temperature presets that attempt to fix white balance issues (tungsten to daylight).
CTOrange (01 to 04)	Color temperature presets that attempt to fix white balance issues (daylight to tungsten).
Cool	Blue/green overall cast.
Warm	Yellow/orange overall cast.
Sepia	Soft brownish cast.
Blue	Soft blue cast.

Color Filter Presets:	Description:
Solar_Flare	Strong orange cast.
Neo	Greenish overall cast.
Purple	Soft purple cast.
Diffusion Filter Presets:	Description:
Clear	Resets the grading parameters.
Center_Focus (01 to 04)	Variations of a Circle shape with blur on the outside of the mask.
Diffusion_Filter_Blur	Soft blurry highlights.
Black_Diffusion	Soft blurry shadows.
Black_Diffusion_Mist	Heavy blurry shadows.
Diffusion_Glamour	Sublte diffusion preset.
Fog (01 to 04)	Variations of overall fog.
Blur (01 to 04)	Variations of blur.
High_Diffusion (01 to 04)	Variations of blurry highlights.
Heavy_Diffusion	Heavy highlights diffusion.
Film Presets:	Description:
Clear	Resets the grading parameters.
xProcess (01 to 04)	Four variation of cross processing photographic effect.
Bleach_Bypass	Bleach bypass color processing looks.
2_Strips	Emulation of the 2 strips color process.
3_Strips	Emulation of the 3 strips color process.
Kchrome	Film stock looks.
Red_Scale_100	Emulation of photographic processes involving exposing the back side of color negative.

Film Presets:	Description:
Echrome	Film stock looks.
Infrared	Black and white film stock look.
Night_Vision_Blue	Overall blue cast.
Very_Old_Film	Light black and white look with heavy grain.
BW_Aged	Old film with a yellow, green and blue cast.
BW_HighCon	High contrast black and white looks.
Gradient Filters Presets:	Description:
Clear	Resets the grading parameters.
Grad_Blue	Gradient shape with a dipping blue cast at the top of the image.
Grad_Blue_Green	Gradient shape with a dipping blue cast at the top of the image and a green cast at the bottom.
Grad_Amber_Green	Gradient shape with a dipping amber cast at the top of the image and a green cast at the bottom.
Grad_Amber_Purple	Gradient shape with a dipping amber cast at the top of the image and a purple cast at the bottom.
Grad_Red	Gradient shape with a dipping red cast at the top of the image.
Grad_Green	Gradient shape with a dipping green cast at the top of the image.
Grad_Sunset	Gradient shape with a dipping orange cast at the top of the image.
Grad_Sunrise	Gradient shape with a dipping purple cast at the top of the image.
Image Presets:	Description:
Clear	Resets the grading parameters.
Flip	Image is vertically inverted.
Flop	Image is horizontally inverted.
Flip_Flop	Image is both vertically and horizontally inverted.

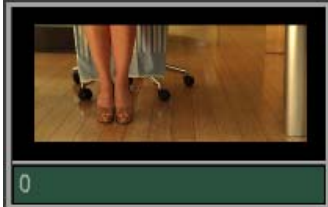

Image Presets:	Description:
Sharpen (01 to 04)	Variations of image sharpening.
Anamorphic	Converts anamorphic images to square pixels.
Color_Negative	Color film negative look.
BW_Negative	Black and white film negative look.
Negative_Masked	Exposed color film negative look.
Vertical_Blur	Vertical blurring.
Horizontal_Blur	Horizontal blurring.
Photocopy	Variations of photocopy looks (color and black and white).
Overexposed	Variations of overexposed looks.
Noise	Variations of black and white looks with noise.
Moon	Moon in the sky created with shapes.
Stars	Stars in the sky created with shapes.
Moon_and_Stars	Moon and stars in the sky created with shapes.
Moon_Stars_and_Clouds	Moon, stars and clouds in the sky created with shapes.
Looks Presets:	Description:
Clear	Resets the grading parameters.
Day_For_Night	Converts a day scene to a night scene.
Film_Noir	1950s drama look.
Expressionism	1960s drama look.
Matrix	Postmodern drama look.
Sixties_slides	Reversal slides look.
Berlin	1970s drama look.
Black_and_White	Black and white realistic look.

Looks Presets:	Description:
BW_Newspaper	Black and white look with grain.
8mm	Projected film stock look.
Drama	Variations of dramatic cold and warm looks.
Dusk	Bluish drama look.
Vivid	Variations of a realistic look.
Murky_Old_Negative	Dramatic low contrast brown cast.
Atomic_Blast	Science fiction dramatic look.
Faded	Variations of a faded look.
Glowy	Pale bluish look.
Glowy_Warm	Pale yellowish look.
Low_Contrast	Low contract look.
Purple_Smear	Purple cast with blurry vertical lines.
Ultraviolet_Flare	Purple cast with blur.
Cool_Darker	Dramatic dark look.
Bright_Yellow_Glow	Hard orange cast.
Pinkish	Pink cast.
Gold	Heavy gold look.
Streaks	Overexposed color flares look.
Warm_Sky	Orange cast sky.
Cool_Thriller	Bluish dramatic look.
Warm_And_Soft	Warm blurry look.
End_Of_Day	Warm and dark overall look.
Reddish	Dark and blurry red look.

Looks Presets:	Description:
Early_Morning	High contrast red and blurry look.
Vignette Presets:	Description:
Clear	Resets the grading parameters.
Vignette_Circle	Variations of circle vignettes with blur and highlights / shadows look
Vignette_Rectangle	Variations of rectangle vignettes with blur and highlights / shadows look.

Viewing Media File Information

When you view grade files in the expanded Grade bin, you can display information about the media files.

NOTE Text information is not displayed in Thumbnail view.

Name Displays the name of the grade file.

Note Displays any notes saved with the grade. Right-click to edit the note.

Project Indicates the project in which the grade was created.

Grade Indicates the original grade in which the grade file was created.

Created by Indicates the user that created the grade.

Scene Indicates the original scene in which the grade was created.

Saved on Displays the date on which the grade was saved.

Cut Indicates the original cut in which the grade was created.

Shot UId Displays the shot's unique ID.

Shot Name Displays the name of the shot saved with the grade.

Reel Name Displays the name of the source reel on which the shot is saved.

Workstation Displays the workstation on which the grade was created.

To sort List view information:

- 1 Do one of the following:
 - Click a column header to sort the list in ascending order by selected column. Re-click the column to sort the list in descending order.
 - Press **Ctrl** and click any column header to reset the sort order by name.

Loading Grading Presets

You can select which grading information you load from a grade file in the expanded Grade bin or the Grade bin using preset lists.

See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

Using Audio

You can hear audio during timeline playback if you import or capture a WAV or AIFF file into the system. The imported/captured file is associated with a cut and begins playback at the same time as the timeline. You can also hear audio during timeline playback if your system is using an external device which detects timecode. When you have selected an audio file or audio tracks to playback with your timeline, all the information (i.e., playback status, selected audio file or audio track, offset, LTC Chase option, and Sync option) are saved in the *Context* file.

NOTE Only one audio file can be associated with the timeline.

For more information on importing/capturing, playing back, and playing out audio, see [Audio](#) (page 2347).

Using Text

When you want to add credits to a cut loaded to the timeline, you can automatically key text files containing an alpha channel over shots in the timeline. To do so, use a text plate EDL that describes how the text files are arranged in the timeline.

To use a text plate with a cut, the text plate file must use a *.cutplate* extension, as well as have the same filename as the *.cut* file you are using. For example, a text plate for *movie.cut* would be named *movie.cutplate*. Store the cut plate for the text files in the *Library* directory—where the loaded cut file is stored. Store the text files in the same scene's *Library\plate* directory.

NOTE If using the Linux version of Lustre, the above filename will use forward slashes.

The following is an example of a text plate EDL.

(a) TCBASE (frame rate) (b) Record in timecode (c) TCSTART (timecode offset) (d) Record out timecode (e) Text file name (f) Record in timecode and start of fade-in (g) Fade-in end timecode (h) Fade-out start timecode (i) Record out timecode and end of fade-out

The text plate EDL contains the following timecode information.

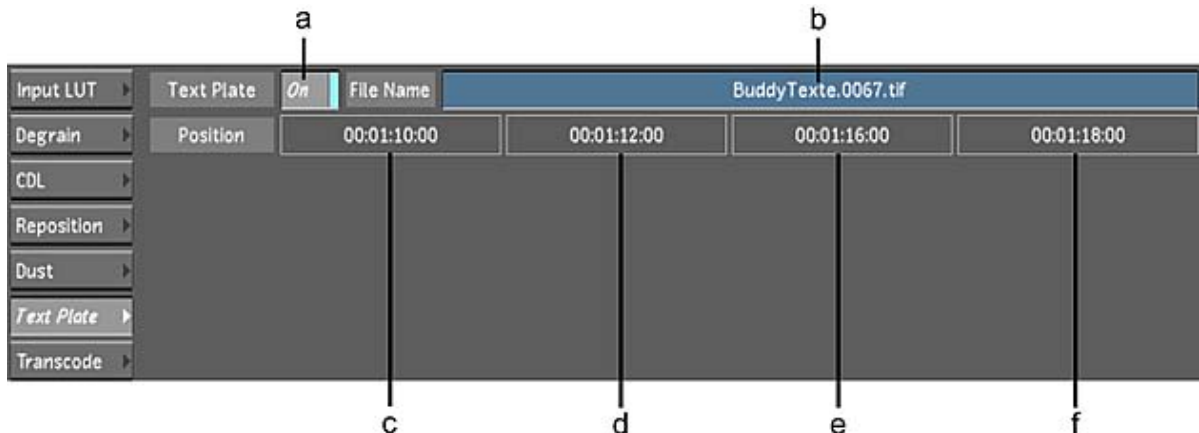

TCBASE Set the frame rate. You can set the frame rate to any rate, such as 24, 25, or 30 fps.

TCSTART Offset the timecode to slip the entire timeline. For example, 00:00:05:00 would slip the text plate 5 seconds earlier in the timeline.

MaxColor Set the colour intensity from 0-1023, where 0 is black and 1023 is white. If this value does not appear in the EDL, the value defaults to 800.

Timecode List the record timecode for each referenced text file. Set the record in timecode and record out timecode, as well as durations for fade-ins and fade-outs.

Use the Text Plate menu to turn text plates on or off.

(a) On/Off button (b) Text file name (c) Record in timecode and start of fade-in (d) Fade-in end timecode (e) Fade-out start timecode (f) Record out timecode and end of fade-out

To turn a text plate on:

- 1 Load the cut file with the text plate to the timeline. See [Managing Cuts](#) (page 1819).
- 2 In the Image menu, click Text Plate.
The Text Plate menu appears.
- 3 In the timeline, go to the timecode where the text plate appears.
- 4 Set the On/Off button to On.

The Text plate is keyed over the shot in the Player. When the text plate is on, you can render the cut with the text plate.

To turn a text plate off:

- 1 In the Image menu, click Text Plate.
The Text Plate menu appears.
- 2 In the timeline, go to the timecode where the text plate appears.
- 3 Set the On/Off button to Off.
The text plate is turned off and no longer appears in the Player.

NOTE The On/Off button applies to all text plates in the timeline.

Monitor Calibration

All monitors display colours differently. The colours that you see on your digital monitor change slightly over time because the back light degrades. This causes the maximum brightness of the monitor to decrease slightly. To ensure a perfect colour match between film and monitor, you need to calibrate the monitor. By regularly calibrating the monitor, you ensure that the image on the screen is consistent from day to day by creating a uniform environment—the basis for the accurate display of image colours.

WARNING When you set monitor calibration settings in the Setup > Calibrate menu, you override the monitor calibration settings already configured through User Management and Project Management. This override only survives for the session. After exiting Lustre and restarting the application, the monitor calibration settings will revert to the default settings configured in User and Project Management.

After you calibrate your monitor in Lustre, the image that you view is an accurate replica of that which is sent to the output buffer—with the monitor calibration Lookup Table (LUT) applied on top. If you output to a log file, you will need a log-to-display LUT. If you output to a linear file, you will need a linear-to-display LUT. The calibration design ensures that any modifications you make to the image are as accurately displayed as technically possible—thus reducing the chance of downstream errors.

You can calibrate the monitor automatically or manually. You can also select and compare up to three Print LUTs (either 1D or 3D) to calibrate your system display with the output from the printer. This nullifies the need for subsequent printer light adjustments.

NOTE You can have any number of Print LUTs on your system; however, you can only select three for quick comparisons.

However, with a 3D LUT, you amalgamate the different stages of calibration into the LUT including the calibration of the monitor and the application of the Print LUT measurements.

Logarithmic and Linear Colour Spaces

You colour grade all the shots in your project in either logarithmic or linear colour space. The colour grading toolsets are dependant on the colour space you select. In Log mode, the toolset is designed for digitized film images originating from a datacine conversion process. In Linear mode, the toolset is designed for images that contain linear data.

If you want to use a logarithmic image in Linear mode, you can linearize it by creating a Log to Lin conversion LUT with the LUT Editor. See [Linear Mode: Creating Conversion LUTs](#) (page 2073).

NOTE In Log mode, no conversion is necessary on input since you are working on digitized film images in logarithmic colour space.

Monitor Calibration Workflow

Because different facilities may be set up differently, there are many monitor calibration scenarios, particularly if you are working with film images. The following workflow scenarios are guidelines for setting up the display environment that you need.

The recommended steps involved in setting up the proper display environment are as follows.

Step:	Refer to:
1. Adjust the black level and picture settings of the graphics monitor.	Adjusting Black Level and Picture Settings (page 1893).
2. Select the colour space you intend to use for the project—logarithmic or linear.	Selecting the Project Colour Space (page 1895).
3. If you are using a colourimeter, automatically calibrate the monitor.	Calibrating the Monitor Automatically (page 1896).
4. If you do not have a colourimeter, manually calibrate the monitor.	Calibrating the Monitor Manually (page 1899).
5. If your video card is set to Dual-Head mode, set LUTs for each monitor.	Calibrating for Dual-Head Mode (page 1899).
6. Select and compare up to three Print LUTs obtained from your lab to determine which best calibrates the display with the printer.	Applying LUTs for Viewing (Print LUTs) (page 1899).

NOTE Before you set up the proper display environment, make sure the graphics board is set to the supported resolution. See the *Autodesk Lustre Software Installation Guide* for your platform.

Adjusting Black Level and Picture Settings

All monitors come with controls to adjust brightness and contrast. Brightness affects the black level setting of the monitor; contrast controls the picture setting.

You should adjust these settings when you first unpack and connect the monitor. When you adjust the monitor, make sure lighting conditions in the room are what they usually are when you are working. Adjust brightness to set the black level first, and then adjust contrast to control the picture setting.

You should not have to change these settings provided you always use your system under consistent lighting conditions. These settings are perception-based, so do not worry about getting perfect results. In the end, you are trying to ensure that black looks black and white looks white.

Brightness (black level) offsets the red, green, and blue signals. Adjust the black level to display black as black without losing the distinction between black and very dark greys. Note the following:

- When the black level is too high, true black appears slightly grey.

- When the black level is too low, dark greys appear black, so you lose subtle details in shadows.

Contrast (picture setting) applies gain to the red, green, and blue signals. Adjust the picture setting to display white properly on the monitor. Note the following:

- If the picture setting is too low, white appears off-white on your display.
- If the picture setting is too high, very light grey is the brightest colour the monitor displays, so you lose subtle detail in highlights.

For more information about adjusting the black level and picture settings of your monitor, read Charles A. Poynton's monitor adjustment guide at:

http://www.poynton.com/notes/brightness_and_contrast/index.html

To adjust the black level setting:

- 1 Load a black frame (RGB 0, 0, 0) to the Storyboard. See [Creating a Cut with Shots in the Library](#) (page 1919).
The black frame appears in the Player. Use this image to set your black level.
TIP You can also create a black frame (RGB 0, 0, 0) in the Curves menu by dragging the RGB curves down.
- 2 In the Main menu, click Setup, and then click Interface to display the Interface menu.
- 3 Set Background to the default value of 30.

A value of 30 creates a subtle contrast between the background colour and the black frame.

- 4 On the monitor, set Contrast to the minimum value.
- 5 On the monitor, set Brightness to the minimum value.
- 6 Slowly increase Brightness on the monitor to increase the black level. When the black image appears lighter than the surrounding background, stop increasing brightness and then decrease it a little.
You should have a good black level value.

To adjust the picture setting:

- 1 Adjust the black level as described in the previous procedure.
- 2 Load a white frame (RGB 1023, 1023, 1023 in Log mode) to the Storyboard. See [Creating a Cut with Shots in the Library](#) (page 1919).
The white frame appears in the Player. Use this image to set your picture settings.
TIP You can also create a white frame (RGB 1023, 1023, 1023) in the Curves menu by dragging the RGB curves up.
- 3 In the Main menu, click Setup, and then click Interface to display the Interface menu.
- 4 Set Background to the default value of 30.

A value of 30 creates a good contrast between the background colour and the white frame.

- 5 On the monitor, set Contrast to the maximum value.
- 6 Slowly decrease Contrast on the monitor to adjust the picture setting. When you begin to see that the white frame turns light grey, stop decreasing contrast and then increase it a little.

TIP If anything, err on the side of dark. Sensitivity to monitor flicker increases with the Contrast value. For the most part, the end result of monitor adjustment processes should be good blacks and whites on a screen you are comfortable looking at.

Selecting the Project Colour Space

Select the colour space that you intend to use for the project. The colour space should correspond to the footage you are using. If you are using film images, select logarithmic colour space. If you are using images with linear data (or you prefer the toolset), select linear.

To select the project colour space:

- 1 In the Main menu, click Setup, and then click Grade.
The Grade menu appears.

(a) Logarithmic colour space button (b) Linear colour space button

- 2 Select a colour space:
 - Click Log to select the logarithmic colour space.
 - Click Linear to select the linear colour space.

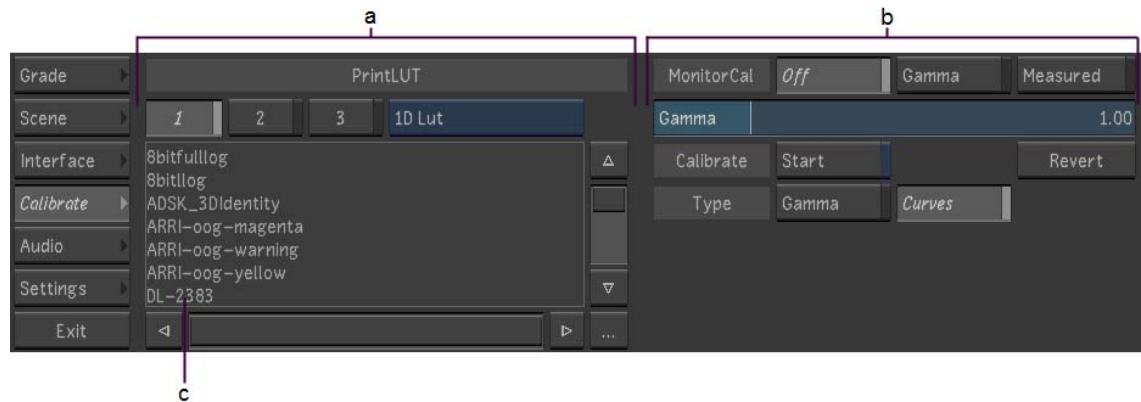

Calibrating a Monitor

In Lustre, you can calibrate your monitor automatically or manually. Automatic monitor calibration is much more accurate than manual monitor calibration methods because manual methods hinge on perception, and your perception of the monitor can vary depending on the surrounding environment.

Access the Calibration tools in the Calibrate menu.

To access the Calibrate menu:

- 1 In the Main menu, click Setup, and then click Calibrate.
The Calibrate menu appears.

(a) Print LUT buttons (b) Calibration tools (c) Print LUT list

Calibrating the Monitor Automatically

Use a colourimeter (an external monitor measurement device) to scan your monitor's output and automatically correct the display.

You should automatically calibrate the monitor at the beginning of each project. If the project is long, you may want to recalibrate the monitor from time to time. Every 200 working hours is a good guideline.

To work with film, using a colourimeter is strongly recommended to get the best results.

Gamma Calibration

You can calculate a gamma correction LUT using one measure. This creates a simple gamma curve.

To automatically calibrate the monitor based on a gamma measure:

- 1 In the Calibrate menu, click Off to disable existing monitor calibration settings.

- 2 Set the calibration type to Gamma.

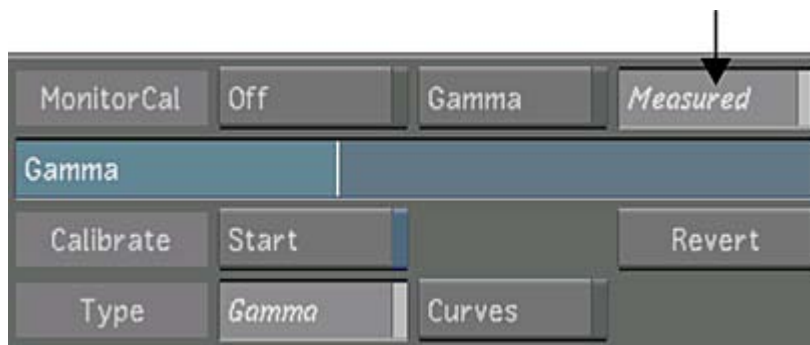

3 Attach the colourimeter to the centre of the screen.

4 Enable Start.

A series of grey patches appears on the screen. After a few moments, a monitor calibration LUT is generated based on the readings and saved to the *monitor.calib* file.

5 Click Measured to apply the monitor calibration settings.

Curves Calibration

You can calculate the gamma correction LUT using a series of colours, which appears on the screen.

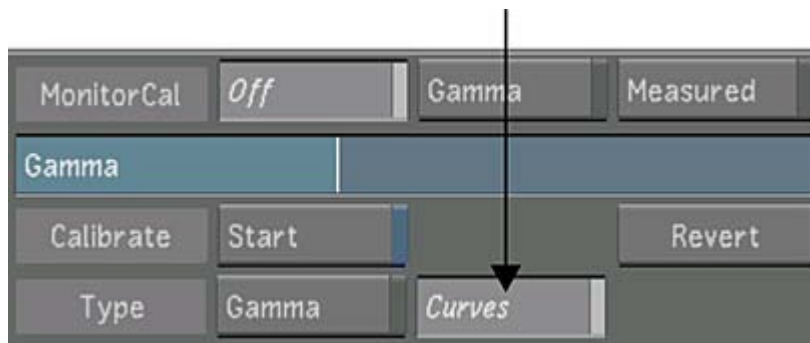

NOTE You can set the colour steps in the *init.config* file. See the *Autodesk Lustre Software Installation Guide*.

To automatically calibrate the monitor based on a curves measure:

1 In the Calibrate menu, click Off to disable existing monitor calibration settings.

2 Set the calibration type to Curves.

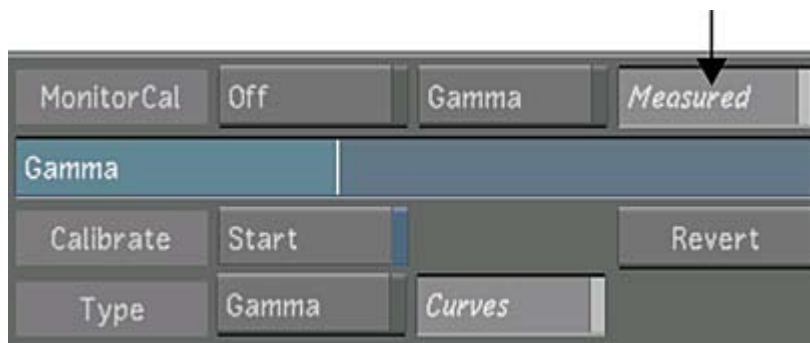

3 Attach the colourimeter to the centre of the screen.

4 Enable Start.

A series of colour patches appears on the screen. After a few moments, a monitor calibration LUT is generated based on the readings and saved to the *monitor.calib* file.

5 Click Measured to apply the monitor calibration settings.

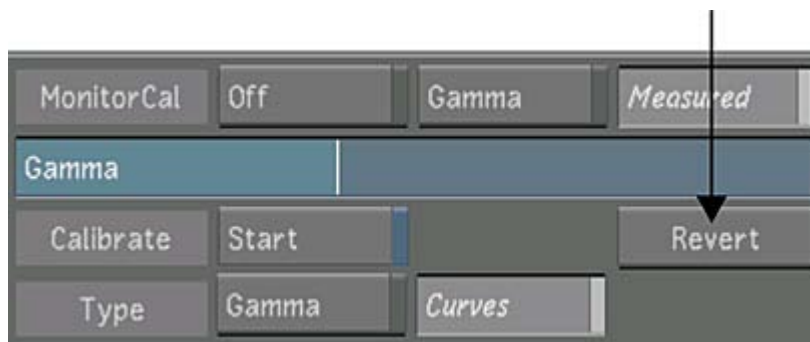

Reverting to a Previous Calibration Setting

If you are not satisfied with the results from the automatic calibration, you can revert to the previous automatic calibration.

To revert to a previous calibration setting:

1 In the Calibrate menu, click Revert.

The LUT that was previously saved to the *monitor.calib* file is used to calibrate the monitor. If you click Revert again, you will apply the settings from the latest LUT.

Calibrating the Monitor Manually

If you do not have access to a colourimeter, you can adjust the monitor gamma level manually.

To calibrate the monitor manually:

- 1 In the Calibrate menu, enable Gamma, and then drag the Gamma slider.

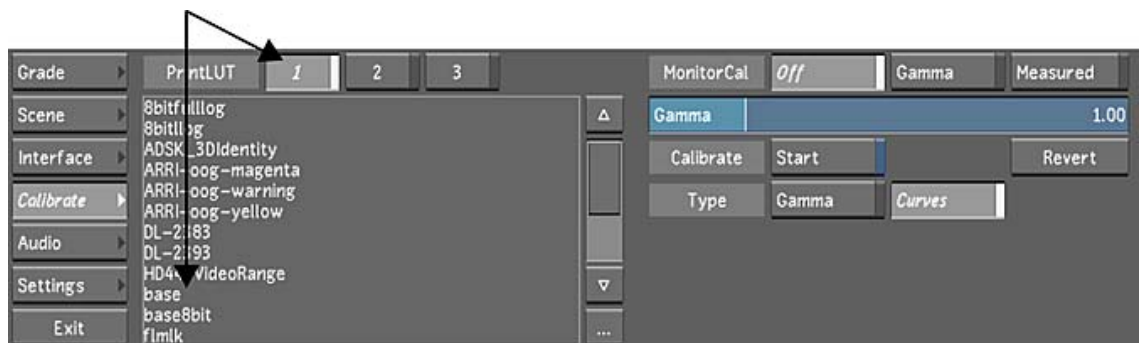

Calibrating for Dual-Head Mode

If the video card on the Lustre system is set to Dual-Head mode, you can set different LUTs for each monitor. This is useful when using different display types, such as a monitor and a plasma screen.

To set different LUTs:

- 1 (Optional) Import a LUT into the LUT list. See [Importing a LUT File](#) (page 2070).
- 2 In the Calibrate menu, click 1 for the main monitor and select a 3D LUT for the main LUT.

NOTE A 3D LUT is processed directly on the video card and therefore ensures better performance in Lustre.

- 3 Click 2 and select any LUT for the second monitor.

NOTE This setup will not affect playback speed unless a 3D LUT is also chosen for the second monitor.

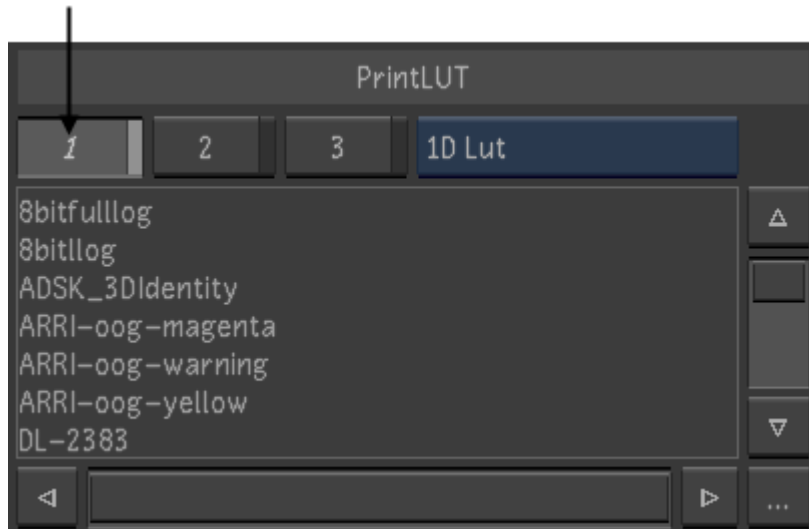

Applying LUTs for Viewing (Print LUTs)

Use viewing LUTs (Print LUTs) to apply preset gamma correction and other transforms to the displayed images. These LUTs allow you to preview images as they will appear on different devices or media without changing the underlying colour values.

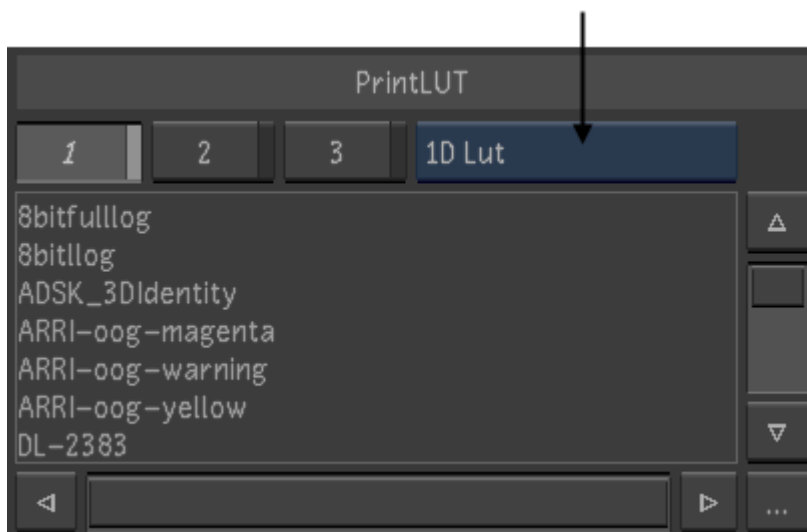

Defining Print LUTs for Viewing

You can define up to three viewing LUTs (Print LUTs) and switch between them for quick comparisons.

- 1 In the Setup / Calibrate menu, click the number of the Print LUT to assign.

- 2 Select the type: 1D Lut, 3D Lut, or Colour Transform.

- 3 Do one of the following:
 - Select an item list.
 - Click the Browse (...) button at the lower right to select a LUT or colour transform from your file system.

The Print LUT is assigned to to the corresponding number.

- 4 Repeat to assign LUTs or colour transforms to the other numbers.

Switching Between Print LUTs for Viewing

You can switch between viewing LUTs (Print LUTs) to change the display of your images anytime during a session.

- 1 Do one of the following:
 - In the Calibrate menu, click 1, 2, or 3.
 - Click the LUT button to toggle through the assigned Print LUTs.

The selected Print LUT is applied to the display.

Browsing for Footage

Accessing the file browser is one of the first steps of the grading process. Use the file browser to locate scanned or captured footage on your direct storage or shared networked storage.

You can import a large number of media file formats via the File Browser using the Wiretap Gateway. You can access a local or remote host that is running a Wiretap Gateway and import Flame and Smoke sequences, for example. For more information about the Wiretap Gateway, refer to the *Autodesk WiretapCentral and Wiretap Gateway Installation and Configuration Guide*.

NOTE The <HOME> prefix will not appear on media coming from the Wiretap Gateway or on managed media residing on the Standard FS.

Natively Supported Media File Formats

The following file formats are all natively supported in Lustre:

- DPX (8-bit, 10-bit, 16-bit)
- Cineon (8-bit, 10-bit)
- TGA (8-bit, 16-bit)

- TIFF (8-bit, 16-bit)
- SGI (8-bit, 16-bit)
- BMP (8-bit, 8-bit w/alpha)

NOTE The BMP format is only supported on Windows.

For more information on Wiretap Gateway supported media files, see Wiretap Gateway Supported Ingest File Formats.

Wiretap Gateway Supported Media File Formats

Tables in this topic:

Image Sequence

Format	Extension	Import	Export	Depth
Alias®	.als	yes	yes	8 bits
ARRIRAW	.ari	yes	—	12 bits
NOTE Always presented as a clip, never as a sequence of RAW images. Supports material shot on camera using ARRI SUP 7 or earlier, and features from version 4.4 of the ARRIRAW SDK.				
Cineon®	.cin	yes	yes	10 bits
DPX	.dpx	yes	yes	8, 10, 12, 16 bits and ADX encoding.
DPX - Single channel	.dpx	yes	—	See Note.
NOTE Monochromatic DPX files from the following film scanners have been validated: <ul style="list-style-type: none"> ■ FilmLight Northlight (10 & 16-bit) ■ DigitalFilmTechnology SCANITY™ (10 & 16-bit) ■ Imagica (8, 10 & 16-bit) Lustre supports single channel DPX files only when imported through Wiretap Gateway.				
Gateway	.clip	yes	—	n/a
HDR	.hdr	yes	—	32 bits

Format	Extension	Import	Export	Depth
JPEG	.jpg	yes	yes	8 bits
OpenEXR	.exr	yes	yes	8, 10, 12u, 12, 16 fp bits
	Export includes OpenEXR with RLE (Run-Length Encoding) compression. NOTE <ul style="list-style-type: none"> ■ Lustre does not render RGBA OpenEXR files. Do not use the Same As Scans rendering option. Use the OpenEXR RGB rendering option if you want to render 16-bit half float media files. ■ Lustre does not support OpenEXR 32 bit fp files. 			
OpenEXR 2.0	.exr	yes	—	8, 10, 12u, 12, 16 fp bits
	NOTE <ul style="list-style-type: none"> ■ Multi-part and deep pixel features are not supported: only the first part of a multi-part file can be accessed, and deep pixel channels are ignored. ■ Lustre does not render RGBA OpenEXR files. Do not use the Same As Scans rendering option. Use the OpenEXR RGB rendering option if you want to render 16-bit half float media files. ■ The resolution of the matte channels has to be identical to the beauty pass that will be used for secondary color grading. 			
Photoshop	.psd	yes	—	8 or 16 bits
	NOTE Supports RGB and RGBA.			
Pict (Macintosh®)	.pict	yes	yes	8 bits
Pixar	.picio	yes	yes	8 bits
Portable Network Graphics	.png	yes	—	8 or 16 bits
	NOTE Supports alpha.			
Precomp	.precomp	yes	—	8, 10, 12u, 12, 16 fp, or 32 fp bits
SGI®	.sgi	yes	yes	8 or 16 bits
Softimage®	.pic	yes	yes	8 bits
TARGA®	.tga	yes	yes	8 bits
Tdi/Maya®	.iff	yes	—	8 or 16 bits

Format	Extension	Import	Export	Depth
Tiff	.tif	yes	yes	8 or 16 bits
Wavefront®	.rla	yes	yes	8 or 16 bits

QuickTime

Format	Extension	Import	Export	Depth

MXF

Format	Extension	Import	Export	Depth
AVC-Intra 50	.mxf	yes	yes	
				NOTE Panasonic P2
AVC-Intra 100	.mxf	yes	yes	
				NOTE Panasonic P2. Import includes support for 1080/60p.
AVC-Intra 200	.mxf	yes	—	
DNxHD	.mxf	yes	yes	
				NOTE Includes support for formats: 36, 60, 75, 90, 90x, 110, 110x, 115, 145, 175, 175x, 185, 185x, 220, 220x.
DV 25	.mxf	yes	—	
				NOTE Panasonic P2
DVCPRO	.mxf	yes	yes	
				NOTE Panasonic P2
DVCPRO 50	.mxf	yes	yes	
				NOTE Panasonic P2 (PAL & NTSC)
DVCPRO HD	.mxf	yes	yes	
				NOTE Panasonic P2. Available in 1080p@25/50, 1080p@24/30/60, 720p@25/50, and 720p@24/30/60.
SonyRAW	.mxf	yes	—	
				NOTE Includes support for Sony F65, F55, and F5 camera outputs.
XAVC	.mxf	yes	—	
				NOTE Includes support for Sony F55 and F5 camera outputs.
XDCAM	.mxf	yes	—	

Format	Extension	Import	Export	Depth
	NOTE MPEG-2 IMX 30, 40, and 50			
XDCAM HD	.mxf	yes	yes	
	NOTE MPEG-2 long-GOP. Import supports 4:2:0 and 4:2:2. Export: 4:2:2.			

NOTE Flame Premium exports MXF as OP-1a files (including the timecode). The is audio encoded as PCM, 16-Bit or 24-Bit. Avid applications support OP-Atom MXF files: use the AMA MXF plug-in to bring the OP-1a files into an Avid application.

MP4

Format	Extension	Import	Export	Depth
H.264	.mp4	yes	—	
XDCAM EX	.mp4	yes	—	
	NOTE MPEG-2 long-GOP			

Other Streaming Codecs

Format	Extension	Import	Export	Depth
AVCHD	.mts or .m2ts	yes	—	
	NOTE Only linear PCM audio is supported. Some cameras can record AC-3 audio, but this format is not supported. Only the video portion of AVCHD media with AC-3 audio content is accessible from Flame Premium.			
R3D	.r3d	yes	—	RAW
	Supports REDCODE RAW 2 and 3, RED SDK version 4.4, including MONOCHROME R3D media. Starting with Flame 2013 20th Anniversary Edition Extension Extension 2 Service Pack3, changes to the RED SDK affected how the DRX setting was computed for all R3D clips. If you are using clips imported with a earlier version, review the clips DRX setting.			

Audio File Formats

Format	Extension	Import	Export	Depth
AIFF	.aiff	yes	yes	16 or 24
AIFF-C	.aifc	yes	yes	16, 24, 32 (float)
Audio Visual Research	.avr	yes	yes	16

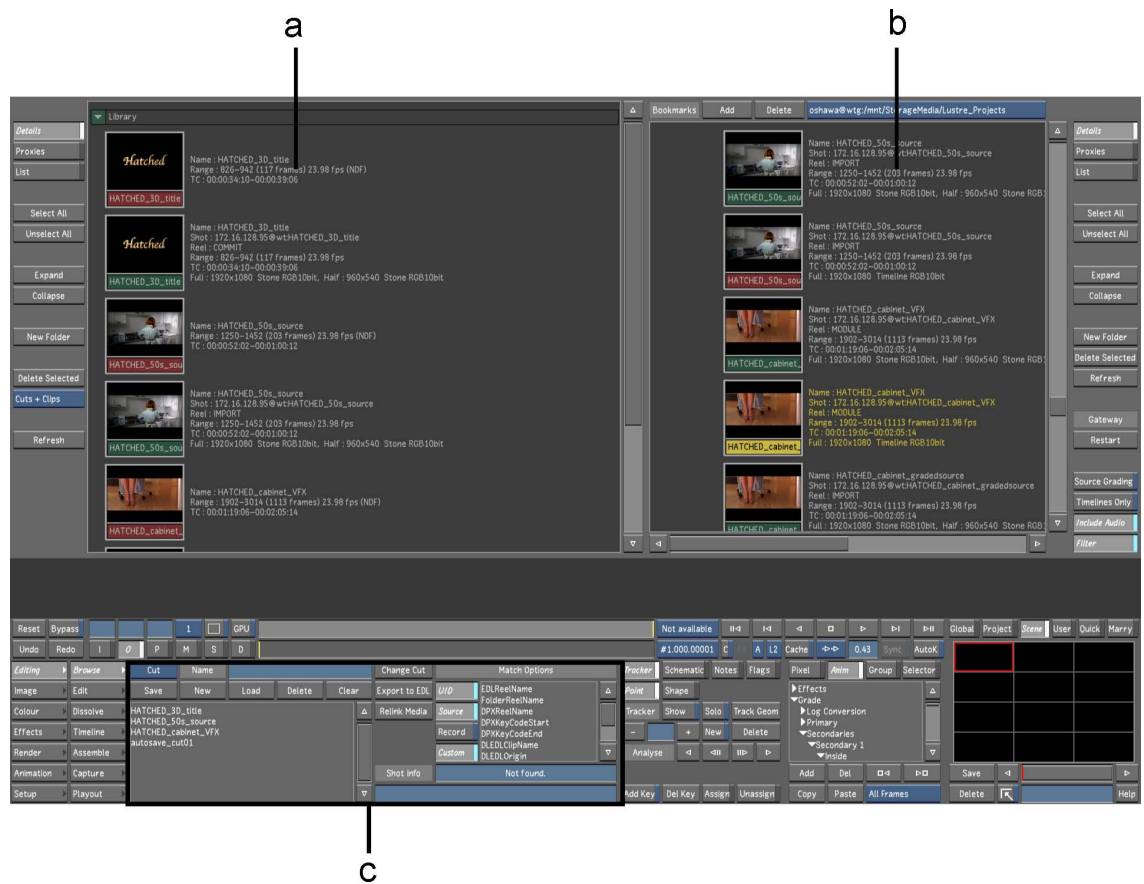

Format	Extension	Import	Export	Depth
Berkeley/IR-CAM/CARL Sound (BISCF)	.bsf	yes	yes	16
MP3	.mp3	yes	yes	16
Nextsnd	.au	yes	yes	16, 24, 32 (float)
WAVE	.wav	yes		16, 24, 32 (float)
WAVE - Broadcast	.wav	yes	yes	16, 24, 32 (float)
	NOTE Includes support for RF64 files (BWF-compatible format that supports files larger than 4 GB).			
WAVE - Extensible	.wav	yes	—	16, 24, 32 (float)
	NOTE Audio tracks are imported as regular audio tracks, without mapping the channels to spatial locations.			
NOTE Files of any sample rate can be imported, but they are all resampled to 48 kHz.				

Accessing the File Browser

Use the file browser to locate shots and load them into the Library.

To access the file browser:

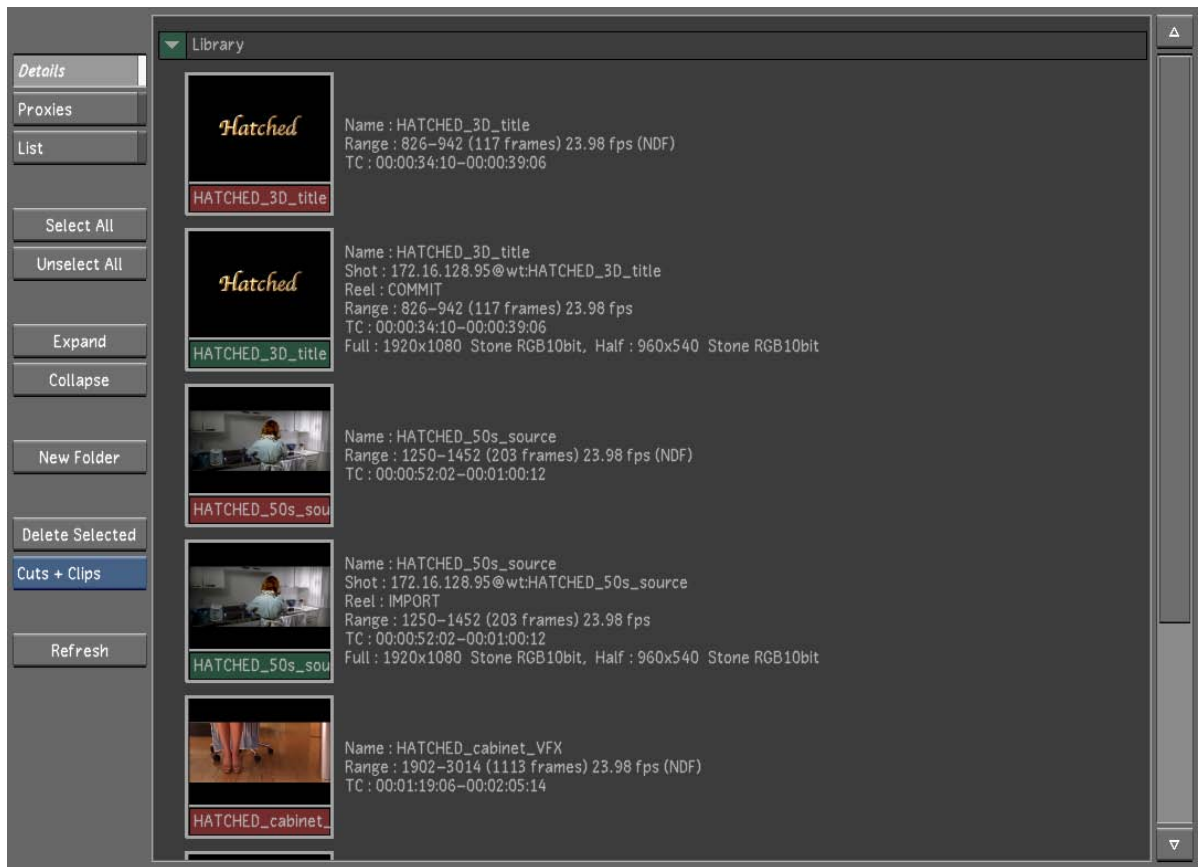

- 1 Click Editing, and then click Browse.
The Browse menu and the file browser appear.

Footage courtesy of EVN PRODUCTIONS(a) Library (b) File browser (c) Browse menu

When you are in the Browse menu, the work area is divided into three areas.

Library Use to organize your cuts and clips.

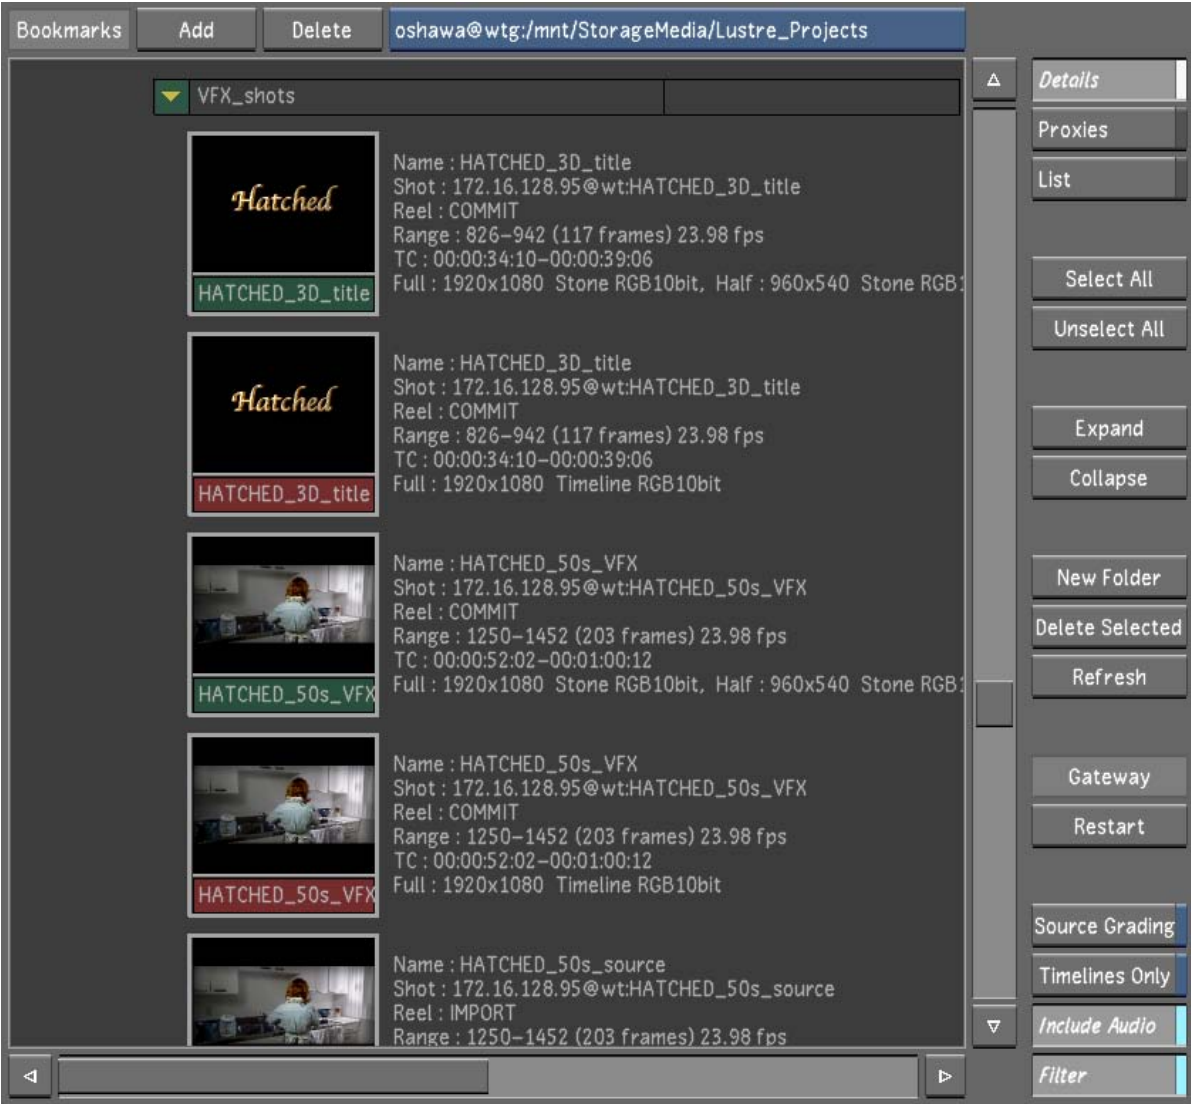

Footage courtesy of EVN PRODUCTIONS

Click:	To:
Details	Display clips in Thumbnail and Text view.
Proxies	Display clips in the Library as thumbnails.
List	Display clips in Text view.
Select All	Select all cuts and clips in the Library.
Unselect All	Deselect the selected cuts and clips in the Library.
Expand	Display the contents of the selected folder.
Collapse	Hide the contents of the selected folder.
New Folder	Create a new folder. First select the main folder under which the new one is to be created. Rename the folder by right-clicking it and entering a new name (the root, <i>Library</i> , cannot be renamed).
Delete Selected	Delete selected item.

Click:	To:
Cuts/Clips option box	Select the type of media to delete within the selection. The options are: Cuts, Clips, Cuts+Clips.

File browser Use to locate footage and bring it into the Library. When accessing footage from the local or network storage, always place the files into the Scans Full home directory. Footage located under this directory will show a <HOME> prefix before their path when imported in the library.

Footage courtesy of EVN PRODUCTIONS

Click:	To:
Add	Add the current folder location to the bookmark list in the Bookmarks box.
Delete	Remove the folder displayed in the Bookmarks box from the bookmark list.
Details	Display clips in Thumbnail and Text view.

Click:	To:
Proxies	Display clips in the Library as thumbnails.
List	Display clips in Text view.
Select All	Select all clips in the file browser.
Unselect All	Deselect the selected cuts and clips in the Library.
Expand	Display the contents of the selected folder.
Collapse	Hide the contents of the selected folder.
New Folder	Create a new folder in the currently selected folder. Rename the new folder by right-clicking it and entering a new name (the root folder cannot be renamed). Clips already in the file browser cannot be moved to the new folder.
Delete Selected	Delete selected shots.
Refresh	Rescan the file systems and update the file browser with up-to-date information.
Timelines Only	Display only the timelines in the File Browser. See Browsing for Remote Footage (page 2375).
Include Audio	Imports audio tracks from the Wiretap server. See Importing Audio From Wiretap (page 2349).
Filter	Hide specified folders (defined in the <i>init.config</i> file) from the file browser view.

Browse menu Use to create and manage the cuts in the project. See [Managing Cuts](#) (page 1819).

Viewing Media File Information

In the File Browser or the Library, you can view information about the media files that make up the clip.

You can view the files in different modes.

Footage courtesy of EVN PRODUCTIONS

The following information is displayed in List and Details view modes.

Shot place Points to the location of the media files that make up the clip.

Full Indicates the resolution and file format of the full-resolution images that make up the clip.

Half Indicates the resolution and file format of the half-resolution images that make up the clip.

Range Displays the range of frames in the shot sequence that make up the clip.

Frames Displays the number of frames that make up the clip.

Timecode Displays source in and out timecode values that make up the clip.

In the Browse menu, you can also view information about a selected shot in the Storyboard.

Bookmarking Folder Locations

You can quickly access file system folder locations using bookmarks. Bookmarks can be applied to local or remote file system folders, BrowseD, Wiretap and Wiretap Gateway server.

The Bookmarks box contains three default shortcuts.

- Scans Full Home navigates to the project Scans Full Home location.
- Current Shot Location navigates to the folder location of the source media for the current shot.
- Current Render Location navigates to the folder location of the rendered media for the current shot.

To add a folder:

- 1 Navigate to the folder you want to bookmark and select it.
- 2 If the folder contains subfolders, do one of the following:
 - Collapse the folder to mark only the main folder for bookmarking.
 - Expand the folder to mark the folder and all subfolders for bookmarking.
- 3 Click Add Bookmarks.
A new entry is added to the Bookmarks box.

To navigate to a folder using bookmarks:

- 1 Click the Bookmarks box.

- 2 Select the bookmarks with the location where you want to navigate.

To delete a Bookmark from the list:

- 1 Select the Bookmark you want to delete.

NOTE

Only one bookmark can be deleted at a time.

- 2 Press Delete Bookmarks, and then confirm the deletion.

User-based Bookmark Data

Bookmark data is user-specific and saved in a file, located inside the User folder location (as defined in the *init.config* configuration file). The file named *UserContext.config* is XML, and it contains the following data:

```
<UserContext user="Marc" parser="1.0" version="2011.1.0.73">
  <BookmarkGroup>
    <Bookmark string="Z:\MEDIA" />
    <Bookmark string="upton@wtg:/QASAN01" />
    <Bookmark string="Z:\Design\cfg" />
  </BookmarkGroup>
</UserContext>
```

TIP Instead of navigating to a location, bookmarks can be added directly to *UserContext.config*.

Library and Reel Creation / Deletion

Library and Reel Creation

When browsing a Wiretap server, you can create Libraries and Library reels, using the New Folder option in the File Browser.

The nature of the newly created folder depends on what is selected:

- If you select a Project, clicking New Folder creates a Library folder within the Project.
- If you select a Library, clicking New Folder creates a Reel folder inside the selected Library.

NOTE If a Library is currently in use in Smoke or Flame, it is marked as Read Only and you cannot create new Libraries or Reels in it until it is no longer in use.

Library and Reel Deletion

When browsing a Wiretap server, it is now possible to delete content like Libraries, Library reels, timelines and source clips.

NOTE If a Library is currently in use in Smoke or Flame, it is marked as Read Only and cannot be deleted until it is no longer in use.

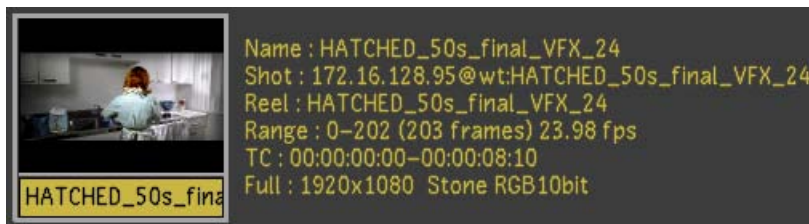

Loading Clips to the Library

Once you locate your clips in the file browser, you move them into the Library so that you can use them in your cuts. Clips in the Library are pointers to the actual media files on the file system. You can view information about the clips in both the file browser and the Library.

There are two ways to interact with clips and timelines in the File Browser and Library:

Select shots/timelines:

- Click on the lower portion of the proxy (red or green), to select the shot/timeline. The lower portion of the proxy becomes yellow. You can select multiple clips by clicking Ctrl as you select them.

Footage courtesy of EVN PRODUCTIONS

If you select the wrong clips/timelines, click any unused grey area in the User Interface to cancel your selection.

Pick shots/timelines

- Click on the image portion of the proxy, to pick the clip/timeline. You can pick multiple clips/timelines at once to move/load them simultaneously.

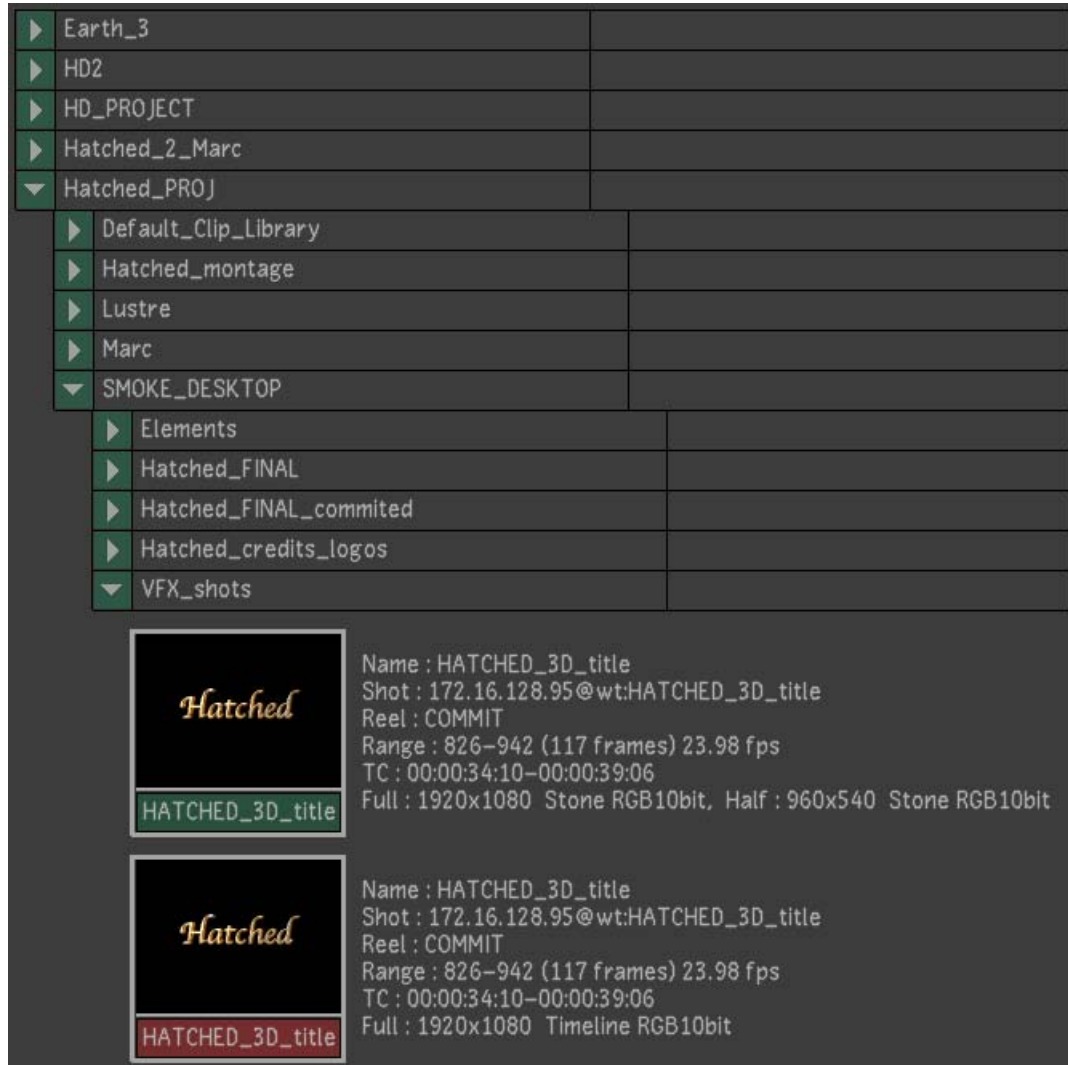

Footage courtesy of EVN PRODUCTIONS

If you pick up the wrong clips/timelines, click any unused grey area in the User Interface to cancel your selection.

To move shots or timelines to the Library:

- 1 Navigate to your clips or timeline.

Footage courtesy of EVN PRODUCTIONS

TIP You can open all of a folder's sub-directories by **Shift**-clicking the arrow to the left of the folder or by using the Expand button.

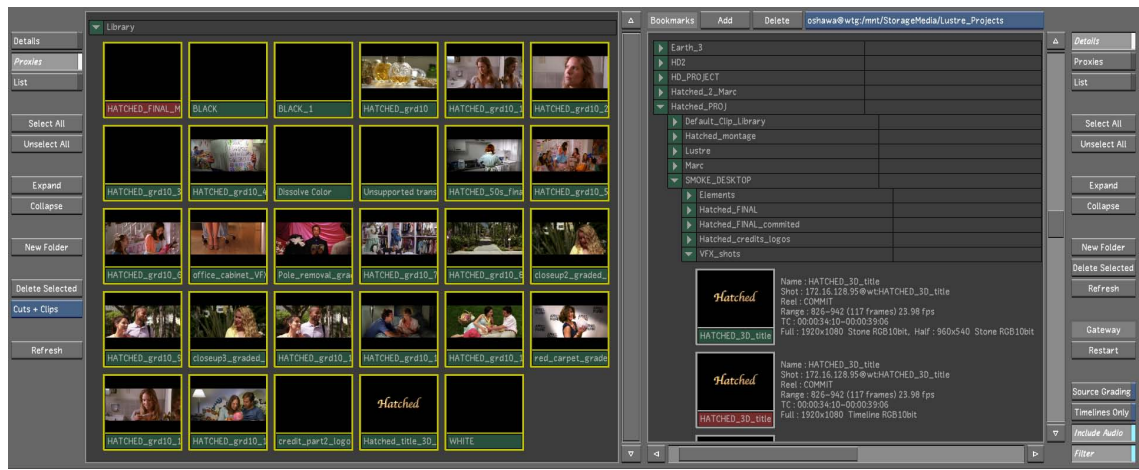

- 2 Select the clips you want to move to the Library.

TIP To select all the clips from a folder, select the folder.

- 3 Drag the selected clips to the Library, and then click to release the clips.

TIP You can drag clips directly from the file browser to the Storyboard. When you do this, the clips are also imported to the Library.

Newly added clips are highlighted. Clips already in the Library are not duplicated.

Footage courtesy of EVN PRODUCTIONS

Deleting Content From the Library

You can delete clips and cuts from the Library.

NOTE Deleting clips from the Library does not delete them from the Storyboard.

To delete selected clips from the Library:

- 1 Select the clips you want to delete.
- 2 Click Delete Selected, and then confirm the action.
All the selected clips are deleted.

To delete all clips from the Library:

- 1 Click Delete All, and then confirm the action.
All the clips are deleted.

Creating a Cut with Shots in the Library

Once the source clips are imported to the Library, you can assemble them using an EDL or by creating a timeline.

See:

[Working with EDL, ALE and Cutlist Files](#) (page 1935)

[Adding Shots to the Storyboard](#) (page 1957)

[Adding Shots to the Timeline](#) (page 1979)

Matching Shots

You can use Matchback to select a shot in the timeline and find it in the Library, or click a shot in the Library and see where it is used in the timeline.

To match a shot from the Timeline or Storyboard to the Library:

- 1 Select the shot by completing one of the following:
 - Click a shot in the Storyboard.
 - Place the Timeline positioner on a shot.
- 2 Press `Shift+Q`.
The selected shot is highlighted in the Library.

To match a shot from the Library to the timeline:

- 1 `Alt`-click the shot in the Library.
The selected shot is highlighted in the Storyboard and the positioner is updated in the Timeline.
- NOTE** If you continue to `Alt-click` the shot in the Library, successive instances of the same shot are highlighted in the Storyboard and positioned in the Timeline.

Transcoding

The Wiretap Gateway server makes it possible for Lustre to easily ingest complex media formats. The Transcode menu displays information related to the format of the currently selected media. The full set of options, which include debayering and colour options are only available for RED, ARRIRAW and Sony F65 RAW files, whereas the LUT and resize options are available for any media file imported through Wiretap Gateway. Transcode parameters are greyed out in the Transcode menu when the file format does not support them.

NOTE

- When importing Sony F65 RAW files, a Scene Linear transformation is applied by default, to convert the 16-bit media to 16-bit half-float. To remove this transformation, select Native, from the Colour Space box in the Image / Transcode / Colour menu.
- Sony F65 RAW files are only available if you install the alternate Red Hat 5 build, which is available for HP Z800 and Z820 workstations.

The transcode settings are defined on a shot-by-shot basis. Some of the settings (e.g., Resize and LUT Options menus) can be applied to the media without having to click the Transcode button, and the other settings are not applied until you click the Transcode button. Once you click the Transcode button, the job is sent to the Backburner Manager where it is transcoded. When you begin transcoding, the transcoded media immediately replaces the current media. After the transcoding is complete, the cut is automatically saved and the media paths and processing options are stored in the cut file.

Once the transcode options are set, you can copy select settings from one shot to another using the Transcode Settings parameters found within the Selector. See [Copying Parameters with the Selector](#) (page 1860).

Transcode Workflow

Once you have imported the RED media and want to improve the playback of this file, follow the typical workflow to transcode your footage.

Step:	Refer to:
1. Set the high-level options.	Transcode Format Settings (page 1922).
2. Set the initial colour correction.	Transcode Colour Settings (page 1925) and Detail, OLPF Compensation, and Noise Reduction in Transcode Format Settings (page 1922).
3. Apply a LUT or a colour transform to the media.	Transcode LUT Options (page 1926).
4. Resize the media.	Transcode Resize Options (page 1929) .
5. Set the output options and transcode the media.	Transcode Output Settings (page 1930).
6. (Optional) Copy the transcode settings from one shot to another.	Copying Parameters with the Selector (page 1860).
7. (Optional) Save the transcode settings as a version.	Transcode Versioning (page 1932).
8. (Optional) Save the transcode settings as a template.	Transcoding Template (page 1933).

Transcode Options

The Transcode menu is divided into five submenus.

NOTE The Settings and Transcode options are available within the Format, Colour, LUT Options, Resize and Output settings tabs.

Format Sets the high-level options for the media decoding (e.g., debayering, resizing, filter, etc.). This submenu is exclusive to RED and ARRIRAW media. See [Transcode Format Settings](#) (page 1922).

Colour Sets the colour settings to be transcoded (e.g., colour and curve settings, etc.). This is useful to set the initial colour correction before grading your footage. This submenu is exclusive to RED and ARRIRAW media. See [Transcode Colour Settings](#) (page 1925).

LUT Options Applies a LUT or colour transform to the media to be transcoded. This is useful for colour space conversion, for example, before grading your footage. See [Transcode LUT Options Settings](#) (page 1926).

Resize Applies a resize to the media, without the need to transcode and generate new media. See [Transcode Resize Options](#) (page 1929).

Output Sets the file output settings (e.g., folder structure, timecode, and image format). See [Transcode Output Settings](#) (page 1930).

Once these values have been set, you can choose to save the settings to a transcoding template (similar to the project and user settings template option). See [Transcoding Template](#) (page 1933).

To enter the Transcode menu, click Image in the Main menu, and then Transcode.

Transcode Format Settings

(a) Fit Method option box (b) Selector

NOTE The Settings and Transcode panel options are also available in the Colour and Output settings tab.

Camera button Enable to load the original RED media values as set by the RED camera. When the RED media is initially imported, this button is automatically enabled. When you change one of the transcode options, this button is automatically disabled to show that these settings are no longer the original RED camera settings.

RSX/RMD button Enable to load the values from the latest version of the RSX/RMD file. When a clip is opened in RED ALERT!™, an RSX/RMD file is saved alongside the R3D file, using the same filename. It contains the additional metadata added to the R3D file within RED ALERT!.

Once you change one of the Lustre transcode options, this button is automatically disabled to show that these settings are no longer the original RSX file settings.

Scene button/Shot button Enable Scene or Shot to transcode either the entire scene or the shot that is selected in the Storyboard.

Heads & Tails button Enable to make sure the heads and tails from the RED media are kept when it is transcoded.

Handles button and Handles field Enable the Handles button when you want to transcode fewer heads and tails than what is currently showing in the footage. Enter a value in the Handles field to determine how many heads and tails to transcode. This option can only be used if the Heads & Tails option is enabled.

Transcode button When the format, colour, and output settings have been established, click this button to send the job to the Backburner Manager and transcode the RED media to a DPX file.

Resize button When enabled, the resize settings (i.e., the W and H fields) are implemented when the RED media is transcoded.

W/H field Enter the desired resize setting. Note that a resize setting that is not directly proportional to the size of the original media takes longer to process.

Fit Method option box To use a different aspect ratio during a resize, select one of the following fit method options to be applied to the exported clip.

Select:	To:
Fill	Fit the source, width, and height into the destination frame. If the source and destination frames do not have the same aspect ratio, the image can become distorted. This is the default option.
Crop Edges	Fit one edge of the source into the destination frame without stretching or squashing the frame. Excess parts of the source frame after resizing are cropped. If the source, after the one edge is resized, is wider than the destination, its overhanging left and right edges are cropped. If the source is taller than the destination, the upper and lower edges are cropped.
Letterbox	Fit the source to the destination frame without squashing or stretching it, and without cropping the source. If the source is wider than the destination, black bars fill the top and bottom of the destination frame. If the source is narrower than the destination, black bars fill the right and left sides of the frame. In all cases, the entire source frame is contained within the destination frame.
Centre/Crop	Fit the source image, centred, over the destination frame. If the source is larger than the destination, it is cropped. If the source is smaller than the destination, it is surrounded by a black border.

Filter option box Select the filter option to determine the quality of the interpolated resize result.

Select:	To get:
Bicubic	Very good results for resizing soft-looking images. Use to sharpen the image. This is the default option.
Mitchell	Best results when resizing a clip to a higher resolution.
Triangle	Moderate results with little processing overhead.
Impulse	Quick, low-quality results.
Lanczos	Best results when resizing a clip containing a variety of patterns and elements to a lower resolution. It is the most complex, with the longest processing time.
Shannon	Excellent results when resizing a clip to a lower resolution. Very similar to Lanczos, but results are a little softer.
Quadratic	Good results for resizing simple images with straight edges. Similar to Gaussian, but with more blurring. Use to soften the image.
Gaussian	Excellent results when resizing a clip with no patterns and a lot of straight edges to a lower resolution. Useful for softening some detail.

NOTE The following settings vary based on the type of media.

Include YUV Headroom Enable to include YUV headroom on import for Quicktime and MXF files.

Scale to Full HD Enable to scale MXF P2 & XDCAM HD narrow content to Full HD resolution on import.

Debayering Hires/Proxy option box Select the level of quality required from the debayering algorithm. Higher resolutions take more time to process. Select one of the following options for the full or proxy footage:

- Full
- Half Premium
- Half Good
- Quarter
- Eighth

Bit Depth option box Select the required bit depth. Your options are:

- 12 bit
- 16 bit fp

Detail option box Select the level of detail extraction required. Your options are:

- Low
- Medium
- High

OLPF Compensation option box Select the level of Optical Low Pass Filter compensation to use. The OLPF is a type of sharpening used to compensate for the optical anti-aliasing filter, which can induce softening of the image during recording.

Noise Reduction option box Select the level of noise reduction applied to the debayered shot.

HDRx Settings Select the HDRx Exposure options.

Exposure option box Select the exposure options of your HDRx media.

Select:	To:
Primary Exposure	Select the main exposure of the R3D file
Highlight Exposure	Select the second exposure of the R3D file.
Blend Exposure	Blend the values between the two exposures to create a single image for grading. This option uses both video tracks of their R3D file. Playback performance may be altered.
Magic Motion	The new HDRx merging option provided by RED. This blending algorithm is used to composite tracks A and X of an HDRx clip.

Select:	To:
High Dynamic Range	Convert the two exposures into a 16-bit half-float image. When this option is selected, the Debayering / Bit Depth option is automatically set to 16-bit fp and the Gamma Curve setting is set to Scene Linear (16bit fp).
RMD	Define the blending options from the RMD. If there is no RMD, the application defaults to using the A track.

Blend slider Set a value to blend the two exposures of a RED HDRx clip. With HDRx Settings set to Blend Exposures, this field behaves like the blend in REDCINE-X. The blend operation is a blend of the two exposures: -1 shows only the Highlight (X frame), 1 only the Primary (A Frame), and 0 a 50-50 mix. With HDRx Settings set to High Dynamic Range, Blend also attenuates the artefacts created by scene motions. Set to 1 unless you are troubleshooting motion artefacts.

Exposure Offset slider Set how much greater the Primary exposure was compared to the Highlight exposure, in units of stops. Only available when HDRx Settings box is set to High Dynamic Range. The Exposure Offset should be set to match the setting on the camera for how many stops separate the Primary and Highlight tracks. This is typically 2 or 3 stops. Enter the same value used to record the footage or you will get bad results.

Highlight Threshold slider Set the threshold when pixels from the Highlight exposure are used instead of the over-exposed pixels from the Primary exposure. Only available when HDRx Settings box is set to High Dynamic Range. Set Highlight Threshold last because import options such as ISO or FLUT lighten or darken the image. Too high and you get clipping (often including a magenta-coloured cast), too low and the midtones and shadows have noise leaking in from the Highlight track.

Offset From File button Enable to apply the exposure offset embedded in the file's metadata rather than setting a value manually.

Selector Select the parameters within the respective list to copy the settings from one shot to another. See [Copying Parameters with the Selector](#) (page 1860).

Transcode Colour Settings

Adjust the values in this Colour settings tab to set the preliminary colour correction to your RED media.

For information on the Settings and Transcode options, see [Transcode Format Settings](#) (page 1922).

Colour Space option box Displays the value of the native colour space of the images, as set in the camera. Overriding this value may produce unexpected results.

Gamma Curve option box Displays the value of the output gamma curve that is applied to the shots.

Colour Science option box

Displays the version of the RED codec currently selected (2.X or 3.X). Using the version 3 of the codec gives you access to the FLUT and the Shadow options in the Colour Settings menu, and enables the Lift/Gamma/Gain menu. It also enables the Curve Settings for you RGB channels.

ISO option box Displays the value of the linear gain operation. RED images are always shot at 320 ISO.

Kelvin slider Displays the perceived colour temperature of the image.

Shadow slider Sets the shadow level.

Flut slider Refines the ISO level. As FLUT units are in stops, a +1 FLUT value is the same as doubling the ISO.

Tint slider Adjust the level of green or magenta in the shadow areas of the shot.

DRX slider Adjust the setting for the Dynamix Range Extension (DRX), which sets how much pixel data is copied from non-saturated channels into saturated channels.

Saturation slider Adjust the intensity of the colours in the footage.

Brightness slider Adjust the red, green, and blue levels across the entire image.

Contrast slider Adjust the gradation between the light and dark areas of the footage.

Exposure slider Displays the exposure increments, which are equivalent to f-stops.

Legacy Gain slider Modifies the red, green, and blue within the shot.

Curve Settings For more information on the curve settings, consult RED.

Transcode LUT Options Settings

From the Transcode / LUT Options menu, you can apply a LUT or colour transform on import to Gateway-imported media. Unlike [Input LUTs](#) (page 2069), the processing is performed in the Gateway rather than in Lustre.

NOTE If you are accessing media that was imported to a Smoke/Flame system with the Cache Source Media option enabled, that media is no longer considered Gateway media. It is seen by Lustre as managed media and hence the LUT and Resize on import options are not available. To work around this, you can perform a Flush Cache Media operation in Smoke / Flame, prior to importing in Lustre.

The LUT Options menu contains the following options:

Conversion LUT Type box Use to select the LUT Type you want to apply. Options are:

- 1D LUT
- 3D LUT
- Colour Transform

Enable button Activate to apply the selected LUT or colour transform.

Custom button Activate to build and apply a custom colour transform. See [Creating a Custom Colour Transform](#) (page 1928).

Conversion LUT list Click to select a LUT or colour transform to apply. Click again to deselect. This list is empty until you import LUTs or colour transforms using the Browse (...) button at the lower right. To remove an item from the list, select it and press the Delete key.

NOTE If you apply a colour transform that outputs floating-point data, the float conversion LUT is automatically applied after. See [Working with Half Float Media](#) (page 2080).

Applying a LUT or Colour Transform on Import

From the Image / Transcode / LUT Options menu, you can apply a LUT or colour transform to media imported using the Wiretap Gateway.

NOTE If you are accessing media that was imported to a Smoke/Flame system with the Cache Source Media option enabled, that media is no longer considered Gateway media. It is seen by Lustre as managed media and hence the LUT and Resize on import options are not available. To work around this, you can perform a Flush Cache Media operation in Smoke / Flame, prior to importing in Lustre.

- 1 From the Conversion LUT Type box, select 1D Lut, 3D Lut or Colour Transform.
- 2 Click Enable.
- 3 Select an item from the list, or click the Browse (...) button to locate and select a different LUT or colour transform. File paths are:

- **1D LUTs:** /usr/discreet/flamepremium<version>/lut/

NOTE The Wiretap Gateway supports Flame-compatible 1D LUT files only. Lustre-compatible 1D LUT files are not supported.

- **3D LUTs:**
 - **Flame Premium:** /usr/discreet/flamepremium<version>/lut/Lustre_Color_3DLUTs/
 - **Lustre Standalone:** /usr/discreet/Lustre_Color/lut/Lustre_Color_3DLUTs/

- **Colour Transforms:** Click the Bookmark field to switch between the **Project**, **Shared**, and **Autodesk** locations. See [Colour Management Files and Locations](#) (page 1581) and [Autodesk Color Transform Collection](#) (page 1602).

In addition to native .ctf files, you can also select files in several other supported LUT and transform formats.

Creating a Custom Colour Transform

You can create and apply a custom colour transform that is applied on import from the Image / Transcode / LUT Options menu. In addition, you can create and apply a custom colour transform that is applied when rendering from the Render / Output menu.

- 1 From the LUT Type box, select Colour Transform.
- 2 Click Enable.
- 3 Click Custom.
- 4 Click Add to insert an empty row.
- 5 Click the Type button and select a type:
 - **Shared:** The default location for shared custom colour transforms (available to all applications that use Autodesk Colour Management).
 - **Project:** The project transform folder (saved with the project).
 - **Autodesk:** The default location for preset colour transforms supplied with the application. See [Autodesk Color Transform Collection](#) (page 1602).
 - **Import:** Browse for colour transforms on your file system.
- 6 After you've selected a colour transform type, click the Transform button and select a transform. In addition to native .ctf files, you can also select files in several other supported LUT and transform formats.

Information is displayed about the transform and the operations it contains.

- 7 To add more transforms to the end of the chain, repeat steps 4 to 6.

You can also:

- Select a row and click the Type or Transform buttons again to change a transform in the chain.
- Select a row and click Delete to remove a transform from the chain.
- Use the Up or Down buttons to reorder the chain. Moving a transform up applies it earlier in the chain, and moving it down applies it later.

All transforms in the list are applied. The highlighted row indicates which transform will be affected by Up, Down, and other buttons. Information about the highlighted transform also appears in the metadata panel.

Exporting a Custom Colour Transform

Once you are satisfied with your custom colour transform, you can export it to file and recall it for later use.

- 1 Create a custom colour transform. See [Creating a Custom Colour Transform](#) (page 1928).
- 2 Click Export.

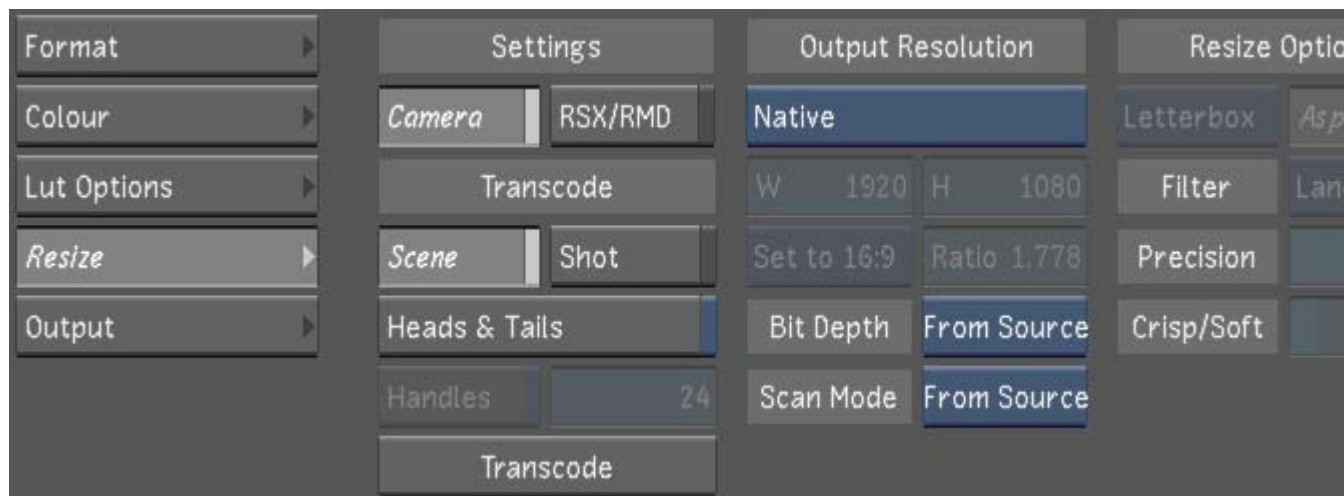

The file browser appears.

- 3 Click the Bookmark field to select the destination location:
 - To store the transform with the project for archiving, save it to the Flame **Project** location (usr/discreet/<project>/synColor/transforms).
 - To make the transform available to other applications that use Autodesk Colour Management, save it to the **Shared** location. This location is stored in the synColor configuration file and can be set in the Flame LUT preferences. The default location is /opt/Autodesk/Synergy/SynColor/Shared/transforms.
 - Saving transforms to the **Autodesk** location is not recommended
- 4 Enter a file name.
You can also enter a nickname and description. This information is included in the metadata that is displayed in the Description box in the Lut Options menu.
- 5 Click Export.

Transcode Resize Options

From the Image / Transcode / Resize menu, you can apply a resize to Wiretap Gateway imported media, without the need to transcode the media. The Resize is dynamically applied to the imported media. Adjust the resize values to define the destination resolution and the framing of the imported media.

NOTE If you are accessing media that was imported to a Smoke/Flame system with the Cache Source Media option enabled, that media is no longer considered Gateway media. It is seen by Lustre as managed media and hence the LUT and Resize on import options are not available. To work around this, you can perform a Flush Cache Media operation in Smoke / Flame, prior to importing in Lustre.

Output Resolution: Use to define the output resolution, aspect ratio, bit depth and scan mode of the transcoded media.

Resolution Field: Use to set custom resolution values.

Aspect Ratio Field: Select from a list of preset aspect ratios or set your own value.

Bit Depth Field: Use to define the bit depth of transcoded media.

Scan Mode Field: Use to define the scan mode of transcoded media.

Resize Options: Use to define the Fit Method, Resize Filter type, the Precision and the Crispness/Softness of the transcoded media.

Fit Method Box: Use to select the Fit Method applied to transcoded media. Options are:

- Fill (the default option)
- Crop Edges
- Letterbox
- Center/Crop

Resize Filter Type Box: Use to select the Resize Filter type applied to transcoded media. Options are:

- Impulse
- Triangle
- Mitchell
- Bicubic
- Quadratic
- Gaussian
- Shannon
- Lanczos

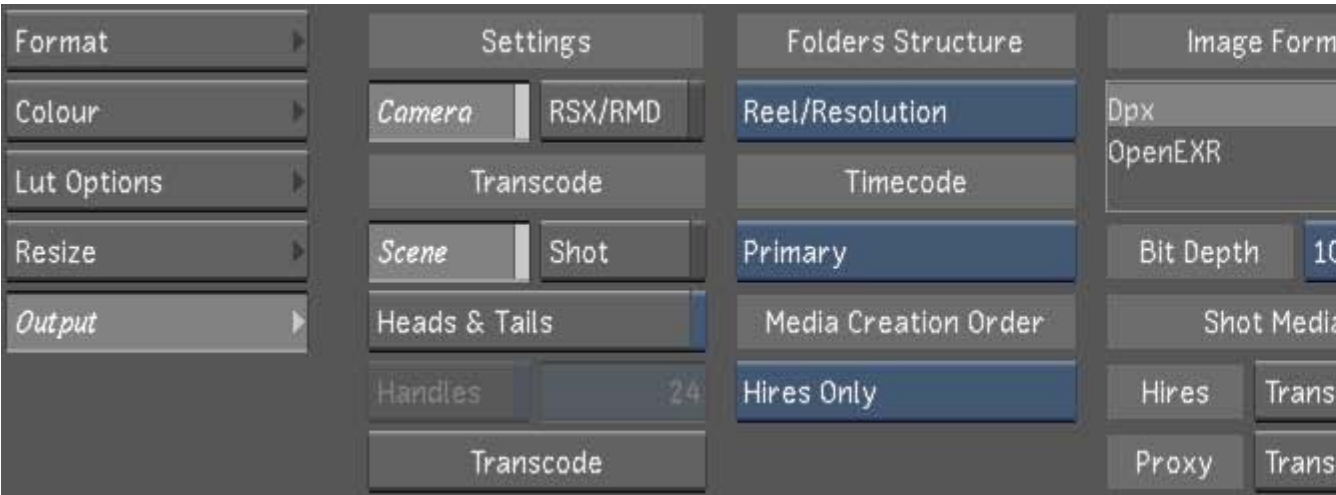

Aspect Button: Enable to use non-square pixel formats. This option is automatically enabled when Fit Method is set to Crop Edges or Letterbox.

Precision Field: Use to set the frequency cut-off point used during the Resize.

Crisp/Soft Field: Use to set the amount of blur used during the Resize.

Transcode Output Settings

Use the Output settings to set an output destination for your transcode job and to change how the timecode is used.

For information on the Settings and Transcode options, see [Transcode Options](#) (page 1921).

Folders Structure option box Defines how the transcoded media is organized on the storage.

Select:	To:
Reel/Resolution	Establish a <reel name>/<resolution> folder structure. This is the default option.

Select:	To:
Reel/Shot/Resolution	Establish a <reel name>/<file name>/<resolution> folder structure.

Timecode option box Select which RED media timecode to transcode. Note that when conforming an EDL, overriding the timecode data of the clips with a different timecode track will prevent relinking in the Autodesk Visual Effects and Finishing applications.

Select:	To:
Primary	Select either the Time of Day or Edgecode timecode. Only select this option if you know which timecode has been set as the primary.
Time of Day	Establish a timecode field that is set by the internal clock from the RED camera.
Edgecode	Establish a timecode field that is set by the camera operator.

Media Creation Order option box Defines the high-resolution and proxy media transcoding order.

Select:	To:
Proxy/Hires	Transcode the proxy media for all the shots first, and then the high-resolution media is transcoded.
Hires/Proxy	Transcode the high-resolution media for all the shots first, and then transcode the proxy media.
Hires only	Transcode only the high-resolution media. This is the default and recommended media creation option. This allows you to work on the native proxy as the high resolution is transcoded.
Proxy only	Transcode only the proxy media.

Image Format list Select the type of file you want the RED footage to be transcoded to.

- Dpx
- OpenEXR

Bit Depth option box Select the bit depth to transcode your RED media to. The default is 10 bit.

Shot Media Hires/Proxy Transcoded button

Enable to view the Hires/Proxy transcoded media and disable to view the original RED media.

Transcoded Hires/Proxy fields Enter, or browse to, the location of the transcoded RED media directory. This directory must be an existing directory that is located on either a Wiretap server or a Wiretap Gateway. For Linux workstations, use the backward slash.

NOTE The Folders Structure, Media Creation Order, and Image Format options are not applied if you are transcoding to the Wiretap server.

Transcode Versioning box

Use to save, update, load and delete Transcode versions to apply to your media. See Transcoding Versions.

Transcode to:	Type:
Wiretap Server	<server_name>@wt:/stonefs/Test_transcode/Transcode

Transcode Versioning

You can create and store multiple transcode settings for any given RED/ARRIRAW source. All of the transcode settings and their versions are stored in the Library source clip. Because the settings are stored in the Library source clip, you can update the transcode settings in a shot and share those settings with all shots originating from the same source clip. Each shot is still free to use its own version of the transcode settings. You can also share the transcoded media with other timelines that use the same shot, eliminating the need to transcode footage that has already been transcoded.

You can use the Transcode Version box to create, update, load and delete transcode versions.

To create a transcode version

- 1 Select a shot from your storyboard.
- 2 Type a name for your transcode version in the Comment field.
- 3 Click the New button.
- 4 Adjust your transcode settings.
- 5 Click the Save button.

NOTE

- You must click New before you start editing the settings, otherwise you will be editing the currently selected Transcode version.
- The default version of the transcode settings is labeled "Transcode00 Camera Settings". These settings are from the camera, as stored in the metadata of the R3D/ARRIRAW file. These settings can be recalled at any time by enabling the Camera button.

To load a Transcode version

- 1 Select a shot from your storyboard.
- 2 Select a Transcode version from the list.

- 3 Press the Load button.

To update a Transcode version

- 1 Select a shot from your storyboard.
- 2 Select a Transcode version from the list.
- 3 Adjust your Transcode settings.
- 4 Click the Save button.

NOTE When you modify the transcode settings of a shot, all shots originating from the same source clip are updated with the new settings and the changes will immediately be visible on all shots sharing the updated transcode settings.

To delete a Transcode version

- 1 Select a Transcode version from the list.
- 2 Click the Delete button.

Transcoding Template

You can save multiple transcode versions in a transcoding template. Once all settings have been established for your different transcoding versions, you can choose to save these settings as a template. You can create, load or delete a transcoding template.

Creating a New Transcoding Template

When you are working on a RED/ARRIRAW media project, you may want to apply the same transcoding settings to new footage as you import them. Being able to apply the settings from a previous session can ease the transcoding process.

There are two ways to create a new template:

- By setting the values, saving your transcode versions and saving a new template.
- By loading a previously-saved template, making the necessary changes to the settings, and saving the new template.

To create a new transcoding template:

- 1 Set the values and save your transcode versions.
- 2 In the Transcoding Template field, enter a name and click Save.

NOTE You should enter a name that will help you distinguish what type of settings you have selected.

To create a new transcoding template from an existing template:

- 1 From the Transcoding Template list, select the template to use as baseline.
- 2 Click Load.

WARNING Rename the new template, or you will overwrite the original template with the new settings.

- 3 Click Save.

Your template is saved.

Loading a Transcoding Template

To load a transcoding template:

- 1 From the Transcoding Template list, select the template you want to apply.
- 2 Click Load.

Your template is loaded.

Deleting a Transcoding Template

To delete a transcoding template:

- 1 Select the template you want to remove from the Transcoding Template list.
- 2 Click Delete and then confirm.

Your template is deleted.

Conform

Working with EDL, ALE, and Cutlist Files

You can automatically recreate a timeline as it was edited during the offline editing stage of post-production provided you have all the source footage that was used, and a CMX3600-formatted EDL, ALE, or Cutlist file that describes how the source footage is arranged in the timeline. The process of rebuilding the timeline is called *assembling*.

When Lustre loads an EDL, ALE, or Cutlist file, it builds the timeline based on the following information:

- Source In/Source Out timecode or Record In/Record Out timecode.
- Tape/reel name. If the Use Reel Name button is enabled, Lustre verifies that the sources come from the correct tape. The tape name is part of the file path, and is always located one level above the resolution directory. For example, if the source files are located in `.../Scans/myclip/001/2058x1556/...`, then the tape name is 001.
- Source table. The source table enables the support of EDL reel names longer than eight characters.
- Dissolves. When Lustre finds a dissolve in the EDL, ALE, or Cutlist file, it places a dissolve of the specified duration at the appropriate transition.
- Speed changes. When a speed change is encountered in an EDL, ALE, or Cutlist file, the speed of the appropriate event is adjusted in the timeline using the Retime option.

To assemble an EDL, ALE, or Cutlist file, the system matches shot timecode values to source timecode in the EDL, ALE, or Cutlist file. Shot timecode values can be interpreted using two methods:

- By reading the timecode from the DPX file header. This method is intended for file formats (such as DPX files) that can contain embedded timecode values in the file header.
- By converting the shot's filename into timecode. The filename is established during the film scanning process.

The following table illustrates how a filename is converted into timecode.

Filename	Timecode 25 fps
00000.dpx	00:00:00:00
00024.dpx	00:00:00:24
00025.dpx	00:00:01:00
00060.dpx	00:00:02:10
00600.dpx	00:00:24:00
06000.dpx	00:04:00:00
06001.dpx	00:04:00:01

EDL Display and Functionality

When you load an EDL, ALE, or Cutlist file, its events appear in the Assembly window, located in the upper-left portion of the interface.

<div><div>a</div><div>Show EDL</div><div>Show TL</div><div>Select All</div><div>Unselect All</div><div>Mark For Capture</div><div>Mark For Match</div><div>Delete Selected</div><div>Delete All</div><div>Slip</div><div>Ripple Rec</div></div>	<div><div>b</div><table><tr><th>Event</th><th>Reel Name</th><th>Transition</th><th>Source In</th><th>Source Out</th><th>Record In</th><th>Record Out</th><th>KeyCode Start</th><th>KeyCode End</th><th>Media</th></tr><tr><td>1</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:00:02</td><td>00:00:00:00</td><td>00:00:00:01</td><td></td><td></td><td>Linked</td></tr><tr><td>2</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:05:08</td><td>00:00:00:01</td><td>00:00:05:08</td><td></td><td></td><td>Linked</td></tr><tr><td>3</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:05:08</td><td>00:00:05:08</td><td>00:00:10:15</td><td></td><td></td><td>Linked</td></tr><tr><td>4</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:01:11</td><td>00:00:10:15</td><td>00:00:12:00</td><td></td><td></td><td>Linked</td></tr><tr><td>5</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:02:19</td><td>00:00:12:00</td><td>00:00:14:18</td><td></td><td></td><td>Linked</td></tr><tr><td>6</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:01:06</td><td>00:00:14:18</td><td>00:00:15:23</td><td></td><td></td><td>Linked</td></tr><tr><td>7</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:01:06</td><td>00:00:15:23</td><td>00:00:17:03</td><td></td><td></td><td>Linked</td></tr><tr><td>8</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:05:08</td><td>00:00:17:03</td><td>00:00:22:10</td><td></td><td></td><td>Linked</td></tr><tr><td>9</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:05:08</td><td>00:00:22:10</td><td>00:00:27:17</td><td></td><td></td><td>Linked</td></tr><tr><td>10</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:05:08</td><td>00:00:27:17</td><td>00:00:32:24</td><td></td><td></td><td>Linked</td></tr><tr><td>11</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:05:08</td><td>00:00:32:24</td><td>00:00:38:06</td><td></td><td></td><td>Linked</td></tr><tr><td>12</td><td>REEL01</td><td>Cut</td><td>00:00:05:07</td><td>00:00:05:08</td><td>00:00:38:06</td><td>00:00:38:07</td><td></td><td></td><td>Linked</td></tr><tr><td>13</td><td>REEL01</td><td>Cut</td><td>00:00:03:20</td><td>00:00:03:21</td><td>00:00:38:07</td><td>00:00:38:08</td><td></td><td></td><td>Linked</td></tr><tr><td>14</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:00:02</td><td>00:00:38:08</td><td>00:00:38:09</td><td></td><td></td><td>Linked</td></tr><tr><td>15</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:01:40:01</td><td>00:00:38:09</td><td>00:02:18:09</td><td></td><td></td><td>Linked</td></tr><tr><td>16</td><td>REEL01</td><td>Cut</td><td>00:00:00:02</td><td>00:00:00:03</td><td>00:02:18:09</td><td>00:02:18:10</td><td></td><td></td><td>Linked</td></tr><tr><td>17</td><td>REEL01</td><td>Cut</td><td>00:00:00:01</td><td>00:00:00:05</td><td>00:02:18:10</td><td>00:02:18:14</td><td></td><td></td><td>Linked</td></tr><tr><td>18</td><td>REEL01</td><td>Cut</td><td>09:36:00:00</td><td>09:36:00:04</td><td>00:02:18:14</td><td>00:02:18:18</td><td></td><td></td><td>Need Match</td></tr></table></div>	Event	Reel Name	Transition	Source In	Source Out	Record In	Record Out	KeyCode Start	KeyCode End	Media	1	REEL01	Cut	00:00:00:01	00:00:00:02	00:00:00:00	00:00:00:01			Linked	2	REEL01	Cut	00:00:00:01	00:00:05:08	00:00:00:01	00:00:05:08			Linked	3	REEL01	Cut	00:00:00:01	00:00:05:08	00:00:05:08	00:00:10:15			Linked	4	REEL01	Cut	00:00:00:01	00:00:01:11	00:00:10:15	00:00:12:00			Linked	5	REEL01	Cut	00:00:00:01	00:00:02:19	00:00:12:00	00:00:14:18			Linked	6	REEL01	Cut	00:00:00:01	00:00:01:06	00:00:14:18	00:00:15:23			Linked	7	REEL01	Cut	00:00:00:01	00:00:01:06	00:00:15:23	00:00:17:03			Linked	8	REEL01	Cut	00:00:00:01	00:00:05:08	00:00:17:03	00:00:22:10			Linked	9	REEL01	Cut	00:00:00:01	00:00:05:08	00:00:22:10	00:00:27:17			Linked	10	REEL01	Cut	00:00:00:01	00:00:05:08	00:00:27:17	00:00:32:24			Linked	11	REEL01	Cut	00:00:00:01	00:00:05:08	00:00:32:24	00:00:38:06			Linked	12	REEL01	Cut	00:00:05:07	00:00:05:08	00:00:38:06	00:00:38:07			Linked	13	REEL01	Cut	00:00:03:20	00:00:03:21	00:00:38:07	00:00:38:08			Linked	14	REEL01	Cut	00:00:00:01	00:00:00:02	00:00:38:08	00:00:38:09			Linked	15	REEL01	Cut	00:00:00:01	00:01:40:01	00:00:38:09	00:02:18:09			Linked	16	REEL01	Cut	00:00:00:02	00:00:00:03	00:02:18:09	00:02:18:10			Linked	17	REEL01	Cut	00:00:00:01	00:00:00:05	00:02:18:10	00:02:18:14			Linked	18	REEL01	Cut	09:36:00:00	09:36:00:04	00:02:18:14	00:02:18:18			Need Match

(a) EDL event buttons (b) EDL events

TIP Clicking a header will sort the EDL according to the selected data type.

Use the following buttons to facilitate EDL event management.

Click:	To:
Show EDL	View the currently loaded EDL.
Show TL	View timeline shot information. In order to display shot information for the currently loaded EDL, you must first assemble it.
Select All	Select everything in the EDL event list.
Unselect All	Deselect all selected events.
Mark For Capture	Flag the currently selected event for capture. See Metadata Maintained for Missing Shots (page 1948).
Mark For Match	Flag the currently selected event to be matched to a shot in the Library.
Delete Selected	Delete selected events. NOTE This button is only functional when the timeline is not displayed.

Click:	To:
Delete All	Delete all events. NOTE This button is only functional when the timeline is not displayed.
Slip	Offset the shot's Source In/Out or Record In/Out timecodes without affecting the length of the shot. If you offset the Source In timecode, the Source Out timecode will be adjusted automatically, and vice versa. The same applies to Record In and Record Out timecodes.
Ripple Rec	Apply modifications made to a shot's Source In timecode to the Record Out timecodes for all subsequent events in the EDL.

EDL and Keycode Assembly Workflow

The recommended steps for EDL or Keycode assembly are as follows.

Step:	Refer to:
1. Access the file browser.	Accessing the File Browser (page 1909).
2. Load shots into the Library.	Loading Clips to the Library (page 1917).
3. Add CDL data to an EDL file to associate CDL data to individual events (shots).	Adding CDL Data to an EDL File (page 1938).
4. Copy the EDL into Lustre.	Importing an EDL, ALE, or Cutlist File (page 1939).
5. Assemble the EDL to automatically build your footage into a timeline.	Assembling an EDL (page 1941).
6. Optional: Trim or edit the shots in the timeline as needed. If you perform this step, you may have to export the timeline as an EDL.	Editing (page 1954), and Exporting Shots to an EDL (page 1945).
7. Save the assembled EDL as a cut.	Creating a New Cut (page 1819).

Example of a Possible CDL Workflow

To facilitate the transfer of colour intent from the production to the post-production world, many productions do on-set grading. This means that simple colour grading is done at the same time as production. Here is a simplified sequence of events explaining the process:

- Production is shooting content on film or digital.
- Film is processed.
- Film is scanned.
- DPX files are copied to FireWire® drive for production.

- Colourist on set uses third party application to grade DPX.
- CDL data is created (as EDL comment or XML files).
- Post facility receives CDL and starts dailies grading/preview or DI based on CDL (on-set) intention.
- Offline editorial receives dailies for editorial.
- EDL are generated for conform.
- Colour grading process starts.

Adding CDL Data to an EDL File

You can add CDL data to an EDL file either inline (CDL slope, offset, and power data embedded directly in the EDL), or through an XML reference.

An XML reference can be either a *.ccc* or *.cdl* file; both have one single XML file with multiple shot information. However, Lustre will only read the first SOP grouping (data for a single shot) of colour correction from either of these files. Therefore, users must have one XML file for each event.

The CDL specification defines CMX EDL comments as the transport mechanism. CDL data can be expressed as EDL data with the CDL values or as an XML file.

Storing Inline CDL Parameters as Notes in an EDL File

Add CDL data directly to an EDL file to transport simple primary grading data to the Lustre colour grading application.

The ASC_SOP note associates all nine ASC CDL colour values with the edit that precedes the note. The first three numbers are the R, G, and B values of the slope parameter. The second three numbers are the RGB values for offset. And, the last three numbers pertain to the RGB values for the power parameter.

Each parameter's three values are grouped by parentheses, and a space will separate the grouped parameters from each other and the Note ID string ("*ASC_SOP"). This note limits the parameter values to five digits of precision. This allows all nine parameters to fit into one 80- column note. An example of the inline CDL data added to the EDL file is as follows.

Each of the numbers that represents a colour value of a parameter should be in the form of a two to five digit number with a decimal point placed anywhere between the most and least significant digits (for example, from 0.0 or 0.0001 to 9999.9). This prevents the decimal from being missed or misinterpreted. The numbers that represent the offset parameters may have an optional leading minus sign. There is a leading space at the head of each number, except for the first value of each parameter (the Red value), which has a leading left parenthesis instead. The last value of each parameter (the Blue value) has a trailing right parenthesis. There is a space between the NOTE ID String ("*ASC_SOP") and the first left parenthesis.

To manually add CDL data to an EDL file (inline method):

- 1 Open your EDL file in a text editor.
- 2 Open the file with raw CDL data.
- 3 In the CDL data file, copy the SOP information for the first shot.
- 4 In the EDL file, enter the CDL data in a new line after the line identifying the clip name.

NOTE Make sure you begin the new line with the *ASC_SOP note ID.

- 5 Perform this procedure for each shot for which you have CDL data.

Storing CDL Parameter References to ASC CDL XML Files or ASC CCC XML Files

The ASC_CC_XML note begins with the '*ASC_CC_XML' note ID string and is followed by the file name that associates that shot with a unique XML file. This XML file follows the XML implementation of the ASC CDL. An example of the reference line added to the EDL file is as follows.

```
010 216R05 V C 05:40:12:18 05:40:14:09 01:00:29:16
01:00:31:07
FROM CLIP NAME: 0054
*ASC_CC_XML cc1009
```

NOTE In the previous example, the reference to 'cc1009' is a reference to the XML file cc1009.cdl (if it's a CDL XML file), or cc1009.ccc (if it's a CCC XML file).

NOTE The reference to the XML file must not include the '.cdl' or '.ccc' suffixes in the EDL file.

WARNING If you use both CDL and CCC files, make sure you do not assign the same name for any CDL file to a CCC file. If Lustre finds a CDL file with the name that is referenced in the EDL file, it will only read the CDL file, even if a CCC file with the same name exists.

To manually add CDL or CCC file references to an EDL file:

- 1 Open your EDL file.
- 2 In the EDL file, find the shot information for the shot corresponding to the XML file you wish to reference.
- 3 Enter the XML file reference information corresponding to the shot in a new line after the line identifying the clip name.

NOTE Make sure you begin the new line with the *ASC_CC_XML note ID.
- 4 Perform this procedure for each shot for which you have a corresponding XML file (either a *.cdl or *.ccc file).

Importing an EDL, ALE, or Cutlist File

Before you can assemble an EDL, ALE, or Cutlist file, you have to copy the file into the current scene's *Library* directory.

NOTE The file must have a *.edl, *.ale, or *.ctl file extension or it will not appear in the EDL list.

There are two ways to import EDLs into Lustre:

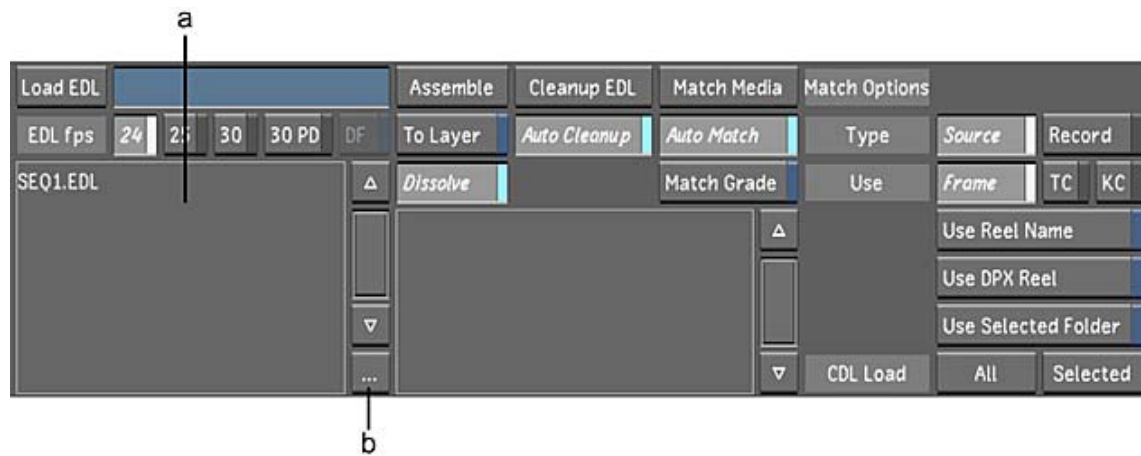

- Outside of Lustre, files can be copied manually to the *Library* directory of the current scene. If running the Windows version of Lustre, save the EDL to the C:\Program Files\Autodesk\Lustre<version>\projects\<project_name>\Library folder. If running the Linux version of Lustre, save EDLs in the /usr/autodesk/lustre_<version>/projects/<project name>/Library directory.

NOTE Press Ctrl+R to refresh the EDL list to see recently copied files.

- Within Lustre, copies of EDL files are imported using the Import file browser.

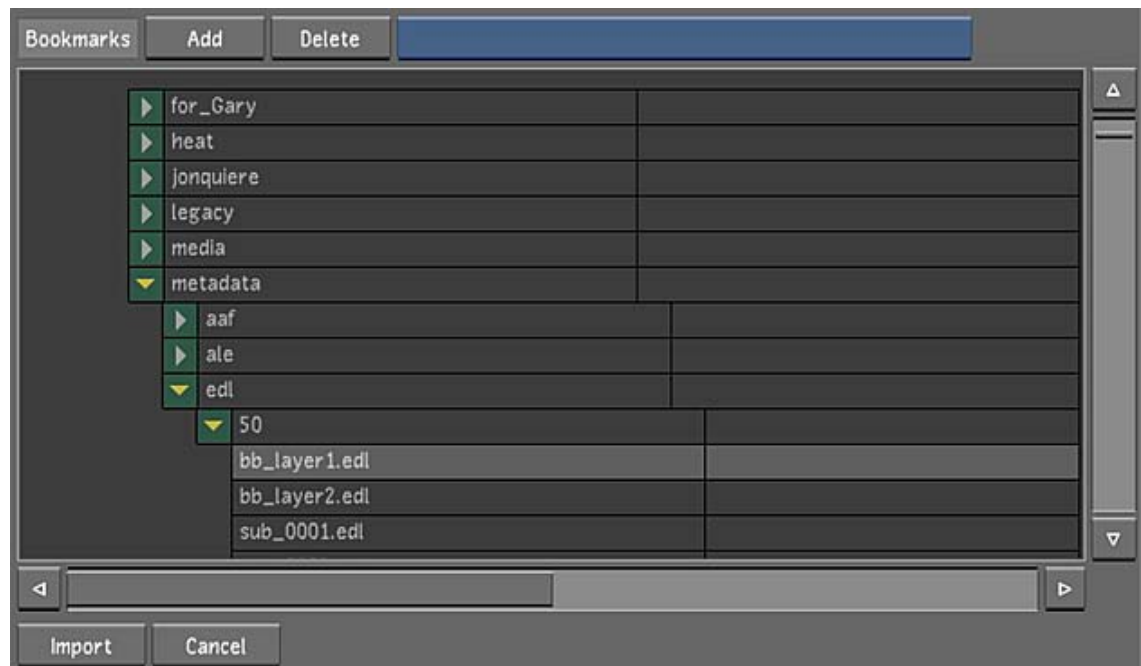

To import a copy of an EDL, ALE, or Cutlist file while in Lustre:

- 1 Select the Editing/Assemble menu.
The Assemble options appear.

(a) EDL list (b) Browse button

- 2 In the EDL List, click the Browse button.
The Import file browser appears.

- 3 Navigate to the appropriate source folder and select one or more EDL files (You can also use [bookmarks](#) (page 1915) to retain a list of folder locations). Traditional methods of multi-selecting (**Shift-click**, **Ctrl-click**) are enabled.
- 4 Click Import.

WARNING If an EDL with the same filename is already in the EDL list, the Import button will turn red. You must click again to confirm that you want to overwrite the file.

TIP If no files are selected, you can also press **Enter** to cancel file selection and close the Import file browser.

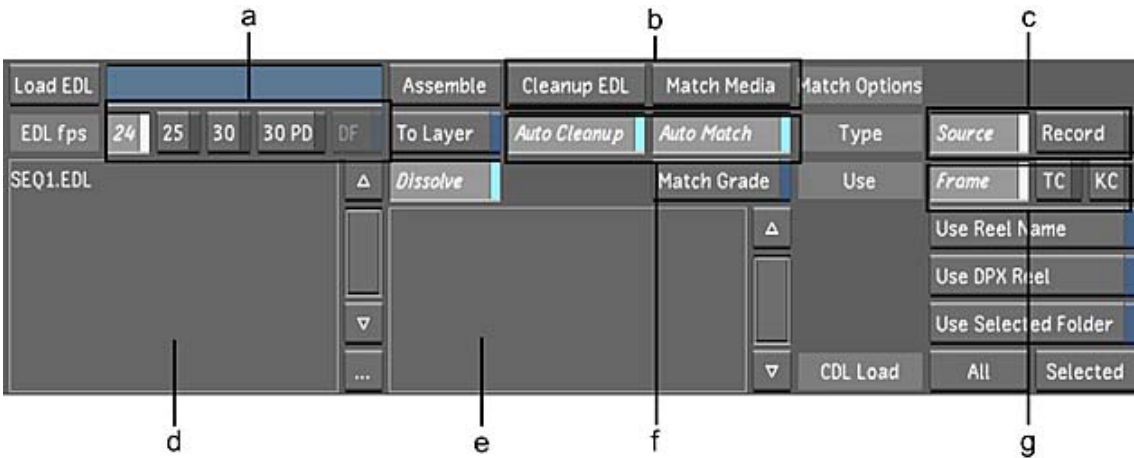

A copy of the file is imported into the *Library* folder, and appears in the EDL list.

Assembling an EDL

Use an EDL to rebuild a timeline using original source footage that matches the edited timeline from the offline editing stage of post-production. It is also possible to add the assembled EDL to a new layer of the current timeline.

To assemble an EDL:

- 1 Load the shots that you want to assemble into the Library.
 - 2 Click Editing, and then click Assemble.
- The Assemble menu appears.

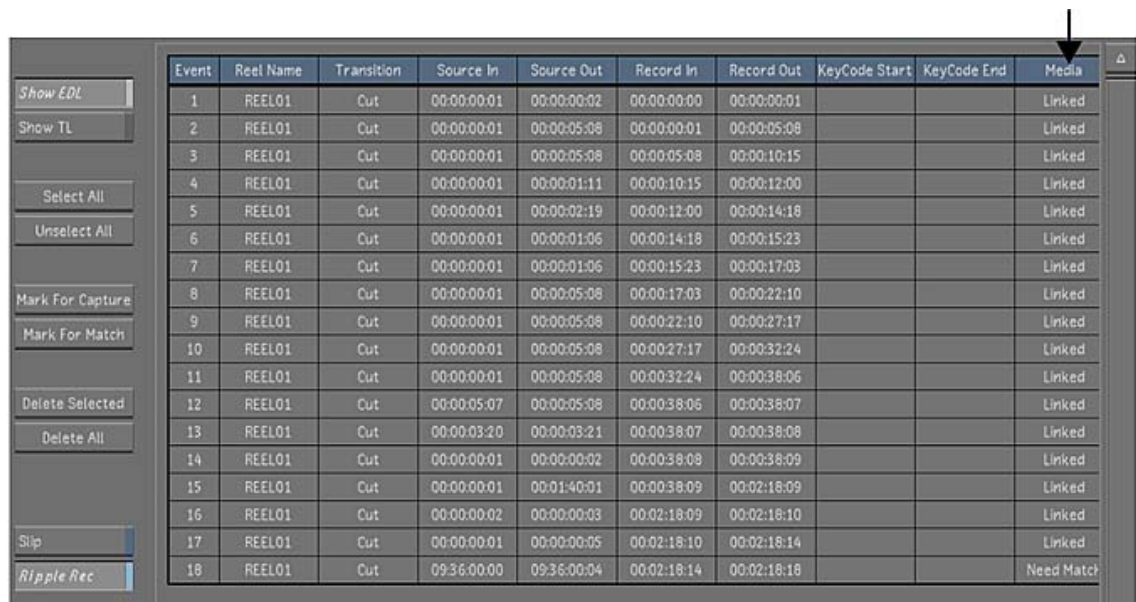

(a) Frame Rate buttons (b) Manual options (c) Base of assembly buttons (d) EDL list (e) Log window (f) Assemble options (g) Timecode buttons

- 3 (Optional) Import an EDL into the EDL list. See [Importing an EDL, ALE, or Cutlist File](#) (page 1939).
- 4 Select the EDL you want to load from the EDL list.
- 5 Determine the base of assembly by enabling one of the following.
Source Recreates a timeline according to how the source footage was arranged.
Record Assembles the timeline using the timecode of the final edited clip.
NOTE If you selected Record as your base of assembly and your shots include dissolves, enable First-Last Key Anim Type on the Setup page of the Animation menu. See [Synchronizing Keyframe Functionality](#) (page 2231).
- 6 Click the Frame Rate button that corresponds to your EDL's frame rate. The following frame rates are supported.

Enable:	To:
24	Load a 23.98 or 24 fps EDL.
25	Load a 25 fps (PAL) EDL.
30	Load a 29.97 or 30 fps (NTSC) EDL.
30 PD	Convert an NTSC EDL to 24 fps and load the converted EDL.
DF	Load a 29.97 fps drop frame mode (NTSC) EDL.

- 7 Enable Match Name to match the timecode and tape name in the EDL to your shots.
- Lustre tries to detect the Tape name in the EDL to the shots' directory path. This path is fixed—the correct directory should be one level above the resolution directory. For example, if the tape name in the EDL is BTE164, the matching shot is at:
- ```
<HOME>\scans\BTE164\2048x1556\0002487.dpx
```
- TIP** To match the EDL reelname to the reelname in the DPX header, enable the Use Reel Name button in the System & Menu page of the user configuration. See [System & Menu Settings](#) (page 1807).
- 8 Enable Dissolve to include any dissolves in the EDL.
- NOTE** Only dissolve transitions are supported when loading an EDL. Other transitions are replaced by cuts.
- WARNING** Continuing this process creates a new cut from the EDL. If you have not saved your work, it will be lost. Therefore, it is a good idea to start from an empty cut before loading an EDL.
- 9 Enable either Frame or Timecode depending on how you want Lustre to read the shot's timecode when assembling the EDL.
- Enable Frame to convert the shot filename to a timecode value.
  - Enable Timecode to use the timecode value stored in the file header.
- NOTE** For information on Keycode assembly, see [Keycode Assembly](#) (page 1946).
- 10 Click Load EDL.
- The system checks to make sure that the EDL is a valid CMX3600-formatted EDL. If the EDL is not valid, a message appears in the Load log and the EDL is not loaded.
- NOTE** ALE and Cutlist files are also valid. See [Keycode Assembly](#) (page 1946).
- 11 To perform an EDL cleanup, do one of the following:
- Click EDL Cleanup to perform cleanup prior to assembling.
  - Enable Auto Cleanup to automatically perform cleanup during assembly.
- When Lustre performs an EDL cleanup, it arranges EDL events according to record timecode and deletes problematic events. For example, if an EDL has two events with conflicting timecodes, the event with the lower number is deleted during cleanup.
- 12 To match EDL event timecodes to shot timecodes in the Library, do one of the following:
- Click Match Media to match EDL event timecodes to available shot timecodes in the Library prior to assembling.
  - Enable Auto Match to automatically match EDL event timecodes to available shot timecodes in the Library during assembly.
- The matching process links EDL event timecodes to media timecodes in the Library. The match status is indicated in the Media column of the Assembly window. Successful matches are indicated by a Linked status, whereas unsuccessful matches generate a Need Match status.

| Event | Reel Name | Transition | Source In   | Source Out  | Record In   | Record Out  | KeyCode Start | KeyCode End | Media      |
|-------|-----------|------------|-------------|-------------|-------------|-------------|---------------|-------------|------------|
| 1     | REEL01    | Cut        | 00:00:00:01 | 00:00:00:02 | 00:00:00:00 | 00:00:00:01 |               |             | Linked     |
| 2     | REEL01    | Cut        | 00:00:00:01 | 00:00:05:08 | 00:00:00:01 | 00:00:05:08 |               |             | Linked     |
| 3     | REEL01    | Cut        | 00:00:00:01 | 00:00:05:08 | 00:00:05:08 | 00:00:10:15 |               |             | Linked     |
| 4     | REEL01    | Cut        | 00:00:00:01 | 00:00:01:11 | 00:00:10:15 | 00:00:12:00 |               |             | Linked     |
| 5     | REEL01    | Cut        | 00:00:00:01 | 00:00:02:19 | 00:00:12:00 | 00:00:14:18 |               |             | Linked     |
| 6     | REEL01    | Cut        | 00:00:00:01 | 00:00:01:06 | 00:00:14:18 | 00:00:15:23 |               |             | Linked     |
| 7     | REEL01    | Cut        | 00:00:00:01 | 00:00:01:06 | 00:00:15:23 | 00:00:17:03 |               |             | Linked     |
| 8     | REEL01    | Cut        | 00:00:00:01 | 00:00:05:08 | 00:00:17:03 | 00:00:22:10 |               |             | Linked     |
| 9     | REEL01    | Cut        | 00:00:00:01 | 00:00:05:08 | 00:00:22:10 | 00:00:27:17 |               |             | Linked     |
| 10    | REEL01    | Cut        | 00:00:00:01 | 00:00:05:08 | 00:00:27:17 | 00:00:32:24 |               |             | Linked     |
| 11    | REEL01    | Cut        | 00:00:00:01 | 00:00:05:08 | 00:00:32:24 | 00:00:38:06 |               |             | Linked     |
| 12    | REEL01    | Cut        | 00:00:05:07 | 00:00:05:08 | 00:00:38:06 | 00:00:38:07 |               |             | Linked     |
| 13    | REEL01    | Cut        | 00:00:03:20 | 00:00:03:21 | 00:00:38:07 | 00:00:38:08 |               |             | Linked     |
| 14    | REEL01    | Cut        | 00:00:00:01 | 00:00:00:02 | 00:00:38:08 | 00:00:38:09 |               |             | Linked     |
| 15    | REEL01    | Cut        | 00:00:00:01 | 00:01:40:01 | 00:00:38:09 | 00:02:18:09 |               |             | Linked     |
| 16    | REEL01    | Cut        | 00:00:00:02 | 00:00:00:03 | 00:02:18:09 | 00:02:18:10 |               |             | Linked     |
| 17    | REEL01    | Cut        | 00:00:00:01 | 00:00:00:05 | 00:02:18:10 | 00:02:18:14 |               |             | Linked     |
| 18    | REEL01    | Cut        | 09:36:00:00 | 09:36:00:04 | 00:02:18:14 | 00:02:18:18 |               |             | Need Match |

**NOTE** It is not necessary for all shots to be available prior to conforming. For example, shots with a Need Match status can be captured after the initial conform and assembled with the rest of the EDL later. In the meantime, media metadata will be maintained and black frames will be added where the shots would have appeared. You can also update shots after conforming. See [Metadata Maintained for Missing Shots](#) (page 1948).

- 13 Enable or disable the To Layer depending on how you want to assemble the new cut.
  - Enable To Layer to assemble a cut to a new layer above the existing layer(s) in the currently loaded cut.
  - Disable To Layer to overwrite the currently loaded cut with the newly assembled cut.
- 14 Click Assemble to conform the EDL.

**NOTE** If a timeline has not been loaded, then a cut is automatically created with the same name as the EDL.

**NOTE** When a timecode gap occurs between EDL events, black frames are inserted between the events to fill the gap.

- 15 (Optional) To manually match shots in the Library to EDL events, use the Replace Shot tool to add the correct footage into the blank shots. See [Replacing Shots](#) (page 1969).

After working on a previously assembled EDL, to ensure the same grading is applied to the newly assembled EDL, you need to apply the match grade option. See [Match Grade](#) (page 1944).

---

**NOTE** You can also assemble an EDL with CDL data. See [Assembling an EDL with CDL Data](#) (page 1953).

---

#### To assemble an EDL to the currently opened Timeline:

- 1 In the Editing menu, click Assemble.
- 2 Enable To Layer.
- 3 Load the EDL.

The EDL is now assembled to a new layer in the current Timeline.

**NOTE** The record timecode of the EDL is used as the in point when assembling an EDL to a layer of an existing Timeline.

**To load the EDL as a new Timeline:**

- 1 In the Editing menu, disable To Layer.
- 2 Load the EDL.  
The EDL is loaded to a new Timeline. If there is already an existing cut, it replaces the current cut with the newly assembled EDL.

**Match Grade**

The Match Grade feature allows you to apply current grade settings to a new assembled timeline without having to create a new cut file and use the Change Cut option. For information about the Change Cut option, see [Changing a Cut](#) (page 1824).

When you enable Match Grade during a timeline assembly, the function applies the appropriate grade to any shots that are also included in the current cut. Match options are also available to allow you to specify the basis of the match.

**To apply the current grade settings to a new assembled timeline:**

- 1 Make sure a graded cut is already loaded into the timeline.
- 2 To specify the basis of the match, select one or more Match Options from the Browse menu.

**UID** Performs matching based on the shot's unique ID.

**NOTE** UUIDs are regenerated every time a new cut file is created in Lustre.

**Source** Performs matching based on source data, such as a shot's source timecode, ID, and tape/reel name.

**Record** Performs matching based on record data, such as an EDL's record timecode.

**Custom** Performs matching based on the keyword that is selected in the custom list.

If the Custom option is enabled, there is a list of keywords to which you can associate the custom option.

| Select:        | To:                             |
|----------------|---------------------------------|
| EDLReelName    | Match the reel name of the EDL. |
| FolderReelName | Match the folder reel name.     |
| DPXReelName    | Match the DPX reel name.        |

| Select:         | To:                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------|
| DLEDLClipName   | Match the clip name of the shot coming from the Wiretap server.                           |
| DLEDLOrigin     | Match the image import path and file name of the timeline coming from the Wiretap server. |
| DLEDLSourceId   | Match the media source's unique ID of the timeline coming from the Wiretap server.        |
| DLEDLSegmentId  | Match the segment's unique ID of the timeline coming from the Wiretap server.             |
| DLEDLStartTc    | Match the start source timecode of the timeline coming from the Wiretap server.           |
| DPXKeyCodeStart | Match the DPX header keycode start.                                                       |
| DPXKeyCodeEnd   | Match the DPX header keycode end.                                                         |
| EDLComment      | Match the unique comment that is applied to the original cut from another application.    |

- 3 In the Assemble menu, enable Match Grade.
- 4 Assemble the EDL, ALE, or CTL file.
- 5 Click Browse to display the Browse menu.
- 6 Save the new cut file.
- 7 Click Setup, and then click Grade to display the Grade menu.
- 8 Click New Version to save the grade with the newly associated cut.

When working with a multi-layer timeline and Solo mode is disabled, the layers are flattened and only the grade settings from the shots that are visible in the Storyboard are applied to the newly assembled timeline. When working with a multi-layer timeline and Solo mode is enabled, only the grade settings from the active layer are applied to the newly assembled timeline. If the new timeline has multiple layers, then the grade setting is applied to each layer.

## Exporting Shots to an EDL

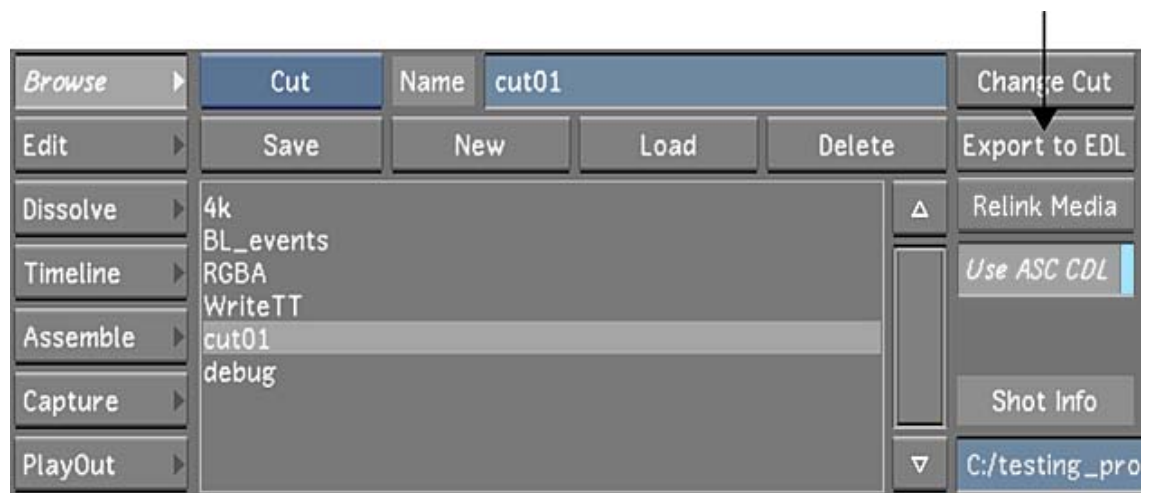

You can export your cut file as a CMX3600 EDL. The exported EDL is saved with the name of the currently loaded cut, plus a \*.edl file extension, and is placed in the scene's *Library* directory.

When exporting a multi-layer timeline and Solo mode is disabled, the layers are flattened and only the shots that are visible in the Storyboard are exported. When exporting a multi-layer timeline with Solo mode enabled, only the shots in the soloed layer are exported.

### To export a timeline as an EDL:

- 1 Access the Editing/Browse menu.
- 2 If it is not already loaded, load the cut you want to export. See [Managing Cuts](#) (page 1819).
- 3 Click Export to EDL.

A CMX3600 EDL is created from the shots in the current timeline and placed in the scene's *Library* directory.

## Keycode Assembly

You can load ALE (\*.ale) and Cutlist files (\*.ctl) as EDLs in the Assemble menu. Once loaded, you can use their keycode information for media assembly.

Most keycode types are fully supported in ALE and Cutlist file assembly. However, if Lustre encounters an unknown keycode type, it cannot parse its information. In these cases, add the missing keycode type name and value manually to the *init.config* file, located in *C:\Program Files\Autodesk\<version number>* on the Windows version of Lustre, or in */usr/autodesk/<version number>* on the Linux version of Lustre. For example, if the missing type is FN and the keycode value is 123456, you would enter the following in the *init.config* file:

**FN 123456**

**To load and assemble ALE and CTL files:**

- 1 Load the shots that you want to assemble into the Library.
- 2 Click Editing, and then click Assemble.
- 3 (Optional) Import an EDL into the EDL list. See [Importing an EDL, ALE, or Cutlist File](#) (page 1939).
- 4 Select the ALE or Cutlist file from the list.

- 5 Select the appropriate EDL Frame Rate.
- 6 Click KC to assemble media according to the file's keycode information.

- 7 Click Load EDL.  
The system checks to make sure it is a valid ALE or Cutlist file. If not, the file is not loaded.
- 8 To perform a cleanup on the ALE or Cutlist file, do one of the following:
  - Click EDL Cleanup to perform the cleanup prior to assembling.
  - Enable Auto Cleanup to automatically perform cleanup during assembly.

When Lustre performs a cleanup on an ALE or Cutlist file, it arranges events according to record timecode and deletes problematic events. For example, if an ALE file has two events with conflicting timecodes, the event with the lower number is deleted during cleanup.
- 9 To match ALE or CTL event timecode/keycode to shot timecode/keycode in the Library, do one of the following:
  - Click Match Media to match event timecode/keycode to available shot timecode/keycode in the Library prior to assembling.
  - Enable Auto Match to automatically match event timecode/keycode to available shot timecode/keycode in the Library during assembly.

The match status is indicated in the Media column of the Assembly window. Successful matches are indicated by a Linked status, whereas unsuccessful matches generate a Need Match status.

**NOTE** It is not necessary for all shots to be available prior to conforming. See [Metadata Maintained for Missing Shots](#) (page 1948).

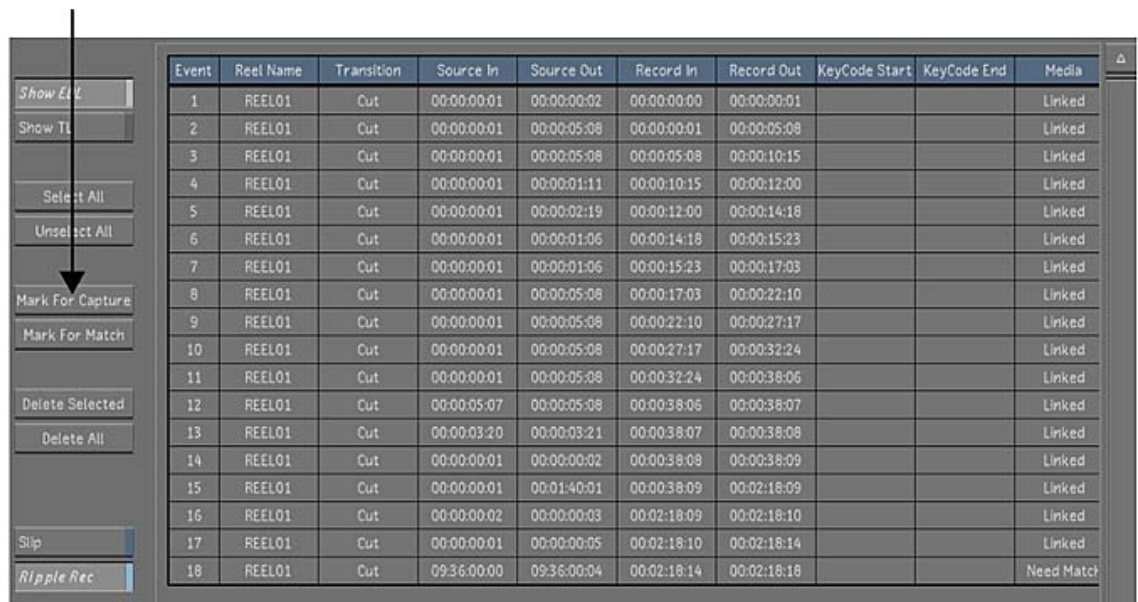

- 10 To manually match shots in the Library to ALE or CTL events, use the Replace Shot tool to add the correct footage into the blank shots. See [Replacing Shots](#) (page 1969).
- 11 Click Assemble to conform the ALE or CTL file and build the cut.

## Metadata Maintained for Missing Shots

If certain shots in the EDL, ALE or Cutlist file are not yet available, or if you would like to update shots that are already linked to events with new shots, you can mark them for capture. Shots can be individually captured either before or after the initial conform. Metadata for missing shots will be maintained for inclusion at a later time, and black frames will be inserted in the timeline where the shot should be. In the meantime, work can begin on the available shots.

**To mark missing shots for capture:**

- 1 In the Editing menu, click Assemble to display the Assemble menu.
- 2 In the Assembly window, **Ctrl**-click each event to be marked for capture.
- 3 Click Mark For Capture.

- 4 In Editing, click Capture to display the Capture menu.
- 5 In the Capture Format group, select the video file format you want to create during the capture operation. See [Capture Menu Options](#) (page 2299).

- 6 In the Naming group, enter values in the Capture, Tape, and Resolution fields.
- 7 Click EDL, and then confirm the action.

The capturing session begins.

The tape currently loaded in the VTR is ejected. You are prompted to enter the first tape needed in the EDL. Once you enter the tape, Lustre begins capturing automatically. The words “Capture from tape...” appear in the Player. There is no video displayed in the Player during capture.

In the Log window, information is displayed about the capture process. If more than one tape is required, you are prompted when it is time to enter the next tape.

- 8 In Editing, click Match Media.
- 9 To assemble the EDL to include the newly-captured shots, click Assemble.

## Colour Decision List (CDL)

The American Society of Cinematographers Colour Decision List (ASC CDL) colour correction specification defines a common language format for primary colour correction. It is becoming a standard defined by the ASC and has been adopted by most major manufacturers.

CDL is expressed by nine numbers (three RGB triplets) representing predefined colour functions: offset, slope, and power. The format of CDL is standardized so results in one colour corrector can be duplicated in

another corrector, so long as they both support the ASC CDL format. Currently, ASC CDL only supports primary colour correction, with the exception of chrominance (saturation change).

ACS CDL information can be stored as comments in an EDL from a Smoke and Flame, during the export EDL process. The ACS CDL comments from a Smoke and Flame EDL are supported in Lustre for import and export.

When you import an EDL with CDL comments or a sequence with CDL data from Smoke or Flame, the CDL data is stored in the Cut file. If you modify that CDL data, it gets saved with the Grade. This means that you can revert back to the original CDL data, by reloading the original Cut.

---

**NOTE** If you create the CDL data in Lustre, from scratch, it is only stored in the Grade, not the Cut.

---

## CDL Menu

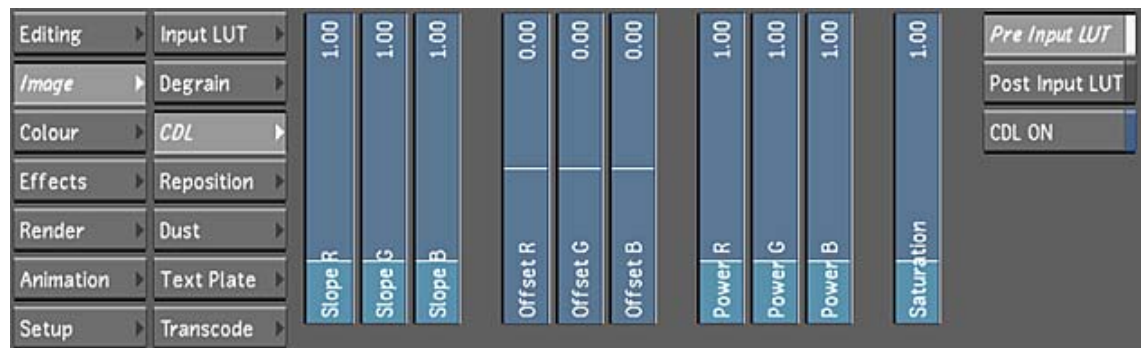

The CDL menu allows you to:

- Change the four basic transfer functions (slope, offset, power, and saturation).
- Select whether you would like the transfer functions to be applied before, or after, an Input LUT is applied.
- Enable or disable the transfer functions you have set.

To access the CDL menu:

- 1 In the main menu, click Image.
- 2 Click CDL.

The CDL menu is displayed.

---

**NOTE** The CDL panel is not accessible from the ACS or the CP-100.

---

**TIP** You can increase or decrease the value quickly by holding **Shift** and dragging the slider, or slowly by holding **Alt** and dragging the slider.

---

### Slope

When you change the slope transfer function, it allows you to change the lift and gain of the image without shifting the black level that is established by the offset. The following is a graph displaying how the slope value affects your image.

The following are the values to set the slope:

- Default value is 1.00 (i.e., no change).
- Minimum value is 0.00.

- Maximum value is 5.00.

### Offset

The offset transfer function either raises or lowers the overall brightness of the component, while keeping the slope constant.

The following are the values to set the offset:

- Default value is 0.00 (i.e., no change).
- Minimum value is -5.00.
- Maximum value is 5.00.

### Power

The power transfer function changes the intermediate shape and is the only non-linear function.

The following are the values to set the power:

- Default value is 1.00 (i.e., no change).
- Minimum value is 0.00.
- Maximum value is 5.00.

### Saturation

The saturation transfer function adjusts the intensity of the colours.

The following are the values to set the saturation:

- Default value is 1.00 (i.e., no change).
- Minimum value is 0.00.
- Maximum value is 5.00.

### Pre/Post Input LUT

You can decide to apply the CDL data either before (Pre) or after (Post) applying an Input LUT.

---

**NOTE** Applying CDL data after applying an Input LUT will work only if the Input LUT is enabled within the Input LUT module.

---

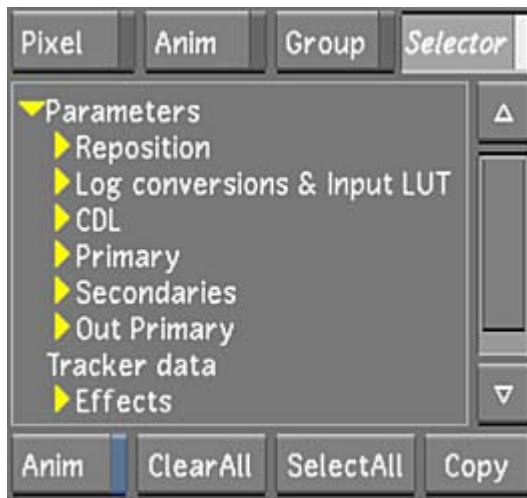

### CDL On/Off

The CDL On/Off toggle allows you to either enable or disable CDL data. Since the Bypass All function does not bypass both the Input LUT and CDL, you would use the CDL On/Off button to 'mute' the effect of the CDL.

## CDL Parameters in the Selector

The Selector contains the following CDL parameters:

- Slope (RGB sliders)
- Offset (RGB sliders)
- Power (RGB sliders)
- Pre/Post Input LUT
- CDL On/Off

You can use the Selector to:

- Select the CDL section you want to copy/paste from shot to shot.
- Selectively load CDL data saved in the individual grades that are saved in the Grade bin.

### Copying Parameters with the Selector

Lustre allows you to copy CDL parameters with the Selector in the same way as they would copy grading parameters. The parameters the Selector can copy are as follows:

- Colour grading parameters
- Input LUT selections
- CDL parameters
- Repositioning values
- Tracker data
- Effects
- Render flag settings

## Loading CDL Data in the EDL Panel

The EDL panel contains an interface to support loading CDL data.

When you load an EDL into Lustre, the CDL data is not converted at that time. You can conform and assemble the EDL as you normally would do. However, if you want to use the CDL data of the currently loaded EDL, you need to use the CDL Load options to apply the CDL data to the cut file.

### CDL Load Options

When you are ready to use CDL data, you can select one of two actions listed in the CDL Load list:

- All: Clicking All reads all CDL data from all the EDL events in the EDL Editor and applies the converted data to the events on the timeline by matching the record timecode (REC TC) value.
- Selected: Based on the selected events in the EDL Editor, the Selected action reads the CDL data of the selected events, then converts and applies each one of them to the events on the timeline by matching the REC TC value.

(a) CDL Load options

**NOTE** Loading CDL data does not erase the current grade applied to the shots. Loading CDL data only loads the data into the CDL panel. If the CDL data is already loaded, it will be overwritten with the newly loaded CDL data.

You can use a different EDL to conform and a different EDL to import CDL data. To load data from another EDL, **Ctrl**-click a CDL Load button. The data will be loaded using the Match Options from a cut selected in the Cut Name list. See [Changing a Cut](#) (page 1824).

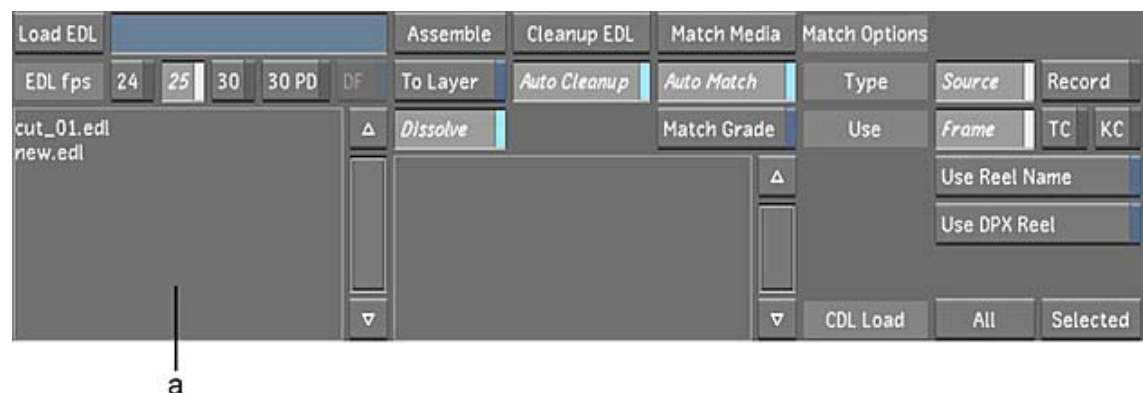

### Assembling an EDL with CDL Data

The following procedure assembles an EDL with CDL data.

**To assemble an EDL with CDL data:**

- 1 Drag the shots that you want to assemble into the Library.
- 2 Select the Editing/Assemble menu.

The Assemble options appear.

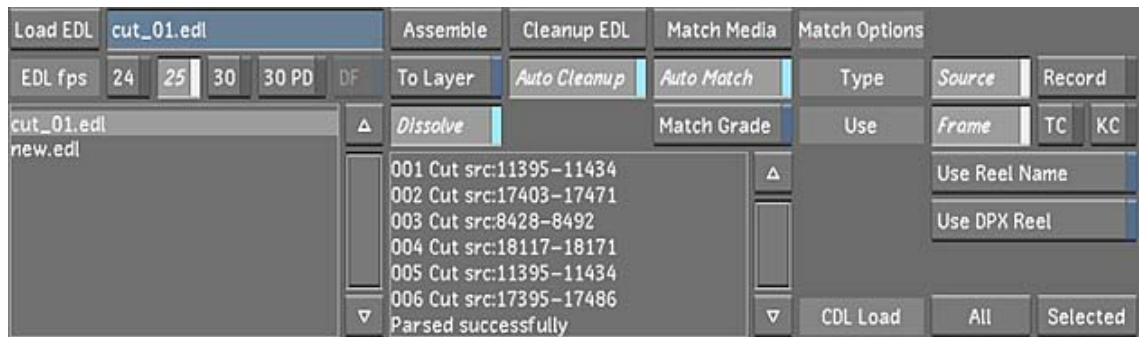

(a) EDL list

- 3 Select the EDL that contains the CDL data that you want to load from the EDL list.
- 4 Click Load EDL.

The selected EDL loads.

**NOTE** For more information on assembling an EDL, see [Assembling an EDL](#) (page 1941).

- 5 Click Match Media to match the EDL event timecodes to the available shot timecodes in the Library prior to assembling.
- 6 Click Assemble to conform the EDL and build the cut.  
The EDL events in the Assembly window are cleared.
- 7 Select the same EDL and click Load EDL.
- 8 Click CDL Load All or CDL Load Selected. See [CDL Load Options](#) (page 1952).  
The CDL data is now part of the current cut.

### CDL EDL Comment

CDL data for a given shot is represented as a comment in the EDL file.

```
0001 VT029 V C 09:11:16:20 09:11:22:22 01:00:13:05 01:00:19:07
*ASC_SOP (1.0 1.0 1.0) (0.0 0.0 0.0) (1.0 1.0 1.0)
```

There is one CDL comment line per event. See [Adding CDL Data to an EDL File](#) (page 1938).

### CDL XML File

CDL data for a given shot is represented as a reference in the EDL file to an XML file.

```
0003 VT032 V C 12:11:43:21 12:11:52:07 01:00:27:05 01:00:35:15
*ASC_CC_XML cdn03345
```

**NOTE** The ASC CDL specification allows more than one colour correction data set per XML file. Lustre only supports a single colour correction data set per CDL and XML file. See ASC CDL specifications for more detail.

See [Adding CDL Data to an EDL File](#) (page 1938).

### CDL XML Files Location

To be able to use XML files, place them in an import sub-folder located in the project's Library folder:

```
<my project>/<scene 1>/<Library>/<import>
```

## Editing

Use the Editing tools in Lustre to make modifications to your cuts, for example, to move, trim, cut, delete or replace shots. You can also add dissolves between shots, perform a confidence check, or use scene detection.

Typically, you perform editing operations before colour grading. In this way, the colourist works on only the frames that are destined for the final master.

Perform a confidence check to detect changes in scenes. A confidence check is a process in which you manually compare the frames in an assembled EDL to frames captured from an offline digital cut. With a confidence check, you ensure that the scanned film frames match the frames that were edited together during the offline edit. This is an important step in guaranteeing that the final colour-graded timeline is in sync with the audio that appears in the final edited master.

With scene detection, you can take a long captured shot that spans multiple scenes and automatically introduce splices each time the scene changes. You can then grade the new shots separately. Do this, for example, when you are capturing a final edited HD master into Lustre for colour grading.

## Representing the Timeline

The sequence of shots in a cut file is referred to as the timeline. Lustre has two visual ways of representing the timeline: the Storyboard and the multi-layer timeline.

When there is only one layer in the timeline, the Storyboard is simply the thumbnail view of the sequence of shots in the cut. When there are multiple layers in the timeline, the Storyboard is the thumbnail view of the flattened timeline, taking into consideration shots in a cut that represents a single-layer view of the timeline (see [Top Vertical Priority](#) (page 2001)). This single layer corresponds with one of the following, depending on the soloing and muting status:

- The active layer of the multi-layer timeline, where either the active layer is soloed or the remaining layers are muted
- The default (flattened) view of the multi-layer timeline, where soloing is disabled

The multi-layer timeline organizes the cut into a multiple layer format. The elements appear as a series of rectangles on a time-proportional grid, with a positioner at the location of the current frame. Multiple layers are useful for grade versioning, roughing out edit sequences, and for multi-layer editing. This allows you to try various edits and colour grading versions on your shots before choosing the one which is used in the final master.

For more information about:

- The Storyboard, see [Editing with the Storyboard](#) (page 1957).
- The multi-layer timeline, see [Multi-Layer Timeline](#) (page 1974).
- Solo mode, see [Solo Mode](#) (page 2006).
- Mute mode, see [Muted Layers](#) (page 2002).

## Accessing the Edit Menu

To modify shots in the timeline, you use the Edit menu.

---

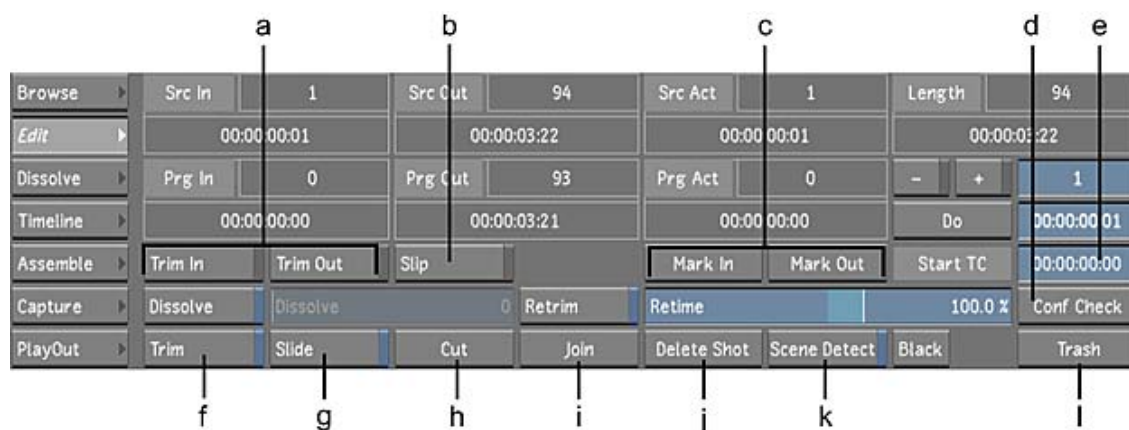

**NOTE** If a layer is soloed, the Edit tools (Trash, Delete, Trim In/Trim Out, and Mark In/Out) default to 'Ripple End' behaviour, regardless of the Ripple Mode setting. If no layer is soloed, however, the Edit tools behave according to the individual Ripple Mode selected (Ripple Off, Ripple Start, or Ripple End) and apply to the active or visible layer that contains the focus point. For more information about Ripple Modes, see [Trimming Ripple Mode](#) (page 1997).

---

**To access the Edit menu:**

- 1 In the Main menu, click Editing.
- 2 Click Edit.

The Edit menu appears.

(a) Trim In/Out buttons (b) Slip button (c) Mark In/Out buttons (d) Confidence Check button (e) Start TC field (f) Trim button (g) Slide button (h) Cut button (i) Join button (j) Delete Shot button (k) Scene Detect button (l) Trash button

The Edit menu is made up of the following buttons.

**Trim In/Trim Out** Allows you to enter the number of frames to trim at the in or out point for the current shot. See [Trimming the Head and Tail of a Shot](#) (page 1961).

**Slip** Moves the source frames within a shot without adjusting the shot's position in the timeline. See [Slipping a Shot](#) (page 1963).

**Mark In/Mark Out** Sets the in or out point of the current shot at the Current Frame positioner in the Shot timebar. See [Changing In and Out Points for a Shot](#) (page 1965).

**Start TC** Sets the frame number or timecode at which you would like the timeline to begin. If you enter a frame number, it is converted into the corresponding timecode value and vice versa. See [Modifying the Timeline's Starting Record Timecode](#) (page 2008).

**Trim** Interactively sets the shot's in and out points when you drag left and right in the viewers. Use the left viewer to trim the in point and the right viewer to trim the out point. See [Trimming Interactively](#) (page 1964).

**Slide** Slides a cut point forward or backward. See [Sliding the Cut Point between Shots](#) (page 1966).

**Cut** Cuts one shot into two at the Current Frame positioner. See [Inserting Cuts](#) (page 1967).

**Join** Joins two shots coming from the same source clip with consecutive source timecode. See [Joining Shots](#) (page 1968).

**Delete Shot** Deletes a shot from the timeline.

**Scene Detect** Starts a scene detection process. When changes in your footage are above a threshold, a cut is introduced. See [Using Scene Detection](#) (page 2010).

**Confidence Check** Allows you to compare your current timeline with a clip coming from a digital cut of your offline edit. See [Performing a Confidence Check](#) (page 2008).

**Trash** Deletes shots from the Library or Storyboard when you drag them to the Trash button.

## Global Access to Editing Hotkeys

When you enable the Editing While Grading button in the User settings, you can access the following editing hotkeys from any Lustre menu except the colourist multi-layer timeline.

| Press:  | To:                                                                         |
|---------|-----------------------------------------------------------------------------|
| Shift+C | Cut the shot in two at the current frame.                                   |
| Shift+J | Join the shot that was cut in two.                                          |
| Shift+T | Start interactive visual trimming.                                          |
| Shift+R | Start interactive visual sliding between the current and the previous shot. |
| Shift+S | Start a scene detection.                                                    |

For more information about the Editing While Grading button, see [System & Menu Settings](#) (page 1807).

## Editing with the Storyboard

The Storyboard is a thumbnail representation of the shots in a cut and provides a Storyboard view of the active timeline layer. For a timeline with multiple layers, if Solo mode is disabled (this is the default), the Storyboard always displays the topmost layer. If Solo mode is enabled, the Storyboard displays the layer according to the location of the focus point. Lustre includes an assortment of tools for adding shots to, and rearranging shots in, your Storyboard. Once you place a shot in the Storyboard, you can modify it.

## Adding Shots to the Storyboard

You can add shots or timelines to the Storyboard by dragging them from the Library. You can also drag shots or timelines directly from the file browser and drop them into the Storyboard. In this case, the shots are also placed into the Library (if they are not already there).

---

**TIP** To add shots to the Storyboard where the insertion marker is positioned, enable Solo mode in the Timeline menu. If you do not do this, added shots are automatically appended to the end of the timeline. See [Multi-Layer Timeline](#) (page 1974).

---

### To add shots to the Storyboard:

- 1 Select shots in the Library.

The order in which you click shots in the Library determines their order in the Storyboard.

**TIP** If you select the wrong shots, click any empty grey area under the Storyboard. This releases the selected shots from the cursor.

- 2 Drag the shots to the Storyboard.

A yellow insertion marker appears on the Storyboard.

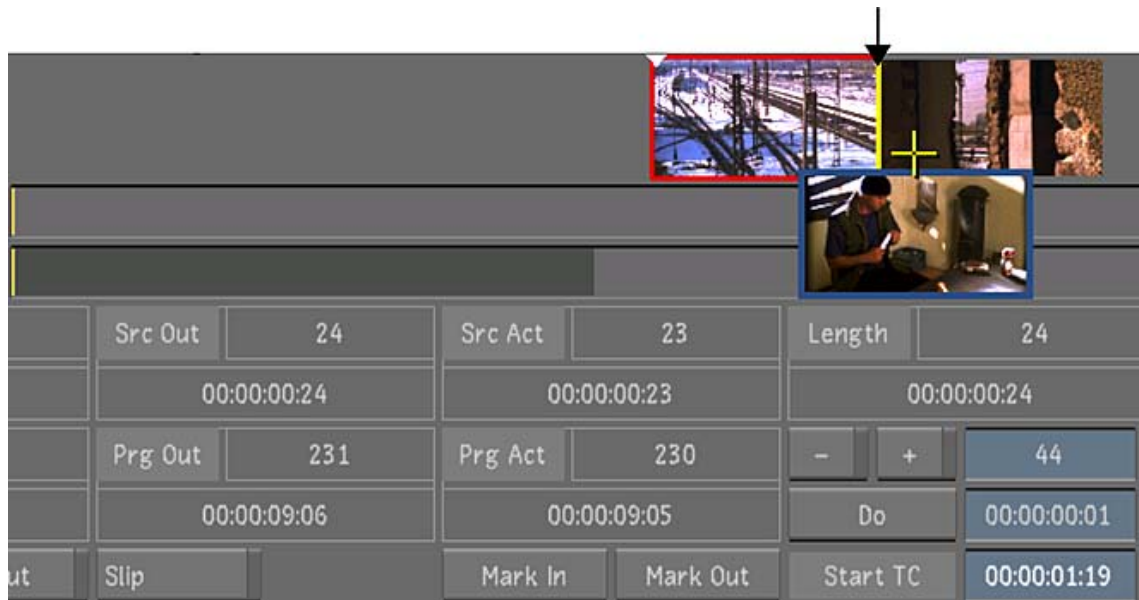

Image courtesy of Hungarian Academy of Film & Theatre, 3rd year

As you move the cursor back and forth along the Storyboard, the insertion marker moves.

- 3 Click to add the shots to the Storyboard.  
The shots are added to the end of the Storyboard if Solo mode is disabled or to the location of the insertion marker if Solo mode is enabled.

## Reordering Shots in the Storyboard

You can reorder the shots in the Storyboard.

---

**NOTE** Solo mode in the Timeline menu must be enabled.

---

**To reorder a shot in the Storyboard:**

- 1 In the main menu, click Editing.
- 2 Click Timeline.  
The Timeline menu appears.
- 3 Enable Solo.
- 4 Drag the shot you want to move.  
The shot becomes partially transparent.
- 5 Drag the shot elsewhere in the Storyboard.  
A yellow insertion marker shows where the shot will be placed.
- 6 Release the mouse, then click it again, to complete the edit.

**TIP** If you select the wrong shots, click the grey area to the left of the Trash button. This releases the selected shots from the cursor.

# Duplicating Shots in the Storyboard

You can duplicate shots in the Storyboard.

**NOTE** Solo mode in the Timeline menu must be enabled.

## To duplicate shots in the Storyboard:

- 1 After adding a shot to the Storyboard, drag the shot from the Library a second time to create a duplicate.

**TIP** If you select the wrong shots, click the grey area to the left of the Trash button. This releases the selected shots from the cursor.

**TIP** To insert a duplicated shot to the insertion marker location of the Storyboard, you must enable Solo mode in the Timeline menu. See [Multi-Layer Timeline](#) (page 1974). Otherwise, the duplicated shot is inserted at the end of the Storyboard.

# Deleting Shots

You can delete shots from the Library, Storyboard, or multi-layer timeline (see [Deleting Elements](#) (page 1984)). Deleting shots from the Library does not delete them from the Storyboard or multi-layer timeline, and vice versa.

Be aware that Timeline Solo and Ripple mode affects how the shots are deleted in the Edit menu. If Solo is enabled, the Trash and Delete tools default to Ripple End behaviour. If Solo is disabled, the Trash and Delete tools behave according to the Timeline Ripple mode (see [Trimming Ripple Mode](#) (page 1997)) and apply to the layer that the focus point is on.

(a) Delete Shot button (b) Trash button

## To delete a shot from the Storyboard:

- 1 Click Editing, and then click Edit to display the Edit menu.
- 2 Select the shot, and then do one of the following:
  - Click Delete Shot and then confirm the deletion.
  - Click and drag the shot to the Trash button, and then confirm the deletion.
  - Press **Shift+D**.

The selected shot is deleted.

## Trimming from the Edit Menu

Use the Trimming tools to adjust the frames used in your edits. When you trim, you are either adding frames to or removing frames from the head or tail of the shots in your cut.

Be aware that timeline Solo and Ripple mode affects how the shots are trimmed in the Edit menu. If Solo is enabled, the Trim In/Trim Out and Mark In/Out tools default to Ripple End behaviour. If Solo is disabled, the Trim In/Trim Out and Mark In/Out tools behave according to the Timeline Ripple mode (see [Trimming Ripple Mode](#) (page 1997) and [Slip & Slide Ripple Mode](#) (page 1998)) and apply to the layer that the focus point is on.

You can trim by entering exact frame values, by dragging frames interactively, or by marking in and out points. You can also trim by sliding the cut point between shots or slipping the frames used in a shot.

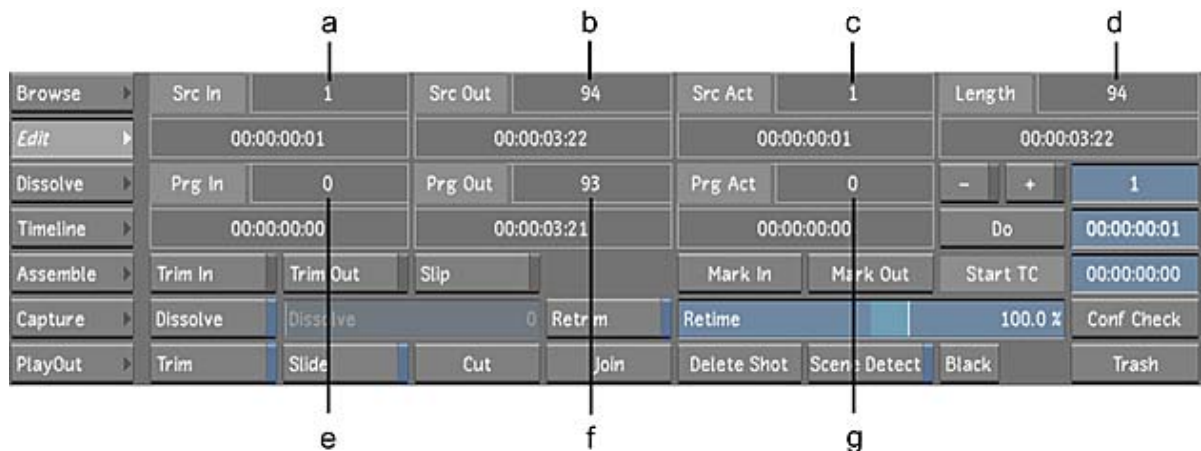

## Viewing Shot Information

When trimming, you will occasionally need information about the frames and timecode in your shots and cuts.

You can find shot information in the Edit menu.

For example, refer to the Src In field to determine if you can add a few frames to the start of the shot, or check whether you changed the length of the timeline by checking the value in the Length field.

You cannot enter values directly in these fields. They are updated when you scrub through the shot or Storyboard. For each field, the actual frame number is displayed, as well as the corresponding timecode value.

**(a)** Src In field **(b)** Src Out field **(c)** Src Act field **(d)** Length field **(e)** Prg In field **(f)** Prg Out field **(g)** Prg Act field

Use the following fields to view shot information.

**Src In** Displays the selected shot's Mark In frame number and timecode.

**Src Out** Displays the selected shot's Mark Out frame number and timecode.

**Src Act** Displays the absolute frame number of the current frame in the source material.

**Length** Displays the total length of the current shot in the timeline in frames and timecode.

**Prg In** Displays the program in point for the selected shot.

**Prg Out** Displays the program out point for the selected shot.

**Prg Act** Displays the current program frame number of the timeline.

---

**NOTE** The appropriate fields are highlighted when you enter an editing mode, indicating where editing operations affect your frames.

---

## Trimming the Head and Tail of a Shot

You can trim frames from the head or tail of one or more shots. The head is the first source frame that you specify to use in the shot. The tail is the last source frame that you use in the shot.

You specify the number of frames to trim from either the head or tail. If you do not want to change the overall length of your timeline, when you add frames to, or subtract frames from, one end of a shot, you should subtract from or add the same number of frames to the other end.

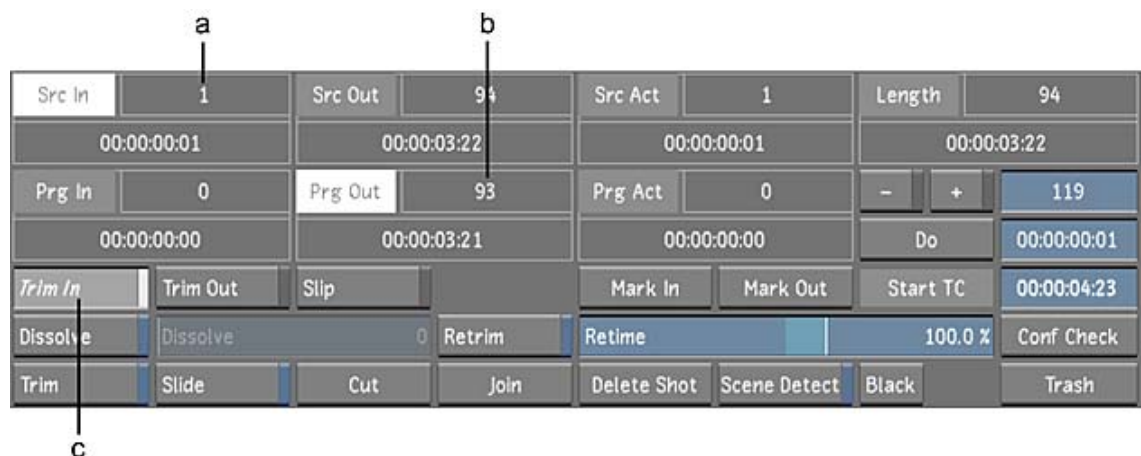

Remember that you cannot add more frames to a shot than the available number of handles. Also, you cannot trim a shot completely out of existence. If you want to delete a shot, use the Delete Shot button. See [Deleting Shots](#) (page 1959).

**To trim frames at the in point for one or more selected shots:**

- 1 Select the shot you want to trim in the Storyboard. The selected shot's border turns red. To select multiple shots on the Storyboard, right-click each shot. The borders turn aqua.

**NOTE** You can only add frames if your shots have available handles.

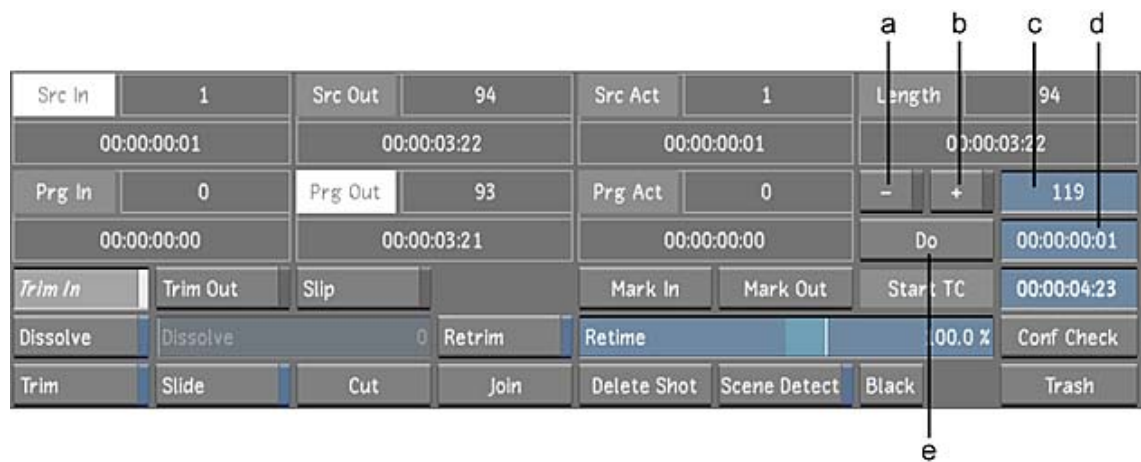

- 2 Click Editing in the main menu, and then click Edit.  
The Edit menu appears.

(a) Src In field (b) Prg Out field (c) Trim In button

- 3 Click Trim In to go into Trim In mode.  
Src In and Prg Out are highlighted because these values are changed by the Trim In operation.
- 4 Add frames to or remove frames from the mark in (or head):
  - Click + to add frames.
  - Click - to subtract frames.

(a) - (minus) button (b) + (plus) button (c) Frame field (d) Do field (e) Do button

**NOTE** If you do not click either + or -, the trim operation removes an absolute number of frames.

5 Do one of the following:

- Click the Do field, then click the frame field and enter the number of frames to add or subtract by using the numeric keypad. The frame number is converted into the corresponding timecode value.
- Click the Do field and enter the timecode for the number of frames to add or subtract. The timecode is converted into the corresponding frame number.

**NOTE** Ctrl-click the field to clear it.

6 Click Do.

The specified number of frames is added to or subtracted from the shot(s). The Length field is updated to display the number of frames now used.

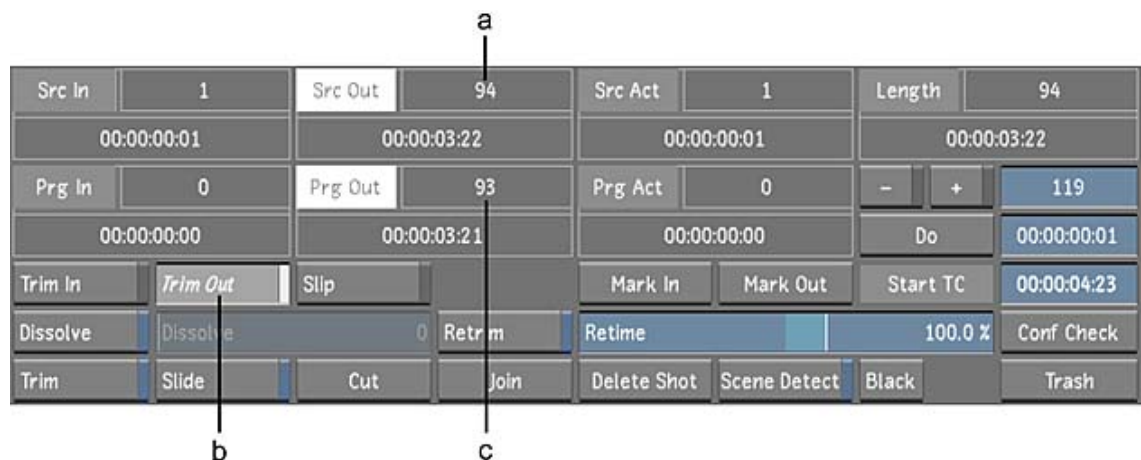

**To trim frames at the out point for one or more selected shots:**

- 1 Select the shot you want to trim in the Storyboard. The selected shot's border turns red. To select multiple shots on the Storyboard, right-click each shot. The borders turn aqua.

**NOTE** You can only add frames if your shots have available handles.

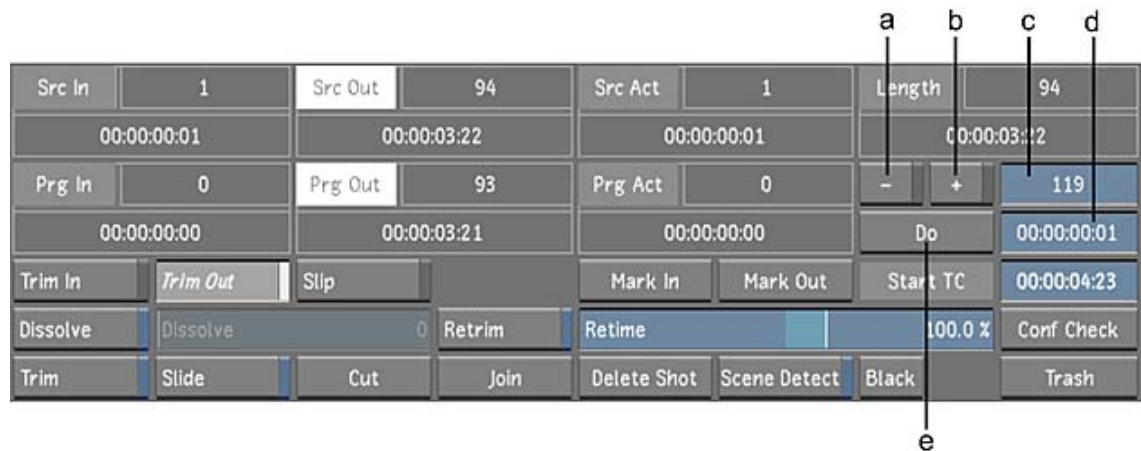

- 2 Click Editing in the main menu, and then click Edit.

The Edit menu appears.

(a) Src Out field (b) Trim Out button (c) Prg Out field

- 3 Click Trim Out to go into Trim Out mode.  
Src Out and Prg Out are highlighted because these values are changed by the Trim Out operation.
- 4 Add frames to or remove frames from the mark out (or tail):
  - Click + to add frames.
  - Click - to subtract frames.

(a) - (minus) button (b) + (plus) button (c) Frame field (d) Do field (e) Do button

**NOTE** If you do not click either + or -, the trim operation removes an absolute number of frames.

- 5 Do one of the following:
  - Click the Do field, then click the frame field and enter the number of frames to add or subtract by using the numeric keypad. The frame number is converted into the corresponding timecode value.
  - Click the Do field and enter the timecode for the number of frames to add or subtract. The timecode is converted into the corresponding frame number.

**NOTE** **Ctrl**-click the field to clear it.

- 6 Click Do.

The specified number of frames are added to or subtracted from the shot(s). The Length field is updated to display the number of frames now used in the shot.

## Slipping a Shot

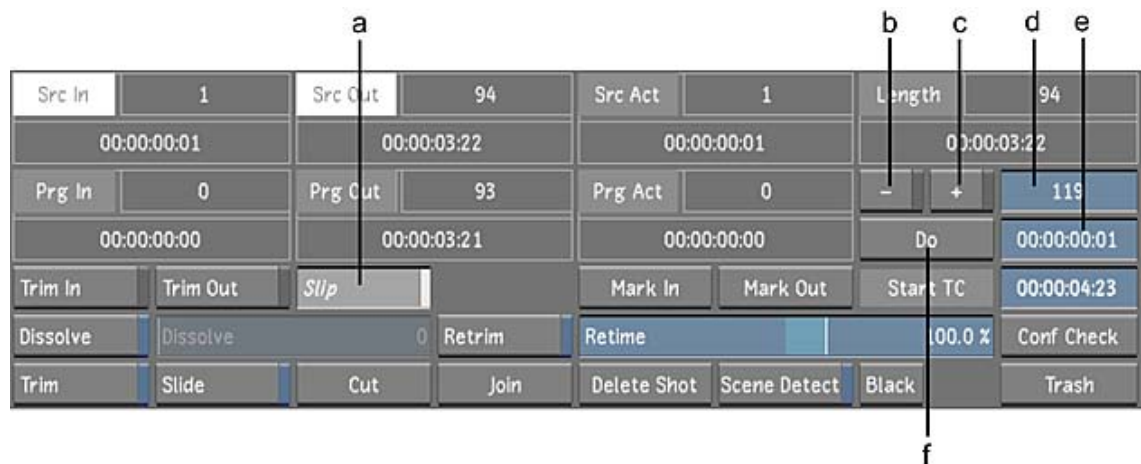

You can slip the frames used in one shot without adjusting the shot's position in the timeline. You may need to slip your shot to synchronize action in the picture to the audio or because unwanted frames are appearing at either the head or tail.

**To slip one or more shots:**

- 1 Select the shot you want to slip in the Storyboard. The selected shot's border turns red. To select multiple shots on the Storyboard, right-click each shot. The borders turn aqua.

**NOTE** You must have available handles to slip a shot.

- 2 Click Editing in the main menu, and then click Edit.  
The Edit menu appears.

(a) Slip button (b) - (minus) button (c) + (plus) button (d) Frame field (e) Do field (f) Do button

- 3 Click Slip to go into Slip mode.  
Src In and Src Out are highlighted.
- 4 Slip forward or backward:
  - Click + to slip forward.
  - Click - to slip backward.
- 5 Do one of the following:
  - Click the Do field, then click the frame field and enter the number of frames you want to offset the shot by. The frame number is converted into the corresponding timecode value.
  - Click the Do field and enter the timecode for the number of frames to offset the shot by. The timecode is converted into the corresponding frame number.

**NOTE** Ctrl-click the field to clear it.
- 6 Click Do.  
The shot or shots are offset by the specified number of frames. The Src In and Src Out fields are updated to display the frames used.

## Trimming Interactively

You can trim frames interactively. When you trim interactively, you scrub the Player to add frames to, or remove frames from, the in or out point.

**To trim interactively:**

- 1 In the Storyboard, select the shot you want to trim.
- 2 Click Editing in the main menu, and then click Edit to display the Edit menu.
- 3 Enable Trim.

**TIP** If the Editing While Grading button is enabled in the User settings, you can start interactively trimming shots from any menu by pressing **Shift+T**. For more information about the Editing While Grading button, see [System & Menu Settings](#) (page 1807).

In Trim mode, you see the first frame of the shot in the left viewer, and the last frame in the right viewer.

- 4 Do one of the following:
  - To trim frames at the head, click the left viewer and then drag the cursor left to add frames or right to subtract frames.
  - To trim frames at the tail, click the right viewer and then drag the cursor right to add frames or left to subtract frames.
- 5 For greater control of the trim operation, middle-click as you drag to decrease the start frame by one frame or right-click to increase the offset by one frame.
- 6 To exit the Interactive Trim mode, do one of the following:
  - Click Trim.
  - Press the **ESC** key.

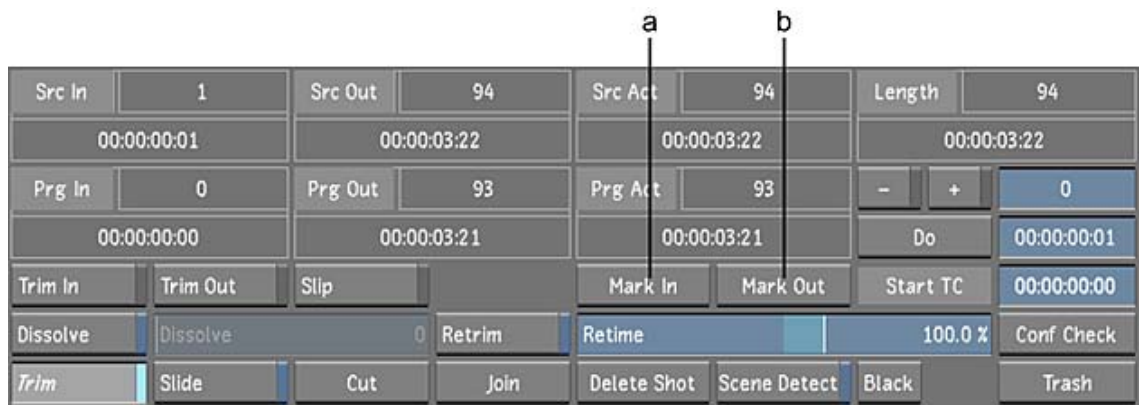

## Changing In and Out Points for a Shot

You can change the in and out points for a shot. This is like trimming, except you can only shorten a shot by changing the in or out points.

The in point is the first frame used in a shot. The out point is the last frame. Setting a new in or out point shortens the total length of a shot. The frames that you remove by changing the in or out point become available handles that you can use in later trimming operations.

### To change the in or out point for a shot:

- 1 In the Storyboard, select the shot you want to modify, and then scrub to the frame you want to mark as the in point.
- 2 Click **Editing**, and then click **Edit**.  
The Edit menu appears.

(a) Mark In button (b) Mark Out button

- 3 Click Mark In.  
The extra frames are trimmed from the head of the shot.
- 4 Scrub to the frame you want to mark as the out point.
- 5 Click Mark Out.  
Extra frames are trimmed from the tail of the shot.

**NOTE** You must go into one of the Trim modes to add frames back to the head or tail of the shot.

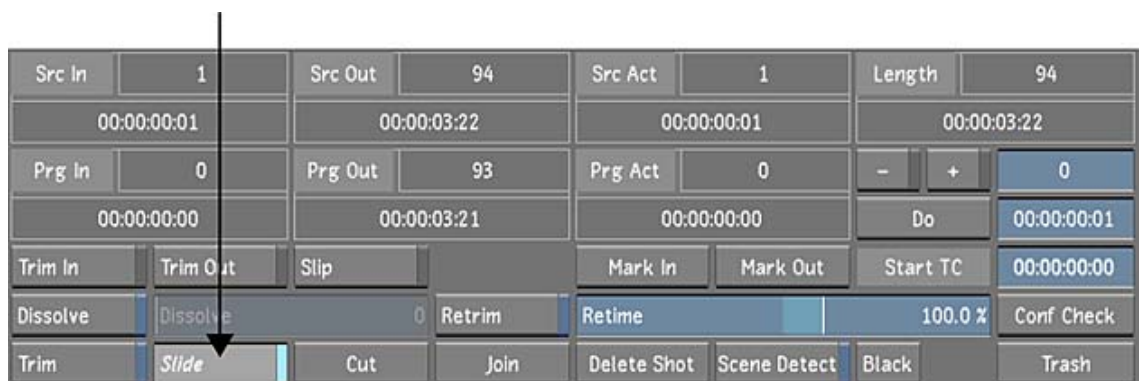

## Sliding the Cut Point between Shots

You can interactively move the cut point between two shots forward or backward, if handles are available. Using Slide does not adjust the overall length of your timeline. By removing frames from one side of the cut, you automatically add frames to the other side.

You may want to slide the cut point to synchronize the cut to audio or simply to use different frames in your shot.

**To slide a cut point:**

- 1 In the Storyboard, select the shot to the right of a cut point.
- 2 Click Editing, and then click Edit to display the Edit menu.
- 3 Click Slide.

**TIP** If the Editing While Grading button is enabled in the User settings, you can start interactive visual sliding between the current and the previous shot from any menu by pressing **Shift+R**. For more information about the Editing While Grading button, see [System & Menu Settings](#) (page 1807).

In Slide mode, you see the outgoing frame before the cut in the left viewer and the incoming frame after the cut in the right viewer.

- 4 Drag in either viewer to move the cut point.  
If both clips have available handles, drag to the left or right to move the cut point.  
Frames are added to one side of the cut and subtracted from the other to keep the total timeline duration the same. When you run out of handles, you can no longer continue sliding in the same direction.
- 5 For greater control of the slide operation, middle-click the mouse to decrease the cut point by one frame or right-click to increase the cut point by one frame.
- 6 To exit the Interactive Slide mode, do one of the following:
  - Click Slide.
  - Press the **Esc** key.

The timeline is updated when you exit Slide mode.

## Inserting Cuts

You can cut a shot into two shots. This is useful when you want to insert cuts between scenes, or if you need to apply separate grades within a shot.

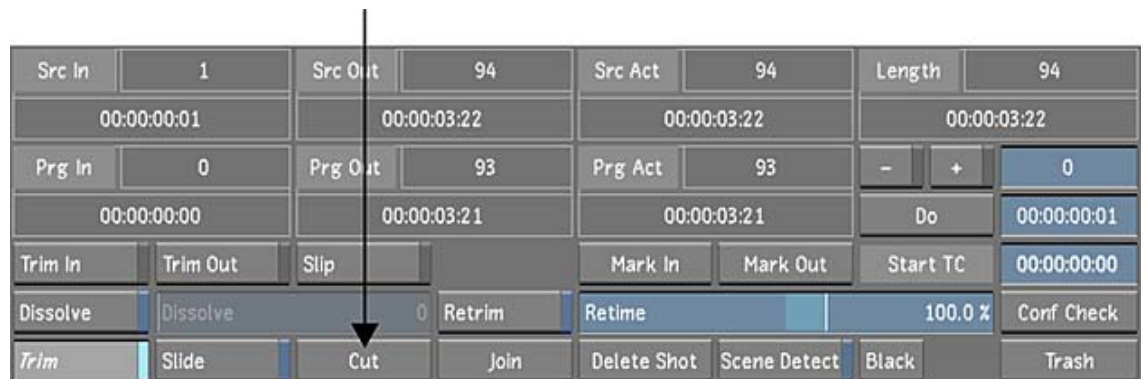

---

**NOTE** If working on field-based material, you cannot apply a cut between two fields of an image.

---

To insert a cut in a shot:

- 1 In the Storyboard, scrub to the position where you want to introduce the cut.
- 2 Click Editing, and then click Edit to display the Edit menu.
- 3 Click Cut.

The shot is cut into two separate shots.

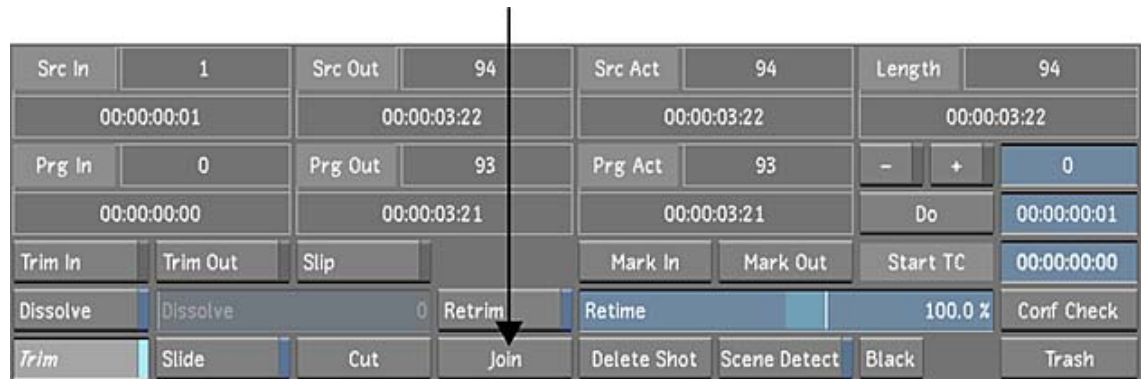

**TIP** If the Editing While Grading button is enabled in the User settings, you can insert a cut from any menu by pressing **Shift+C**. For more information about the Editing While Grading button, see [System & Menu Settings](#) (page 1807).

## Joining Shots

You can rejoin a shot that is cut. The shots have to come from the same original source, must be adjacent in the Storyboard, and must be incrementing timecode. Join recreates the original sequence, even if there is material missing from the current Storyboard. For example, if you create a cut and trim out something in the middle of the original shot, you can join the shots back together and the missing frames are put back.

**To join shots together:**

- 1 In the Storyboard, select the right-most (also known as the B-side) of the previously cut shots.
- 2 Click Editing, and then click Edit to display the Edit menu.
- 3 Click Join.

The shots are joined together.

**TIP** If the Editing While Grading button is enabled in the User settings, you can join shots from any menu (except the colourist multi-layer timeline) by pressing **Shift+J**. For more information about the Editing While Grading button, see [System & Menu Settings](#) (page 1807).

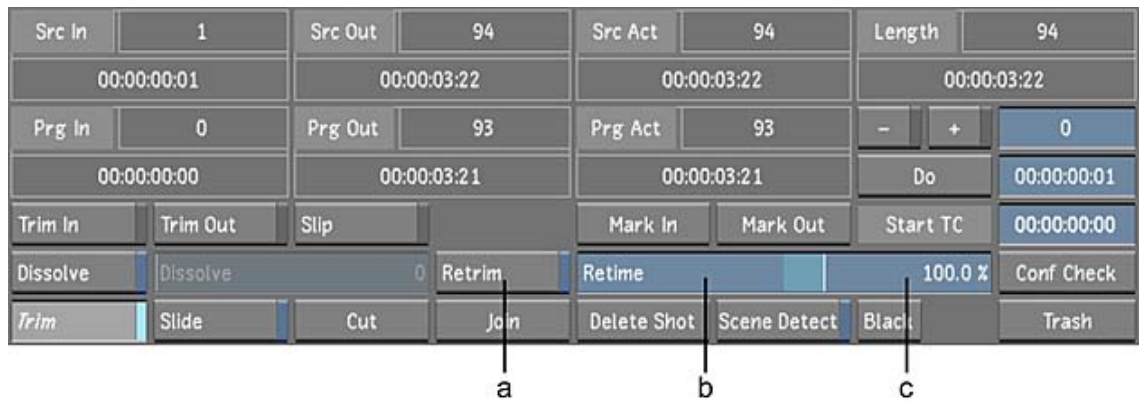

## Changing Playback Speed

Use the Retime option to change the playback speed of your shots. When you change the playback speed of a shot, Lustre duplicates or removes frames as needed so that the shot plays at the specified constant frame rate. Changing the speed changes the length of the shot, so you may need to trim the shot after you change the speed.

**To change a shot's playback speed:**

- 1 Select the shot in the Storyboard that you want to adjust.
- 2 Click Editing, and then click Edit.

(a) Retrim button (b) Retime slider (c) Retime field

- 3 Enable Retrim to trim the shot so that the same source in and out points are used. You can also trim the shot using the tools in the Edit menu.  
If you do not enable Retrim, the source out point changes shots. This is especially noticeable when you speed up a shot, since you may end up with black frames at the end of the adjusted shot. You can remove the black frames using the trimming tools. See [Trimming from the Edit Menu](#) (page 1960).
- 4 Drag the Retime slider to the new playback speed or right-click on the Retime slider to enter a retime value in the Retime field.
- 5 Play back the shot to see the effect of the speed change.

## Replacing Shots

You can take a shot from the Library (the source shot) and swap it with another shot in the Storyboard (the destination shot). You can replace the destination shot with a source shot starting at the first frame of the source, or you can replace the destination shot with a source for which you have offset the starting frame.

**NOTE** You can also replace a shot in the Timeline menu using the Library view. See [Replacing Shots in the Timeline](#) (page 1981).

When replacing shots, you do not modify the overall duration of the timeline.

### To replace a shot in the Storyboard without offsetting the source shot:

- 1 Shift-click the shot in the Library (the source shot) that you want to use to replace the shot in the Storyboard (the destination shot).
- 2 Move the source shot over the destination shot in the Storyboard.  
The destination shot is highlighted with an orange box.
- 3 Click the destination shot.  
The destination shot is replaced by the source shot.

### To replace a shot in the Storyboard with an offset source shot:

- 1 Shift-click the shot in the Library (the source shot) that you want to use to replace the shot in the Storyboard (the destination shot).
- 2 Move the source shot over the destination shot in the Storyboard.  
The destination shot is highlighted with an orange box.
- 3 Shift-click the destination shot.

A dual view appears. In the left viewer, you see the original shot and in the right viewer you see the new shot.

**4** Drag in the right viewer.

The start frame of the first shot begins to change. You can see by how much you are offsetting the start frame by referring to the numbers in the upper-left corner of the screen.

**5** For greater granularity, middle-click and drag to decrease the start frame by one frame and right-click and drag to increase the offset by one frame.

You can also use the numeric keypad to change the offset. Specify a negative number and then press **Enter** to decrease the offset or specify a positive number and then press **Enter** to increase the offset.

**6** Press **Enter** on the numeric keypad to complete the replace shot operation.

---

**NOTE** If the source shot is shorter than the destination shot, or if you offset the source starting point too much, part of the destination shot will not contain any images. Instead, an X appears in the viewer for these frames.

---

## Creating Dissolves

Use dissolves to create a gradual blend between two shots. A dissolve is a transition that causes the outgoing shot to gradually disappear at the same time as the incoming clip gradually appears. Depending on the number of available handles, you can use dissolves to create long, gradual changes, or you can create dissolves with short durations (called soft cuts).

---

**NOTE** Centre dissolves are created automatically if you import an EDL that contains dissolves. However, other transitions, like wipes, are replaced by straight cuts.

---

## Adding a Dissolve

You can add a dissolve between two shots provided that there are a sufficient number of underlying handles.

---

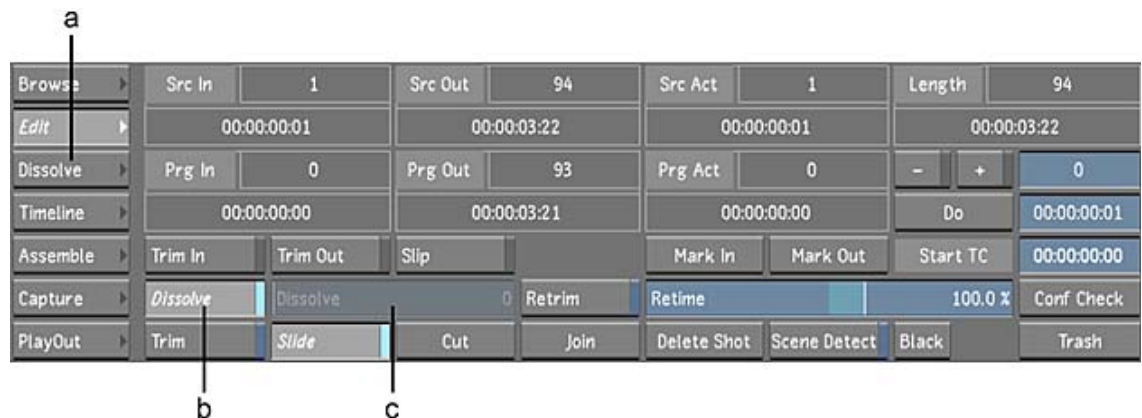

**NOTE** You must have sufficient handles to add a dissolve. If you do not, use the Retrim tool. For more information, see [Creating Additional Handles for Dissolves](#) (page 1971).

---

To add a dissolve between two shots:

**1** Click **Editing**, and then click **Edit**.

The **Edit** menu appears.

(a) Dissolve menu button (b) Dissolve button (c) Duration slider

- 2 Place the positioner on or near the transition to which you want to add a dissolve.

**NOTE** You can also add a fade-in at the beginning of the timeline and a fade-out at the end. Also, when adding a fade-in or fade-out to a gap on Layer 1, Lustre automatically fills the gap with a virtual colour source clip.

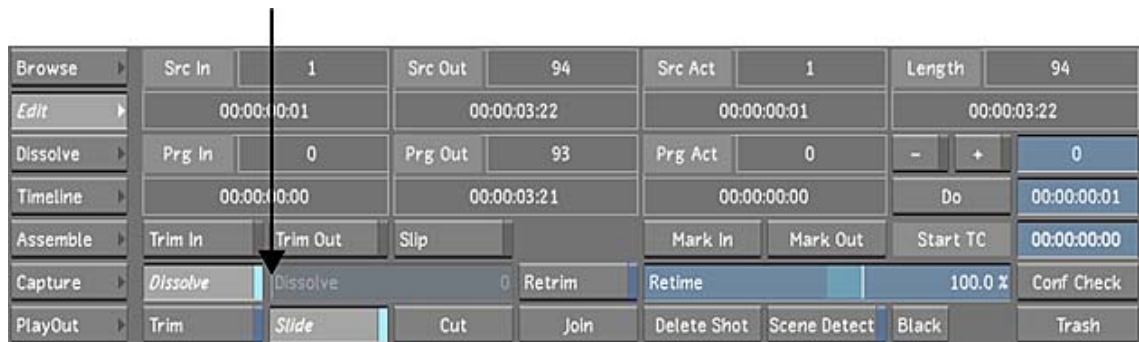

- 3 Enable Dissolve, and then drag the Dissolve slider to set the dissolve duration.
- 4 To edit the shape of the Dissolve curve, see [Editing Dissolves](#) (page 1972).

## Changing Dissolve Duration

You can change the duration of a dissolve at any time.

**To change dissolve duration:**

- 1 Select the shot to the left of the dissolve.
- 2 In the Edit menu, drag the Dissolve slider to adjust the dissolve duration or right-click the slider for the pop-up entry.

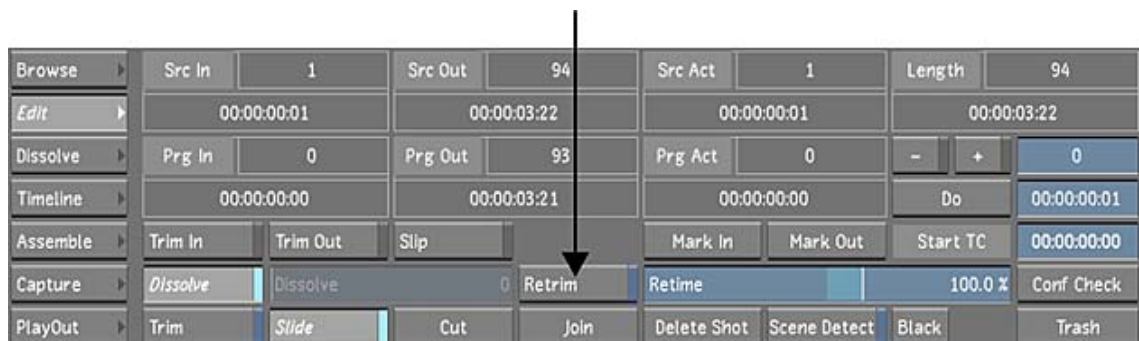

## Creating Additional Handles for Dissolves

You can trim handles from outgoing and incoming shots and use them to add a dissolve.

**To create handles for a dissolve:**

- 1 In the Storyboard, select the shot to the left of the cut point to which you want to add a dissolve.
- 2 In the Edit menu, enable Retrim.

- 3 Enable Dissolve, and then drag the Dissolve slider to set the duration or right-click the slider for the pop-up entry.  
Frames are automatically trimmed from the tail of the outgoing clip and the head of the incoming clip.

## Editing Dissolves

The Dissolve menu allows you to animate your dissolve. Use the controls located in the lower left side of the Dissolve editor to add, delete, copy, paste and navigate between keyframes. Navigate the timeline to edit any transition using the Dissolve menu's editor and curve window. Use the navigation buttons, the hotkeys or the Autodesk Control Surface to navigate the timeline.

### TIP

To enter the Dissolve editor from the timeline, you can double-click on the Dissolve icon.

Right-click to zoom the Dissolve curve and middle-click to pan. To reset the Dissolve curve, press the Home key on the keyboard.

Keyframe controls are located on the lower left side of the Dissolve curve window. On the right side of the Dissolve curve window, you will find the Animation Controls and the Animation options. See [Animation](#) (page 2214).

**Dissolve button** Enable the dissolve located at the current transition.

### WARNING

Re-enabling a disabled dissolve will restore dissolve metadata (e.g., duration, orientation) for the current session only. Saving the cutfile with the Dissolve button disabled does not save the original dissolve settings.

**Duration field** Set the length of the dissolve. The default value is the defined in the User settings. See [Tools Settings](#) (page 1811).

**Orientation box** Define the orientation of the dissolve.

| Select:   | To:                                                 |
|-----------|-----------------------------------------------------|
| Centred   | Place the dissolve in the middle of the transition. |
| From Cut  | Start the dissolve at the cut point.                |
| Up To Cut | End the dissolve at the cut point.                  |

**Curve Type box** Select the type of dissolve curve.

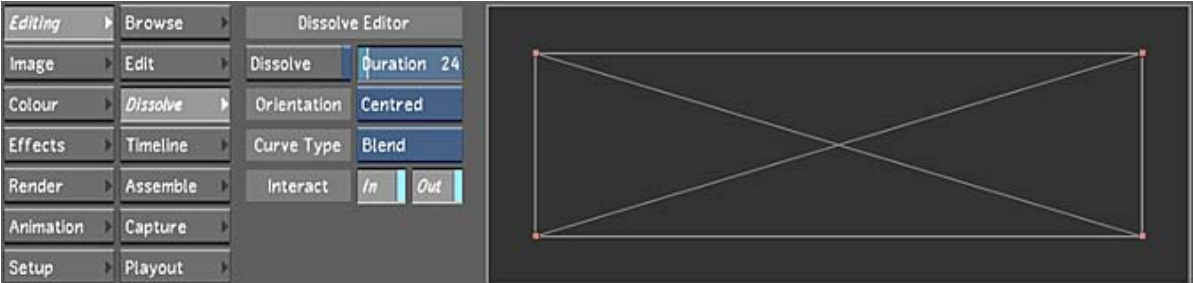

| Select:  | To:                                                                                                                                                                                                                                                                                   |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Blend    | Display two curves to blend between the outgoing and incoming shots.                                                                                                                                                                                                                  |
| Dissolve | Display a dissolve curve similar to that found in Smoke and Flame. Display buttons in the Dissolve editor to edit and navigate between keyframes.<br><br><b>NOTE</b> Importing a timeline with dissolves from Wiretap server 2011 Extension 1 or higher will include dissolve curves. |

**In and Out buttons** Enable to blend between the outgoing and incoming shots. Enabled when the Curve Type is set to Blend.

Use the windows in the Dissolve menu to edit the rate at which the dissolve changes.

The Blend Curves window displays two curves: one represents the outgoing shot and the other represents the incoming shot. These curves are plotted on a graph that shows time vs. percent visible. When curves are at the top of the window, the frames at that point in time are 100% visible. Curves near the bottom correspond to 0% visible frames.

By default, each curve progresses in a linear fashion from one corner of the window to the opposite corner.

**NOTE**

Cutfiles from versions prior to Lustre 2011 Extension 1 will display the Blend curve.

**To modify the Dissolve curve:**

- 1 In the Editing menu, click Dissolve to display the Dissolve menu.
- 2 In the Curve Type box, select Dissolve.

**To modify the Blend curve:**

- 1 In the Editing menu, click Dissolve to display the Dissolve menu.
- 2 In the Curve Type box, select Blend.
- 3 Enable Interact In or Out to specify whether you are modifying the outgoing or incoming frames of the dissolve. You can also work on both curves simultaneously.

You can change the start or end visibility to any value between 0-100%; however, you cannot adjust the time at which a dissolve starts or ends in the Dissolve Curves window. To do this, return to the Edit menu and use the Dissolve slider.

## Turning Dissolves Off

Use the Dissolve button in the Edit menu or the Dissolve menu to toggle a dissolve on and off.

## Resetting Dissolves

To reset the Dissolve curve to its default value (i.e., two keyframes), press the Reset button in the Lustre user interface.

## Adding a Virtual Black Clip using the Storyboard

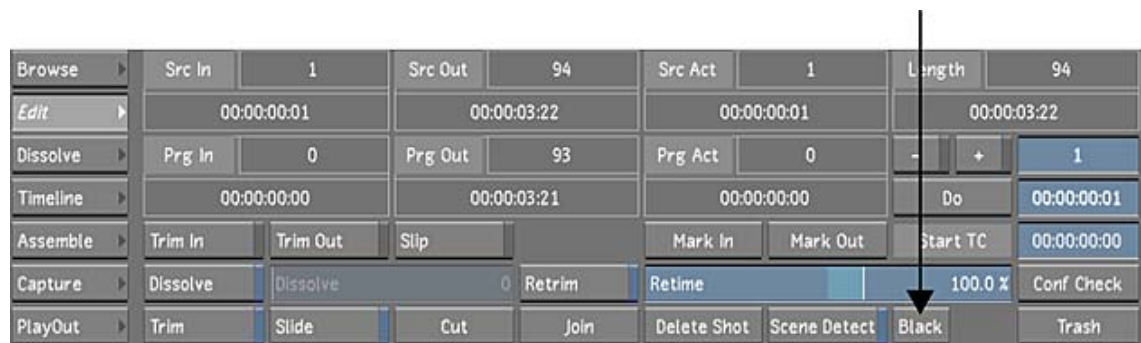

Virtual black clips can be added anywhere on the timeline. The default duration of each clip is one second, according to the current project frame rate. See [Adding Black Media to the Timeline](#) (page 1983).

To add a virtual black clip using the Storyboard:

- 1 In the Main menu, click Editing, and then Edit.

**NOTE** Solo mode must be enabled if you want to add the black clip to a specified position. See [Multi-Layer Timeline](#) (page 1974). If Solo mode is disabled, the black clip is inserted at the end of the timeline.

- 2 Click Black.

- 3 Move the clip to the Storyboard.  
A yellow insertion marker appears at the cut where the black clip is entered.

**NOTE** The status of Ripple and Snap modes is taken into account when adding black media.

- 4 Insert the clip on the Storyboard.

**NOTE** You can change the virtual clip's colour in the Virtual Black Clip Colour group in the Project settings. See [Engineering Settings](#) (page 1795).

## Multi-Layer Timeline

The multi-layer timeline view organizes footage or elements into a multi-layer format. You can scroll, pan, and zoom the multi-layer timeline, as well as rearrange elements on the timeline by dragging and dropping.

The multi-layer timeline in Lustre supports Video Tracks and Video Layers. However, vertical compositing is not supported in Lustre.

Multi-layer timeline editing is useful for roughing out edit sequences and grade versioning. In addition, shot selections are now linked between the timeline and the Storyboard.

You can also copy the grading information in the multi-layer timeline or colourist multi-layer timeline. See [Copying Grading Information in the Colourist Timeline](#) (page 2098).

The multi-layer timeline allows you to display footage, play out to tape, and render in accordance with rules that prioritize some shots or layers over others. See [Displaying the Multi-Layer Timeline](#) (page 2001).

## Timeline Menu

There are various areas to work with when you access the Timeline menu:

- Storyboard. See [Storyboard Viewing Options](#) (page 2022).
- File browser. See [Accessing the File Browser](#) (page 1909).
- Library. See [Accessing the File Browser](#) (page 1909).
- Player and full-screen Player. See [The Player](#) (page 1848).

---

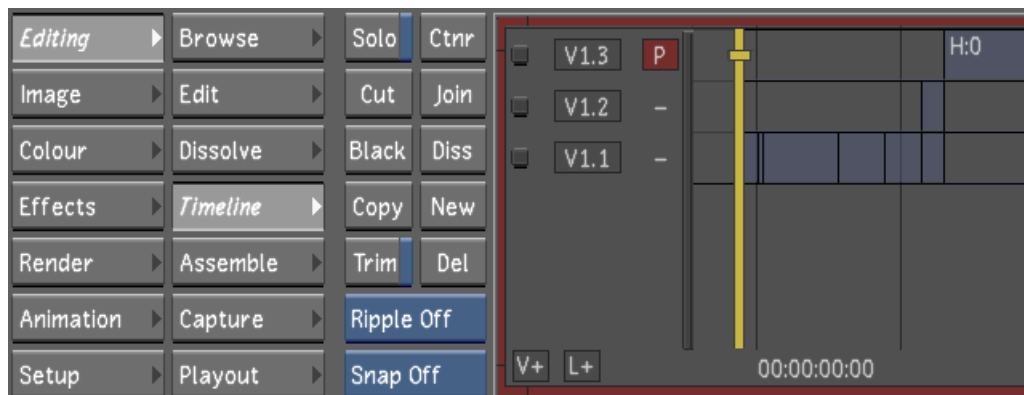

**NOTE** From the Timeline menu, you can press **Enter** to toggle through these different views.

---

**To access the Timeline menu and multi-layer timeline:**

- 1 In the Main menu, click Editing.
- 2 Click Timeline.

The Timeline menu and the multi-layer timeline canvas appear.

The multi-layer timeline is made up of the following components.

(a) Layer selector (b) Track/Layer name (c) Primary Track/Layer indicator (d) Positioner (e) Track/Layer selector (f) Element Head (g) Element (h) Element Tail (i) Shot Priority indicator (j) Add Video Track button (k) Add Video Layer button (l) Starting timecode (m) Gap (n) Canvas

**Layer selector** Selects the entire layer in preparation for an operation.

**Track/Layer name** The name of the layer, where V stands for Video and L for Layer. Adding a layer generates V1L2, V1L3, etc.

**Primary Track/Layer indicator** Indicates which Track/Layer is set to Primary. Click the left side of the track (-) to set the track as Primary (P).

**Positioner** The play head for the Player. The frame directly beneath the positioner is displayed in the Player and is the current location for an edit. The positioner's location is reflected in the Source Timecode or Timeline Information field. See [Monitoring the Location of the Current Frame](#) (page 2020).

**Focus point** When Solo mode is enabled, the focus point indicates the current layer and which layer is displayed in the Storyboard. When Solo mode is disabled, the top layer acts as the primary layer and is displayed in the Player and Storyboard. The focus point also determines to which layer a cut or dissolve is added. Together, the position of the focus point and the positioner is reflected in the Source Timecode or Timeline Information field. See [Monitoring the Location of the Current Frame](#) (page 2020).

**Element Head** Number of available frames for trimming, succeeding a transition.

**Element** The media in the timeline.

**Element Tail** Number of available frames for trimming, preceding a transition.

**Shot Priority indicator** Graphical representation of a shot with priority. See [Shot Priority](#) (page 2003).

**Add Video Track button** Adds a new Video Track to the timeline.

**Add Video Layer button** Adds a new Video Layer to the timeline.

**Gap** The absence of media. In a multi-layer context and when Solo mode is disabled, gaps are also transparent.

**Canvas** Click the canvas to zoom in/out and move the timeline.

The Timeline menu is made up of the following buttons.

**Solo** When Solo mode is enabled, Lustre displays, plays out to tape, or renders only the layer on which the focus point is positioned.

---

**NOTE** The Solo state is not saved in the grade file.

---

**Cut** Adds a splice at the positioner location on the focused layer.

**Black** Generates one second of black media that can be added to the timeline.

**Copy** Copies the current selected elements to the clip board. Copied elements are displayed in red. Drag and drop the copied elements to the destination timecode or layer.

**Trim** Trims the head and/or tail of an element.

**Ripple mode** Determines whether the length of the edit sequence is affected when new material is inserted into or removed from the timeline.

**Snap mode** Affects how elements are placed when gesturally moved or copied to the Timeline.

**Ctnr** Adds a container to the timeline.

**Join** Removes the splice on selected elements coming from the same source clip with consecutive source timecode.

**Diss** Adds a dissolve at the positioner location on the focused layer.

**New** Copies the current element to the next available top layer with grade data.

**Del** Deletes the current selection.

## Timeline Navigation Controls

The following is a list of hotkeys and mouse gestures commonly used to navigate within the Timeline menu.

| Press:                                    | To:                                           |
|-------------------------------------------|-----------------------------------------------|
| Right <b>Alt</b>                          | Go to the previous frame.                     |
| Right <b>Ctrl</b>                         | Go to the next frame.                         |
| Left arrow                                | Go to the previous element.                   |
| Right arrow                               | Go to the next element.                       |
| Up arrow                                  | Move the focus point to the layer above.      |
| Down arrow                                | Move the focus point to the layer below.      |
| Middle mouse button and drag              | Move the multi-layer timeline.                |
| Right mouse button and drag               | Zoom into or out of the multi-layer timeline. |
| Left mouse button and drag the positioner | Move the positioner.                          |

Additional multi-layer timeline navigation controls are shown below.

(a) Scroll timeline canvas up (b) Vertical scroll bar (c) Scroll timeline canvas down (d) Vertical zoom control (e) Home/selected Focus view (f) Scrub area

**Scroll timeline canvas up** Displays the top layers located outside of the canvas view.

**Vertical scroll bar** Quickly moves the multi-layer timeline view up or down.

**Scroll timeline canvas down** Displays the bottom layers located outside of the canvas view.

**Vertical zoom control** Enlarges or reduces the size of the layers.

**Home/selected Focus view** Click this button to reset the vertical/horizontal zoom and position of the canvas view to display the entire timeline. **Alt** + press this button to zoom into the selected shot(s).

**Scrub area** Click or drag in this area to quickly move to any point in the timeline.

## Viewing Element Information

It is possible to vertically expand the size of a layer to see more information about the element.

**To vertically expand the layer:**

- 1 Click +.

More information about the element is revealed.

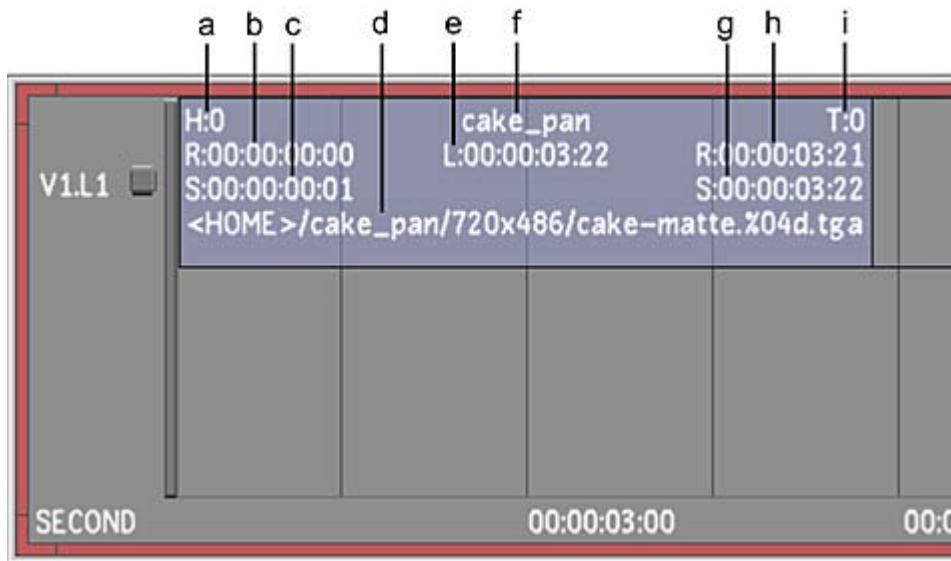

**NOTE** Each time you press +, more information is revealed.

**To minimize the layer:**

- 1 Click -.

Other layers become visible.

The following information is displayed about an element.

(a) Head (b) Start record timecode (c) Start source timecode (d) Shot location (e) Length of element (f) Name of element (g) End source timecode (h) End record timecode (i) Tail

## Editing in the Timeline

The following sections describe how to perform various basic timeline operations.

### Creating a Timeline

When you add shots to the Storyboard view or assemble an EDL, Lustre creates a timeline. You can then perform editing operations or colour grade the sequence. A timeline can also be called a cut file.

### Adding Shots to the Timeline

You can add shots by dragging and dropping from the Library or Browser to the multi-layer timeline or to the Storyboard. See [Adding Shots to the Storyboard](#) (page 1957).

---

**NOTE** Snap and Ripple mode affects how shots are added to the timeline.

---

#### Interchange with Flame or Smoke

When dropping content, coming from a Smoke or Flame project to a Lustre timeline, the sequence or the clip is inserted as a layer above the current video layer or track, at the content's record timecode. This functionality is useful when importing revised editorial content from Smoke & Flame into the currently opened Lustre timeline.

---

**NOTE** In order to drop imported content from Wiretap server at its native record timecode, the selected sequence must be dropped directly from Media Browser to the current sequence. Dropping the selected sequence to the Media Library first, and then dropping this sequence into the current sequence will use the timeline Snap options (Off, Positionner or Transition) rather than its native record timecode.

---

## Importing Timelines as Source Clips

Drag and drop timelines (clips with a red background) from the library to the Lustre timeline to build a timeline containing multiple conformed EDLs (for example, multiple scenes of a project).

You can drag and drop the timeline clips to the Storyboard or Timeline view:

- **Storyboard:** inserts the incoming timeline to the end of the current timeline on the primary track or layer, while preserving the video tracks and layers.
- **Timeline:** inserts the incoming timeline at the drop point or according to the defined Snap option. The layer where you drop the timeline(s) defines where a multi-layer timeline is created.

---

**NOTE** Grading metadata is not part of the timeline structure. Use Marry Grade to share grading data between timelines.

---

## Snapping Elements

Snap mode affects how elements are placed when gesturally moved or copied to the timeline. Snap mode consists of the following three options.

**Snap Off** Drops the element at the location that you choose.

---

**NOTE** An element can be overwritten if you drop one element over another.

---

**Snap Trn** Snaps the element to the closest transition.

**Snap Pos** Snaps the element to the positioner.

## Selecting Elements

You can select multiple elements to move, copy, or delete. Use the following modifier keys to create a selection.

**To select elements in a continuous selection:**

- 1 Click the first element in the selection.
- 2 Press **Shift** and click the last element.  
All elements between the first element and the last element you clicked are selected.

**NOTE** This function only works within the same layer.

#### To select elements in a broken selection:

- 1 Press **Ctrl**.
- 2 Click the elements you want to select.  
Various elements in broken sequence are now selected.

**NOTE** To remove elements from a multiple selection, press **Ctrl** and select the elements you want to remove from the selection.

---

**TIP** You can use **Shift** to define a selection on a layer and then hold **Ctrl** and start a new selection on another layer (with **Shift** or **Ctrl**).

---

## Moving Elements

You can move an element or a selection of elements within the same layer or to another layer.

#### To move an element or a selection of elements within the same layer or to another layer:

**NOTE** The status of Ripple and Snap modes are taken into account when dropping elements. See [Trimming With Ripple Mode](#) (page 1996) and [Snapping Elements](#) (page 1980).

- 1 In the multi-layer timeline, select the element you want to move.  
The selected element becomes yellow.
- 2 Drag the element and drop it at the destination.

## Replacing Elements in the Timeline

You can now replace shots and select a timeline segment as the destination. The replaced shot starts at the location of the original shot and gap or tail handles appear to fill the original duration.

- 1 Load the timeline you want to modify.
- 2 In the library, press **SHIFT** key and select a clip. Release **SHIFT** key.
- 3 Move the selection over the timeline segment you want to replace and click on the segment.

The shot is replaced and the grading on the original shot is preserved. Tail media or Gap is seen in the timeline if the shots don't have the same duration.

### Replacing Shots in a Stereo Timeline

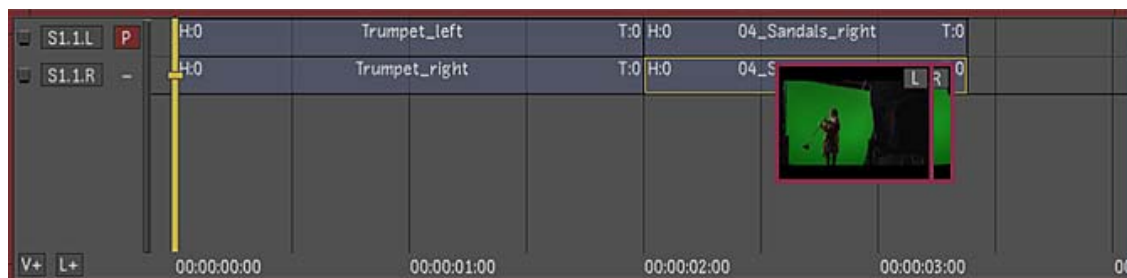

When working on a Stereoscopic project, you can perform a shot replace that applies to both eyes at the same time.

---

**NOTE** In Stereo, you must replace the shot for both eyes. It is not possible to use Replace Shot for only one eye.

---

- 1 Load the timeline you want to modify.
- 2 In the library, hold SHIFT key and select the Left clip. A "L" icon appears on the top right side of the thumbnail.
- 3 Navigate library to find the Right clip, hold SHIFT key and select the Right clip. A "R" icon appears on the thumbnail. Release SHIFT key.
- 4 Move the selection over the Storyboard or Timeline segment you want to replace and click on the thumbnail.

Both Left and Right shots have been replaced with the selection and the grading on the original shots is preserved.

## Swapping Elements

You can swap any two shot elements by selecting them in the timeline or Storyboard. The shots can be in different layers.

**To swap shots within the same layer or between two layers:**

**NOTE** When swapping elements, the status of the Ripple mode is always Ripple Off.

- 1 In the multi-layer timeline, select two shots. See [Selecting Elements](#) (page 1980).

The selected elements become yellow.

**WARNING** If the shots do not have the same duration, the shot with the longer duration is trimmed, and the shot with the shorter duration is followed by a gap.

- 2 Press Shift+’.

The shot positions are interchanged.

## Copying Elements

You can copy one or more elements within the same layer, or from one layer to another. In addition, when copying across layers, you can maintain a vertical lock on the shots you are copying to preserve their 'horizontal' place in the timeline.

---

**NOTE** The status of Ripple and Snap modes are taken into account when dropping elements. See [Trimming With Ripple Mode](#) (page 1996) and [Snapping Elements](#) (page 1980).

---

#### To copy elements within a layer:

- 1 In the multi-layer timeline, select the element(s) you want to copy. See [Selecting Elements](#) (page 1980)
- 2 Click Copy.  
The copied element(s) become red.
- 3 Drag the elements to a new position in the timeline.
- 4 Click the mouse button to complete the copy.

#### To copy a single element from one layer to another layer:

- 1 In the multi-layer timeline, select the element you want to copy.
- 2 Click Copy.  
The copied element becomes red.
- 3 Position the cursor over the element you wish to copy and click and hold the left mouse button.  
**NOTE** To maintain a vertical lock on the copied element, hold down the `Shift` key.
- 4 Drag the element to the desired layer and horizontal time position.
- 5 Release the mouse button (and the `Shift` key, if required) to complete the copy.

#### To copy multiple elements from one layer to another layer:

- 1 In the multi-layer timeline, click once on the far-left element you want to copy in the layer.
- 2 Select the remaining elements you want to copy. See [Selecting Elements](#) (page 1980).
- 3 Click Copy.  
The copied elements become red.
- 4 Position the cursor over any of the elements you wish to copy and click and hold the left mouse button.  
**NOTE** To maintain a vertical lock on the copied elements, hold down the `Shift` key.
- 5 Drag the elements to the desired layer and horizontal time position on the Timeline.
- 6 Release the mouse button (and the `Shift` key, if required) to complete the copy.

## Adding Black Media to the Timeline

You can add black media to the timeline to create a space (or fades) between elements. By default, a black clip is one second in duration, based on the project's frame rate.

To add black media to the timeline using the Storyboard, see [Adding a Virtual Black Clip using the Storyboard](#) (page 1974).

#### To create black media:

- 1 In the Timeline menu, click Black.  
A black shot appears attached to the mouse cursor.
- 2 In the timeline, position the cursor of the black shot where you want the black media to appear.  
**NOTE** The status of Ripple and Snap modes is taken into account when adding black media.
- 3 Click the mouse button to drop the shot.  
The black media is now in place.

## Deleting Elements

You can delete selected elements in the timeline in numerous ways.

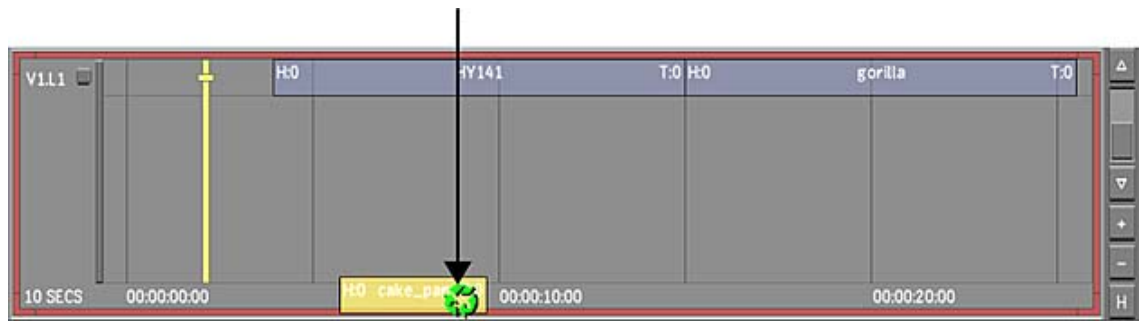

---

**NOTE** Deleting an element is affected by the Ripple mode. For example, if Ripple Off is enabled, deleting a shot leaves a gap.

---

To delete the element(s) from the timeline:

- 1 Select the element(s). See [Selecting Elements](#) (page 1980).
- 2 Do one of the following:
  - Click Del, and then confirm the deletion.  
If no selection is made, the element with focus is deleted.
  - Press Shift+D.  
If no selection is made, the element with focus is deleted.
  - Drag the selection outside the red border of the Timeline. When the recycle symbol appears, drop the element(s) to delete it.

**NOTE** You can also delete shots in the Storyboard view. See [Deleting Shots](#) (page 1959). The Timeline immediately reflects the changes.

## Gaps in the Timeline

A gap is an empty space in the timeline. On a single layer, a gap is displayed as a hole in the multi-layer timeline. A red X is displayed in the Player when the positioner is located on a gap. Gaps are also displayed as 'GAP' in the Source Timecode field.

When working with a multi-layer timeline, a gap located on the top layer shows the elements located below (Solo mode disabled only).

Gaps can be modified like other clips. They can be trimmed by using Ripple Start and Ripple End mode (see [Trimming Ripple Mode](#) (page 1997)). Their length can also be increased or decreased by modifying the clips around them. Gaps can be selected, copied, or deleted.

# Working With Containers, Matte Containers and Multi-channel Clips

Containers, matte containers and multi-channel clips are a convenient way of grouping elements on the timeline. They can each be represented in the timeline as a single element.

- A [container](#) (page 1985) is composed of multiple versions of the same shot with different grades or multiple shots.
- A [matte container](#) (page 1987) is composed of a primary track and one or more external mattes.
- A [multi-channel clip](#) (page 1990) is a source clip that contains one or multiple matte channels.

**Note the following functionality while working with containers, matte containers, and multichannel clips:**

- Containers, matte containers and multi-channel clips can be part of a sorted selection. When a timeline is sorted, it is not possible to enter inside the containers.
- You can apply retime effects on containers, matte containers and multi-channel clips. All shots inside a container get the same retime effects. When you drag and drop clips to a container, the shots you add also get the same retime effect.
- You can collapse a selection of shots, containers, matte containers and multi-channel clips. When the timeline is collapsed, the matte media in matte containers and multi-channel clips are still available for grading, but you cannot enter inside these timeline segments when they are collapsed.
- You can remove containers and matte containers on multiple selections.

## Matte Workflow

You can import mattes like any other source clip. Use one of the following workflows with externally generated mattes:

- Use a matte container created in Lustre and import a matte as a source clip.
- Use multi-channel clips when you want to add matte channels to a source clip and share this footage with multiple timelines in Lustre. These clips can be created from Lustre or generated outside the application using the Autodesk Wiretap Gateway XML schema.
- Use a matte container created in Smoke and Flame through Wiretap.

---

**NOTE** The legacy external matte workflow that required the manual modification of matte files to match the source footage file name and location is now obsolete. You cannot load mattes that were created prior to Lustre 2012. You must recreate them.

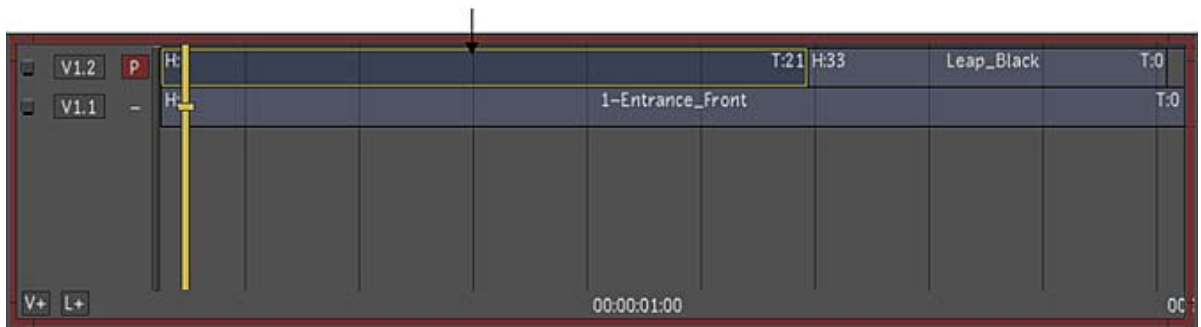

---

## About Containers

Use containers to store multiple versions of the same shot with different grades or multiple shots. Grading is applied on the shots inside the container and not on the result of the container.

Containers on the timeline are dark grey in colour:

On the storyboard, a dark grey box on the left corner of the thumbnail indicates a container:

Inside a container you can work with video tracks and layers:

- When working on layers inside the container, you can perform any editorial task, add versions and use Shot Priority to define the output of the Container.

---

**NOTE** Do not use Solo on layers inside a Container to define the container output because Solo is not saved with the grading data. Use Shot Priority instead.

---

#### To create a container:

- 1 Select one or more timeline segments.
  - 2 Click the Ctnr button.
- Container segments/elements appear dark grey in the record timeline.

#### To enter a container:

- 1 Double-click the container segment.
- The contents of the container are displayed.

#### To exit a container:

- 1 Click the Up Arrow button (next to L+ button, located at the bottom left side of the timeline).
- The contents of the container are collapsed into a single segment.

#### To add a clip to a layer in a container:

- 1 Double-click the container to open it.
- 2 Click L+ to add a new layer.

- 3 Select the clips from Library.
- 4 Drag the clips to the layer in the container.

Use containers to hold multiple versions of grading on a shot.

#### To create a new version of the grading without entering the container:

- 1 Hold down the `Ctrl` key and click the New button.  
A new version on vertical layer appears inside the container.

#### To remove a container:

- 1 Place the positioner on the container, or select the container.  
The selection overrides the positioner.
- 2 Hold down the `Alt` key and click the Ctnr button.  
The container is removed and the container contents are inserted on the current timeline.

## About Matte Containers

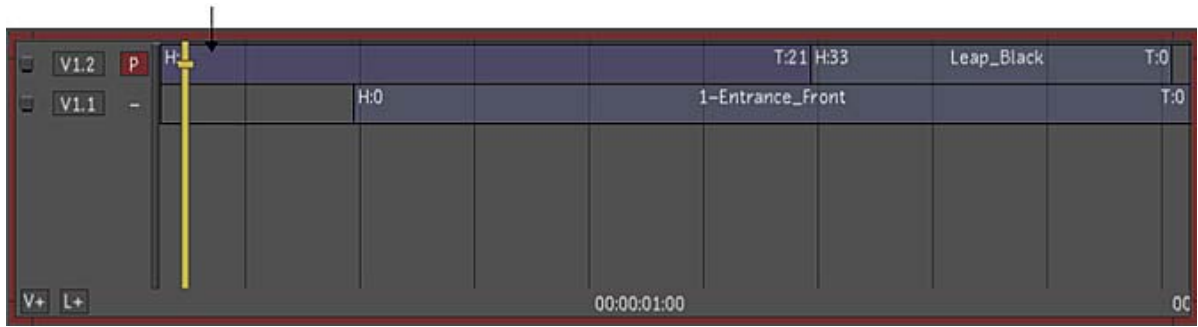

Use matte containers to perform secondary colour grading and effects with externally generated mattes.

Matte containers are composed of timeline segments that contain two video tracks:

- The primary video track contains the shot.
- The secondary video track contains the matte. Use the matte for secondary colour grading and effects.

It is possible to build complex multi-layered content inside a matte container. However, only the source media of the matte track is used for secondary colour grading. Effects created on the matte, including dissolves, are not used in secondary colour grading.

Matte containers on the timeline are purple:

On the storyboard, a purple box on the left corner of the thumbnail indicates a matte container:

If there is a gap or virtual colour clip on a matte track and an external matte is enabled (R/G/B/A buttons), the matte is seen as opaque (black) so any correction will not be seen on the graded image. This behavior is also true for multi-channel clips where no matte media is available (displayed as gap).

You can create matte containers from both monoscopic and stereoscopic media.

#### To create a matte container:

- 1 Select one or more timeline segments.
- 2 Press Ctrl and click the Ctnr button.  
The segment turns purple to indicate that you have created a matte container.

#### To change a video track inside a matte container from Primary to Secondary:

- 1 Do one of the following:
  - Click the left side of the video track (-) to make it Primary (P).
  - Middle-mouse-click on the left side of the track or channel (-) to make it Secondary (S).

Enter, exit and remove a matte container in the same manner as a container.

## Adding a Matte to a Matte Container

There are two ways to add a matte to a matte container.

- By entering the matte container and adding the matte to a video track.
- Adding a clip from the library to the timeline without entering the matte container directly.

The matte clip must have the same resolution as the front clip in a matte container.

#### To enter a matte container and add a matte to it:

- 1 Display the timeline and the library.
- 2 On the timeline, double-click the matte container to enter it.
- 3 Click V+ to add a new track.
- 4 Drag and drop a clip from the library to the track on the timeline.

- 5 (Optional) Set the matte as the secondary.

**To add a matte to a matte container without entering it:**

- 1 Display the timeline and the library.
- 2 Select the matte you want to add to the container from the library.
- 3 Press C trl, drag and drop a matte onto the matte container segment on the timeline to insert the matte at the first frame of the first shot inside the matte container.
- 4 (Optional) You can drag and drop a matte onto the matte container while holding Ctrl+Alt to insert the matte at the first frame of the In point of your timeline segment rather than the first frame of the source clip. This is useful when working with scene detected footage requiring mattes.

---

**NOTE** The Ctrl+Alt option is exclusive to Lustre 2012 Extension 1.

---

You can drag and drop multiple mattes into a matte container. The first matte you add is the secondary track. You can apply any matte in your container to a separate secondary colour grading layer in the Colour | Secondaries menu. See [Selecting a Matte to Grade Secondary Layers](#) (page 1989).

To add a matte to a stereoscopic matte container, you must drop mattes one at a time to add them to the matte container. You cannot select both a left and right matte at the same time and drop them on a clip to create a stereo matte container.

**To add a matte to a stereoscopic matte container:**

- 1 Display the timeline and the library.
- 2 Hold down Ctrl or Ctrl+Alt and drag and drop a matte onto the matte container segment that corresponds to the stereo eye.
- 3 Hold down Ctrl or Ctrl+Alt and drag and drop a second matte onto the matte container segment that corresponds to the other stereo eye.

---

**NOTE** The Ctrl+Alt option is exclusive to Lustre 2012 Extension 1.

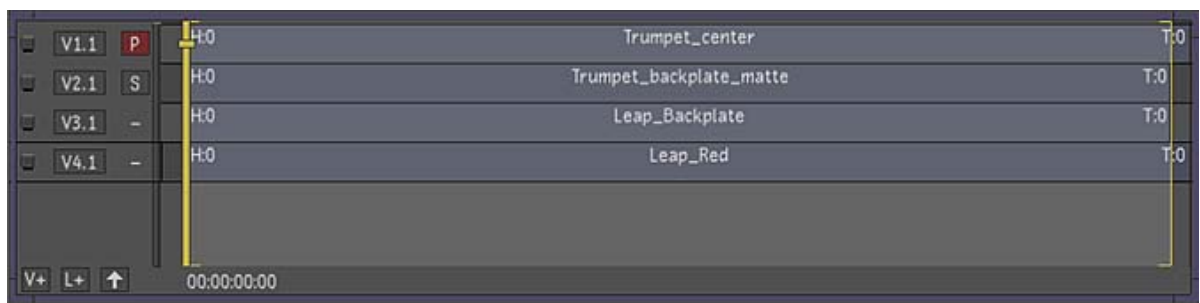

---

## Selecting a Matte to Grade Secondary Layers

By default, the Secondary track in a matte container or multi-channel clip is selected for grading.

You can select a different matte track or channel for each secondary layer of colour grading. This is useful when you want to grade the image based on the values in its colour channels. You can make this change from the Colour | Secondaries menu, rather than going into the matte container on the timeline.

Here is a matte container with 3 matte tracks, V2.1 is set as the secondary.

In the Secondaries menu, you can enable a different matte for each secondary layer. Enable a secondary. Then click the Matte button and select the matte track to apply to the secondary.

See [Working with Mattes](#) (page 2180).

## About Multi-channel Clips

A multi-channel clip is a source clip that contains one or multiple matte channels. Add matte media to source clips in the Lustré timeline to create a multi-channel clip and use the matte for secondary colour grading and effects. See [Working with Mattes](#) (page 2180).

On the timeline, the multi-channel clip is labelled Multi.

On the storyboard, the multi-channel clip is labelled Multi.

When you create a multi-channel clip, the source clip is modified in the library. Next time you use the source clip, the matte will be available. Any modification done inside the multi-channel clip is replicated in the library source clip.

---

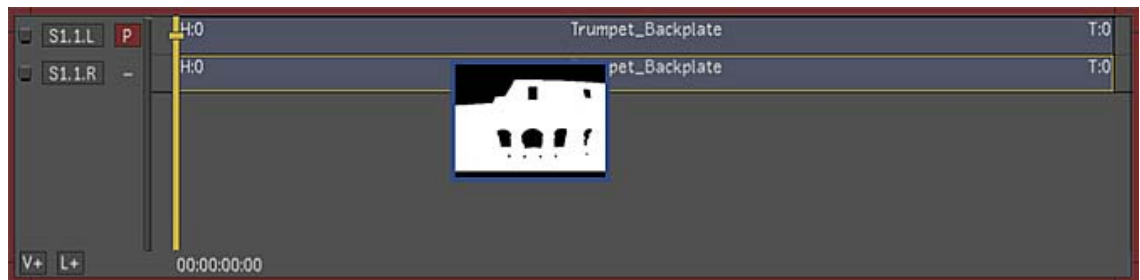

**NOTE** When rendering a timeline that contains multi-channel clips from Lustré to Smoke or Flame, a matte container is created.

---

The front and the matte clip can be different file types or bit depth, but they must have the same resolution to create a multi-channel clip.

### To create a stereoscopic multi-channel clip:

- 1 Add the left and right source media to the stereo timeline.
- 2 Hold Ctrl and drag the matte clip from the library and drop it on the source media on the timeline that corresponds to the stereo eye.

**TIP** Dragging and dropping while holding Ctrl drops the matte at the first frame of the source clip. Holding Ctrl+Alt while dragging and dropping inserts the matte at the first frame of the In point of the desired timeline segment.

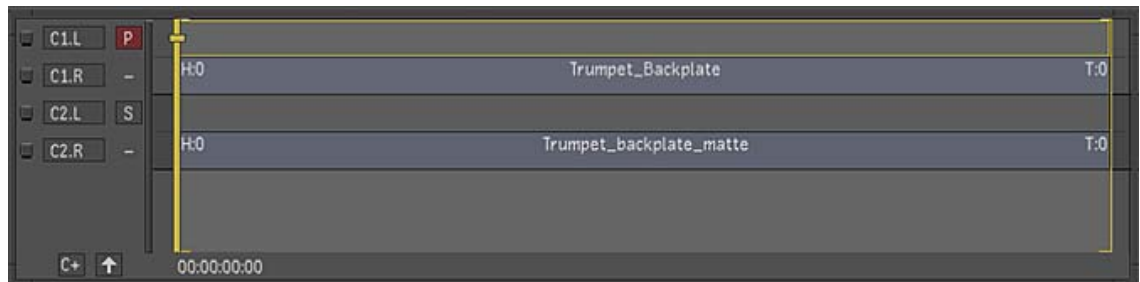

**NOTE** The Ctrl+Alt option is exclusive to Lustre 2012 Extension 1.

Dragging and dropping while holding Ctrl drops the matte at the first frame of the source clip. Holding Ctrl+Alt while dragging and dropping inserts the matte at the first frame of the In point of the desired timeline segment. The Ctrl+Alt option is exclusive to Lustre 2012 Extension 1.

A "multi" icon appears on the Stereo timeline segments, but only one of the stereo sources is updated in the Library.

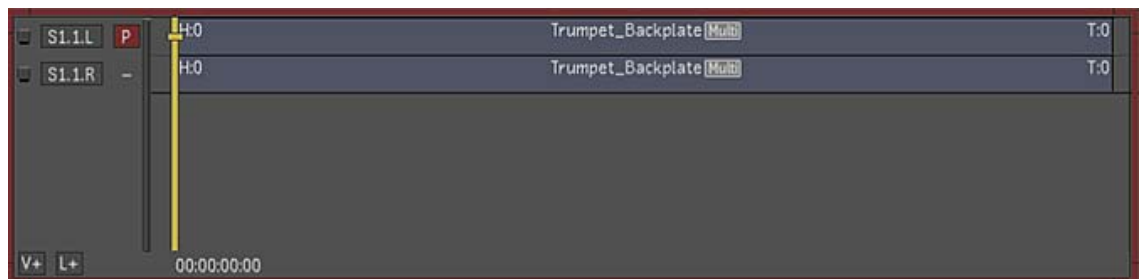

If you open the multi-channel clip, you see that the channels for the other eye are empty.

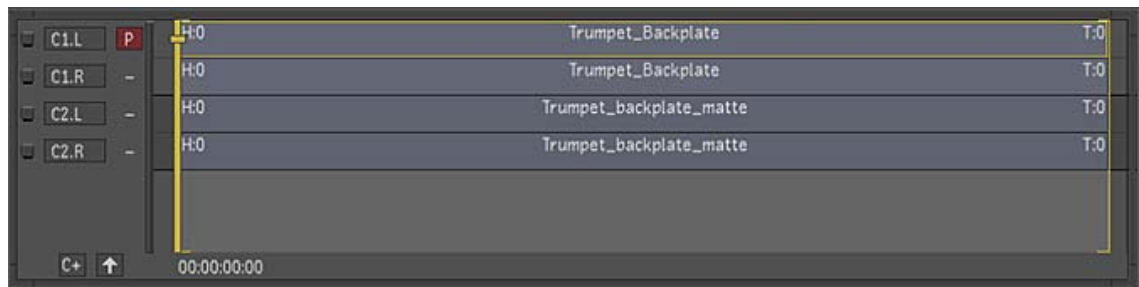

- 3 Hold Ctrl and drag the other matte clip from the library and drop it on the source media on the timeline that corresponds to the other stereo eye.

A "multi" icon appears for the other stereo source in the library.

If you open the multi-channel clip now, you see that the front and matte clips for both.

**NOTE** When creating a stereoscopic multi-channel clip, you must drag and drop a left clip to the left eye and a right clip to the right eye in the timeline so that each segment is identified as multi-channel. Lustre does not support stereoscopic eyes that are in different states.

**To enter a multi-channel clip:**

- 1 Double-click the multi-channel timeline segment.  
The matte media is located on the Secondary video channel (C2).

**To convert a multi-channel clip to a standard source clip:**

- 1 Delete all channels from C2 and up.
- 2 Exit the multi-channel clip.

## Edit the Timing of a Matte in a Multi-Channel Clip to Match the Source Clip

Timing modifications done inside a multi-channel segment are saved in the source clip in the library. All instances of that source clip are updated to use the new timing.

You can only slip a shot to adjust its timing. You cannot trim.

To protect the structure of the source footage, it is not possible to add dissolves or layers inside the multi-channel clip. Use matte containers for more complex editing.

**To create a temporary grade to help you set the timing of a matte in a multi-channel clip:**

- 1 Exit the multi-channel clip on the timeline.
- 2 Enable a Secondary.
- 3 Enable one of the External Matte channels (R/G/B/A).
- 4 Modify the grading so that you can see the matte media over the image.
- 5 From the Timeline menu, enter the multi-channel clip.
- 6 Slide the clip in the timeline to change the timing. Use the display of the matte over the shot to help you find the right starting frame.
- 7 Click the Up arrow to exit the multi-channel segment. You are now ready to grade your shot.

## Multi-Channel Clip Management

### Automatic Creation of Multi-Channel Clips with Matte / MultiMatte Folder Structure

You can create folder structures that automatically generate Multi-Channel clips and automatically add and sync the matte media located in the *matte/multimattes* folder to the source clip. If there is a *matte/multimattes* folder located within the resolution folder of the source media files, Lustre displays the source clip as a Multi-Channel clip.

---

**NOTE** Grade files created with pre-2012 versions of Lustre and using external mattes are converted to Multi-Channel clips and can be imported in Lustre 2013.

---

Matte media files must have the following attributes:

- The index (frame numbers), in the source/mattes file names have to match. You can have any number of characters before the frame number value, as long as the frame numbers at the end of the filename match, they will be compatible. For example, *shot1\_10000.dpx* is compatible with *000010000.tif* as well as with *lustrematte10000.tif*.
- The matte media files must be of the same resolution as the clip.
- The mattes must be either RGB or RGBA files.

### Single Matte Media Structure

Here are some examples of media structures that Lustre uses for automatic Multi-Channel clip creation with a single matte.

**Simple source clip (one clip in one folder):**

- /scans/project/0001/1920x1080/[10000-10100].dpx
- /scans/project/0001/1920x1080/matte/[10000-10100].tif

The resulting clip in Lustre displays as a Multi-Channel clip that has a matte channel spanning all the frames of the source clip.

---

**NOTE** When Lustre creates a Multi-Channel clip, the matte channel has the same duration as the source clip. If the matte media does not cover the full duration of the source clip, the portions without matte media is seen as opaque when in the "O" view. As a result of this, the secondary grading cannot be displayed.

---

### Simple source clip (one clip in one folder) with partial matte media:

- /scans/project/0001/1920x1080/[10000-10100].dpx
- /scans/project/0001/1920x1080/matte/[10040-10055].tif

The resulting clip in Lustre displays as a Multi-Channel clip that has a matte channel spanning frames 40 to 55. The matte channel still covers the entire duration of the source clip but secondary grading is not visible on the portions of the clip where there is no matte media even if the RGBA Matte buttons are enabled.

### Multiple source clips located in a single folder:

- /scans/project/0001/1920x1080/[10000-10100].dpx
- /scans/project/0001/1920x1080/[20000-20100].dpx
- /scans/project/0001/1920x1080/[30000-30100].dpx
- /scans/project/0001/1920x1080/matte/[10000-10100].tif

In this source clip structure, multiple source clips are located inside a single folder along with a *matte* folder but it only contains matte files for the first sequence that has the frame range of 10000-10100.

The media files that do not have matte files with a corresponding frame range are read as standard source clips.

## Multiple Mattes Media Structure

You can create a folder structure to store multiple matte clips by creating a *multimattes* folder instead of *matte*. The *multimattes* folder must contain a subfolder for each matte sequence to be included in the multi-channel clip, as in the example below:

### Simple source clip (one clip in one folder) with multiple matte media:

- /scans/project/0001/1920x1080/[10000-10100].dpx
- /scans/project/0001/1920x1080/multimattes/matte1/[10000-10100].tif
- /scans/project/0001/1920x1080/multimattes/matte2/[10000-10100].tif
- /scans/project/0001/1920x1080/multimattes/matte3/[10000-10100].tif

This structure creates a 4-channel Multi-Channel clip (media + 3 mattes) with a matte on channels 2, 3 and 4.

---

**NOTE** The *multimattes* subfolders do not have to conform to any particular naming convention. You can name the *multimattes* subfolders as you like. Lustre sorts the subfolders and the mattes in alphanumeric order.

---

### Simple source clip (one clip in one folder) with "matte" and "multimattes" structure:

You can also mix and match the *matte* and *multimattes* structure, as in the example below:

- /scans/project/0001/1920x1080/[10000-10100].dpx
- /scans/project/0001/1920x1080/matte/[10000-10100].tif
- /scans/project/0001/1920x1080/multimattes/matte1/[10000-10100].tif
- /scans/project/0001/1920x1080/multimattes/matte2/[10000-10100].tif
- /scans/project/0001/1920x1080/multimattes/matte3/[10000-10100].tif

This structure creates a 5-channel Multi-Channel clip (media + 4 mattes) with a matte on channels 2, 3, 4 and 5.

## Synchronizing an Existing Cut and Source Clips with Newly Added / Removed Matte Media

When working on a project, it may happen that the matte media files located in *matte* and *multimattes* folder are modified (edited, added or deleted). In this case, Lustre can synchronize the cut or grade file and the source clips with the external matte files.

**To synchronize the cut or grade file and source clips with the external matte files:**

- 1 Select the Cut to update from the Cut List or the Grade to update from the Grade List.
- 2 Hold the Shift key.
- 3 Click Load.

Lustre synchronizes the shots in the Timeline and the clips in the Library with the content of the *matte* / *multimattes* folders. It then updates the clips, converting them to multi-channel when mattes are present or leaving them as single-channel when no mattes are found.

## OpenEXR and External Mattes

You can create multi-channel OpenEXR files (multiple channels embedded in the OpenEXR file) that are displayed as multi-channel clips in Lustre. You can also use OpenEXR files with a *matte* / *multimattes* folder structure to automatically generate a multi-channel clip. When working with multi-channel OpenEXR files with an external *matte* / *multimatte* folder, you must always manually resync the cut / grade to have access to the matte channels. To do this:

- 1 Import your multi-channel OpenEXR clip.

**NOTE** At this stage, only the embedded RGB mattes are available.

- 2 Save your cut/grade.
- 3 Press Shift on the keyboard and load your cut or your grade.

All embedded and external mattes are now available.

## Trimming Elements

Trimming adds head or tail frames to the element or subtracts head or tail frames from the element. You can trim using the trim cursors in the timeline canvas. For a specific trim cursor to appear, you must place the cursor over the required position within the element (i.e., head, tail, or middle section of the element). For example, when you place the cursor over the start of the element (the head), the trim head cursor appears.

The following editing changes are automatically updated in the Player:

- trimming
- slipping
- sliding

**NOTE** You can also access some of the multi-layer timeline features through the Colourist's Timeline. See [Colour Grading Basics](#) (page 2081).

## Trimming Cursors

The following cursors are used when trimming or slipping and sliding an element.

| Cursor                                                                            | Cursor name         |
|-----------------------------------------------------------------------------------|---------------------|
|  | Trim head cursor    |
|  | Trim tail cursor    |
|  | Slip cursor         |
|  | Slide cursor        |
|  | Slip & slide cursor |

## Trimming With Ripple Mode

Whether Ripple mode is enabled or disabled it determines how the elements are trimmed. When Ripple mode is disabled, the overall duration of the sequence does not change when trimming. When you remove frames from the head or tail, it creates a gap (see [Gaps in the Timeline](#) (page 1984)). If there is an element located before of after the trimmed element, only a head or tail trim is possible. To slip & slide an element with Ripple mode disabled can only be done if there are handles at the head and/or tail of the shot. See [Slip & Slide](#) (page 1998).

When Ripple mode is enabled, the overall duration of the sequence changes when trimming. Removing frames from the head or tail does not create a gap and the elements located before or after the trimmed element move in time (based upon the Ripple Start or Ripple End mode). You can slip & slide an element with Ripple mode enabled on any element when there are available handles.

**NOTE** If a layer is soloed, the Edit tools (Trash, Delete, Trim In/Trim Out, and Mark In/Out) default to 'Ripple End' behaviour, regardless of the Ripple Mode setting. If no layer is soloed, however, the Edit tools behave according to the individual Ripple Mode selected (Ripple Off, Ripple Start, or Ripple End) and apply to the active or visible layer that contains the focus point. For more information about Ripple Modes, see [Trimming Ripple Mode](#) (page 1997).

### To trim an element:

- 1 Enable Trim.
- 2 Select a Ripple mode (i.e., Ripple Off, Ripple Start, or Ripple End). See [Trimming Ripple Mode](#) (page 1997).

- 3 Set the cursor on either the head or the tail of the element and the corresponding head or tail cursor appears.
- 4 Click and drag the element.
  - Dragging the element in the same direction of the head or tail cursor adds frames to the element.
  - Dragging the element in the opposite direction of the head or tail cursor removes frames from the element.

## Trimming Ripple Mode

There are three types of Ripple mode when trimming.

**Ripple Off** Trimming does not affect the duration of the timeline.

**Ripple Start** Trimming moves in time the element located before the trimmed element.

**Ripple End** Trimming moves in time the element located after the trimmed element.

## Slipping an Element

Slipping simultaneously trims the head and tail of the element without changing its position in the sequence. The duration of the shot is not altered. Other elements in the edit sequence are not affected and the total duration of the sequence does not change. You can slip a single element or a selection.

---

**NOTE** Slipping is a non-ripping action.

---

**To slip an element:**

- 1 Enable Trim.
- 2 Position the cursor on the middle of the element that you want to slip.  
The slip & slide cursor appears.

- 3 Press the , (comma) key.  
The slip & slide cursor changes to a slip cursor.

- 4 Click and drag the element right or left.

## Sliding an Element

Sliding changes a shot's position in the edit sequence without changing the head or the tail frames. It simultaneously slides the shot under the cursor and trims the head and tail of the surrounding gaps.

---

**NOTE** Sliding can only occur if there is a gap before and/or after the element.

---

You can slide an element or a transition. See [Transitions](#) (page 1999).

---

**NOTE** When you slide the first or last segment of the element, it changes the total length of the sequence. When you slide the middle of the element, the sequence does not ripple.

---

**To slide an element:**

- 1 Disable Trim.
- 2 Position the cursor on the middle of the element that you want to slide.

- 3 Click the element.  
The slide cursor appears.

- 4 Drag the element right or left.

## Slip & Slide

Slip and slide changes a shot's position in the edit sequence, as well as the head and tail frames. The media of the element stays at the same position in the sequence, but the location of the element changes.

---

**NOTE** Slipping and sliding can only occur if the element has available handles.

---

**To slip and slide an element:**

- 1 Click Trim.  
This enables the Trim mode.
- 2 Position the cursor on the middle of the element that you want to slip & slide.  
The slip & slide cursor appears.
- 3 Click and drag the element right or left.

### Slip & Slide Ripple Mode

There are three types of Ripple mode when you slip and slide.

**Ripple Off** With Ripple Off, only the first and last shot of the Timeline and any shot surrounded by a gap, can slip and slide. The slip & slide operation adds a gap and changes the length of the edit sequence.

**Ripple Start** The slip & slide operation moves in time the element located before the trimmed element and inserts a gap after the slip & slide element.

**Ripple End** The slip and slide operation moves in time the element located after the trimmed element and inserts a gap before the slip & slide element.

## Transitions

A transition is a way to go from one element to another. There are two types of transitions:

- Splices
- Dissolves

## Splices

When you add a shot to the Timeline, it automatically creates a splice. A splice is where one element ends and the following element begins, creating a hard transition. It is also possible to add a splice to an element in the Timeline to divide the element into two sections. You can remove a splice from an element, creating a continuous element.

**To add a splice:**

- 1 Click and drag the focus point to the layer you want to splice.
- 2 Move the positioner to the exact location of the element you want to splice.

- 3 Click Cut.
- A splice is added.

**To remove a splice:**

- 1 Place the positioner on the right-most (also known as the B) side of the previously cut shot.
- 2 Click Join.

**NOTE** You cannot join elements coming from two different shots. You can join two shots coming from the same source clip with consecutive source timecode.

## Dissolves

A dissolve is the blending of two elements over a defined period of time. By default, Lustre adds a dissolve centred over the transition. You can slide the dissolve to make it start before or after the transition.

Also by default, a dissolve is set to be one second, based upon the project's frame rate (e.g., 24, 25, or 30 frames per second). You can change the duration by trimming the dissolve or by using the dissolve duration field in the Edit menu.

When you are working with multiple layers, elements located on the top layer can dissolve to a gap that reveals the content located on the bottom layer, therefore creating the equivalent of a dissolve between two shots.

### Adding a Dissolve

There are two ways to add a dissolve to the upcoming transition of the layer under Focus.

**To add a dissolve:**

- 1 Place the focus point and positioner on top of the A-side of the transition where you would like to create your dissolve.
- 2 Do one of the following:
  - Click Diss.
  - Press D.

A dissolve is centred over the transition.

---

**WARNING** When building Timelines with multiple layers and transitions from layer to layer, avoid dissolving from a shot to a dissolve located on another layer. Dissolve only from a shot to a shot, otherwise, Lustre displays a red 'X'.

---

### Removing a Dissolve

You can remove a dissolve from the Timeline.

**To remove a dissolve:**

- 1 Select the dissolve, or multiple dissolves.  
The dissolve turns yellow.
- 2 Do one of the following:
  - Press **Shift +D**.
  - Click Del.

### Editing a Dissolve

There are a couple of ways to change the duration of a dissolve.

#### To change the duration of the dissolve:

- 1 Right-click and drag the timeline to make sure the right dissolve is showing.
- 2 Place the positioner on the dissolve you want to modify.  
**NOTE** The positioner needs to be located before the dissolve.
- 3 Click Edit.  
The Edit menu appears.
- 4 Drag the Dissolve slider to set the dissolve duration. See [Changing Dissolve Duration](#) (page 1971).

#### To change the duration of the dissolve using Trim mode:

- 1 Enable Trim.
- 2 Click and drag the dissolve using the Trim Head or Trim Tail cursor.

### Changing the Orientation of a Dissolve

By default, Lustre adds a dissolve centred over the transition, but you can change the orientation of the dissolve. See [Editing a Dissolve](#) (page 2000).

#### To change the start/end point of the dissolve:

- 1 Enable Trim.
- 2 Move the cursor over the dissolve you want to modify. The slip & slide cursor appears.
- 3 Click and drag the dissolve to its new position.

**NOTE** When you add a dissolve, make sure there are enough handles for the duration of the transition. If you add a dissolve over a transition between two elements that do not have head/tail frames, the dissolve goes from the outgoing element to black and from black to the upcoming element. Trimming or slipping the elements may help solve the problem.

## Displaying the Multi-Layer Timeline

When there are multiple layers and you display footage in the Player, or play out to tape, or render, Lustre's default behaviour (called Top Vertical Priority) is to display the visible shots from a top-down view of the flattened timeline. This behaviour is further customized by muting layers and prioritizing individual shots. It is also possible to override Top Vertical Priority by soloing a single layer, which forces Lustre to display, play out to tape, and render only that layer.

When selecting segments in the multi-layer timeline, the Storyboard view shows the same selection. See [Selecting Shots in the Storyboard](#) (page 2024).

### Top Vertical Priority

With exceptions, at any given point in a timeline with multiple layers, the top shot in a vertical stack of layers is the shot that is displayed, rendered, or played out to tape. This is the Top Vertical Priority rule and it is the default behaviour of the multi-layer timeline when Solo mode is disabled (See [Solo Mode](#) (page 2006)).

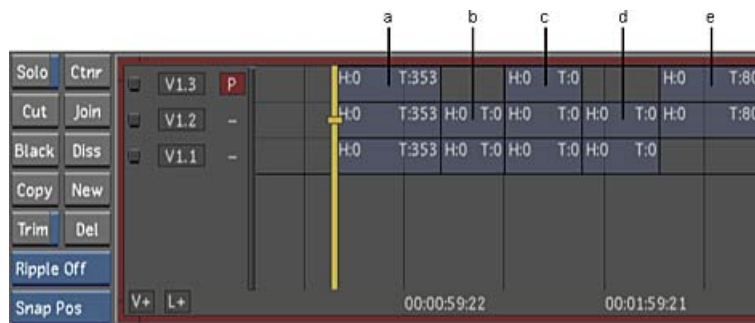

When there is a gap in the top layer, this gap is transparent when looking down on the timeline; Lustre looks in progressively deeper layers (going from top to bottom in a vertical stack) until it finds the top vertical shot to display. To visualize this, it may help to imagine looking down on the multi-layer timeline so that

you would have to see through the top layers in order to see the bottom layers. Your view from the top is a 'flattened' view of the timeline.

The only exception to the Top Vertical Priority rule is layer soloing (see [Solo Mode](#) (page 2006)). There are a couple of features which alter the way the Top Vertical Priority rule works; layer muting (see [Muted Layers](#) (page 2002)), and shot priority (see [Shot Priority](#) (page 2003)).

The following example illustrates how top vertical priority determines which shots are displayed, played out to tape, and rendered. It also illustrates how the displayed shots come from various layers throughout the course of the timeline. For simplicity's sake, in this example, there are no muted layers and no shots assigned with shot priority.

(a) Shot 1 (L3) (b) Shot 2 (L2) (c) Shot 3 (L3) (d) Shot 4 (L2) (e) Shot 5 (L3)

You can use the timeline information field to verify the layer and shot being displayed at any given point in the timeline. See [Monitoring the Location of the Current Frame](#) (page 2020). For example, in the following screen capture, the shot being displayed is shot 3 on Layer 2, and the current frame is frame 183.

## Muted Layers

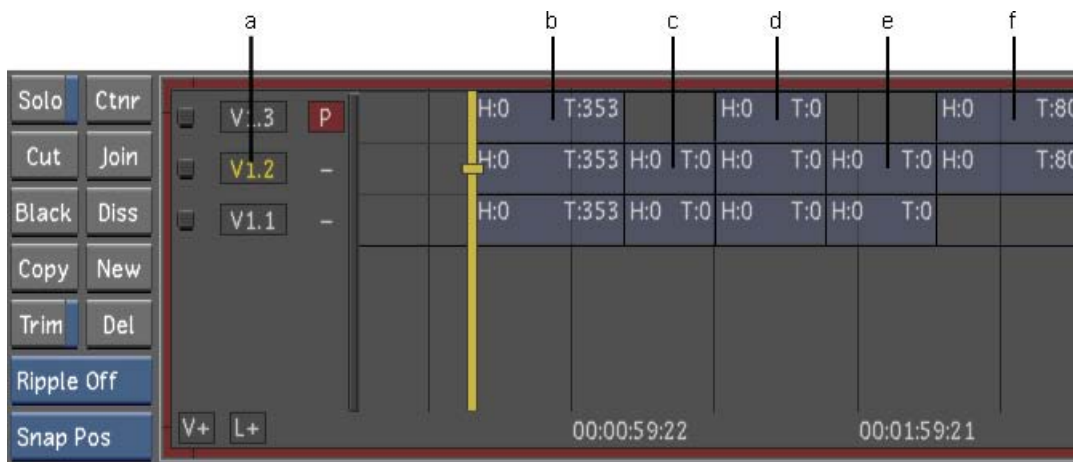

When a layer is muted, Lustre ignores this layer when applying Top Vertical Priority. That is, at a given point in the timeline, if a muted layer has Top Vertical Priority, Lustre looks at progressively lower layers in the vertical stack until it finds a shot in an unmuted layer, and then displays that shot.

---

**WARNING** If you are using the mute function as a method to create editorial or grade versioning, please keep in mind that the status is not part of the grade file data structure. Therefore, this state is not saved upon exiting Lustre.

---

The following example illustrates how a muted layer is used within a multi-layer timeline to determine what shots are displayed in the Storyboard and Player when the Top Vertical Priority rule is applied.

(a) Muted layer (b) Shot 1 (L3) (c) Shot 2 (L1) (d) Shot 3 (L3) (e) Shot 4 (L1) (f) Shot 5 (L3)

In this example, Layer 2 is muted. Therefore, only the shots in Layer 1 and Layer 3 are active.

#### To mute a layer:

- 1 Do one of the following:
  - Ctrl-click the name of the layer you want to mute (e.g., V1.L1).
  - Shift+M to mute the layer with focus.

The layer name indicator turns yellow.

#### To unmute a layer:

- 1 Do one of the following:
  - Ctrl-click the name of the layer you want to unmute (e.g., V1.L1).
  - Shift+M to unmute the layer with focus.

### Shot Priority

When you work in the Top Vertical Priority mode (Solo is disabled), you can assign priority on a shot-by-shot basis. A 'priority shot' in a given layer is displayed even if there are shots in the layers above it in the timeline. In the case where there are multiple priority shots in a vertical stack, the priority shot with Top Vertical Priority is displayed or updated accordingly in the Player. Furthermore, the Storyboard thumbnails are updated according to priority after an initial refresh. Lustre represents a priority shot in the multi-layer timeline as a shot with a red dot.

The following behaviours are expected when using the shot priority function:

- Shot priority information is saved to the cut file.
- A priority shot survives trimming, slipping, and sliding operations.
- When using the New button to create a new layer, the reproduced shot in the new layer preserves shot priority.
- When using the Copy button to copy a shot, the reproduced shot does not preserve shot priority.
- You can assign shot priority to a virtual black clip.
- You cannot assign shot priority to a gap.
- When performing a change cut operation with a cut that contains multiple versions of the same shot but with different grades, the shot priority feature allows you to designate the version of grading you would like to be transferred to the same shot in the new cut. However, if a muted layer has a priority shot, the grading metadata for this shot is not transferred to the new cut.

- In the case where a shot dissolves into another priority shot on a different layer within the vertical stack of shots, then the first shot does not dissolve seamlessly into the priority shot. For a seamless dissolve into a priority shot, you must create a dissolve on the layer of the priority shot.

In the following example, there is a dissolve on Layer 3 between shot 1 and shot 2. The dissolve begins near the end of shot 1, but once shot 2 on Layer 1 begins, the dissolve does not continue. Instead, shot 2 begins without showing the second half of the dissolve effect.

|                          |      |   |     |       |      |       |      |
|--------------------------|------|---|-----|-------|------|-------|------|
| <input type="checkbox"/> | V1.3 | P | H:0 | T:353 |      |       |      |
| <input type="checkbox"/> | V1.2 | - | H:0 | T:353 | H:13 | T:397 | H:45 |
| <input type="checkbox"/> | V1.1 | - | H:0 | T:353 | H:13 | T:397 | H:45 |

In the following example, the dissolve works as expected because the dissolve is on the same layer as the priority shot.

|                          |      |   |     |       |      |       |      |
|--------------------------|------|---|-----|-------|------|-------|------|
| <input type="checkbox"/> | V1.3 | - | H:0 | T:353 |      |       |      |
| <input type="checkbox"/> | V1.2 | - | H:0 | T:353 | H:13 | T:397 | H:45 |
| <input type="checkbox"/> | V1.1 | P | H:0 | T:353 | H:13 | T:397 | H:45 |

- When one priority shot overlaps another in a different layer, the priority shot with Top Vertical Priority is displayed. In overlap situations, this means that one or more shots are displayed that begin part way through or end part way through the shot.

In the following example, the first Layer 3 shot is displayed completely and then the Layer 2 shot is displayed starting somewhere in the middle of the shot.

|                          |      |   |     |       |       |     |  |
|--------------------------|------|---|-----|-------|-------|-----|--|
| <input type="checkbox"/> | V1.3 | P | H:0 | T:353 | H:45  |     |  |
| <input type="checkbox"/> | V1.2 | - |     | H:702 | T:357 | H:0 |  |
| <input type="checkbox"/> | V1.1 | - | H:0 | T:353 |       |     |  |

---

**WARNING** If you mute a layer that has a priority shot, that shot is not displayed, played out to tape, nor rendered.

---

The following example illustrates shot priority in the multi-layer timeline.

(a) Muted layer (b) Shot 1 (L3) (c) Shot 2 (L1) (d) Shot 3 (L1) (e) Shot 4 (L1) (f) Shot 5 (L3)

In this example, Layer 2 is muted and Shot 3 in Layer 1 is a priority shot.

#### To assign shot priority to a shot:

- 1 In the multi-layer timeline, **Shift+right-click** the shot (in the desired layer) to which you would like to assign priority.  
A red dot appears on the shot.

#### To assign shot priority to the shot in focus:

- 1 In the multi-layer timeline, make sure the positioner and its focus point are focused on the shot to which you apply priority.
- 2 Press **Shift+\.**  
A red dot appears on the shot in focus.

#### To assign shot priority to several selected shots with the Shot Priority flag:

- 1 In the multi-layer timeline, select all the shots to which you wish to assign shot priority. See [Selecting Elements](#) (page 1980).
- 2 **Shift+right-click** one of the selected shots to assign shot priority to that shot.  
The Shot Priority flag is enabled.

- 3 In the Flags menu, left-click the Shot Priority flag.  
The Shot Priority flag is highlighted.

**NOTE** The indicator is enabled only if the positioner and focus point is over a priority shot.

- 4 Click Set Sel.  
All the selected shots are assigned shot priority.

**To assign shot priority to the current shot of the currently active layer:**

- 1 In the Timeline menu, enable the Flags button.
- 2 Right-click the Shot Priority flag.  
A red dot appears on the current shot of the currently active layer.

**To remove shot priority from a shot:**

- 1 In the multi-layer timeline, **Shift**+right-click the shot with priority.  
The red dot is removed from the shot.

**To select all shots that are assigned shot priority:**

- 1 In the Timeline menu, enable the Flags button.
- 2 In the Flags menu, left-click the Shot Priority flag.  
The Shot Priority flag is highlighted.
- 3 Click Select.  
All priority shots are selected.

## Solo Mode

When you enable Solo mode in the multi-layer timeline and place the focus point over a layer, Lustre displays only this layer (including its gaps) in the Storyboard and Player. In addition, this is the only layer that is played out to tape and rendered locally.

A soloed layer in Lustre overrides the effects of layer muting and shot priority (see [Muted Layers](#) (page 2002) and [Shot Priority](#) (page 2003)). That is, even when a layer is muted, if you subsequently solo this layer, this

layer alone is displayed. Likewise, when there are shots with shot priority in several layers, a soloed layer is still the only layer displayed.

---

**NOTE** If you are using the solo function as a method to create editorial or grade versioning, please keep in mind that the status is not part of the grade file data structure. Therefore, this state is not saved upon exiting Lustre.

---

The following example illustrates how a soloed layer overrides other layer and shot prioritizing factors.

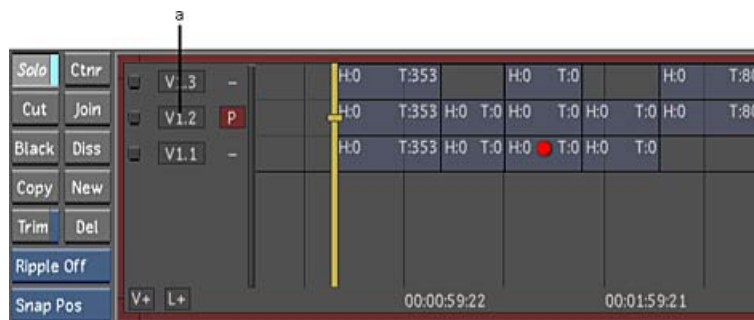

When Solo mode is enabled, the Storyboard is updated to display shots from only the soloed layer. When Solo mode is disabled, what Lustre displays is governed by what layers are muted, the presence of shots assigned with priority, and typical Top Vertical Priority behaviour.

In the following example, Layer 2 is soloed. In this case, only Layer 2 is displayed in the Player and Storyboard, played out to tape, and rendered. It should be noted that although there is a shot assigned with shot priority in Layer 1, only Layer 2 shots are displayed because Solo mode takes priority.

---

**WARNING** If a layer is soloed, the Edit tools (Trash, Delete, Trim In/Trim Out, and Mark In/Out) default to 'Ripple End' behaviour, regardless of the Ripple Mode setting. If no layer is soloed, however, the Edit tools behave according to the individual Ripple Mode selected (Ripple Off, Ripple Start, or Ripple End) and apply to the active or visible layer that contains the focus point. For more information about Ripple Modes, see [Trimming With Ripple Mode](#) (page 1996).

---

(a) Soloed layer

To solo a layer:

- 1 Move the focus point of the positioner to the layer you wish to solo.
- 2 Enable the Solo button.

To un-solo a layer:

- 1 Disable the Solo button.

**NOTE** This operation un-solos the layer regardless of where the focus point is.

## Rendering the Timeline

There are numerous scenarios when you render a timeline. See [Rendering](#) (page 2258).

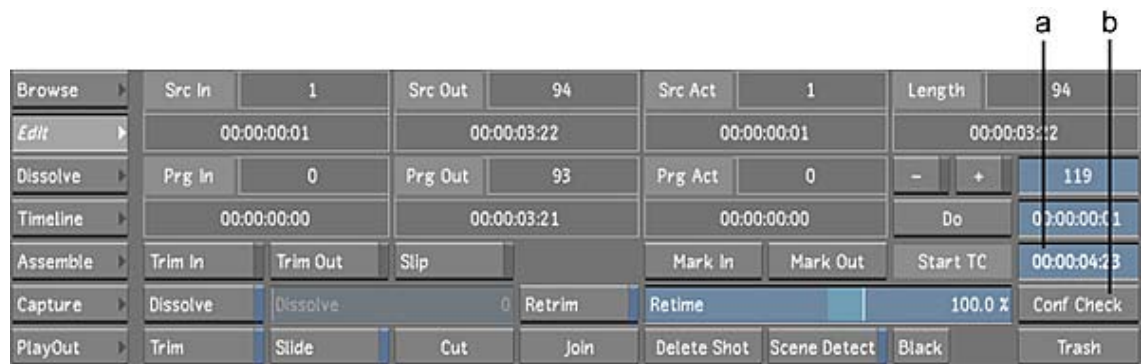

# Modifying the Timeline's Starting Record Timecode

You can change the timeline's start timecode by entering either a start timecode or the number of frames you want to start from. Modifying the start timecode does not delete frames that precede the new start frame.

To modify a shot's starting timecode:

- 1 Click **Editing** in the main menu, and then click **Edit** to display the Edit menu.
- 2 Do one of the following:
  - To enter a timecode, click in the **Start TC** field and use the numeric keypad to enter the timecode at which you would like the timeline to begin. This value is converted into the corresponding frame number (as shown in the frame field).
  - To enter a frame number, click the **Start TC** field, then click the frame field and use the numeric keypad to enter the frame number at which you would like the timeline to begin. The frame number is converted into the corresponding timecode value.

**NOTE** Ctrl-click either the frame or Start TC field to clear it.

(a) Frame field (b) Start TC field

- 3 Press **Enter** on the numeric keypad.

## Performing a Confidence Check

A confidence check is a process in which you manually check the contents of your timeline (which you created by assembling shots from the scanned film frames) against a digital reference cut captured directly from an offline edit video tape or other medium. This is an important step in ensuring that the assembled timeline contains the frames specified by the offline editor. If, for any reason, there is an offset between your current timeline and the digital cut, your picture could end up out of sync with the sound.

**NOTE** The confidence checking function allows you to synchronize the start frames of the timeline and digital reference cuts and does not involve a synchronization of timecodes.

To perform a confidence check:

- 1 Load or create the timeline by doing one of the following:
  - Loading a current timeline. See [Importing Timelines as Source Clips](#) (page 1980).
  - Creating a newly assembled timeline from an EDL. See [Working with EDL, ALE, and Cutlist Files](#) (page 1935).
- 2 Save the current cut, create a new cut, and load it.

- 3 Capture the footage you want to use as a point of comparison (this is the offline digital cut). See [Capturing Material](#) (page 2305).
- 4 Click Editing, and then click Edit to display the Edit menu.
- 5 Drag the digital reference cut from the Library to the Confidence Check button.

A split screen display appears. The current first frame is loaded in the left viewer and the digital cut is loaded in the right viewer with the first frame displayed.

- 6 Navigate between shots to make sure each timeline shot starts on the exact same frame as in the reference cut. You must check the two versions by eye in search of discrepancies. If, for any shot, you determine the two start frames (timeline and reference) do not start on the same frame, synchronize the start frames.

Synchronize the reference cut to the timeline by offsetting the reference cut in the right viewer:

- Left-click the reference image (right-side image) and drag left to scrub in reverse.
- Left-click the reference image and drag right to scrub forward.
- Middle-click the reference image to go one frame forward.
- Right-click the reference image to go one frame backward.

- 7 Navigate within each shot by stepping through the cut points frame-by-frame to make sure there are no shots that are offset.

If you determine there are shots that are offset, you can use the Editing tools (trim, slip, and slide) to adjust the shots to the correct frames. This is usually performed in the timeline cut and not the reference cut.

To trim from the Edit menu, see [Trimming from the Edit Menu](#) (page 1960).

To trim from the Timeline menu, see [Trimming Elements](#) (page 1995).

It is important to note that when matching your timeline to a reference clip, several editing changes are automatically updated in the Player without the need to release the mouse button:

- trimming
- slipping
- sliding

- 8 Save the current cut.

The confidence check reference is saved with the cut. When using a clip from the Library for a Confidence Check, the reference clip, its timing offset and the viewing mode (Single or Dual and Wipe position) are saved with the cut information. When reloading a cut, you do not need to manually reload the Confidence Check clip and set the proper offset value. Simply clicking the Conf Check button (located in the Editing/Edit menu) displays the confidence check view with the reference clip and the defined offset value.

**NOTE** Only source clips can be used as a Confidence Check reference. Sequences are not supported.

# Using Scene Detection

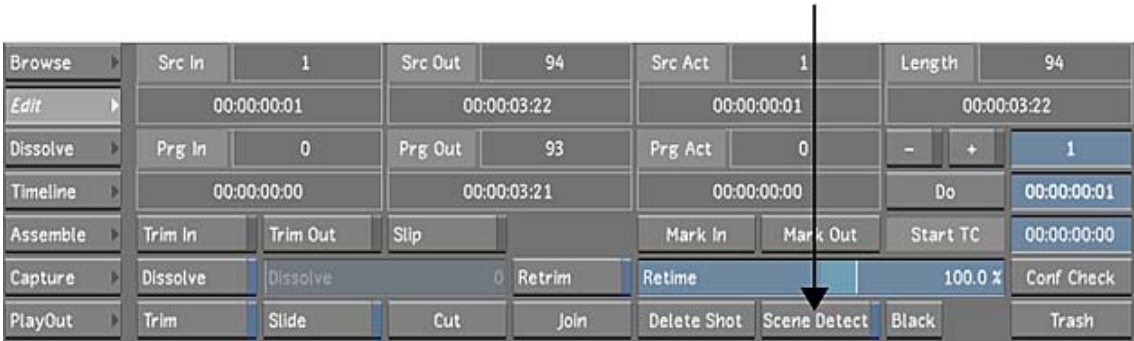

Use scene detection when you are working on a single shot made up of multiple scenes. Scene detection locates the frames when scenes change and splices the shot at those points. When you apply scene detection to a shot in the Storyboard, it is broken up into numerous smaller pieces that you can then colour grade independently.

For example, you may have a finished edited HD master tape that needs to be colour graded before it is ready for broadcasting. You can capture the entire tape as one shot, and then use scene detection to cut it into separate shots. You can then colour grade each shot one-by-one.

**NOTE** Lustre uses the scene's Src In number to assign unique ID numbers during scene detection. This ensures that any scene captured more than once has the same number assigned to it, which is useful when scenes are transferred from Lustre to other effects applications, and back again. By using the Src In number as the basis for assigning numbers, the grading metadata applied to a scene that has been captured and put through scene detection more than once, is maintained.

**To use scene detection:**

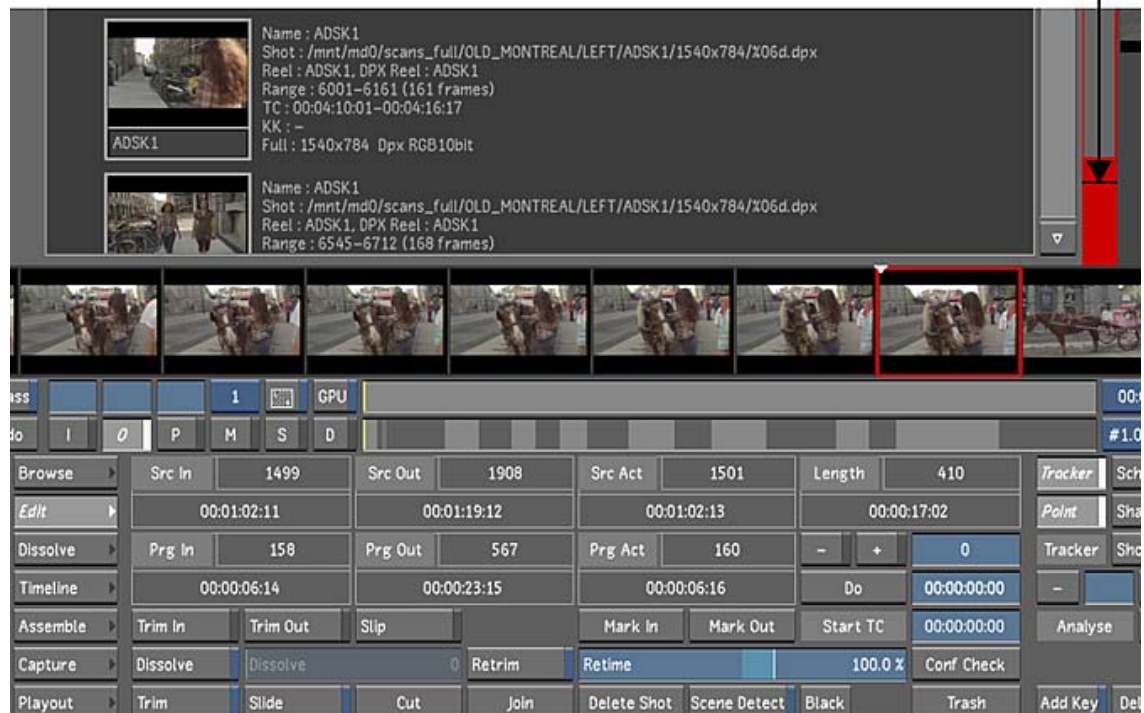

- 1 Capture from an edited video tape. See [Capturing Material](#) (page 2305).
- 2 Create a new empty cut. See [Managing Cuts](#) (page 1819).
- 3 Drag the digitized shot from the Library to the Storyboard.
- 4 Click Editing, and then click Edit to display the Edit menu.
- 5 Enable Scene Detect.

**TIP** If the Editing While Grading button is enabled in the User settings, you can start a scene detection from any menu by pressing **Shift+S**. For more information about the Editing While Grading button, see [System & Menu Settings](#) (page 1807).

A threshold indicator bar appears to the right of the Library. When a scene change is detected, the indicator jumps and turns red, and a splice is introduced into the Storyboard, Timeline, and timebar at that frame. When the process is completed, a series of shots is created in the Storyboard.

- 6 You can change the threshold by dragging the thin black horizontal line in the threshold indicator up or down. When you lower the threshold value, a small amount of change is enough to trigger a splice. If the value is too low, splices appear in the middle of a scene. If the value is too high, some changes may not be detected. Generally, the default threshold value gives a good result.

- 7 Press **Spacebar** to pause the scene detection process.

**NOTE** To continue a paused scene detection, press **Spacebar** again. To stop scene detection, hold down your left mouse button.

- 8 If, for any reason, a scene change is not detected, you can add a cut manually by clicking **Cut**. See [Inserting Cuts](#) (page 1967).

## Playing, Viewing, and Sorting Shots

Lustre offers multiple options for playing, viewing, and sorting shots during the creative process. Use the Player to play one or more shots with your choice of view options, such as proxy resolution with the red colour channel displayed. Move through shots on the timeline using one of several navigation methods. Sort the shots in the timeline so grading can be completed with more ease. Use a reference shot to facilitate tasks such as colour matching. View the reference shot in a separate window or in split-screen with the current shot. If the addition of multiple effects are slowing down playback time, you can cache frames to bring the playback speed closer to real-time.

### Playing Shots

You can play shots in the Player from any menu in Lustre using either playback controls or hotkeys. To play shots, you must first load them into the Storyboard. See [Creating a Cut with Shots in the Library](#) (page 1919).

You can also use a full-screen Player to view shots without the clutter of menus. This Player is particularly useful for viewing 2K footage at full resolution.

When you play shots in the Player, you can do the following:

- Loop the entire Storyboard.

- Loop the current shot in the Storyboard.
- Loop between in and out points.

---

**NOTE** For information on playing shots with audio, see [Using Audio](#) (page 1890).

---

**To play shots in a cut:**

- 1 Load your shots into the timeline. See [Adding Shots to the Timeline](#) (page 1979).
- 2 Click the Play Mode button to cycle through playback range options.

**(a)** Playback controls **(b)** Play Mode button

| Select: | To specify a looped playback range: |
|---------|-------------------------------------|
|         | Of the entire timeline.             |
|         | Of the current shot.                |
|         | Between in and out points.          |

- 3 To set in and out points, go to the start and end frame and mark the in and out points.

| Press:  | To:                      |
|---------|--------------------------|
| Shift+I | Mark an in point.        |
| Shift+O | Mark an out point.       |
| Shift+L | Clear in and out points. |

- 4 Use the following playback controls or hotkeys to play your shot forward or backward.

| Click: | Or press:  | To:                    |
|--------|------------|------------------------|
|        | Up Arrow   | Play the cut forward.  |
|        | Down Arrow | Play the cut backward. |

| Click:                                                                            | Or press: | To:                                                  |
|-----------------------------------------------------------------------------------|-----------|------------------------------------------------------|
|  | N/A       | Stop playback.                                       |
| N/A                                                                               | Spacebar  | Start or stop playback in the direction last played. |

**NOTE** For information on navigating to a particular frame, see [Navigating through Shots](#) (page 2018).

## Using the Full-Screen Player

The full-screen Player allocates the entire screen to the image. Use it when you want to maximize screen space for viewing shots, for example, while colour grading.

There are no playback controls available in the full-screen Player. Instead, you use hotkeys and mouse gestures to play shots, access both playheads, display two or more shots at the same time, and pan and zoom the image. You can also display the Storyboard, vectorscope, histogram, and waveform monitor. See [Viewing Colour Distribution](#) (page 2092).

**NOTE** The histogram, vectorscope, and waveform monitors do not dynamically update when GPU is enabled. They retain the colour distribution of the image prior to GPU being enabled.

The full-screen Player is available from all menus except the Editing menus.

### To use the full-screen Player:

- 1 From any menu in Lustre except the Editing menus, press `Enter`.  
The full-screen Player appears.
- 2 Use hotkeys or mouse gestures to play the shot, zoom in or out, pan the image, change the view, or switch playheads. You can also display the Storyboard, vectorscope, histogram, and waveform monitor. See [Player Hotkeys](#) (page 2039) for a list of the hotkeys and mouse gestures commonly used in the full-screen Player.
- 3 To exit the full-screen Player, press `Enter` again.

## Viewing Reference Images

The Player has two playheads, A and B, which allow you to quickly access two different areas of your cut. Lustre keeps track of the location of the current frame on each playhead as you navigate through the cut, so you can instantly return to that location by switching playheads.

You can use the playheads to view reference images while you work. Reference images are useful when you want to create continuity grades, apply input LUTs, or create effects with Sparks. You can also switch between the current shot and a reference shot if you do not need to view them simultaneously.

It is recommended that you work on your shot in Playhead A and load the reference images into Playhead B. For example, in Playhead B, you can view a reference image from the shot adjacent to the one you are currently working on in Playhead A. Visually compare the two images to match the saturation, whites and blacks, and the colours of the shot you are working on to the image in the reference buffer. The Playhead button indicates which playhead is active.

**TIP** After you have assigned shots to the playheads, you can view them together in Dual View. See [Using Dual View](#) (page 2029).

**To view a reference image loaded from a cut:**

- 1 Press **F1** or select **A** from the Playhead button and then select the shot in the Storyboard.

The shot you are working on is assigned to Playhead A.

- 2 In the Storyboard, go to the frame you want to use for the reference image.
- 3 Press **K** to store the frame in the reference buffer.  
The current frame overwrites the last frame loaded into the reference buffer.
- 4 Press **F2** or select **B** from the Playhead button.  
The shot is assigned to Playhead B.
- 5 Press **L** or click the **S** button to display the reference image in Playhead B.

The reference image appears in the Player.

**TIP** At any time, press **L** to toggle between the original shot (**O** button) and the reference image (**S** button).

The current shot on each playhead is indicated by the border colour in the Storyboard.

| Border colour: | Indicates the current shot on: |
|----------------|--------------------------------|
| Bright red     | Playhead A (active).           |
| Bright purple  | Playhead B (active).           |
| Dimmed red     | Playhead A (inactive).         |
| Dimmed purple  | Playhead B (inactive).         |

- 6 To work on the shot you assigned to Playhead A, press **F1** or select **A** from the Playhead button.  
The shot you are working on is selected. You can move back and forth between the shots in Playhead A and Playhead B by pressing **F1** and **F2**, respectively.

**To view a reference image loaded from a Grade bin:**

- 1 Press **F1** or select **A** from the Playhead button and then select the shot in the Storyboard.  
The shot you are working on is assigned to Playhead A.

- 2 In the Grade bin, right-click the frame you want to use for the reference image.  
The frame from the Grade bin overwrites the last frame you loaded into the frame buffer.
  - 3 Press **F2** or select **B** from the Playhead button.  
The shot is assigned to Playhead B.
  - 4 Press **L** or click the **S** button to display the reference image in Playhead B.  
The reference image appears in the Player.
- TIP** At any time, press **L** to toggle between the original shot (**O** button) and the reference image (**S** button).
- 5 To work on the shot you assigned to Playhead A, press **F1** or select **A** from the Playhead button.  
The shot you are working on is selected. You can move back and forth between the shots in Playhead A and Playhead B by pressing **F1** and **F2**, respectively.

**To switch between a reference image and the shot you are working on:**

- 1 Load the reference image to the frame buffer. Do one of the following:
  - Press **K** to load the current frame in the Storyboard to the frame buffer.
  - Right-click a Grade bin thumbnail.
- 2 In the Storyboard, select the shot you are working on.  
The shot appears in the Player.
- 3 To toggle between the reference image and the shot you are working on, press **L**.

## Panning and Zooming the Image

You can pan and zoom the image from any menu in Lustre except the Editing menus. You can pan and zoom in both the Player and the full-screen Player.

**To pan the image:**

- 1 Place the cursor over the image, press and hold the middle mouse button, and drag in the direction you want to pan.

**To zoom the image:**

- 1 Do one of the following:
  - Place the cursor over the image, press and hold the middle and right mouse buttons, and drag right to zoom in or left to zoom out.
  - Press and hold the mouse button in the Zoom field and drag right to zoom in or left to zoom out. Click once in the field to reset it to 1.00 (Player only).
  - Right-click in the Zoom field to display the calculator, and then use it to enter a zoom value.

**TIP** Zooming normally occurs in increments of 0.1. However, to quickly jump between a zoom factor of 1.00 and 2.00, press **F10**.

# Setting Image View Options

Lustre has several view options. As you work on a grade, you can:

- Display various versions of the image (for example, before or after secondary colour grading).
- Toggle between full resolution and proxy resolution.
- Display a specific channel of the image.
- Switch between fields when working with interlaced footage.
- Switch between viewing LUTs.

## Setting the View Mode

Use the View Mode buttons to view different versions of the image as you work on your grade.

To set the view mode:

- 1 Click one of the View Mode buttons.

| Click: | Or press: | To view:                                                                                                                                                                                                                                                                                                   |
|--------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I      | I         | The image with colour corrections made in the Grading and Curves menus only.<br><b>NOTE</b> You cannot select this mode if no corrections have been made in the Secondaries menu.                                                                                                                          |
| O      | O         | The output image, which contains the result of all corrections applied. This is the default viewing mode.                                                                                                                                                                                                  |
| P      | P         | The printed, or rendered image. See <a href="#">Rendering</a> (page 2258). If the frame has not been rendered, a red X appears in the image window.<br><b>NOTE</b> If you rendered a shot and still see a red X in the image window, press <b>Shift+P</b> to force Lustre to re-detect all rendered files. |
| M      | F11       | The matte on a secondary correction. Press F11 to toggle between Secondary (Overlay) and Matte (Greyscale) view modes for the matte. See <a href="#">Creating a Secondary by Keying a Range of Colours</a> (page 2159).                                                                                    |
| S      | L         | The stored reference image. See <a href="#">Viewing Reference Images</a> (page 2013).                                                                                                                                                                                                                      |

The image changes to the selected view mode.

## Selecting the Resolution

While working, you can display the full-resolution version of shots or half-resolution proxies in both the Player and full-screen Player. Displaying proxies speeds up interaction and playback on shots with many effects added to them. Half-resolution proxies are also useful for playing to projectors and for saving disk space—they take up only 1/4 of the space of the original footage. For example, you can store proxies on the server and full-resolution footage on the main storage device.

You can switch between full and half resolution any time. Generating and displaying proxies does not affect your original footage in any way. The resolution is independent of the grade file data.

To display proxies, you must first generate them. See [Generating and Viewing Proxies](#) (page 2271).

**To set the resolution:**

- 1 In any menu, click the Full/Half Resolution button.

The resolution toggles between full and half (proxy) resolution. An ungenerated proxy appears as a red X with a black background.

**NOTE** Buttons for switching between full and half resolution are also found in the Grade and Render menus.

## Setting the Active Field for Display in the Player

Interlaced video formats divide frames into two line-based fields. One field consists of the first and subsequent odd lines in the frame, and the other field consists of the second and subsequent even lines in the frame. During the recording process, the images that make up each field are recorded at slightly different moments. For example, when recording NTSC, field 1 is recorded 1/60th of a second before field 2.

While in Output view mode, Lustre can only display one field at a time. The field that is displayed is the active field. When you render the footage, both fields are processed.

---

**NOTE** Setting the active field affects preview display only and does not impact the final output. Rendering is performed according to field dominance grade settings selected during project creation.

---

**To set the active field:**

- 1 Toggle the F1/F2 button.

**NOTE** You need to select Interlaced in the Setup > Grade menu in order to enable this button.

This switches the view in the Player between field 1 and field 2.

## Setting the Viewing LUT

Use the LUT button to display the image using one of three Print LUTs selected for viewing purposes. See [Defining Print LUTs for Viewing](#) (page 1900).

To cycle between LUTs:

- 1 Click the LUT button one or more times.

The button label changes to L1, L2 or L3, indicating the currently loaded LUT.

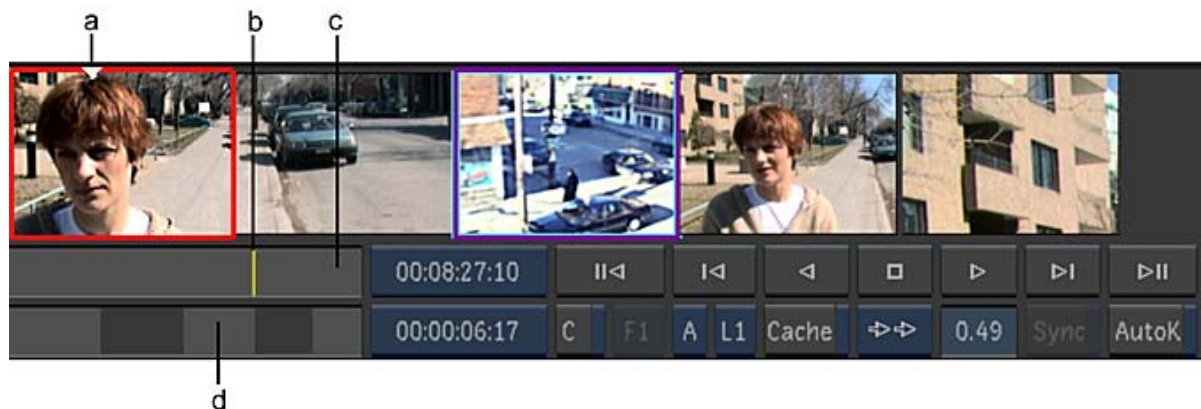

## Navigating through Shots

Various methods are available for navigating through the shots in your cut. You can navigate using:

- Storyboard and the shot and scene timebars.
- Playback controls and hotkeys.
- Timecode field.
- Timecode calculator.

## Navigating Using the Timebar and Storyboard

Lustre has two timebars to help you navigate through your cut. The Shot timebar represents the current shot, and the Scene timebar represents all the shots in the cut. Use either timebar to move to another frame.

(a) Storyboard position arrow (b) Shot positioner (c) Shot timebar (d) Scene timebar

In the Scene timebar, shots are represented by grey bars in alternating shades of grey, which makes them more visible. The length of each bar is proportional to the length of the shot. Each timebar has a positioner that indicates the location of the current frame. In the Storyboard, the position arrow also indicates the position of the current frame.

**To move to a new location in the cut:**

- 1 Click either the Scene or Shot timebar.  
The positioner moves to the frame corresponding to the location you clicked.

**To scrub through one or more shots:**

- 1 Drag the positioner of either timebar to the left or right.

**To pan the Storyboard:**

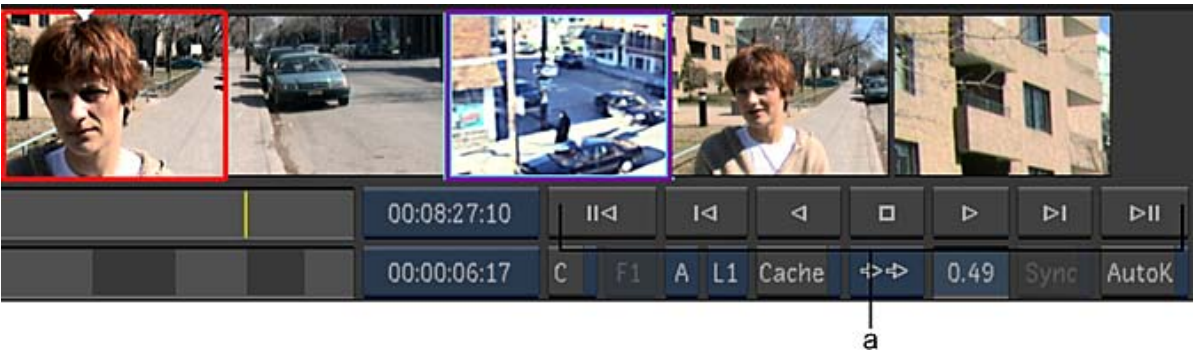

- 1 Place the cursor over any thumbnail, press the middle mouse button, and drag to the left or right.

**To go to the first frame in a shot:**

- 1 Click the shot thumbnail in the Storyboard.

**Navigating with the Playback Controls and Hotkeys**

You can use playback controls to navigate through shots. There are hotkey equivalents for several of these controls.

| Playback Control                                                                    | Hotkey     | Description                                                                                        |
|-------------------------------------------------------------------------------------|------------|----------------------------------------------------------------------------------------------------|
|  | N/A        | Goes to the first frame in the cut. To step one frame back, right-click the button.                |
|  | Left Arrow | Goes to the first frame in the shot. Click or press repeatedly to move backward from shot to shot. |
|  | Down Arrow | Plays the cut backward.                                                                            |
|  | Spacebar   | Stops playback.                                                                                    |

| Playback Control                                                                  | Hotkey      | Description                                                                                                                                                                |
|-----------------------------------------------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Up Arrow    | Plays the cut forward.                                                                                                                                                     |
|  | Right Arrow | The playback control goes to the last frame in the shot. The hotkey goes to the first frame in the next shot. Click or press repeatedly to move forward from shot to shot. |
|  | N/A         | Goes to the last frame in the cut. To step one frame forward, right-click the button.                                                                                      |

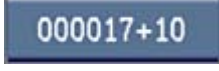

## Monitoring the Location of the Current Frame

The Source Timecode field indicates the source timecode for the current frame. The timeline information field indicates the location of the current frame, as well as other information pertaining to the shot.

**(a) Source Timecode field (b) Timeline Information field**

You can click the timeline information field one or more times to display other information, as described in the following table.

| Information:                                                                        | Indicates:                                                                                                          |
|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
|  | Frame number of the current frame.                                                                                  |
|  | Frame rate (when playing shots).                                                                                    |
|  | Timecode of the current frame.                                                                                      |
|  | Frame number in film feet/frames.                                                                                   |
|  | Layer, Shot, and Frame numbers of current frame in the following format:<br>#LL.SS.FF (LL-Layer, SS-Shot, FF-Frame) |

# Navigating With the Timecode Calculator

The timecode calculator is displayed when you right-click in the timeline information field with either the frame number or timecode of the current frame displayed.

**(a) Timeline Information field (b) Timecode calculator**

You can use the timecode calculator to do the following:

- Jump to a specific frame on the Storyboard.
- Calculate timecodes from frame count and vice versa.
- Switch between drop frame and non-drop frame timecodes (NTSC only).
- Convert drop frame timecodes to non-drop frame timecodes and vice versa.

The timecode calculator operates much like the standard Lustre calculator, but with some differences.

| Click:                         | To:                                                                                                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| The calculator's numeric field | Jump to the frame number that corresponds with the value entered in the calculator's numeric field.                                    |
| Add                            | Jump ahead the number of frames entered in the calculator's numeric field.                                                             |
| Sub                            | Jump back the number of frames entered in the calculator's numeric field.                                                              |
| . (period)                     | Insert two zeroes in the calculator's numeric field.                                                                                   |
| TC/FRM                         | Switch between the timecode and frame number. This button indicates the current state. TC indicates timecode, and FRM indicates frame. |

| Click: | To:                                                                                                                                                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DF/NDF | Switch between drop frame and non-drop frame timecodes. This button indicates the current state. DF indicates Drop Frame mode. NDF indicates Non-Drop Frame mode. This button is only enabled if 30 or DF is set as the project frame rate in the Setup Project menu. |

**NOTE** If you enter a timecode or frame number that exceeds the shot or Storyboard limit, nothing will happen.

**To calculate timecodes from frame counts:**

- 1 Click the timeline information field until the frame number is displayed.
- 2 Right-click the timeline information field to display the timecode calculator.
- 3 Using the timecode calculator's numeric keypad, enter a frame number.
- 4 Click FRM. The corresponding timecode is displayed.

## Storyboard Viewing Options

The Storyboard is a thumbnail representation of your timeline. Each individual thumbnail represents a single shot. The Storyboard has multiple viewing options. You can:

- Show or hide the Storyboard.
- Display the Storyboard in regular or large view.
- Select one or more shots.
- Identify selected shots by means of their selection colours.
- Refresh Storyboard thumbnails.
- Collapse the Storyboard thumbnails.
- Automatically update the Storyboard thumbnails.

## Showing and Hiding the Storyboard

You can hide the Storyboard to increase the space available for the image you are working on. You can do this from all menus except the Editing menus — the Storyboard is always visible from the Editing menus.

**To show or hide the Storyboard:**

- 1 Press Tab.

## Setting the Storyboard View

You can display the Storyboard in regular or large Storyboard view. In regular Storyboard view, it appears below the image window. In large Storyboard view, it appears to the left of the browser, where the Library is usually displayed. Large Storyboard view displays more shots at once in the Storyboard.

You can do all operations, such as selecting or deleting shots, from either Storyboard view. You can display the large Storyboard view from all menus except the Editing menus, in which case, the Library always appears to the left of the browser.

To toggle between regular and large Storyboard view:

- 1 Press Q.  
The Storyboard switches views. When you switch to large Storyboard view and are viewing 2K images, the image changes to half resolution to accommodate the Storyboard.

## Updating the Storyboard Thumbnails

As you are making changes to the shots within your timeline, you may want to automatically see the changes within the Storyboard thumbnail. The update Storyboard option allows this to happen.

To enable or disable the automatic Storyboard thumbnail update option:

- 1 Do one of the following:
  - Within the Setup > Interface menu, click the Update Storyboard button.

- Press Shift+1.
- Within the Display & Interface menu of the user configuration settings, click Update Storyboard. See [Display & Interface Settings](#) (page 1805). Refer to “Display & Interface Settings” in the “Project Management” chapter in the Lustre User Guide.

If the Update Storyboard feature is enabled and you make changes to any shot that is not currently in the Player, a grey dot will appear on the bottom-right corner of the thumbnail. The grey dot signifies that a change has been made to that shot, but the thumbnail has not been automatically updated.

When you apply changes to a group of shots, only the thumbnail of the current shot within the Player is automatically updated. To update the other thumbnails, click the Storyboard thumbnail with the grey dot.

## Selecting Shots in the Storyboard

You can select a single shot or multiple shots in the Storyboard. Multi-select shots to copy parameters, delete multiple shots, and create groups.

When selecting Storyboard thumbnails, the multi-layer timeline shows the same selection. Likewise, when selecting multi-layer timeline segments, the Storyboard shows the same selection. It should be noted that:

- The Storyboard view shows segments as being selected provided these segments are the topmost shot or have shot priority.
- The Storyboard view shows all segments in the multi-layer timeline if Solo mode is enabled.

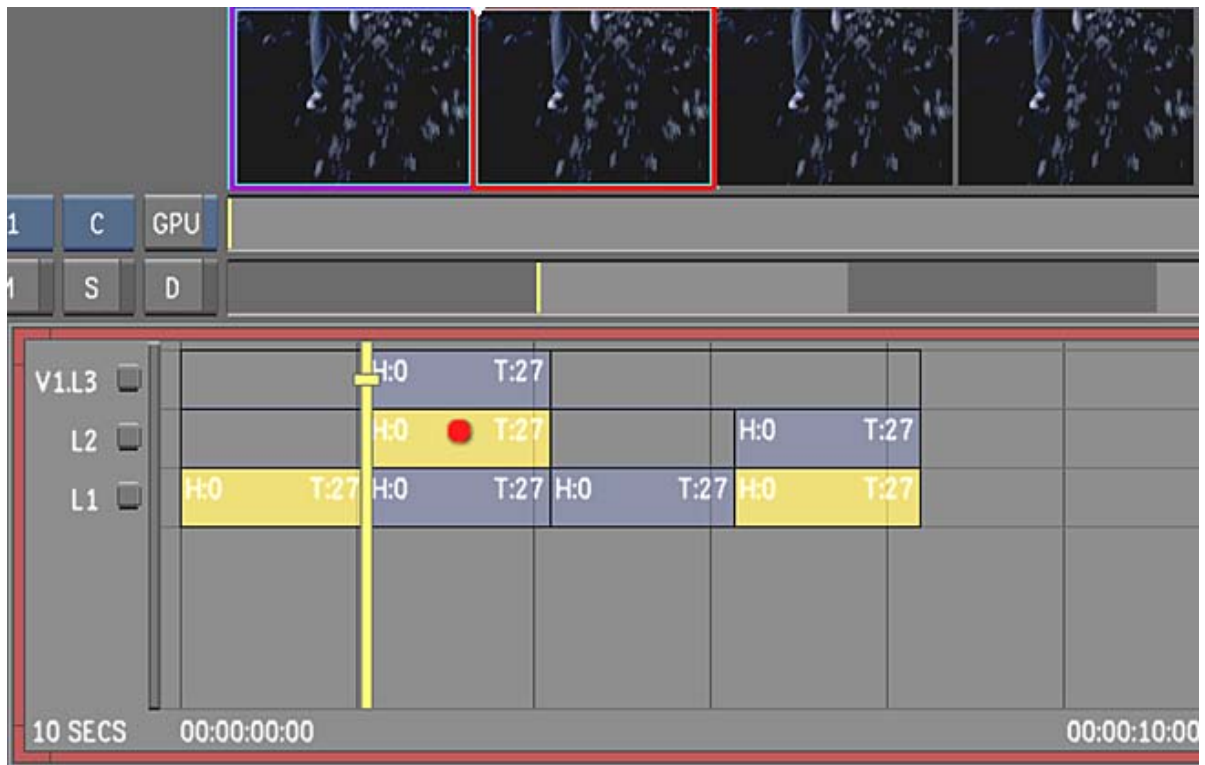

Image courtesy of Moviworld / UK File & TV Company / Videolab

In the above example, all the selected shots in the multi-layer timeline are displayed and selected in the Storyboard view except for the far-right Layer 1 shot. The Layer 1 shot on the far right is neither displayed nor selected in the Storyboard. For more information about top vertical priority and shot priority, see [Top Vertical Priority](#) (page 2001).

### To select a single shot:

- 1 Click the thumbnail.  
The border changes to red, indicating it is the current shot.

### To select multiple shots:

- 1 Click the first shot you want to select.  
The border changes to red, indicating it is the current shot.
- 2 Right-click the subsequent shots you want to select.  
The border of each subsequent selected shot changes to aqua.

### To select a range of shots:

- 1 Right-click the first shot you want to select and drag across the range of shots while holding down the mouse button.

### To deselect multiple selected shots:

- 1 Right-click the selected shots.

## Storyboard Selection Colours

As you work with shots in the Storyboard, the border colours indicate the selection state, as described in the following table.

| Colour: | Indicates:                                                             |
|---------|------------------------------------------------------------------------|
| Red     | The current shot on Playhead A.                                        |
| Pink    | The source shot picked up in the Library for a Shot Replace operation. |
| Aqua    | Multiple selected shots (except for the current shot).                 |
| Yellow  | Shots included in a group (in Gang mode).                              |
| Purple  | The current shot on Playhead B.                                        |
| Orange  | A target shot in a Shot Replace operation.                             |
| Blue    | A shot picked up from the Library.                                     |
| Green   | A shot picked up from the file browser.                                |

## Refreshing Storyboard Thumbnails

As you work on your material, you must refresh the Storyboard thumbnails so that they will reflect the changes made to the image. You can refresh them anytime. You can refresh the current shot, or refresh multiple thumbnails at once.

### To refresh a single Storyboard thumbnail:

- 1 Select the thumbnail you want to refresh. You can be on Playhead A or B.  
The thumbnail border turns red if you are on Playhead A, or purple if you are on Playhead B.
- 2 Press . (period).

### To update multiple Storyboard thumbnails simultaneously:

- 1 Press Shift+. (period).  
The thumbnails from the current shot onwards are updated.
- 2 To stop the update process, click any mouse button.

## Displaying Only Selected Shots in the Storyboard

In the multi-layer timeline you can select shots on multiple layers and collapse the Storyboard so that only selected shots are visible. This is useful to isolate certain types of shots for grading, such as outdoor scenes. In addition, in the multi-layer timeline, you can select all the shots on all layers and use the collapse function to align all layers sequentially in the Storyboard.

---

**NOTE** Another way to present a multi-layer timeline selection in the Storyboard for grading purposes is to select either A-Mode or C-Mode for sorting the timeline. For more information about the Timeline Sort feature, see [Timeline Sort Mode](#) (page 2033).

---

When you enable the collapse function, Lustre disables the Edit, Dissolve, Editing > Timeline, and Colour > Timeline menus. If you are in one of these menus when you enable the collapse function, Lustre takes you to the Colour > Grading menu. This behaviour guards against accidentally modifying the editorial structure on footage not being displayed while in the collapsed view.

The viewing order of shots in the collapsed view of the Storyboard starts from shot 1 in Layer 1 and goes to the last shot in Layer 1 before starting on the first shot of Layer 2.

In the following example, all shots on all layers are selected. The order in which shots are displayed in the Storyboard when the collapsed view is enabled is from a to g.

In the following example, several shots are selected and some are not. The order in which shots are displayed in the Storyboard when the collapsed view is enabled is from a to e.

To align all shots on all layers into a single Storyboard sequence:

- 1 In the multi-layer timeline, select all shots on all layers. See [Selecting Elements](#) (page 1980).
- 2 Press **F** on the keyboard, or enable the **C** button.

All shots on all layers are displayed in the Storyboard.

**NOTE** To disable the collapse function, press **F** on the keyboard again, or click the **C** button again.

To align a selection of shots from one or more layers into a single Storyboard sequence:

- 1 In the multi-layer timeline, select the desired shots. See [Selecting Elements](#) (page 1980).
- 2 Press **F** on the keyboard, or enable the **C** button.

All selected shots are displayed in the Storyboard.

**NOTE** To disable the collapse function, press **F** on the keyboard again, or click the **C** button again.

## Setting the Viewing Options

Lustre has several ways to view and work with single or multiple shots in the Player or the SDI monitor.

Within the Viewing Options, you can select the following:

- **Colour View** You can display all of the colour channels of an image, or individual channels in greyscale. The greyscale versions of colour channels represent, in values of grey, the amount of that colour channel found in each part of the image. The darker the grey, the greater the amount of colour present.

- **Single View** This is the default viewer. You can select which playhead you want to display in the Player (i.e., Playhead A or B).
- **Dual View** You can display the image of Playhead A and Playhead B at the same time. See [Using Dual View](#) (page 2029).  
If you are working in a stereoscopic project, you can also use this mode to display the image for the Left and Right Eye of the current frame at the same time. See [Viewing Stereoscopic Footage in Dual View](#) (page 2255) .
- **Multi View** You can display 2, 4, 9, or 16 shots. See [Using Multi View](#) (page 2031).

To enable the viewing options:

- 1 Enable the Viewing Options button. The look of this button depends on the viewing option that is currently selected.

The Viewing Options panel appears to the left of the Grade bin.

- 2 Select the colour view option.  
Cycle through the following options:
  - Colours
  - Red Channel
  - Green Channel
  - Blue Channel
  - Luminance

- 3 Select the number of shots to view using the Viewer option box.

| Select:     | To display:                                                                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Single View | The default viewer. The viewer displays the image of the current playhead.                                                                                                                                                                                                        |
| Dual View   | The images of Playhead A and Playhead B. See <a href="#">Using Dual View</a> (page 2029). For a stereoscopic project, it displays either Playhead A and Playhead B, or the Left Eye and the Right Eye. See <a href="#">Viewing Stereoscopic Footage in Dual View</a> (page 2255). |
| Multi View  | 2, 4, 9, or 16 shots. See <a href="#">Using Multi View</a> (page 2031).                                                                                                                                                                                                           |

The Viewing Options are also accessible through the Autodesk Control Surface panel. See: [Player Viewing Options](#) (page 2485) in “The Autodesk Control Surface” chapter of this User Guide.

#### To return to the Single view:

- 1 Do one of the following:
  - Press F5.
  - Right-click the Viewing Options button.

This returns you to the default Single view.

**NOTE** Disabling the Viewing Options button does not disable the viewing options you have selected.

## Using Dual View

The two images displayed in Dual view are the current frames on Playheads A and B. Dual view is useful for matching two shots or for copying colour correction parameters from one shot to another. You can view images side by side, or use a wipe. With a wipe (i.e., horizontal or vertical), you see a portion of each image. You can control the position of the wipe bar by adjusting the Value slider.

In a stereoscopic project, you can view the image of the Left Eye in one viewer and the image at the same frame of the Right Eye in the other. See [Viewing Stereoscopic Footage in Dual View](#) (page 2255). Refer to “Viewing Stereoscopic Footage in Dual View” in the “Stereoscopy” chapter of the *Lustre User Guide*.

#### To display Dual view:

- 1 Do one of the following:
  - Enable the Viewing Options button, and in the Viewer option box, select Dual View.
  - With the Viewing Options button enabled, press F3 or click the Viewer option box to cycle through the viewer options until Dual View is displayed.
  - If you are in Single view, and the previous mode was Dual view, press F5 to toggle between the two views.

The last used mode in Dual view is displayed.
- 2 Press F4 to cycle through the display modes.
  - **2-up** The current frames on Playheads A and B are displayed side by side.

- **Horizontal Wipe** The images assigned to Playheads A and B appear on the top and bottom, respectively.

- **Vertical Wipe** The images assigned to Playheads A and B appear on the left and right, respectively.

**TIP** When applying a wipe, use the Value slider to edit the percentage of the viewer that displays the image on Playhead B.

**NOTE** If you are working in a stereoscopic project, you can blend the Right Eye image over the Left Eye. See [Viewing Stereoscopic Footage in Dual View](#) (page 2255).

## Using Multi View

Multi view is useful for viewing your sequence in a Storyboard format while developing continuity between shots. With Multi view, you see the entire image, and you can cycle through viewing 2, 4, 9, or 16 shots.

**To view multiple shots simultaneously in the Player:**

- 1 (Optional) Select up to 16 shots. See [Selecting Shots in the Storyboard](#) (page 2024).

**NOTE** If you do not select any shots, you will see the first shots in the sequence in Multi view.

- 2 Do one of the following:
  - Enable the Viewing Options button, and in the Viewer option box, select Multi View.
  - With the Viewing Options button enabled, press **F3** or click the Viewer option box to cycle through the viewer options until Multi View is displayed.
  - If you are in Single view, and the previous mode was Multi view, press **F5** to toggle between the two views.  
The last used Multi view mode is displayed.
- 3 Press **Ctrl+F5** to cycle through the display modes.

The first two shots displayed are the current frames on Playheads A and B. The rest of the shots displayed are the selected shots, displayed sequentially from left to right in the order of selection.

**NOTE** If no shots are selected, after the first two shots, shots starting at the third shot in the cut are displayed sequentially from left to right.

- 4 (Optional) Pan the displayed shots by holding and dragging the middle mouse button within the Player, or scale the displayed shots by holding and dragging the middle and right mouse buttons within the Player.

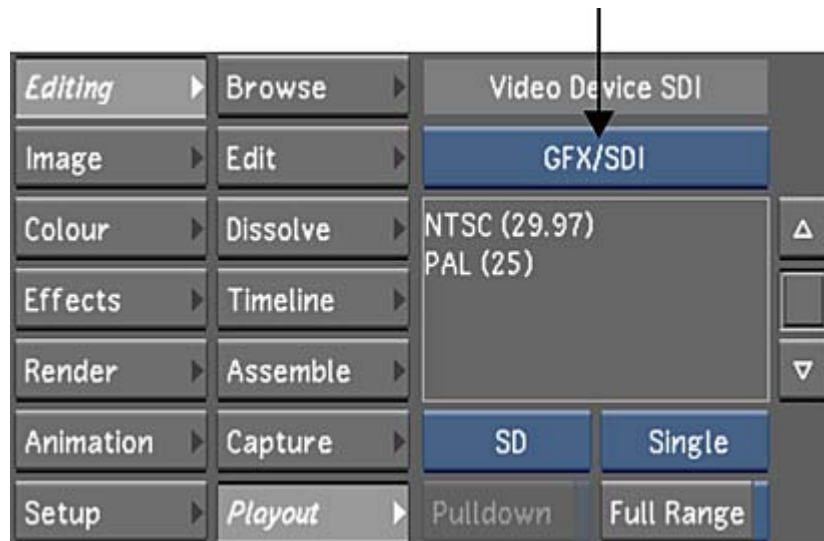

You can make a new selection of shots while you are in Multi view. After you have selected the new shots, press **F6** to update the Multi view display with the new shots.

## Viewing Multiple Shots on the SDI Monitor

You can use Dual view and Multi view in the SDI monitor.

**To view multiple shots on the SDI monitor:**

- 1 Click **Editing** in the Main menu, and then click **Playout**.  
The Playout menu is displayed.
- 2 Make sure **GFX/SDI** is selected in the Video/Graphics Raster option box.

- 3 From the Raster list, select the video resolution and scan mode that corresponds with your footage.
- 4 Press **F7** to activate the SDI output mode.
- 5 Complete one of the following:
  - To view two frames on the SDI monitor, perform the procedure for viewing two frames. See [Using Dual View](#) (page 2029).
  - To view multiple shots on the SDI monitor, perform the procedure for viewing multiple shots. See [Using Multi View](#) (page 2031).

---

**NOTE** You cannot view horizontal wipes, vertical wipes, or blends on the SDI monitor.

---

## Timeline Sort Mode

Sometimes it may be easier for you to grade a timeline if the shots are in a different order than the final sequence. You can rearrange the order of the shots so common shots are grouped together, graded, and then returned to their original order. The timeline sort mode allows you to do this. You can modify the order of the shots in your assembled EDL and then apply grading to those shots. Once you have finished grading the sorted shots, you can output the shots to a VTR (via the write telecine tape feature), save the shots as a new cut, or return the shots to their original order. You can sort the shots either by the record timecode or by the reel name and source timecode.

By default, all the shots are sorted into a single layer when you use the timeline sort mode (whether you are sorting a single-layered timeline or a multi-layered timeline). You can also choose to sort only the selected shots within the timeline. If you are working with a multi-layered timeline, be aware of layers that are muted or if a layer is soloed. If a layer is soloed, then only the shots in that layer can be sorted. If any layers are muted, the shots within those layers cannot be sorted. As well, the same shot can appear in numerous layers. These shots are sorted from the bottom to top layer.

When the timeline is sorted, only the source media is shown, therefore, you cannot modify or collapse the timeline and dissolves and retimes are not visible. The Edit and Dissolve menus are greyed out and all the options within the Timeline menu and the Colourist Timeline menu are also greyed out. You also cannot add or delete shots while the shots are sorted.

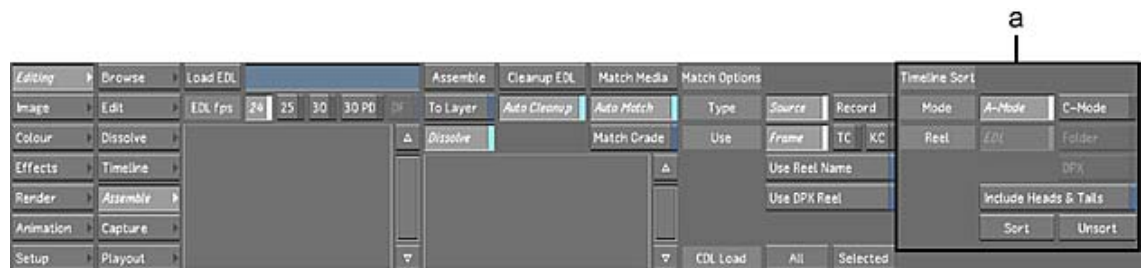

## Accessing the Timeline Sort Feature

To sort the shots within your timeline, you can access the Timeline Sort section in the Assemble menu.

To access the Timeline Sort feature:

- 1 In the Main menu, click Editing.
- 2 Click Assemble.

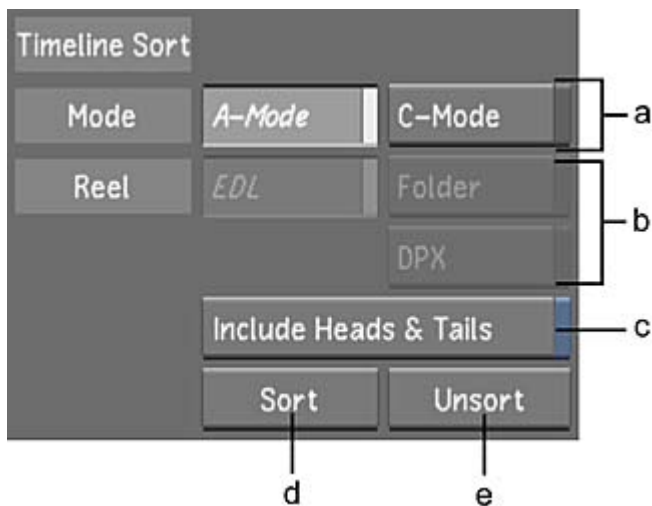

The Timeline Sort section appears.

(a) Timeline Sort mode buttons

The Timeline Sort section is made up of the following buttons.

(a) Sort mode options (b) Reel options (c) Heads & Tails button (d) Sort button (e) Unsort button

**A-Mode button** When enabled, this sorts either the entire timeline or selected shots by the order of the shots in the sequence. If you have a multi-layer timeline, the shots are organized by their time location in the sequence. See [Sorting with A-Mode](#) (page 2034).

**C-Mode button** This mode sorts either the entire timeline or the selected shots by the reel name and the source timecode. The Reel options (e.g., EDL, Folder, and digital picture exchange (DPX)) are only available for a C-mode sort. See [Sorting with C-Mode](#) (page 2036).

**EDL button** The EDL option sorts the shots by the EDL reel name (in ascending alphanumerical order) and by source timecode.

**Folder button** This option sorts the shots according to the folder name (or directory if you are using Linux) your scans or footage are saved into and by source timecode.

**DPX button** Shots are sorted by DPX reel name and source timecode.

**Include Heads & Tails button** When enabled, the sorted shots' heads and tails portions are expanded to let you see and work on the entire shot. It also allows you to work on other parameters (e.g., animation, tracking feature, etc.) without disturbing the initial edits (such as dissolves). This option is available for both A-mode and C-mode and is disabled by default.

**Sort button** Once a sort mode, a reel option (if applicable), and the heads and tails option have been selected, click Sort to organize your shots according to those criteria. The editing tools are disabled and a green border appears around the timeline canvas.

**Unsort button** Click Unsort to return the timeline back to its original sequence. The editing tools are enabled.

## Sorting with A-Mode

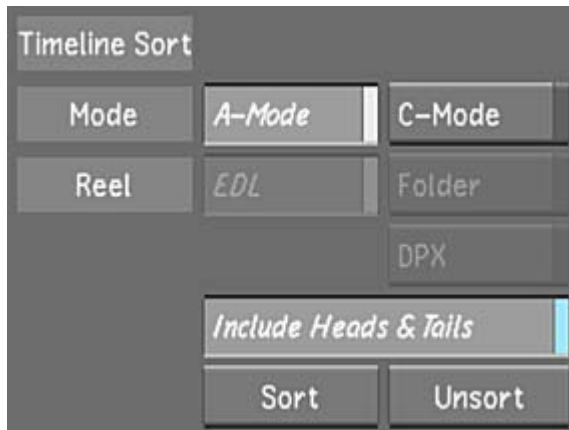

When you use A-mode to sort your timeline, your shots are organized according to their time location within the sequence (i.e., the record timecode). The shots are displayed one after another on a single layer and any dissolves and retimes are not displayed.

**To sort the shots using A-mode sort:**

- 1 Click Editing and then click Assemble to display the Timeline Sort section.
- 2 Select the shots you want to sort. If you want to sort the entire timeline, you do not need to select any shots.

- 3 Enable the A-Mode button and choose whether you want the head and tail frames to be exposed.

**NOTE** If any of your shots have a retime value with heads and tails, the Retrim button (in the Edit menu) must be enabled so the sort function can calculate the handles properly.

- 4 Click Sort.

The shots are now sorted by the record timecode. A green border appears around the timeline canvas to indicate that you are working in a sorted timeline.

**NOTE** You cannot do any editorial work or delete and add shots while you are in the sorting mode. As well, undo actions are disabled.

Once you have completed grading the shots, you can do one of the following:

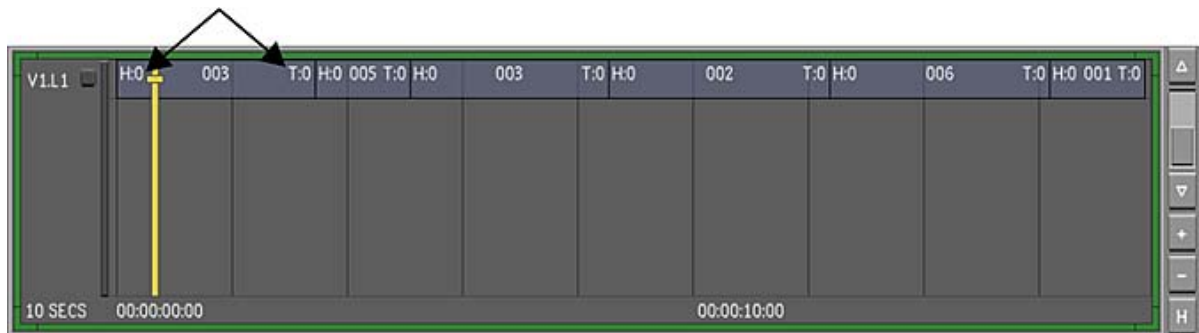

- Create a new cut list with the sorted shots. See [Creating a New Cut](#) (page 1819).
- Render the sorted shots. See [Rendering Shots](#) (page 2259).
- Play out the sorted shots to a VTR. See [Playing Out to a VTR](#) (page 2321) and [Writing Telecine-Style Tape](#) (page 2331).
- Return the sorted shots to their original order.

**To return the sorted shots to their original order:**

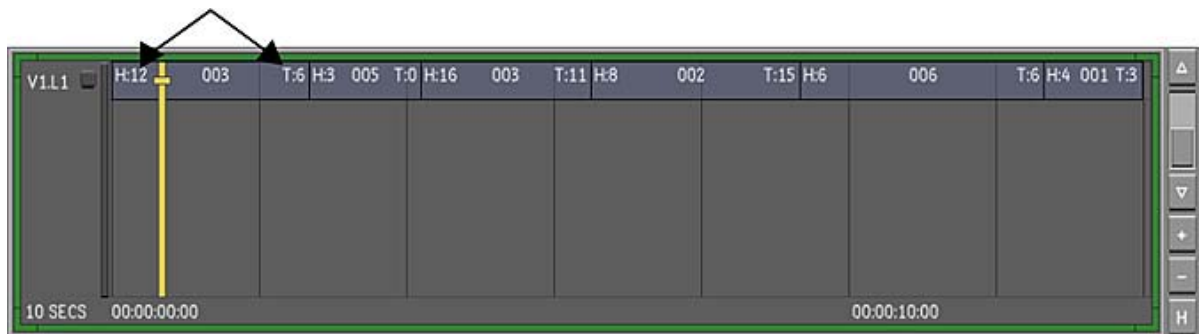

- 1 Do one of the following:
  - Click Unsort.
  - Press **Alt+F8**.

## A-Mode Sort Using Hotkeys

You can also sort the shots, without accessing the Assemble menu, by using hotkeys. Press **Alt+F9** to sort the shots in A-mode and enable the heads and tails. The heads and tails are showing 0 (zero) so you can work on every single frame within the shot.

Press **Alt+F10** to sort the shots in A-mode and for head and tail frames to remain unexposed (disabled).

## Sorting with C-Mode

When you sort the timeline with C-mode, you are organizing the shots based on the reel name and the source timecode. If the shot does not have a reel/folder name, then the source timecode is used for sorting. The shots are displayed one after another on a single layer and dissolves and retimes are not displayed. You can choose to have your timeline sorted by EDL reel name, folder name, or DPX reel name.

You want to sort the shots by EDL if you are working with a cut that has been assembled from an EDL, or a cut that is based on a Wiretap EDL. When you sort the timeline using the EDL option, the shots are arranged by the EDL reel name in alphanumerical order (numerical before alphabetical), and then by source timecode in ascending order (e.g., from 00:00:00:00 to 23:59:59:29). This data is read from the cut file EDLReelName XML tag.

If you are sorting the timeline with the Folder option, the shots are arranged in alphanumerical order (numerical before alphabetical) by the folder or directory name where you are storing your scans or captured footage (see [Recommended Directory Structure for Projects](#) (page 1780)). You can view the folder name in the file browser. This data is retrieved from the cut file AliasName XML tag. This tag is based on the name of the reel folder or directory when you are working with imported scans or captured footage.

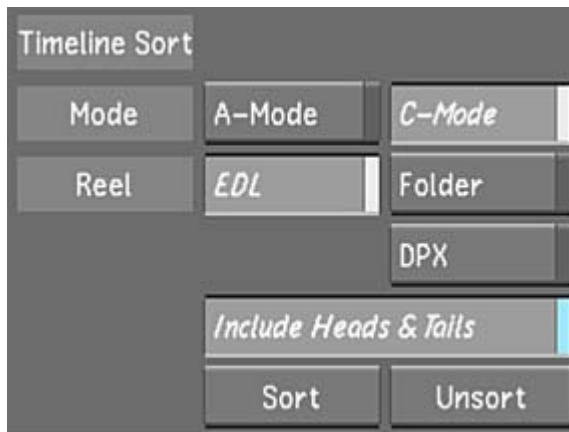

Lastly, you can sort the timeline of DPX files by their reel name. This data is read from the XML tag DPXReelName within the cut file. This XML tag is based on the data in the DPX header of the imported film scans. For more information on XML tags, see [XML in Lustre](#) (page 2409).

**To sort the shots using C-mode sort:**

- 1 Click Editing and then click Assemble to display the Timeline Sort section.
- 2 Select the shots you want to sort. If you want to sort the entire timeline, you do not need to select any shots.

- 3 Enable the C-Mode button, choose a Reel option, and choose whether you want the head and tail frames to be exposed.

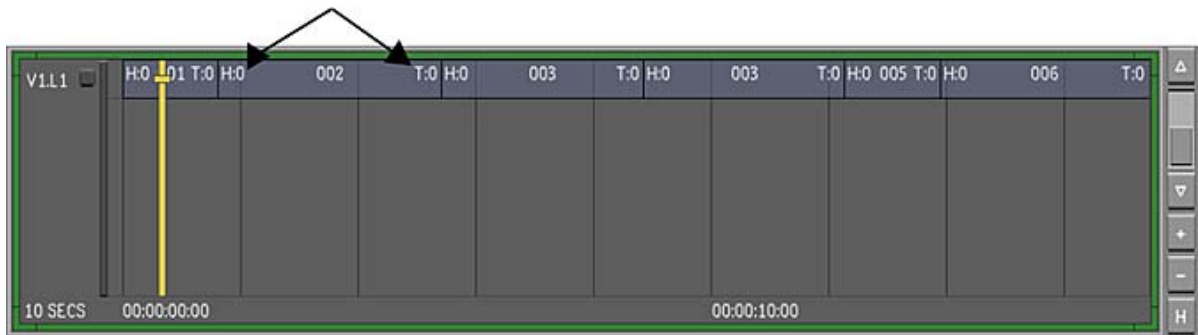

**NOTE** If any of your shots have a retime value with heads and tails, the Retrim button (in the Edit menu) must be enabled so the sort function can calculate the handles properly.

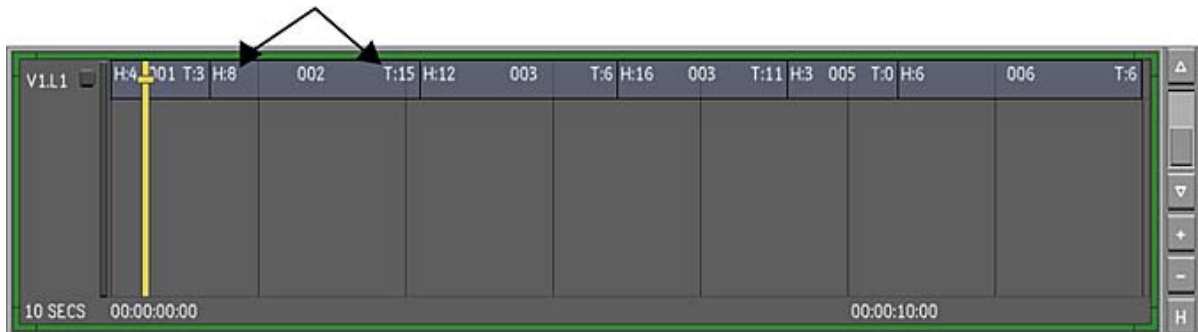

- 4 Click Sort.  
The shots are now sorted according to your criteria. A green border appears around the timeline canvas to indicate that you are working in a sorted timeline.

**NOTE** You cannot do any editorial work or delete and add shots while you are in the sorting mode. As well, undo actions are disabled.

The following image is a C-mode sort using the EDL option with heads and tails enabled. The heads and tails are showing 0 (zero), so you can work on every single frame within the shot.

This image shows the timeline being sorted by the C-mode EDL option and the heads and tails are disabled.

Once you have completed grading the shots, you can do one of the following:

- Create a new cut list with the sorted shots. See [Creating a New Cut](#) (page 1819).
- Render the sorted shots. See [Rendering Shots](#) (page 2259).
- Play out the sorted shots to a VTR. See [Playing Out to a VTR](#) (page 2321) and [Writing Telecine-Style Tape](#) (page 2331).
- Return the sorted shots to their original order.

**To return the sorted shots to the original EDL:**

- 1 Do one of the following:
  - Click Unsort.
  - Press **Alt+F8**.

### C-Mode Sort Using Hotkeys

You can also sort the shots without accessing the Assemble menu. You can sort the shots by using the hotkeys.

| Press:       | To:                                                                            |
|--------------|--------------------------------------------------------------------------------|
| Alt+F11      | Sort the timeline in C-mode by EDL reel name and heads and tails are enabled.  |
| Alt+F12      | Sort the timeline in C-mode by EDL reel name and heads and tails are disabled. |
| Ctrl+Alt+F11 | Sort the timeline in C-mode by folder name and heads and tails are enabled.    |
| Ctrl+Alt+F12 | Sort the timeline in C-mode by folder name and heads and tails are disabled.   |

| Press:             | To:                                                                            |
|--------------------|--------------------------------------------------------------------------------|
| Ctrl+Alt+Shift+F11 | Sort the timeline in C-mode by DPX reel name and heads and tails are enabled.  |
| Ctrl+Alt+Shift+F12 | Sort the timeline in C-mode by DPX reel name and heads and tails are disabled. |

# Caching Frames to Memory for Real-Time Playback

After applying many effects to a shot, you may no longer get real-time playback. To play shots with many effects in real time, you can render and temporarily cache the rendered frames into memory.

You can also navigate through shots with the control surface.

**NOTE** You can also obtain real-time playback by first rendering the shot from the Render Local menu, or with background rendering, and then using the P view mode to play the shot. See [Rendering](#) (page 2258) and [Setting the View Mode](#) (page 2016).

To view shots in real time with memory caching:

- 1 Go to the frame where you want to start viewing in real time.
- 2 Specify looped playback of the current shot, the entire Storyboard, or between in and out points by clicking the Play Mode button. See [Playing Shots](#) (page 2011).
- 3 Enable Cache.

The application renders the current frame and caches the result in memory. It continues forward through the shot or cut (depending on the state of the Play Mode button), caching each frame to memory.

- 4 Click the Stop playback control at the frame where you want to stop caching. Otherwise, caching continues to the end of the shot or cut and then looped playback starts.
- 5 If you stopped caching, press the Play control to start looped real-time playback of the cached frames.
- 6 Use the playback controls to view the cached frames as needed, keeping the Cache button enabled. The cached frames remain in memory until you disable Cache.
- 7 When you have finished viewing the cut, disable Cache by clicking it again or press N to disable memory caching.

# Player Hotkeys

Following is a list of hotkeys and mouse gestures commonly used in the Player and the full-screen Player.

| Press: | To:                             |
|--------|---------------------------------|
| Enter  | Toggle full-screen Player mode. |

| Press:                                   | To:                                                                                                                                                |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| Spacebar                                 | Start or stop playback in the direction last played.                                                                                               |
| Up Arrow                                 | Start forward playback.                                                                                                                            |
| Down Arrow                               | Start backward playback.                                                                                                                           |
| Right Ctrl (right hand side of keyboard) | Frame step forward.                                                                                                                                |
| Right Alt (right hand side of keyboard)  | Frame step backward.                                                                                                                               |
| Shift+I                                  | Mark an in point for loop play.                                                                                                                    |
| Shift+O                                  | Mark an out point for loop play.                                                                                                                   |
| Shift+L                                  | Clear in and out points.                                                                                                                           |
| . (decimal point on the numeric keypad)  | Toggle through play modes (loop timeline, loop shot, and loop in and out points).                                                                  |
| Shift+Spacebar                           | Switch to P (Print) view mode, open the full-screen Player and start playback.                                                                     |
| Middle mouse button and drag             | Pan the image.                                                                                                                                     |
| Middle and right mouse buttons and drag  | Zoom into or out of the image.                                                                                                                     |
| F1                                       | Display the current frame on Playhead A.                                                                                                           |
| F2                                       | Display the current frame on Playhead B.                                                                                                           |
| F5                                       | Toggle between the current view and Single View.                                                                                                   |
| F3                                       | Cycle between Single View, Dual View and Multi View.                                                                                               |
| F4                                       | Activate Dual View. In Dual View, cycle between Dual View options.                                                                                 |
| F6                                       | Update multi-view with the new selection.                                                                                                          |
| F7                                       | Display the Timeline, Player, grading tools, and whichever keyer (HLS or Diamond) is enabled. Also activate the SDI out if the GFX SDI is enabled. |
| F9                                       | Toggle between full- and half-resolution in the Player.                                                                                            |
| Tab                                      | Display and hide the Storyboard.                                                                                                                   |
| Q                                        | Toggle between regular and large Storyboard view.                                                                                                  |

| Press: | To:                                                                     |
|--------|-------------------------------------------------------------------------|
| M      | Enable memory caching.                                                  |
| N      | Disable memory caching.                                                 |
| Alt+1  | Display R, G, and B colour channels separately in the waveform monitor. |
| Alt+2  | Display the histogram.                                                  |
| Alt+3  | Display R, G, and B colour channels together in the waveform monitor.   |
| Alt+4  | Display the vectorscope.                                                |

## Removing Dust

Use the Dust Removal tools in Lustre to remove dust, hair, speckles, and other artefacts on your shots. Lustre removes artefacts for you by cloning pixels over them. The cloned pixels may come from the identical location on the previous and next frames, or from the area surrounding the artefact on the current frame, depending on the repair method that you use. You can locate artefacts on each frame yourself, or use an automatic method of artefact detection over one or more shots.

Dust removal can be done at any time in the project workflow. Also, you can do more than one dust removal pass on the footage. For example, you may choose to perform the main dust removal early on in the project, render the results, and then do a final pass (quality check) after all colour grading is complete.

You can perform dust removal on the original 2K shots or on 1K generated proxies. Working on the 2K version may provide more accurate removal. However, the process will be completed more quickly when using 1K proxies, particularly in the case of automatic removal.

Dust metadata is saved independently of the colour grading data, in a text file stored with the footage. This makes it possible to remove dust on one system while grading on another. You can then combine the metadata into one completed project. Dust removal is non-destructive to the original footage. If you decide to replace the original footage with cleaned up frames, a copy of the original frame is saved and given a unique name. This file can be restored if needed.

## Preparing for Dust Removal

Before removing dust artefacts from your shots, there are several things you should do:

- Identify the best repair type for your footage.
- Determine if you should be using the manual or automated method.
- Optimize the dust removal options for the characteristics of your shots.

## Deciding on a Repair Type

To remove artefacts, you can use either the Motion Estimation or Single Frame repair type.

With Motion Estimation, Lustre looks for colour differences between the current frame, the previous frame, and the next frame within a specified area, and differentiates between motion in the shot and artefacts using

motion estimation calculations based on a specified search area. Large search areas are needed for shots with fast motion since the colour differences between frames will span a larger area than would be required for shots with slower motion. If a colour difference is found between adjacent frames, and is not identified as motion in the shot, it is assumed to be dust. To remove an artefact, Lustre creates a mask for it using a calculation that uses the pixel values on the previous and next frames at the identical location as the artefact.

The Single Frame repair type removes artefacts by cloning pixels adjacent to the artefact on the current frame rather than using pixel values from the previous and next frames.

Generally speaking, the Motion Estimation repair type does a better job than Single Frame, and it should be used when possible. Try Single Frame if the characteristics of the shot or the artefacts prevent the Motion Estimation repair type from successfully identifying and removing artefacts. For example, you will need to use Single Repair if an artefact appears on more than one frame.

## Deciding on Manual or Automated Dust Removal

There are two methods you can use to remove artefacts—manual or automated. With the manual method, you visually identify artefacts frame by frame and specify the area where you want to apply a mask by drawing boxes around them as you go along. With the automated method, Lustre searches for artefacts and creates the boxes automatically, based on search criteria that you specify.

These methods of dust removal only apply to motion estimation.

The method you choose depends on the nature of your footage—how much dust is on it and the complexity of the motion in it. Automatic removal is faster, but you may experience problems with it if the footage has a lot of fast motion or highlights in the motion or elsewhere in the footage. In this kind of footage, the automatic method may mistakenly identify motion as dust, and the clean up job afterwards may be more effort than using manual removal. As a general rule, choose manual removal for footage with complex motion and little dust (most normal feature work), and automatic removal for footage with less motion and large amounts of dust.

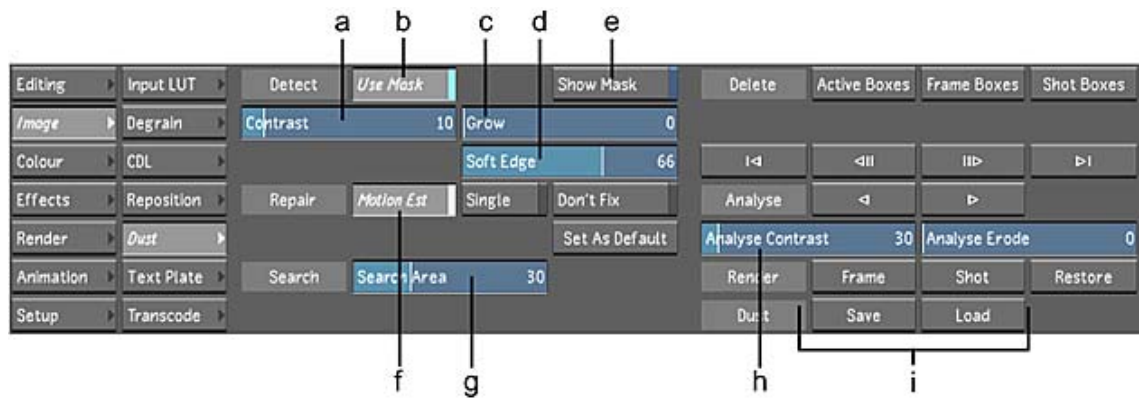

## Optimizing Dust Detection

For most shots, when you set dust removal parameters for one dust artefact, the settings will work well for other artefacts in the shot. Prior to removing dust either manually or automatically, set parameters in the Dust menu to the best settings for the amount of motion and the colour composition of your shot. When the settings are optimized, save them as default settings so they will be applied to all newly created mask boxes.

The optimization settings apply only to dust removal methods that are based on motion estimation.

**To optimize dust removal settings:**

- 1 In the Main menu, click Image.
- 2 Click Dust.  
The Dust menu appears.

(a) Contrast field (b) Use Mask button (c) Grow field (d) Soft Edge field (e) Show Mask button (f) Motion Estimation button (g) Search Area field (h) Analyse Contrast slider (i) Dust Save and Load buttons

### 3 Enable Use Mask.

Lustre will create masks for any artefacts it finds inside dust removal boxes, based on the Contrast and Grow parameters.

### 4 Enable Motion Estimation.

This repair type uses a motion estimation calculation to identify motion in successive frames.

### 5 Set the Search Area.

This parameter controls the size of the area (in pixels) around each pixel in which the motion estimation calculation searches for motion. This enables Lustre to differentiate between motion in the shot and dust artefacts. Estimate the approximate search area required for the amount of motion-caused colour displacement between frames. Set a large area for shots with fast motion, and a small area for shots with slower motion.

**NOTE** If the area set is too small for the speed of the motion, the calculation may mistakenly define colour value differences between frames caused by motion as dust artefacts. However, larger search areas take longer to analyse.

### 6 Adjust the Analyse Contrast slider to set the amount of contrast used to find dust during automatic analysis.

Low contrast values cause the algorithm to accept low colour value differences between corresponding pixels on the current, previous, and next frames. Therefore, low values result in more complete removal of the artefact. However, if the contrast is set lower than actually needed, adjacent pixels are modified more than actually required to remove the dust.

### 7 On the shot you are working on, find a frame containing an artefact that is typical of the artefacts on the footage. Use the Next Frame and Previous Frame buttons or **Ctrl** and **Alt** hotkeys to move forward and backward through the shot.

Zoom in closely on a dust artefact by pressing the middle and right mouse buttons and dragging on the image. You should be close enough to see pixels.

### 8 Draw a box around the dust artefact by dragging the cursor diagonally across the artefact and then releasing the cursor. Surround the artefact closely, but make the box large enough to leave a radius of 5 to 10 pixels around the artefact. See [Working with Boxes](#) (page 2047).

The artefact is repaired according to the current settings. It should be fainter or have disappeared completely.

### 9 Enable Show Mask.

Red pixels identify those areas affected by the removal process.

### 10 Adjust the Contrast value.

Low values result in more complete removal of the artefact. However, if the contrast is set lower than actually needed, adjacent pixels are modified more than actually required to remove the dust. Increase (or decrease) the Contrast value until right before the dust starts to reappear.

- 11 Adjust the Grow parameter and the Soft Edge parameter until the red pixels exactly cover the dust particle.

The Grow parameter controls the number of pixels around the pixels detected by Lustre. The Soft Edge parameter softens the stroke of the pixels specified by the Grow parameter in order to replicate a natural paint stroke.

- 12 Turn off Show Mask.

- 13 Click Set As Default.

The values you just set for all parameters are now default values that will be applied to any new box created either manually or automatically.

You have now set Dust Removal parameters to their optimum values for the shot and you are now ready to remove dust from the rest of the shot using either the manual or automatic method.

## Removing Dust Manually

To remove dust manually, you scan each frame visually for dust artefacts and draw boxes around any artefacts that you find.

**To remove dust manually:**

- 1 Follow all steps in [Preparing for Dust Removal](#) (page 2041).
- 2 Go to the first frame of the shot where you want to find and remove dust.
- 3 On the image window, drag a box around each dust artefact that you find. Make the box as small as possible—to just surround the dust and leave five to ten pixels of space around the artefact. This reduces the portion of the image that is affected by the removal process. See [Working with Boxes](#) (page 2047).
- 4 If needed, tweak the Contrast, Grow, and Soft Edge parameters. Enable or disable Show Mask as needed. Any changes you make are applied only to the artefact in the currently selected box.
- 5 Go to the next frame and check for artefacts, removing them as needed.
- 6 Continue the process frame by frame until the shot is cleared of artefacts.
- 7 If you are unable to successfully remove any artefacts, see [Single Frame Dust Removal](#) (page 2046).

## Removing Dust Automatically

You can have Lustre automatically remove dust from each frame in the sequence by analysing the frames based on specified parameter values. Once the analysis is complete, you will need to verify that each box created is around a legitimate dust artefact, and you may need to tweak the settings for some boxes.

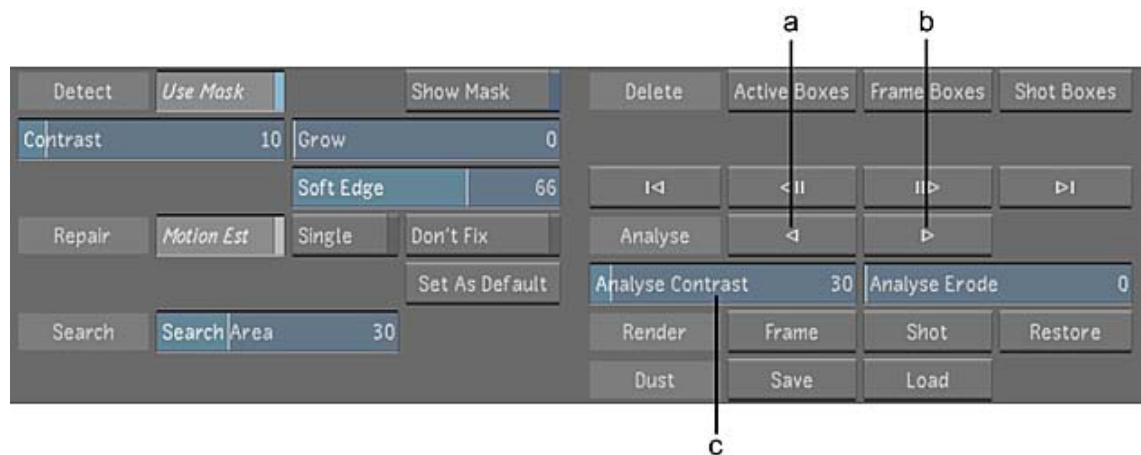

## Analysing the Cut

Analysis starts at the current frame and continues from shot to shot until you stop it. You can analyse forward or backward through the cut.

**To analyse a cut:**

- 1 Optimize dust removal settings. See [Optimizing Dust Detection](#) (page 2042).

- 2 Go to the frame where you want to start analysing.
- 3 Adjust the Analyse Contrast slider as needed.

(a) Backward Analyse button (b) Forward Analyse button (c) Analyse Contrast slider

Low contrast values cause the algorithm to accept low colour value differences between corresponding pixels on the current, previous, and next frames. Therefore, low values result in more complete removal of the artefact. However, if the contrast is set lower than actually needed, adjacent pixels are modified more than actually required to remove the dust.

- 4 Click the Forward Analyse or Backward Analyse button.  
Lustre searches each frame for artefacts based on the parameters you set. It places an active box around each one it encounters and removes the artefact.

#### To stop the analysis:

- 1 Click anywhere in the grey area of the menu.  
Lustre finishes analysing the frame currently being analysed then stops.

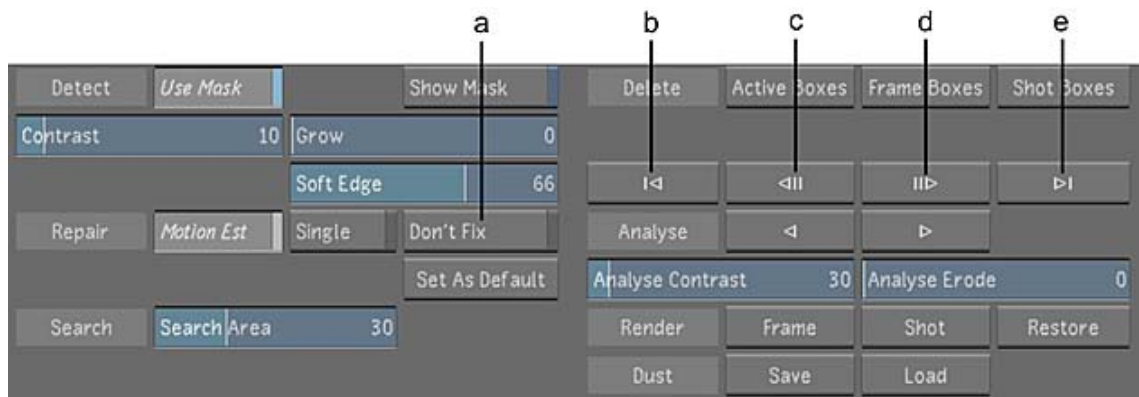

## Post-Analysis Clean-Up

Verify the analysis and tweak the results if needed. You can delete any boxes that are not surrounding legitimate artefacts. You can also tweak the contrast setting on individual boxes if needed.

**TIP** If many boxes were created as a result of motion in the shot rather than dust particles, click Shot boxes to delete all boxes, increase the search area, click Set as Default again, and re-analyse the shot. You may need to experiment a bit to find the best value.

#### To tweak the analysis:

- 1 Visually scan the first analysed frame.  
**TIP** To jump to the first or last frame in a shot where an artefact has been identified, use the First Analysed Frame button or the Last Analysed Frame button.
- 2 If you see a box that is not surrounding an artefact, or that you want to tweak, click inside it to select it.  
It becomes the only active box on the frame.  
**TIP** Click the Previous and Next Box buttons to move from box to box.

**(a) Don't Fix button (b) First Analysed Frame button (c) Previous Box button (d) Next Box button (e) Last Analysed Frame button**

- 3 If you need to see what has been removed, click Don't Fix. This shows you the contents of the box with no removal applied. If the artefact is genuine, click Motion Est again to reapply the Motion Estimation repair type.
- 4 Do one of the following as needed:
  - If the removed object is not an artefact, delete the box by clicking the Active boxes button.
  - If the object is an artefact but is not removed properly, tweak the Contrast, Grow and Soft Edge parameters. Enable or disable Show Mask as needed. When Show Mask is on, red pixels identify those areas affected by the removal process. Any changes you make are applied only to the artefact in the currently selected box.
- 5 If you are still unable to successfully remove the artefact, see [Single Frame Dust Removal](#) (page 2046).

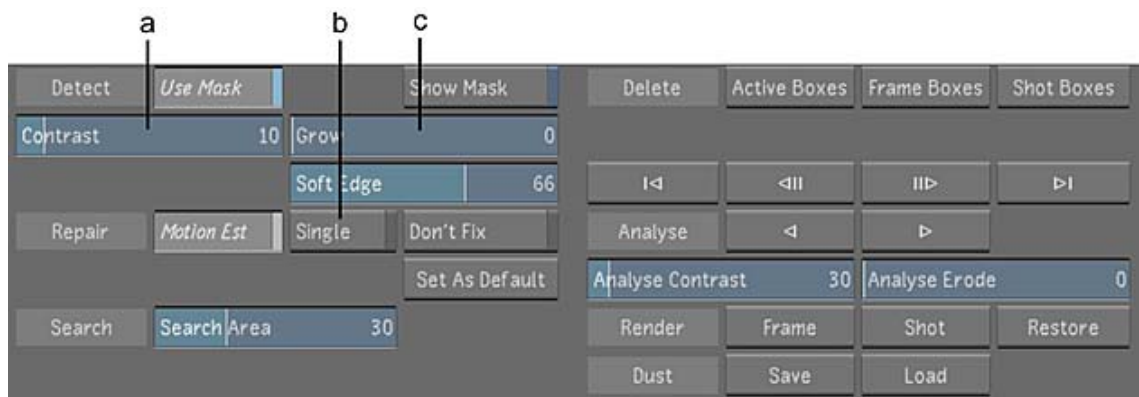

## Single Frame Dust Removal

In some cases, for example, when a dust artefact occurs in an area of very fast motion, the Motion Estimation repair cannot remove a dust artefact. When this happens, you have two methods you can use to remove the artefact. You can simply instruct the system to repair the entire contents of a box, or you can use a Single Frame repair to clone pixels in the area surrounding the problem.

If neither of these work, you can flag the artefact for later removal with the Can't Fix repair type. When you set a box to Can't Fix, no dust removal process is applied to the particle, and the x and y co-ordinates of the box are saved with the dust removal metadata. The removal of the artefact can then be performed using other methods. For example, a simple script could be written that would list the frames with "Don't Fix" boxes on them, and then send the files to a paint program.

### To fix problem dust artefacts:

- 1 In the Main menu, click Image, and then click Dust to display the Dust menu.
- 2 Select the box surrounding the problem artefact.  
All other active boxes on the frame are deselected.
- 3 Turn off Use Mask.  
If the artefact is still visible, turn on Use Mask again and continue to step 4.
- 4 Click Single.

**(a) Contrast field (b) Single button (c) Grow field**

The box border changes from blue to green, indicating the applied Single Frame repair type.

- 5 Set the Contrast, Grow, and Soft Edge parameters to the optimum values. Use Show Mask as needed.

- 6 (Optional) If the artefact is still visible, set the repair type to Don't Fix.

The box border changes to red, indicating the applied Don't Fix repair type.

**TIP** To navigate between boxes set to Don't Fix, right-click the Previous and Next Box buttons.

## Working with Boxes

Whether you choose the manual or automatic method of identifying dust artefacts, you will probably need to adjust the position or size of some boxes, or delete them. Following are basic procedures for working with boxes.

**(a) Vertex (b) Border**

**To create a box:**

- 1 Hold down the left mouse button and drag the cursor diagonally on the image.
- 2 Release the mouse button.

**To select a box:**

- 1 Click inside the box.

The box vertices turn yellow, indicating the box is active (selected). You can only select one box at a time.

**To de-select a box:**

- 1 Right-click inside the box.

**To move a box:**

- 1 Click inside the box and drag it.

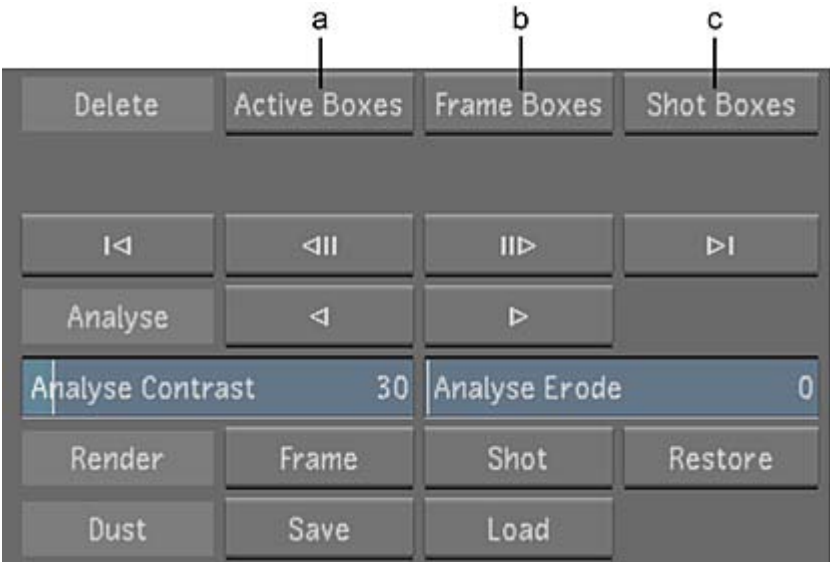

**To re-size a box:**

- 1 Click on a vertex and drag.

**To delete one or more boxes:**

- 1 Do one of the following.

| To delete:                                            | Do this:                                                                          |
|-------------------------------------------------------|-----------------------------------------------------------------------------------|
| The single active box                                 | Select the box and press <code>Backspace</code> or click the Active boxes button. |
| All boxes on the current frame, whether active or not | Click the Frame boxes button.                                                     |
| All boxes on all frames in the current shot           | Click the Shot boxes button.                                                      |

(a) Active boxes button (b) Frame boxes button (c) Shot boxes button

## Infrared Channel Dust Detection

The infrared (IR) channel is available in DPX and Cineon 10-bit files that contain the SGI byte order. This IR channel is collected during the film scanning process at the same time as the visible colour channels (red, green, and blue). Whereas film is mostly transparent to infrared radiation, dust and scratches are not and

therefore appear in the IR channel. Once imported into Lustre, the information contained in the IR channel can be used to detect the appearance of dust and scratches to a higher degree than is possible using standard dust detection techniques.

---

**NOTE** IR dust detection is only available for the Master Station and the Lustre Station.

---

**To perform IR dust detection:**

- 1 With the clip loaded on the timeline, click the Analyse forward button while holding down **Ctrl**.  
The IR dust analysis begins, and boxes are placed around detected problems.
- 2 To reduce the amount of boxes that appear, increase the value in the Analyse Erode slider.

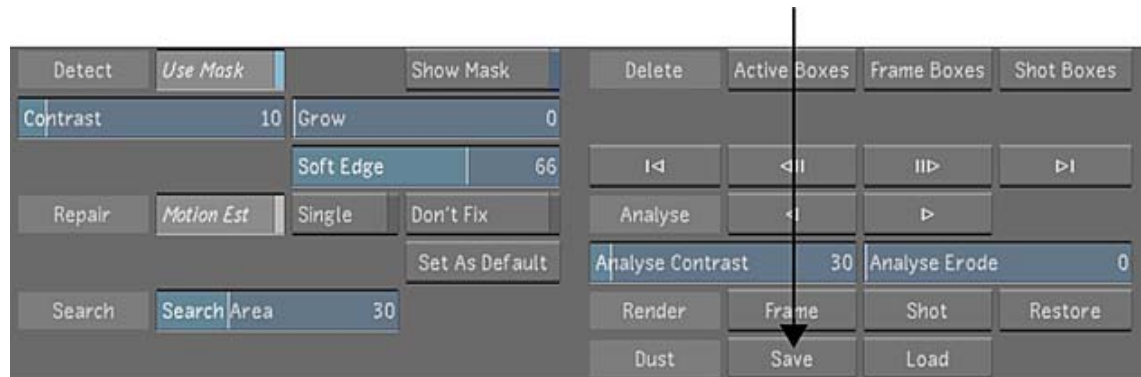

## Options for Saving and Loading Dust Removal Metadata

You can save dust removal metadata manually, or automatically when you save the grade. In either case, the metadata is not saved in the grade file itself, but rather as a separate file called *dustbust.data*, located in the same directory as the original footage. See [Loading Grades for a Cut](#) (page 1823).

When you save dust removal metadata manually, only the dust removal metadata is saved. If your timeline is long and has complex grading applied to it, saving dust metadata separately can save you time. You can also improve system performance by configuring Lustre to load grades without the corresponding dust removal metadata. If required, you can load the dust removal metadata later.

**To save dust removal metadata manually:**

- 1 In the Dust menu, click Save.

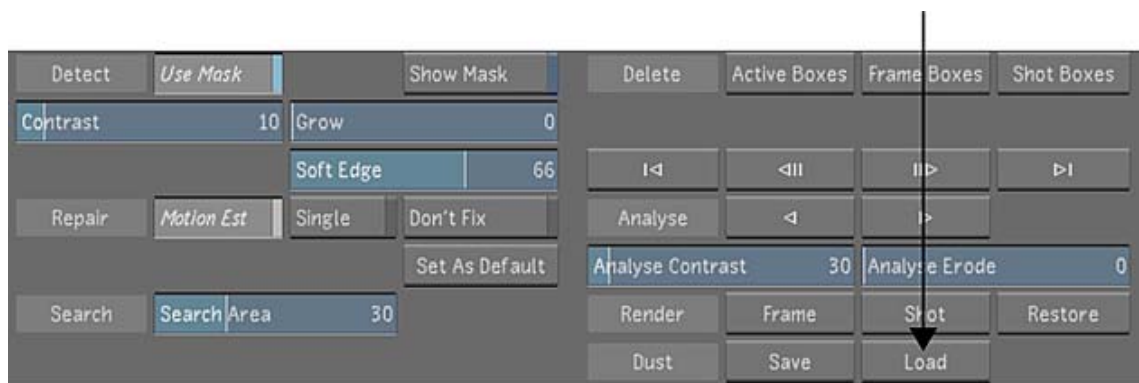

**To ensure that dust removal metadata is not automatically loaded with the grade:**

- 1 In the Setup > Settings menu, select Edit for the user settings.
- 2 In the Tools page, disable the Load Dust Data button.  
Disabling this button ensures that dust removal metadata is not automatically loaded when you load the grade. This can save you time if you need to load a grade and do not mind seeing artefacts on your footage.

**To load dust removal metadata after you have already loaded the grade:**

- 1 In the Dust menu, click Load.

## Rendering the Result

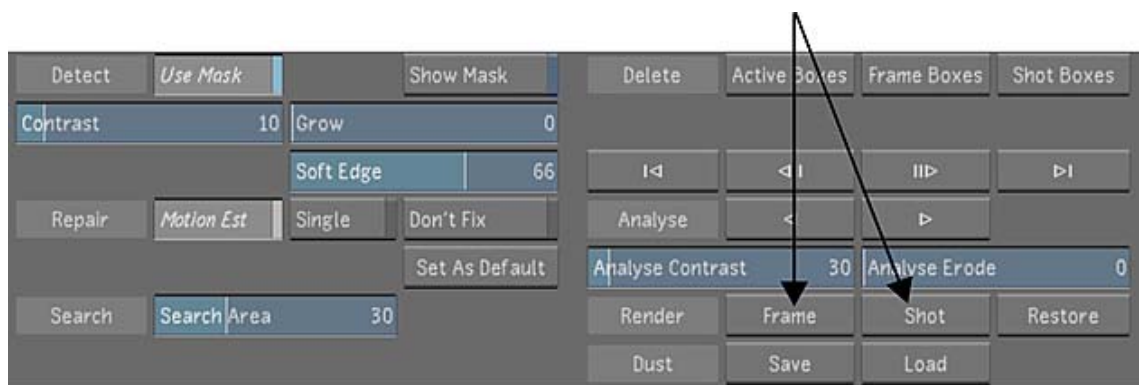

When you are satisfied with the dust removal results, you can render your material. Two rendering options are available depending on whether you render using the Render menu or the Dust menu:

- When you render from the Render menu, you have the option of turning dust metadata on or off. When dust metadata is on, you render dust removal changes made to the grade. Otherwise, dust removal is not included in the render files. Render files are created for the entire region selected for render and saved to a separate directory. See [Rendering Shots](#) (page 2259) and [Rendering Dust Metadata](#) (page 2266).
- When you render from the Dust menu, the render files replace the original files, and the originals are backed up to a sub-directory called *Original*. You can therefore work with dust-free frames while continuing to point to the original footage directories during the course of the project. You can render the current frame or the shot. Only those frames containing changes are rendered. If you change your mind and want to revert to the original shot, you can restore it.

**NOTE** When you render from the Dust menu, the rendered result is visible from all menus except the Dust menu. In this menu, boxes and their settings remain in place, giving you the option to tweak them further and re-render if needed.

### To render from the Dust menu:

- 1 Navigate to the shot containing frames you want to render.
- 2 Do one of the following:
  - To render the current frame, click Frame.
  - To render all frames in the shot that have been modified, click Shot.
  - To render the entire timeline, Shift-click the Shot button.

The frames are rendered.

**To restore the original shot:**

- 1 Navigate to the shot.
- 2 Click Restore and confirm by clicking it a second time.  
The entire rendered shot is replaced with the original.

**NOTE** The boxes are retained. Therefore, if you want to start from scratch, you must delete the boxes first.

## Removing Grain

Use the Degrain tool in Lustre to remove film grain, video noise, and other compression noise from your shots while minimizing damage to the image. Grain removal can be done at any time during the project workflow, but it is typical to perform an initial degrain operation on the source image before primary colour grading begins.

A recommended grain removal workflow consists of the following basic steps. You can view the result as you work. See [Viewing the Result](#) (page 2052).

| Step:                                                                                           | Refer to:                                                                                                    |
|-------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| 1. Define the degrain cache location.                                                           | <a href="#">Project Settings</a> (page 1784) and <a href="#">Rendering Settings</a> (page 1789).             |
| 2. Analyse the grain profile of the input image.                                                | <a href="#">Analysing the Frame</a> (page 2051).                                                             |
| 3. Perform post-analysis cleanup.                                                               | <a href="#">Post-Analysis Clean-Up</a> (page 2055).                                                          |
| 4. Cache the filtered images.                                                                   | <a href="#">Caching the Result</a> (page 2056).                                                              |
| 5. Apply input and secondary grading.                                                           | <a href="#">Primary Colour Grading</a> (page 2101) and <a href="#">Secondary Colour Grading</a> (page 2126). |
| 6. (Optional) Analyse the grain profile of secondaries to de-grain isolated parts of the image. | <a href="#">Removing Grain with Secondaries</a> (page 2058).                                                 |
| 7. Render the result.                                                                           | <a href="#">Rendering</a> (page 2258).                                                                       |

## Analysing the Frame

Before processing the grain filter, the image must be analysed. Use the Grain Analysis panel to perform an analysis on a selected frame. The grain profile for the shot is recalculated each time an analysis is performed. If you navigate to a different frame in the shot and analyze it, the grain profile will be based on the new data.

**NOTE** It is recommended that you perform an analysis on the entire image, then analyse multiple regions of the image, if required.

**To analyse the grain profile of an image:**

- 1 Navigate to the frame you want to analyse.
- 2 Do one of the following:
  - If you want to degrain the entire image, click Degrain in the Image menu.
  - If you want to degrain a region of interest, click Degrain in the Colour menu.
- 3 (Optional) Enable the Sub-Region Analysis button and define an area to analyse. For best results, define multiple regions of uniform colour with no features. See [Working with Sub-Region Boxes](#) (page 2053).
- 4 Click the Analyse button to determine the grain structure.

## Viewing the Result

After the frame is analysed, you can view the result of applying the degrain filter on all or a portion (sub-region) of the image. For increased performance, it is recommended that you select the sub-region where you want to view the filtered result.

**To apply the degrain filter:**

- 1 Navigate to the frame you want to view.
- 2 Do one of the following:
  - If you want to degrain the entire image, click Degrain in the Image menu.
  - If you want to degrain a region of interest, click Degrain in the Colour menu.
- 3 (Optional) Enable the Sub-Region Filtering button and drag to define an area to view with the result. See [Working with Sub-Region Boxes](#) (page 2053).

**NOTE** Unlike sub-region analysis boxes, the sub-region filtering box cannot be deleted, only disabled.

- 4 Enable the Apply Degrain button to view the filter on the image.

## Working with Sub-Region Boxes

To analyse specific regions of the image's grain structure, you need to use sub-region analysis boxes. If you are not satisfied with an analysis of the entire image, you can use sub-regions to constrain the analysis to focus on regions of interest. You will probably need to adjust the position or size of some boxes, or delete them. Following are basic procedures for working with boxes.

**(a) Vertex (b) Border**

### To create a box:

- 1 Enable Sub-Region Analysis.
- 2 Hold down the left mouse button and drag the cursor diagonally on the image.
- 3 Release the mouse button.

### To select a box:

- 1 Do one of the following:
  - Click inside the box.  
The current box is active and all other sub-region analysis boxes are inactive.
  - Right-click inside the box to change its state, without affecting the state of other sub-region analysis boxes.

The vertices of active boxes are yellow (selected). The vertices of inactive boxes are red (disabled).

### To move a box:

- 1 Click inside the box and drag it.

### To re-size a box:

- 1 Click on a vertex and drag.

### To display or hide boxes:

- 1 Press Z.

To delete one or more boxes:

**NOTE** The sub-region filtering box cannot be deleted, only disabled.

- 1 Do one of the following:
  - Press **Backspace** to delete all active boxes.
  - Using the Delete Boxes panel, do one of the following.

| Click: | To delete:                                             |
|--------|--------------------------------------------------------|
| Active | The currently selected box (highlighted in yellow).    |
| Frame  | All boxes on the current frame, whether active or not. |
| Shot   | All boxes on all frames in the current shot.           |

## Locating Sub-Region Analysis Boxes Within a Shot

Use the navigation buttons in the Reference panel to easily locate and navigate between shots that use sub-region boxes for de grain analysis.

To navigate between sub-region analysis boxes:

- 1 Click a button in the Reference panel.

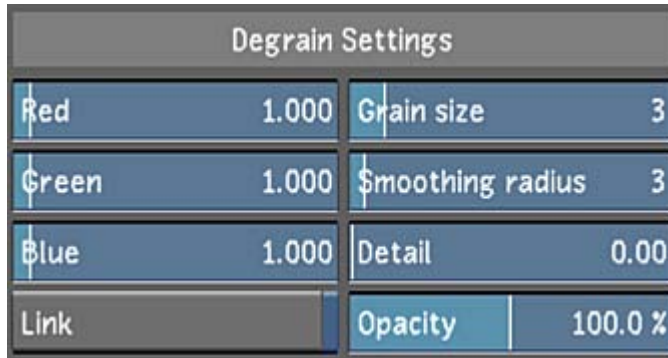

| Click:                                                                              | To display:                                                          |
|-------------------------------------------------------------------------------------|----------------------------------------------------------------------|
|  | The first frame in the shot that has a sub-region box.               |
|  | The previous frame in the shot that has a sub-region box.            |
|  | The reference frame on which the most recent analysis was performed. |
|  | The next frame in the shot that has a sub-region box.                |
|  | The last frame in the shot that has a sub-region box.                |

## Post-Analysis Clean-Up

Once you have analysed the grain profile, you can make adjustments to the profile. You can adjust spatial degrain parameters, or apply a temporal degrain that can include previous or subsequent frames in the shot. A curve is displayed for each colour channel. You can manually adjust a response curve for the gain of each colour channel in the Curve Editor.

### Adjusting Spatial Degrain Settings

You can fine-tune grain removal by changing the spatial degrain parameters in the Degrain Settings panel.

The Degrain Settings menu is made up of the following elements.

**Red slider** Sets the gain for red channel colour values.

**Green slider** Sets the gain for green channel colour values.

**Blue slider** Sets the gain for blue channel colour values. For film scans, the grain is often greater in this channel.

**Link button** Click to change gain values proportionally for all three colour channels.

**Grain Size slider** Sets a value in pixels that is proportional to the size of the grain. The default value is 3, but may be higher for 4K images.

**Smoothing Radius slider** Sets the blur radius. For smoother results, a higher value will add more pixels to the blur, but increase processing time.

**Detail slider** Sets the amount of detail to preserve when the Smoothing Radius is set to a high value. It is recommended you enter 0.05 to 0.15 as an initial value.

**Opacity slider** Sets the level of opacity between the source image and the output with the applied grain filter.

### Applying Temporal Degrain Settings

If you degrain the source image (using the Degrain menu in the Input menu), you can include temporal degrain operations to the grain filter, by comparing the pixel data in past or future frames. These options yield best results when frames include many static or slowly moving objects in the image. Temporal options will improve grain removal results, but it will also increase processing time.

---

**NOTE** When temporal options are used on cached images, the result must be re-cached.

---

**NOTE** Incinerator does not process temporal de grain. Render to view these results.

To use temporal de grain:

- 1 In the Temporal Options panel, enable one or both states.

| Enable: | To include pixel data from:               |
|---------|-------------------------------------------|
| Past    | Previous frames in temporal processing.   |
| Future  | Subsequent frames in temporal processing. |

## Adjusting the Response Curves

Response curves represent the noise intensity for each colour channel. Modify the red, green, or blue response curves to fine-tune the de grain. You can add vertices to a curve to refine your adjustments.

To modify the red, green, or blue curve:

- 1 To display the response curve, click Show Curves.
- 2 Show the response curve you want to modify by clicking the button corresponding to the colour of the curve.  
The selected curve is highlighted.
- 3 Sample the colour you want to use as a reference for your adjustments.  
Red, green, and blue vertical lines representing the colour channels are plotted on the curve.
- 4 Do one of the following:
  - To add a vertex to the curve, place the mouse cursor over the area on the curve where you want to add the vertex and press A.
  - To lock the curve in place while adding a vertex, press Shift+A on the curve.
- 5 Click a vertex to display its tangent handle and then drag the handle to adjust the curve. You can also adjust the curve by dragging the vertex.
- 6 Modify the curve until you are satisfied with the results:
  - To select a vertex, click it. To select several vertices, draw a selection box around them.
  - To move one or several selected vertices, drag a selected vertex. To restrict vertex movement to the Y axis, press Shift while moving the mouse. To restrict vertex movement to the X axis, press Shift+Alt while moving the mouse.
  - To delete vertices, select them and then press D.

## Caching the Result

De grain operations use caching of input images to manage the intensive processing requirements imposed on Lustre. If the Apply De grain button is enabled, a de grained shot is automatically cached when the shot

is initially played back after a Degrain operation. You can also use Lustre ShotReactor and Burn to cache frames. See [Caching Frames with Lustre ShotReactor or Burn](#) (page 2057).

The Degrain menu does not have to be visible for Lustre to continue caching frames.

You can cache the filtered frames created using the CPU. Once cached, Lustre can recall cached frames during future playback in both CPU processing and GPU acceleration mode. See [GPU Acceleration](#) (page 2086). (If any parameters are changed, GPU acceleration must be disabled and images must be reanalysed in CPU mode to update and re-cache the frames.)

When configuring your project in Lustre, you also define the location of cached frames using the project settings. Degrain frames can be cached in a sub-directory of the Scans folder or a user-defined degrain cache file location. See [Project Settings](#) (page 1784) and [Rendering Settings](#) (page 1789).

Only one instance of a frame can be cached in a shot, even if it is used in multiple cuts. If the cached media is saved as a preset, then you can load the cached media into the shot in a different cut. See [Saving and Loading Degrain Presets](#) (page 2059).

## Caching Frames from Wiretap

You can cache frames from media imported from Wiretap and Wiretap Gateway. Cached frames are saved in the user-defined location set in the Degrain Cache field found in Project settings. Media is saved in this location even if, in the Rendering menu, the Degrain File Location option box is set to Save with Scan.

Media that is soft-imported from Wiretap use source files that can be accessed using a file path structure, rather than a Wiretap or Wiretap Gateway address. As a result, soft-imported frames can be saved in Scans Home or the user-defined degrain cache location.

## Caching Frames with Lustre ShotReactor or Burn

You can use ShotReactor (locally or remotely) to cache frames in the background as you work, or Burn to submit a caching job.

---

**NOTE** Degrain frames cannot be cached using Incinerator.

---

If you want to cache remotely to a user-defined location, you must enter a BrowseD file path in the Degrain Cache field. See [Project Settings](#) (page 1784). For example, in Linux, a valid BrowseD file path can have the following structure: `<IP address>:/mnt/storage/<project_name>`. In Windows, it can be `<IP address>:\F:\storage\<project_name>`.

In Linux, to cache remotely using absolute file paths for a user-defined degrain cache location, you must create a shared NFS mount point on the ShotReactor server or Burn node. In Windows, you use a UNC path for the Windows Slave Rendering machine, or use a Samba path to create a mount point on a Burn node.

### To perform background caching using ShotReactor:

- 1 Display the ShotReactor menu. See [Rendering Shots as You Work](#) (page 2274).
- 2 In the ShotReactor panel, toggle the On/Off button to On.
- 3 In the Degrain Only panel, toggle the On/Off button to On.

When the Apply Degrain button is enabled in the Degrain menu, degrain frames are cached after you navigate to another shot.

---

**NOTE** To render degrain frames using ShotReactor, set the Degrain Only panel On/Off button to Off. Graded frames with Degrain will be rendered in the Renders Full Home destination.

---

### To cache using a Burn node:

- 1 Display the Burn menu. See [Submitting a Remote Render Job](#) (page 2277).
- 2 Enable the Degrain Only button.
- 3 Click Burn.

When the Apply Degrain button is enabled in the Degrain menu, the degreined frames are cached.

---

**NOTE** To render degreined frames using a Burn node, disable the Degrain Only button. Graded frames with Degrain will be rendered in the Renders Full Home destination.

---

## Clearing the Cache

You can clear the cached frames for the current shot or clear the *degrain\_cache* folder for the entire cut. The files that will be removed are dependent upon where you choose to save your files.

When degrain cache frames are saved in the Scans directory, the cache for the current shot in the Scans directory can be cleared. When degrain cache frames are saved in a user-defined location, all files stored at that location will be removed.

### To clear the cache for the current shot:

**NOTE** This operation only applies when degrain cache files are saved in the Scans directory.

- 1 In the Rendering menu of the project configuration settings, set the Degrain Cache File Location option box to Saved with Scan.
- 2 In the Image menu, click Degrain.
- 3 Navigate to the shot with the frames you want to clear.
- 4 Click Clear Cache.

### To clear the cache for the project:

**NOTE** This operation only applies when degrain cache files are saved in a user-defined location.

**WARNING** Lustre will delete all files stored in the user-defined location. This includes all degreined frames stored in this location for the entire project, even if it includes files from a different scene. It is strongly recommended that you store cached frames for different projects separately. See [Configuring File Locations in Project Home](#) (page 1781).

- 1 In the Rendering menu of the project configuration settings, set the Degrain Cache File Location option box to Saved with Degrain.
- 2 Do one of the following:
  - In the Image menu, click Degrain.
  - In the Project settings menu, click Rendering.
- 3 Click Clear Cache.

## Removing Grain with Secondaries

After you have applied degrain operations to the input image, you can isolate parts of the image to degrain using secondaries. Degrain operations are cumulative: after initial noise removal, multiple passes using secondaries on the same area will be added to the final result.

When applying a de grain filter to a secondary layer, you cannot use temporal options and cache degraded frames.

**To de grain a secondary layer:**

- 1 In the Colour menu, click Degrain.
- 2 Select a secondary layer. See [Secondary Colour Grading](#) (page 2126).
- 3 (Optional) Add a geometry to constrain the area of de grain analysis and filtering.
- 4 Click Analyse.
- 5 To view results, click Apply Degrain.

## Copying Degrain Information

You can copy all or a selection of the Degrain menu parameters from a shot using the Selector. These parameters include the option to have de grain enabled or disabled on the destination shots. See [Copying Parameters with the Selector](#) (page 1860).

## Saving and Loading Degrain Presets

Once you create a grain profile, you can save it as a preset and reload it for later use or in other shots. A preset saved for an input image can be loaded on a secondary, and vice versa.

See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

## Repositioning Images

Use the Reposition tools to reframe your shots. Generally, when you reframe a shot, you are adjusting the viewable area of your frames within a specified smaller area.

In a stereoscopic project, you may want to reposition images to realign shots for the Left Eye and Right Eye so that they converge correctly. See [Repositioning the Left Eye and Right Eye](#) (page 2251).

---

**NOTE** Support for repositioning depends on the version of the graphics card installed on your system. See your release notes for details.

---

For example, if you are shooting in a widescreen film format and you intend to project the finished film on a television, you have to make certain decisions about how to deliver the content. You can scale and letterbox the film frames, or you can reposition the images in such a way that the important subjects of the scene are visible on screen (at the expense of “unimportant” elements).

If you shot your film in 35mm, but you want to show it in a widescreen format, you will need to crop the frames and adjust the racking—or the vertical positioning—of the image to modify the image's composition.

With letterbox images, you are scaling down a widescreen frame to fit horizontally on a television screen. This process adds black bars across the top and bottom of the screen and reduces the size of the images. However, letterboxing has the advantage of showing the entire image, thus remaining true to the vision of the artists.

a

b

**(a) Original widescreen frame (b) Letterboxed frame**

When you reposition frames, the actual source images are larger than the viewable area. To compensate, you make adjustments to the pan and scan of the frames to emphasize the key elements of a scene. For example, if the original frames show two people facing each other and talking, you may pan back and forth to see the person who is talking. The other person would then be partially or even completely off screen.

a

b

c

**(a) Original widescreen frame (b) Cropped and repositioned frame (c) Final frame**

Use racking when you want to deliver your footage in a wider format than it was shot in. For example, when shooting on 35mm film, you may compose the scene so that the important elements of the image are contained in a narrow horizontal portion of the frame. In such a case, you set a cropping gate, and then adjust the vertical position (scan) of the shot in order to compose the scene as needed.

a

b

**(a) Original 35mm with racking on (b) Cropped frame**

Use the Reposition tools to animate the position, rotation, scaling, and aspect ratio of your shots. Do this, for example, to simulate camera movement, which is useful when you want to make a still shot more dynamic.

You can also use racking and repositioning in conjunction with tracking to stabilize shots with too much motion.

Finally, you can modify shot composition by flipping the shots vertically or flopping them horizontally.

**TIP** For real-time playback of repositioned shots, enable GPU processing by clicking the GPU button. See [GPU Acceleration](#) (page 2086).

## Adjusting the Frame Aspect Ratio

Before you begin repositioning your shots, make sure you have set the aspect ratio of the output frame. You adjust the aspect ratio when your source material was shot in a format that differs from the intended delivery format, for example, if you shot in 35mm film (1.33 aspect ratio), but will deliver in a widescreen-format aspect ratio of 1.85. Or, you may have shot in a widescreen format at a 2.35 aspect ratio but intend to output a format for television (1.33 aspect ratio). For information on adjusting the aspect ratio for a cut, see [Setting the Aspect Ratio](#) (page 1833).

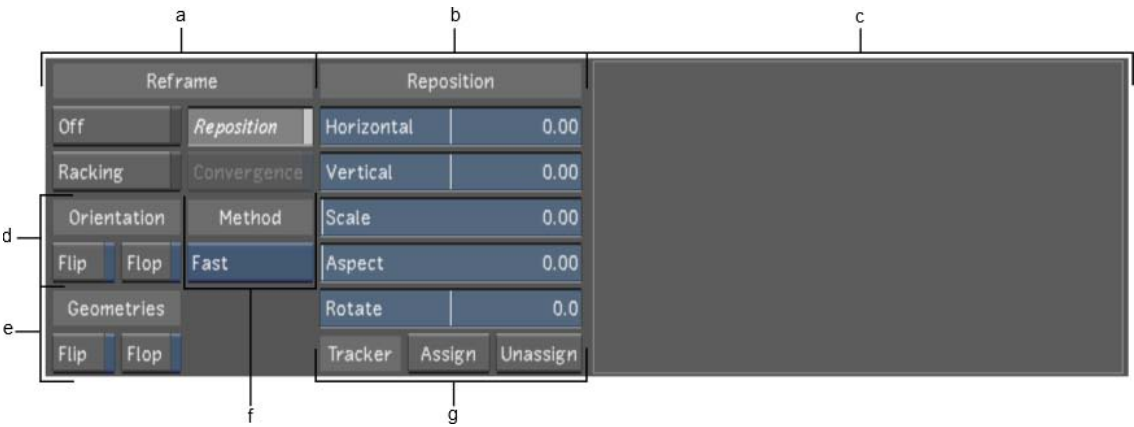

## Accessing the Reposition Menu

Once you select the shot you want to adjust or modify, you can access the Reposition menu. This menu provides the commands you need to reframe an image by:

- Repositioning
- Racking
- Changing the orientation
- Tracking a repositioned or racked shot

To access the Reposition menu:

- 1 Make sure you have set the aspect ratio to match the intended output format. See [Setting the Aspect Ratio](#) (page 1833).
- 2 Select the shot to adjust.
- 3 Click Image, and then click the Reposition menu button.  
The Reposition menu appears.

(a) Reframe panel (b) Reposition sliders (c) Preview window (d) Orientation panel (e) Geometries panel (f) Rendering Method box (g) Tracker Method panel

**Reframe panel** Enables a reframing tool to reposition, rack or converge an image. See [Reframing an Image](#) (page 2062).

**Reposition sliders** Adjust the position of the shot by changing its vertical or horizontal position, rescaling, changing its aspect ratio, rotating or a combination of these repositioning options. See [Repositioning an Image](#) (page 2063).

**Preview window** Displays the the relationship of the visible area (red rectangle) to the original image (blue rectangle). By default, the red reference rectangle is hidden by the blue one: they are equal in orientation and scale.

**Orientation panel** Displays the tools to apply a horizontal or vertical translation to the image. See [Flipping or Flopping a Shot](#) (page 2064).

**Geometries panel** Displays the tools to apply a horizontal or vertical translation to the geometries associated to a secondary, independently of the orientation of the image. See [Flipping or Flopping a Shot](#) (page 2064).

**Rendering Method box** Contains the rendering quality levels of the resulting repositioned image. See [Setting Rendering Quality](#) (page 2069).

**Tracker panel** Controls whether point tracking is enabled or disabled for a repositions image. See [Tracking Repositioned Shots](#) (page 2065).

## Reframing an Image

Depending on how the original film was shot, you may have to reframe your footage at some point to account for the final aspect ratio of the delivery format. It may also be necessary to use the reframe functions to output film frames to common SD formats or DVD.

To adjust the reframing of an image, you can:

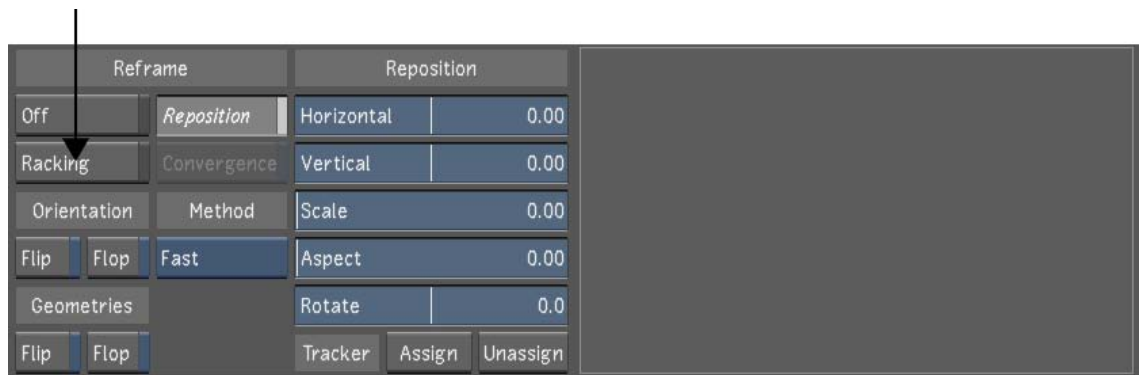

- Use racking to adjust vertical position only.
- Use repositioning to zoom and adjust the position.
- In a stereoscopic project, use convergence to reposition a shot in the assigned eye and apply the equal and opposite repositioning operation to the other eye. See [Repositioning the Left Eye and Right Eye](#) (page 2251).

## Racking an Image

Racking involves adjusting the vertical position of a shot. You need to rack your images after you adjust the aspect ratio. By racking, you ensure that the important element of the shot composition is framed correctly in the final images.

To adjust the racking of an image:

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Enable Racking.

- 3 Use the Vertical slider to adjust the vertical position of the image.
- 4 You can animate the vertical position using the Animation controls. See [Animating Reposition Values](#) (page 2067).

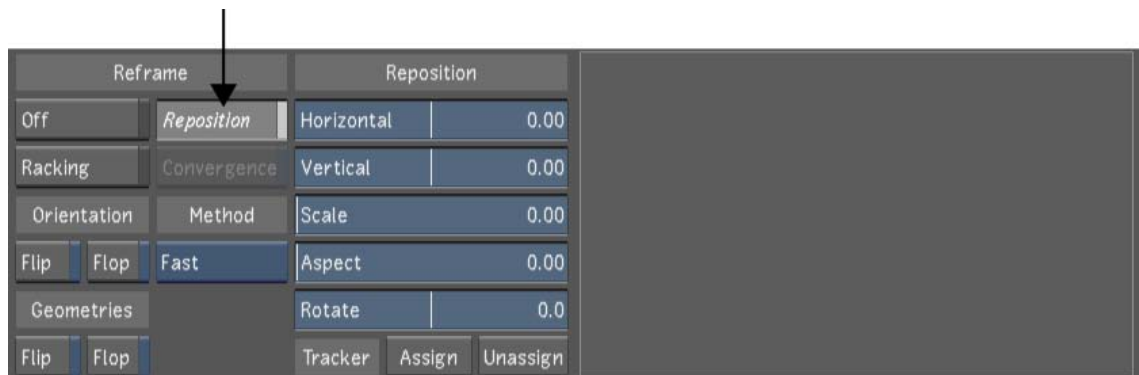

## Repositioning an Image

Repositioning involves scaling, rotating, and horizontally and vertically moving images to ensure that the correct elements are visible in the frame. You need to do this after adjusting the project aspect ratio. If you do not, key elements of the shot composition may be cropped or even completely off screen.

You can zoom into the image and offset the position in the horizontal and vertical directions.

**To reposition an image:**

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Enable Reposition.

- 3 In the Reposition panel, use the sliders to adjust the image scale and positioning as needed.
- 4 You can animate Reposition parameters using the Animation controls. See [Animating Reposition Values](#) (page 2067).

## Turning Off Reframing

You can remove Reframing settings from your shots at any time.

To turn off reframing:

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Enable Off.

## Flipping or Flopping a Shot

Use the Flip or Flop tool to change your shot's orientation.

Original Image

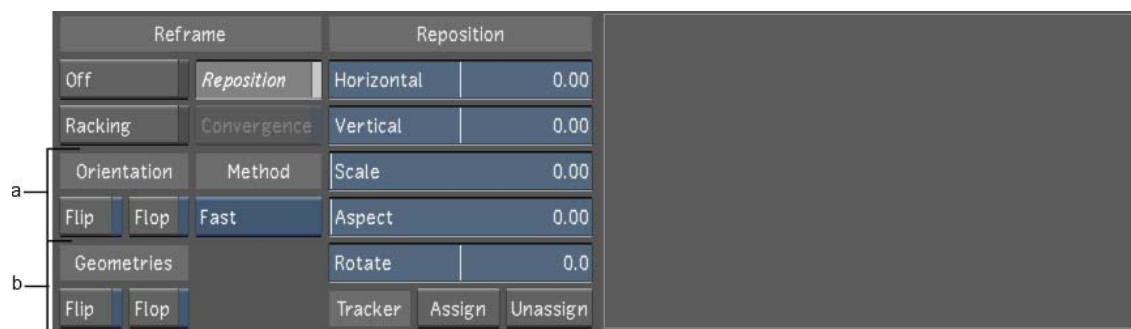

Flipped image

Flopped image

To change the orientation of a shot:

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Enable one or both orientation tools.

**(a) Orientation tools (b) Geometries tools**

| Enable: | To:                                          |
|---------|----------------------------------------------|
| Flip    | Apply a horizontal translation to the image. |
| Flop    | Apply a vertical translation to the image.   |

If you have geometries associated to secondaries, you can apply a horizontal or vertical translation to the geometries, independently of the image's orientation, using the Geometries tools. By default, the geometries will follow the image's orientation.

| Enable: | To:                                               |
|---------|---------------------------------------------------|
| Flip    | Apply a horizontal translation to the geometries. |
| Flop    | Apply a vertical translation to the geometries.   |

**NOTE** When applying a flip or a flop to Stereo3D content from inverted camera rigs, it is important to also enable to corresponding Geometries Flip / Flop to avoid issue when drawing shapes in Sync mode. Flipped or flopped Stereo3D content should always have the same Geometry orientation, regardless of whether or not there are geometries in the shot to avoid issues if you add geometries to the shot later.

## Tracking Repositioned Shots

Use the Point Tracker to stabilize a repositioned shot so that a selected point or shape in the source frame remains fixed in the same spot in the Player. You can use the Point Tracker in conjunction with reframing to stabilize jittery shots, or to automate the repositioning process. For example, if the original widescreen shot contains a pan across a landscape, but you want to fix the view on a house (for television viewing), you track the house, and then assign the tracking data to the Reposition tool. This sets pan and scan values at each frame. The result is that the house remains in the same spot in the repositioned image.

**NOTE** You can use exported stabilizer data from other Autodesk applications to stabilize your shots. See [Loading Tracker and Stabilizer Data from Autodesk Applications](#) (page 2197).

This section is intended to provide an overview of the stabilizing process. See [Animating the Point Tracker](#) (page 2187).

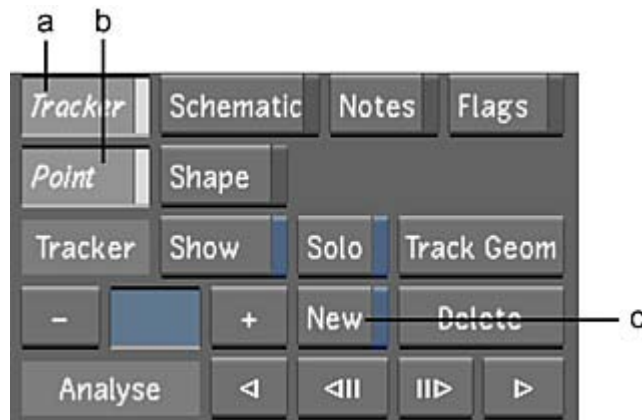

## Using the Point Tracker

You can use the Point Tracker to stabilize a repositioned shot.

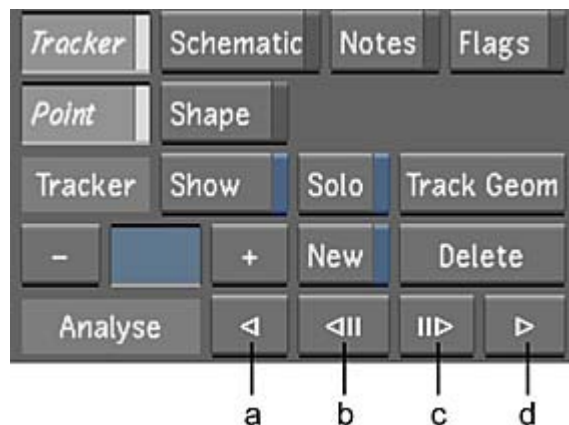

**To assign tracking information to the pan and scan settings of an image:**

- 1 Make sure the aspect ratio value is set up as needed. See [Setting the Aspect Ratio](#) (page 1833).
- 2 Select the shot to track.
- 3 Click Colour, and then click Secondaries to display the Secondaries menu.
- 4 Select the tracking feature by clicking Tracker.
- 5 Select the Point Tracker by clicking Point.
- 6 Enable a new tracker by clicking New.

(a) Tracker button (b) Point button (c) New button

- 7 Click the tracking point in the image.
- 8 Click Image, and then click Reposition to display the Reposition menu.  
A tracking box appears. You can adjust the box as needed to improve the track.
- 9 Click one of the Analyse buttons to begin the tracking process.  
The system tracks the tracking point. After tracking is complete, you may need to make slight adjustments to the tracking data. See [Animating the Point Tracker](#) (page 2187).

(a) Analyse backwards (b) Analyse back one frame (c) Analyse ahead one frame (d) Analyse forward

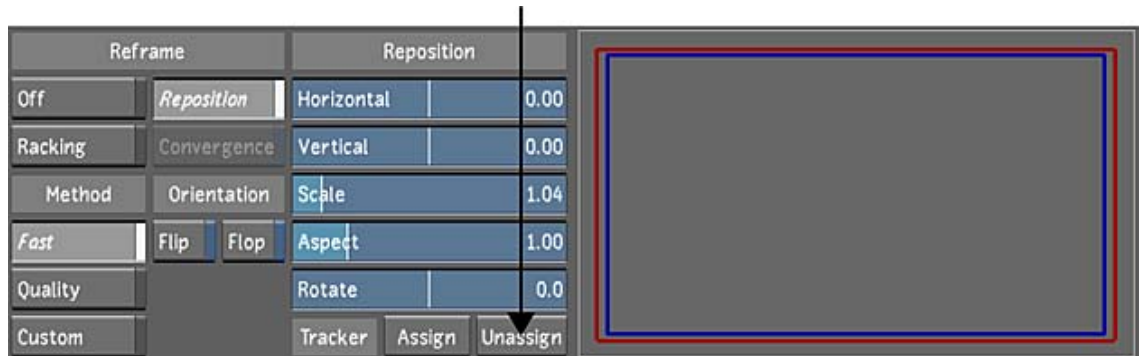

- 10 Enable either Racking or Reposition.
- 11 If you enabled Reposition, scale the image as needed.

- 12 Click Assign to apply the tracking data to the shot.

If you enabled Racking, the tracking point remains fixed vertically. If you enabled Reposition, the tracking point remains fixed both horizontally and vertically.

**To turn off tracking data for a shot:**

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Click Unassign.

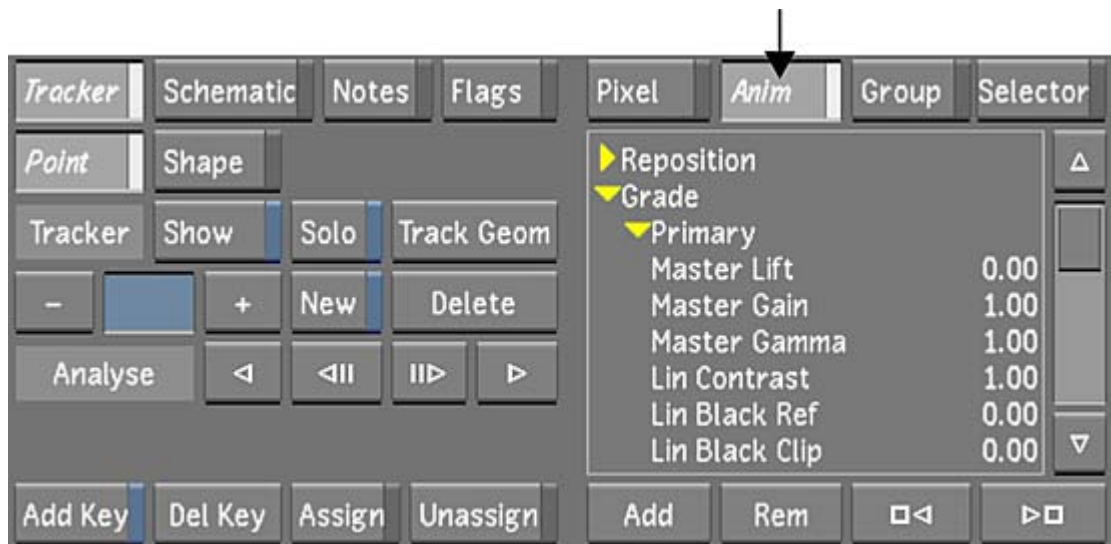

## Animating Reposition Values

Use the Animation controls in conjunction with the Reposition tools to animate the position, rotation, scaling, and aspect ratio of your shots. You can use this feature to simulate camera movement, which is useful when you want to make a still shot more dynamic. You can animate manually or using Autokey.

**To animate reposition values manually:**

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Enable Racking or Reposition.
- 3 Click Anim to display the Animation controls.

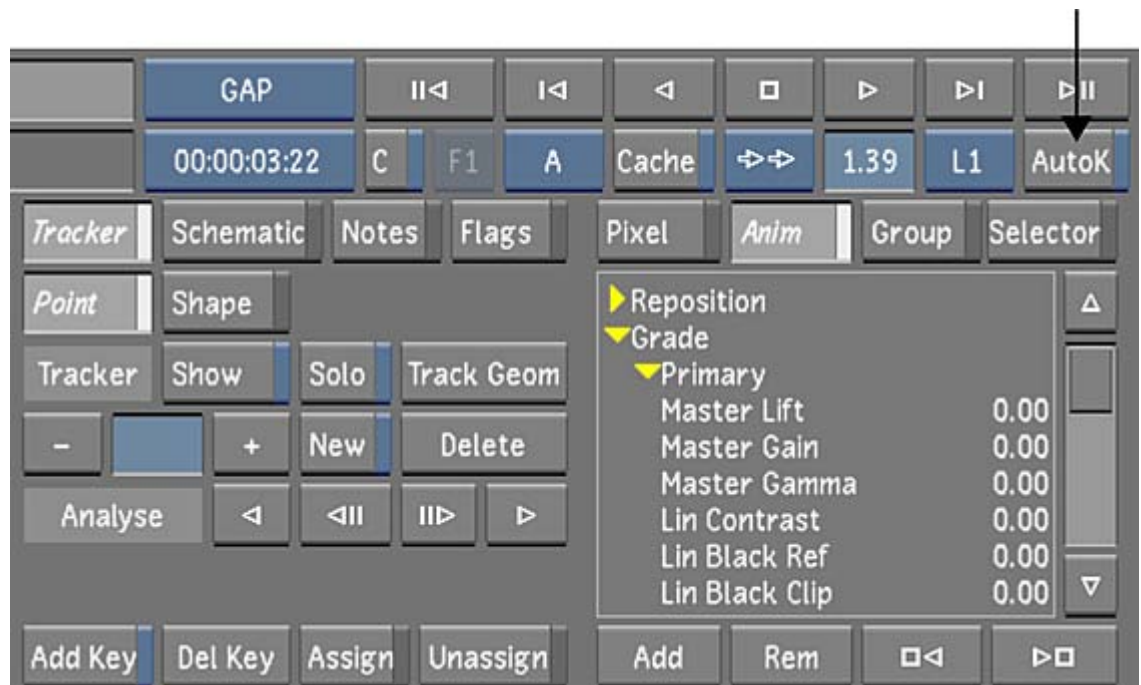

- 4 In the channel hierarchy, select the Reposition directory.

- 5 Move to the first frame of the shot, click Add to add a keyframe, and then adjust either the rotation, scaling, aspect ratio, horizontal or vertical position as needed.
- 6 Move to the last frame of the animation.
- 7 Set the reposition values and then click Add.  
Keyframes are added to the selected channels. The values in between the keyframes are interpolated using Bezier interpolation.
- 8 Scrub to view the animation.
- 9 To modify the animation curve, use the tools in the Animation menu. See [Accessing the Channel Editor](#) (page 2214).

**To animate position and scaling with Autokey:**

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 Enable Racking or Reposition.
- 3 Enable AutoK (Autokey).

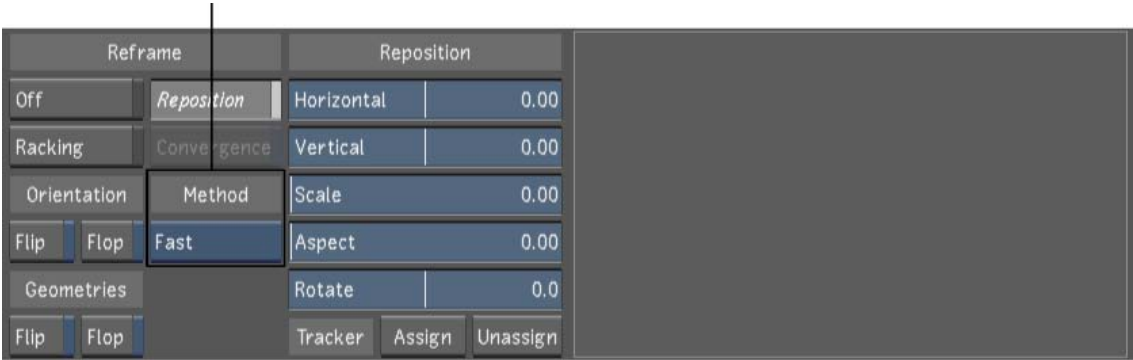

- 4 Move to the first frame of the shot and then adjust the scaling or the positioning as needed.  
Keyframes are automatically added at the current frame to the channel parameter you change.
- 5 Move to the last frame of the animation.
- 6 Set the scaling and the position.  
Keyframes are added to the adjusted channels. The values in between the keyframes are interpolated using Bezier interpolation.
- 7 Scrub to view the animation.
- 8 To modify the animation curve, use the tools in the Animation menu. See [Accessing the Channel Editor](#) (page 2214).

# Setting Rendering Quality

There are several options you can use to modify the way the repositioned images are rendered.

To set reposition rendering quality:

- 1 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 2 From the Rendering Method box, select a rendering method.

| Enable: | To:                                                                                                                                                                                                                |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fast    | Use bilinear rendering. This gives fast display at a lower quality. Generally, you should work in Fast mode.                                                                                                       |
| Quality | Use bicubic rendering. This gives higher quality but requires longer to display the frames. Use this option during MemCache rendering to show exactly how the image scaling will be performed in the final render. |
| Custom  | Use the highest rendering quality. You should use this when performing the final render. This is the default method. It uses a Lanczos resize filter.                                                              |

**NOTE** In Real-Time Deliverable mode, you can select additional custom filters. See [Creating Real-Time Deliverables from the Timeline or Rendered Material](#) (page 2332).

## Input LUTs

Images originating from different media and devices, such as digital cameras or scanned film, have different colour characteristics. On import, you can apply an Input LUT to convert them all to the grading working space prior to the grading process. Unlike LUTs applied for viewing, Input LUTs change the underlying colour values of the pixels.

**NOTE** If you are working media imported using the Wiretap Gateway, you can use the Transcode LUT options instead of an Input LUT. The Transcode LUT options allow you to apply colour transforms based on the Academy/ASC XML colour transform format as well as 3D LUTs and Flame-compatible 1D LUTs, which provides a great amount of flexibility. See [Transcode LUT Options Settings](#) (page 1926).

If running the Windows version of Lustre, save print LUTs in the `C:\Program Files\Autodesk\Lustre<version_number>\lut` folder. If running the Linux version of Lustre, save print LUTs in the

`/usr/autodesk/lustre_<version_number>/lut` directory. Lustre provides industry-standard 3D LUTs which are located in `C:\Program Files\Autodesk\Lustre Color <version_number>` in the Windows version and `/usr/discreet/Lustre_Color` in the Linux version.

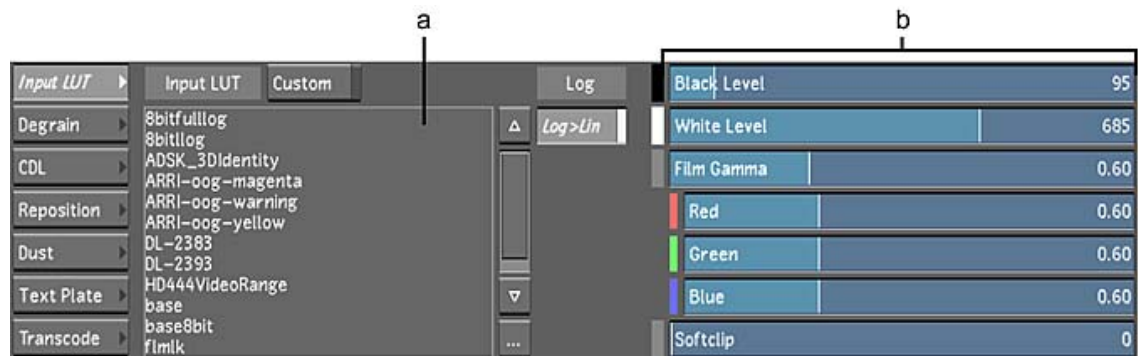

## Accessing the Input LUT Menu

Use the Input LUT menu to apply existing input LUTs to shots. In Linear mode, you can also use the LUT Editor to create Log to Lin conversion LUTs for shots containing logarithmic data.

To access the Input LUT menu:

- 1 In the Main menu, click Image.
- 2 Click Input LUT.

The Input LUT menu appears. Both 1D LUTs and 3D LUTs are listed in the Input LUT list.

(a) Input LUT list (b) LUT Editor (Linear mode)

## Importing a LUT File

Lustre can use the LUT files that you import into the application folder's `lut` directory. The LUT filename is displayed when the LUT list is displayed.

There are two ways to import LUTs into Lustre:

- Outside of Lustre, files can be copied manually to the application `lut` folder. If running the Windows version of Lustre, save print LUTs in the `C:\Program Files\Autodesk\Lustre<version>\lut` folder. If running the Linux version of Lustre, save print LUTs in the `/usr/Autodesk/lustre_<version>/lut` directory.
- Within Lustre, copies of LUT files are imported using the Import file browser.

---

**TIP** Lustre provides industry-standard 3D LUTs which are located in `C:\Program Files\Autodesk\Lustre Color <version>\3D LUTs` in the Windows version and `/usr/discreet/Lustre_Color` in the Linux version.

---

**NOTE** 1D LUTs, 3D LUTs and floating conversion LUTs must have the naming convention, `<name.lut>`, `<name.3dl>`, and `<name.flut>`, respectively, or they will not appear in the LUT list.

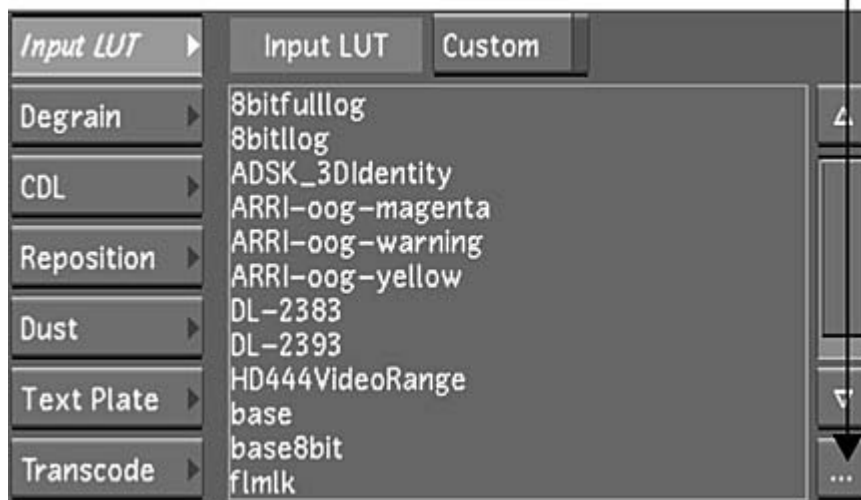

---

All LUT lists contain 1D and 3D LUTs, except the Float Conversion LUT list. Files with the `.flut` extension can be imported to the Float Conversion LUT list are exclusive to that list. See [Calibration Settings](#) (page 1787).

To import a file while in Lustre:

- 1 Open the Input LUT menu. See [Accessing the Input LUT Menu](#) (page 2070).

- 2 In the LUT List, click the Browse button.

The Import file browser appears.

- 3 Navigate to the appropriate source folder and select one or more LUT files (You can also use [bookmarks](#) (page 1915) to retain a list of folder locations). Traditional methods of multi-selecting (Shift-click, Ctrl-click) are enabled.
- 4 Click Import.

**WARNING** If a LUT with the same filename is already in the LUT list, the Import button will turn red. You must click again to confirm that you want to overwrite the file.

**TIP** If no files are selected, you can also press **Enter** to cancel LUT file selection and close the Import file browser.

A copy of the LUT file is imported into the *lut* folder, and appears in the LUT list.

## Applying an Existing Input LUT

An input LUT can be used to convert and gamma correct the logarithmic or linear data. Apply an input LUT to a shot to remap the colour values. Input LUTs are applied on a shot-by-shot basis and can be toggled on and off.

The settings in the Input LUT menu are saved in grade files. This applies to both 1D LUTs and 3D LUTs. When you use a grade from another station that contains an input LUT that does not exist on your station, the input LUT will appear in the Input LUT list, under Extra LUT from Grade. You can apply this LUT to other shots in the timeline.

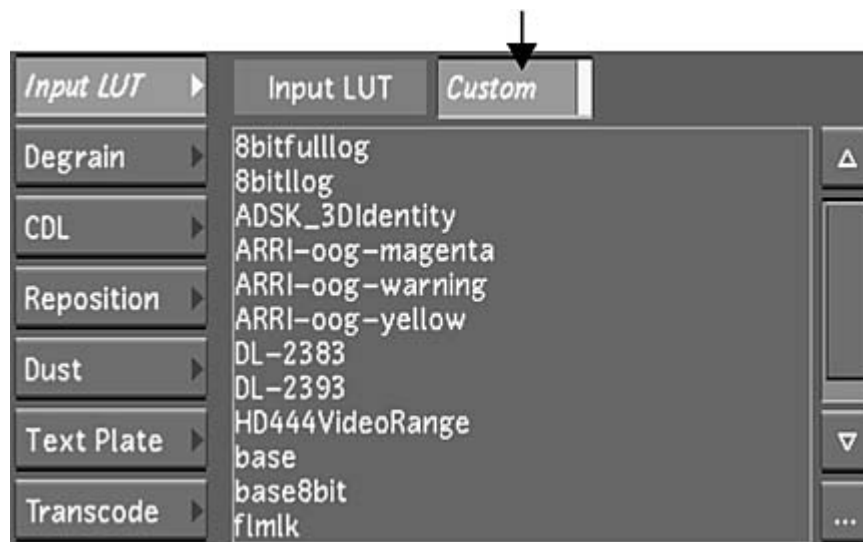

---

**NOTE** When a LUT is imported into Lustre, it is automatically embedded in the grade file and can therefore be rendered on remote rendering systems without the original LUT file being present.

---

### To apply an existing input LUT:

- 1 Select a shot in the Storyboard to which you want to apply an input LUT.
- 2 In the Input LUT menu, select either a 1D input LUT or a 3D input LUT from the Input LUT list and then enable Custom.

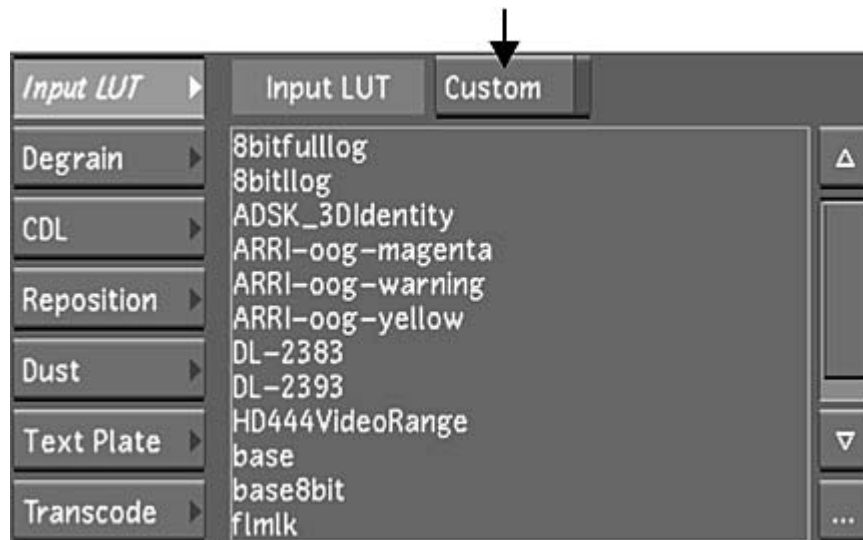

The input LUT is applied to the current shot.

- 3 To select a LUT originating from another station, expand Extra LUT from Grade in the Input LUT list, and then select the LUT.

### To turn off an applied input LUT:

- 1 Select a shot in the Storyboard with an input LUT.
- 2 In the Input LUT menu, disable Custom.

The input LUT is no longer applied to the shot.

- 3 Click the input LUT in the input LUT list to remove it completely.  
The input LUT is deselected.

## Linear Mode: Creating Conversion LUTs

Different film stocks produce various results. Shoots can also occur under many conditions, creating colour variations in the image. To create continuity between shots, you can apply unique Log to Lin conversion LUTs to different shots. Use the LUT Editor to create Log to Lin conversion LUTs. Conversion LUTs are used to gamma correct the shot and convert logarithmic data to linear data.

(a) LUT Editor (b) Pixel Analyser

To create a Log to Lin conversion LUT, the following steps are usually involved:

- 1 Set up the Player to monitor the shot you are converting and a reference image.
- 2 Use the Pixel Analyser to sample corresponding colours from the original and converted shot, as well as a reference image.
- 3 Modify the default conversion settings using the LUT Editor.

## Viewing Reference Images

While creating Log to Lin conversion LUTs, it is important to view reference images. For example, view other shots in the cut to ensure continuity.

You can also view a frame from the shot you are working on to see how it looked on film. To do so, save a reference image to a Grade bin in Log mode, and then load it to the frame buffer in Linear mode. For information on saving shots to a Grade bin, see [Using Grade Bins](#) (page 1865).

When you view reference images, you can switch between the reference image and the current shot, or you can view them both simultaneously.

**To switch between a reference image and the shot you are working on:**

- 1 Load the reference image to the frame buffer by doing one of the following:
  - Go to the frame you want to use in the Storyboard and then press **⌘** to load it to the frame buffer.
  - Right-click a Grade bin thumbnail.

- 2 In the Storyboard, select the shot you are working on.  
The shot appears in the Player.
- 3 To toggle between the reference image and the shot you are working on, press **⌘**.

**To display the reference image and the current shot simultaneously:**

- 1 Assign the shot you want to work on to Playhead A. Press **F1** or select A from the Playhead button, and then select the shot in the Storyboard.

- 2 Press **F2** or select **B** from the Playhead button.  
The shot assigned to Playhead B appears.
- 3 Load the reference image to the frame buffer by doing one of the following:
  - Press **K** to load the current frame in the Storyboard to the frame buffer.
  - Right-click a Grade bin thumbnail.
- 4 Press **L** or click **S** to assign the reference image to Playhead B.

The reference image appears in the Player. At any time, press **L** to toggle between the original shot (**O** button) assigned to Playhead B and the reference image (**S** button).

**TIP** If you want to use a shot from the Storyboard for reference, you can use the shot assigned to Playhead B. In this case, you do not need to load a reference image to the frame buffer.

- 5 Press **F4** to enable Dual View.

- 6 Press **F4** until you display Horizontal Wipe or Vertical Wipe mode.  
The images assigned to Playhead A and Playhead B are displayed. Playhead A is currently selected and displays the shot you are working on. Playhead B displays the reference image.
- TIP** Press **F4** until you are in 2-up mode to view your reference image (Playhead B) and the shot you are working on (Playhead A) in separate viewers.
- 7 To work on the shot you assigned to Playhead A, press **F1** or select **A** from the Playhead button.

The shot you are working on is selected. You can move back and forth between the shots in Playhead A and Playhead B by pressing F1 and F2 respectively.

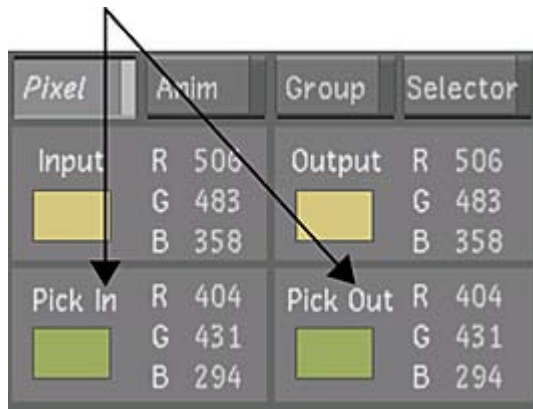

## Comparing Colour Values

While creating the Log to Lin conversion LUT, you can use the Pixel Analyser to sample the shot and compare the original and resulting colour values.

**To compare colour values:**

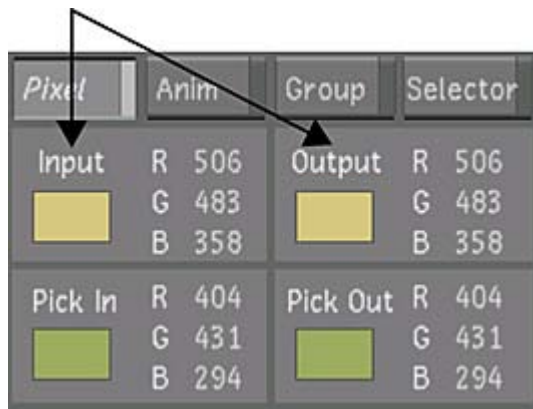

- 1 Click a pixel in the image.

Both the original (Pick In) and modified (Pick Out) colours are displayed simultaneously in the lower section of the Pixel Analyser. The RGB values for the selected pixel are also displayed.

- 2 Compare the colours in your shot to a set of reference values. View the reference image, and then place the mouse cursor over a pixel in the image without clicking it.

The original (Input) and modified (Output) colours in the reference image are displayed simultaneously in the upper section of the Pixel Analyser. If you click the reference image, the reference values will overwrite the previously sampled values.

## Modifying Default LUT Values

When you convert logarithmic data to linear data with the Log to Lin conversion LUT, you can modify several settings from the Input LUT menu:

- The reference white and reference black levels
- The gamma of the incoming film footage
- The softclip value—the degree to which the shoulder of the upper end of the conversion curves is softened

### Modifying Reference White and Reference Black Levels

Reference white and reference black levels define the source white and black range. By default, reference white is set to 685 and reference black is set to 95. Using these values (which correspond with typical Kodak film stock results):

- All incoming pixels with values between 685 and 1023 produce white pixels.
- All incoming pixels with values between 1 and 95 produce black pixels.

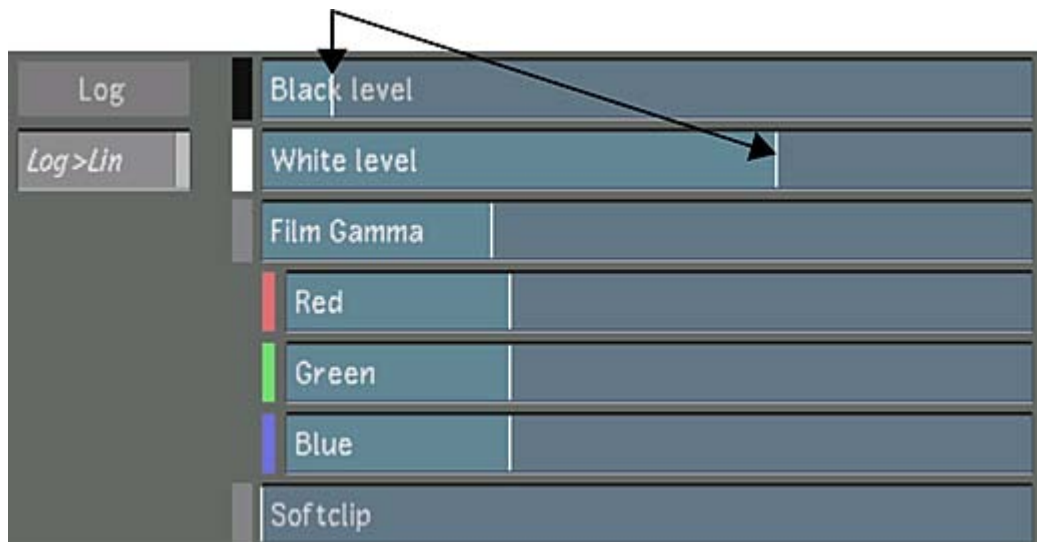

You can modify the reference white and reference black levels for the red, green, and blue channels proportionally or independently.

**To modify reference white or black levels:**

- 1 In the Input LUT menu, enable the Log>Lin button.

- 2 To modify the red, green, and blue channels in the reference white or black levels proportionally, drag the White Level or Black Level slider.

While dragging, the reference white or black level is displayed in the slider.

- 3 To modify the red, green, and blue channels for the reference white or black levels independently, click the White Level tab or Black Level tab to expand the parameter, and then drag the Red, Green, or Blue slider.

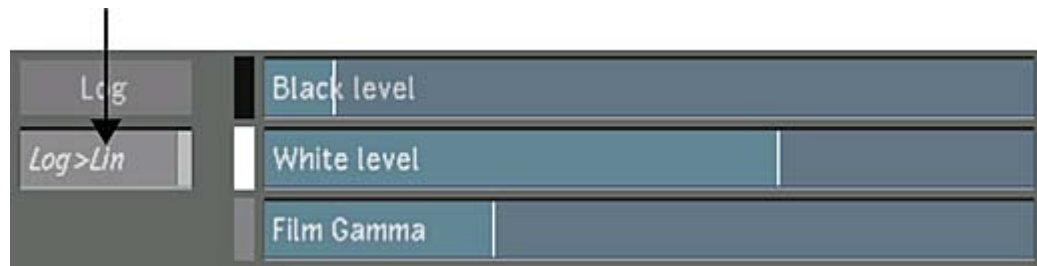

While dragging, the reference white or black level of the selected channel is displayed in the slider.

### Modifying the Gamma of the Incoming Film Footage

Typically, the gamma of a film negative is 0.6. Only adjust this value if your film negative is of a non-standard gamma. You should not have to modify this value by very much. The Film Gamma values affect the gamma correction curve inversely.

To modify the gamma correction curve:

- 1 In the Input LUT menu, enable the Log>Lin button.

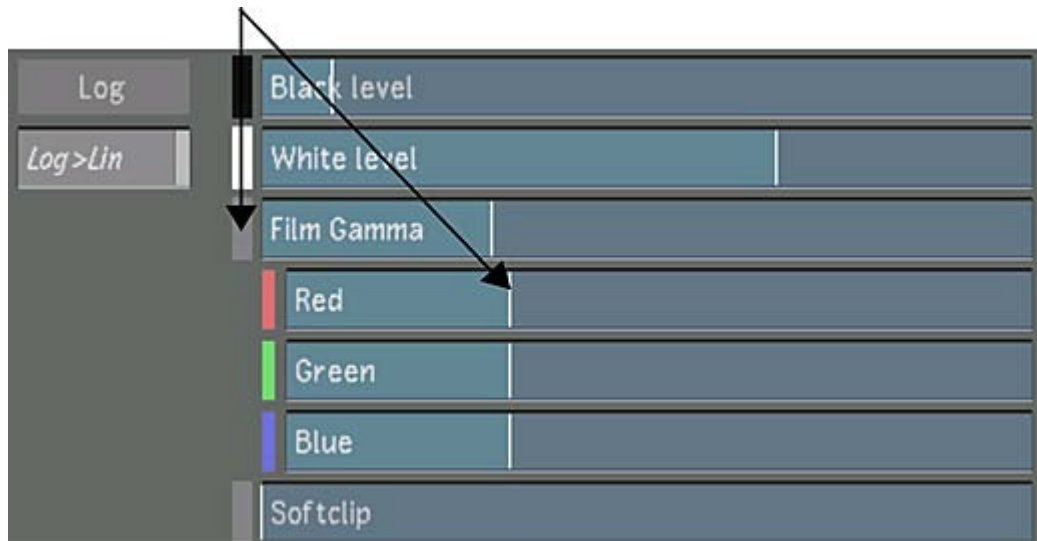

- 2 To modify the red, green, and blue channels for the film gamma levels proportionally, drag the Film Gamma slider.

While dragging, the film gamma level is displayed in the slider.

- 3 To modify the red, green, and blue channels for the film gamma independently, click the Film Gamma tab and then drag the Red, Green, or Blue slider.

While dragging, the film gamma level for the selected channel is displayed in the slider.

### Adjusting Softclip Values

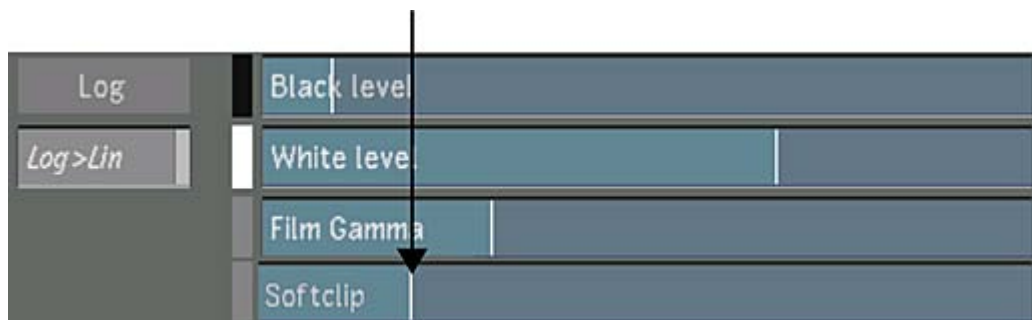

You can soften the shoulder of the gamma correction curve by adjusting the softclip levels. When you soften the shoulder of the conversion curve, you soften the transition of colours toward the reference white value. This results in softer highlights in your shot.

To soften the shoulder of the gamma correction curve:

- 1 In the Input LUT menu, enable the Log>Lin button.

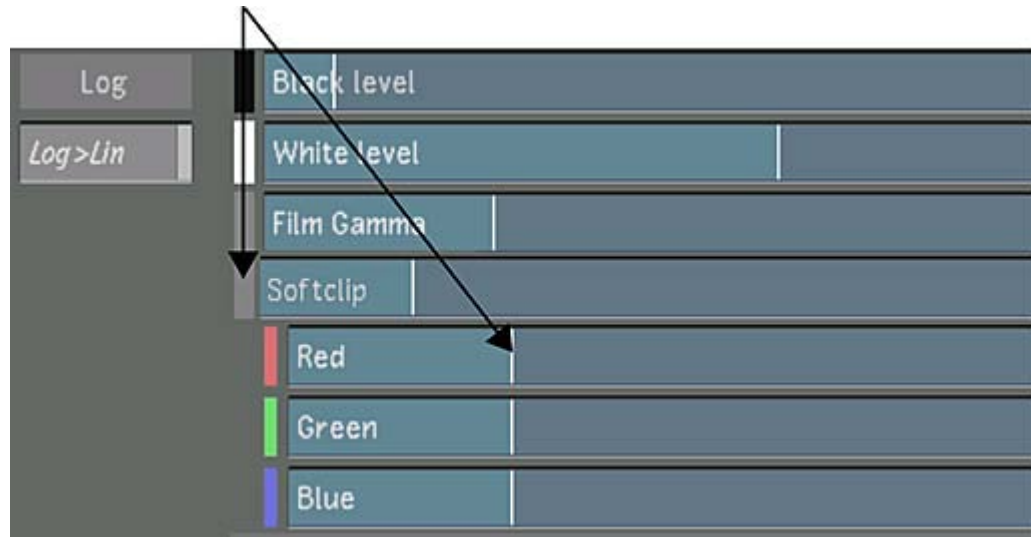

- 2 To modify the red, green, and blue channels for the softclip levels proportionally, drag the Softclip slider.

While dragging, the softclip level is displayed in the slider.

- 3 To modify the red, green, and blue channels for the softclip levels independently, click the Softclip tab and then drag the Red, Green, or Blue slider.

While dragging, the softclip level for the selected channel is displayed in the slider.

## Working with Half Float Media

OpenEXR is a high-dynamic range (HDR) media format supporting multi-resolutions and an arbitrary number of channels and channel types, such as specular, diffuse, alpha, RGB, normals, in a single file. Lustré supports OpenEXR 16-bit RGB only (files with other channels cannot be read). This format is sometimes referred to as "16-bit half float".

Lustré can obtain 16-bit floating-point media in four distinct ways. First, it can acquire the media by way of a Wiretap server. That is to say, by browsing the clip libraries and associated framestores of Visual Effects and Editing applications. Second, it can acquire the media directly, by importing OpenEXR media using a Wiretap Gateway server. Third, OpenEXR files can be read directly without using the Wiretap Gateway server. Fourth, media shot with a RED camera in HDRx mode and where "High Dynamic Range" is selected in the HDRx settings section of the Transcode tab also enter Lustré as 16-bit floating-point. In all cases, you need to tell Lustré how to work with the half float media.

As indicated, OpenEXR represents pixels as floating-point numbers. Internally, Lustré uses a 16-bit integer buffer format (although processing is done in floating-point). Thus, before you can grade OpenEXR media, it must be converted from floating-point to Lustré's special extended-range integer format. This is done by setting a floating-point conversion LUT for the project. This setting is located in the calibration tab of the project settings. Several floating point conversion LUTs are provided as examples.

| LUT         | Description                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| lin_default | A float-conversion LUT which converts the scene-linear floating-point media into an extended range video space suitable for grading using Lustré's linear grading controls. |
| log_default | A float-conversion LUT which converts the scene-linear floating-point media into an extended range logarithmic space                                                        |

| LUT                    | Description                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | suitable for grading using Lustre's logarithmic grading controls. This is the recommended way of grading HDR media.                                    |
| lin_black_limit1       | Similar to lin_default but accomodates media from some digital cameras which may have spurious negative or very low values.                            |
| log_black_limit1       | Similar to log_default but accomodates media from some digital cameras which may have spurious negative or very low values.                            |
| ACESproxy_CDL_workflow | Similar to log_default but the range of scene exposures presented to the ASC CDL match the ACESproxy range. Values outside this range are not clamped. |

Whenever loading half float media, Post Input LUT should be selected in the Image/CDL menu.

**NOTE** The floating-point conversion LUT causes linear images to appear similar to log images in Lustre, instead of the way they appear in Flame by default.

Similar to logarithmic media, HDR media requires a viewing LUT in order to look correct on a display or to render to a video color space. This is sometimes referred to as a tone-mapping LUT. This LUT should be selected in the Output tab of the Render settings. See [Rendering Shots](#) (page 2259).

You can use a tone-mapping Colour Transform such as the ones in the RRT+ODT directory. Alternatively, you can use one of the legacy 1d-LUT tone maps:

| LUT                 | Description                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------|
| lin_default_tonemap | An example tone-map output LUT to be used with the lin_default floating-point conversion LUT. |
| log_default_tonemap | An example tone-map output LUT to be used with the log_default floating-point conversion LUT. |
| identityExtended    | An output LUT which avoids clipping of HDR information when rendering back to floating-point. |

When your goal is to output a floating-point image, either directly to an OpenEXR file, or via rendering to Wiretap as part of an interoperability workflow with an Autodesk Visual Effects and Finishing application, use identityExtended as an output LUT to preserve the extended-range floating-point information. For example, if you are pre-grading OpenEXR media preparing for VFX work, use the identityExtended output LUT during the render.

## Colour Grading Basics

Lustre provides interactive colour grading tools for the creation of continuity grades and artistic colour effects. You can perform advanced colour grading in either logarithmic or linear colour space as well as save colour grading settings for future sessions and ongoing use. While you manipulate the colour content of a

shot, you can monitor reference images, as well as changes you make to the colour distribution of the shot to ensure that you achieve the result you want.

Because grades are saved as metadata rather than as part of the shot, the original image is always preserved—you can adjust colours without the risk of permanently losing the original colour of your image. Grade metadata is stored on a shot-by-shot basis, ensuring that your colour grades are applied to the correct shot regardless of any changes you make to a cut.

## Colour Grading Workflow

The procedures required to digitally colour grade footage depend on your goal, the shots used in your scene, and the architecture—logarithmic or linear—that you are working in. Scenes consisting of footage shot on the same camera equipment and under consistent conditions may be colour graded quickly and easily. Scenes created from footage shot on multiple cameras across several months and under varying lighting and weather conditions require more work.

Because you often work with a wide variety of shots, there are a variety of workflows you can use when grading a scene. However, it is important to keep in mind the order in which colour grading tasks are processed in Lustre.

The following table outlines processing order and a typical colour grading workflow from balancing a shot to performing final adjustments. You may not complete all the procedures. You may also revisit procedures as you create continuity grades and artistic effects.

| Step:                                                                                                                          | Refer to:                                                       |
|--------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| 1. Select the project colour space.                                                                                            | <a href="#">Setting Logarithmic or Linear Mode</a> (page 1831). |
| 2. With primary colour grading, balance colours in the shot and develop a continuity grade to create a consistent colour look. | <a href="#">Primary Colour Grading</a> (page 2101).             |
| 3. Further develop the colour look using the RGB and Hue curves.                                                               | <a href="#">Colour Grading RGB and Hue Curves</a> (page 2117).  |
| 4. Perform secondary colour grading to colour grade objects and colour ranges in the shot.                                     | <a href="#">Secondary Colour Grading</a> (page 2126).           |
| 5. Use Sparks plugins to apply image processing effects such as grain reduction.                                               | <a href="#">Creating Lustre Sparks Effects</a> (page 2199).     |
| 6. Adjust the colour look using the RGB curves.                                                                                | <a href="#">Colour Grading RGB and Hue Curves</a> (page 2117).  |
| 7. Perform any necessary primary colour grading to adjust the colour look and complete the colour grade.                       | <a href="#">Primary Colour Grading</a> (page 2101).             |

## Colour Grading Concepts

Altering the colour content of your footage to create a colour look across a series of shots, scenes, or the entire project is the primary objective of colour grading (also referred to as colour timing). The following concepts are used throughout the colour grading chapters.

## Log and Linear Modes

In Lustre, you can work in Log or Linear mode. The mode you select defines the colour space, your work environment, and the availability of some hotkeys. In Log mode, you colour grade shots using a film-based toolset and can grade in printer lights. In Linear mode, you colour grade shots using a video-based toolset. For example, if you are familiar with printer light grading, or you are grading logarithmic images, work in Log mode (Log mode is a better grading tool, mathematically, for logarithmic images). If you have more experience working with video and are familiar with the linear toolset, you can use Linear mode. Also, if you are working with linear images and are outputting to linear, it is simpler to work in Linear mode than to convert images to and from Log mode.

## Primary Colour Grading

Primary colour grading is applied to the entire image and is used to obtain an overall colour look for each shot used in a series of shots, scene, or entire project. When you perform primary colour grading, you modify the brightness and contrast of the red, green, and blue channels independently. You can modify the red, green, and blue channels together (with the Brightness and Contrast sliders); however, the channels are not codependent—a change made to the red channel does not depend on a change made to the green or blue channel.

You perform primary colour grading at the beginning and end of the colour grading process. In Log mode, you modify brightness, contrast, and saturation across the entire image, as well as brightness in the shadows, midtones, and highlights. In Linear mode, you modify lift, gain, gamma, saturation, and contrast for the red, green, and blue channels across the entire image or in the shadows, midtones, and highlights. You can also clamp minimum and maximum luminance values.

---

**NOTE** The intensity of specific colour channels (red, green, and blue) determines whether the pixel is part of the image shadows, midtones, or highlights.

---

## Curves Colour Grading

Use curves colour grading to further modify the RGB and Hue curves. Curves colour grading is well suited, for example, for colour grading a specific range of colours without having to pull a key. Alter the RGB curves to remap red, green and blue values either simultaneously or individually. Use the Hue curves to perform hue shifts, lighten or darken colour ranges, and saturate or suppress colour or luminance ranges. You can also plot colours and add vertices for increased precision.

RGB curves are processed after the initial primary colour grade, and after the application of Sparks effects (if applicable). Hue curves are processed after the initial primary colour grade only.

## Secondary Colour Grading

Use secondary colour grading to colour grade specific hues and areas in an image. Create secondaries by generating keys and geometries. You can combine keys and geometries to define the area for modification—keys to define a colour or range of colour and geometries to define an area. After areas have been defined, you can colour grade them using the Grading and Curves menus. You can also track objects in the image to animate a geometry used for a secondary colour grade. You can create up to 48 secondary layers. Secondary colour grading is applied after the initial primary colour grade.

## Continuity Grade

One of the first steps in the colour grading process is the creation of a continuity grade—a consistent colour look across a series of shots and over time. Continuity grades convey the time frame and should be invisible to the viewer. Generally, continuity grades are created when you balance the colours in the shots—during the initial primary colour grade.

## Printer Lights

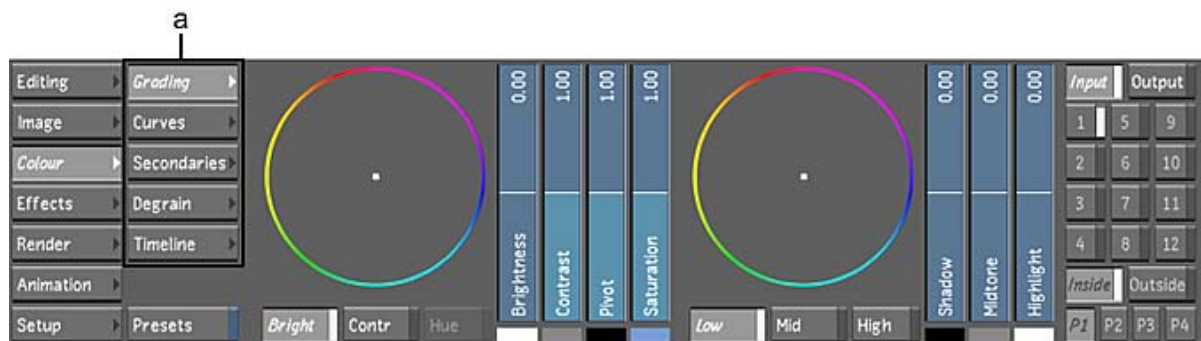

Printer lights are measurements or settings used by colour labs to operate the optical printer that produces the film copy. Because you may want to grade your shots according to printer lights and fstops, Lustre displays the modifications you make to the red, green, and blue content in printer lights when you perform primary and secondary colour grading in Log mode. You set printer light steps that calibrate Lustre with the equipment in the film lab in the Display & Interface tab of the user configuration. See [Display & Interface Settings](#) (page 1805).

## Accessing Colour Grading Menus

Use the Colour menu to access the Grading, Curves, Secondaries, Degrain, and Timeline menus.

To access the Colour menu:

- 1 In the Main menu, click Colour.  
The Colour menu appears.

(a) Colour grading menus

You can access the following colour grading menus from the Colour menu.

**Grading** Create the primary colour grade to colour balance your shots, as well as develop the continuity grade. In Log mode, adjust the brightness, contrast, and saturation across the entire image, or adjust the brightness in the shadows, midtones, and highlights. In Linear mode, adjust lift, gain, gamma, saturation, and contrast across the entire image or in the shadows, midtones, and highlights. You can also clamp minimum and maximum luminance values. Enable the Input button for initial primary colour grading, and the Output button to create the final look.

**Curves** Refine the primary or secondary colour grade. Remap colour values for the red, green, and blue channels individually or all together using the RGB curves. Adjust the hue, saturation, lightness, and luminance using the Hue curves. Enable the Input button to refine the initial primary grade, and the Output button to refine the final colour grade.

**Secondaries** Define up to 48 secondary layers that can then be graded using the Grading, Curves, Degrain, and Sparks Effects menus. Generate keys that define your secondaries by isolating colour ranges in the image. Create and track geometries to include with, or exclude from, the secondary colour grade.

**Degrain** Analyse the grain profile of a frame, and use spatial degrain operations to remove grain and noise with secondary layers. See [Removing Grain](#) (page 2051).

**NOTE** To analyse the source image before you begin primary grading, access the Degrain menu from the Image menu instead.

**Timeline** The colourist's timeline is a simple user interface that allows the colourist to work in a timeline interface without all the timeline editing tools. In this interface you can work in Normal or Solo mode, add cuts and dissolves, and create a new version of a shot. You do not have access to the trimming tools.

## Displaying Colour Menus in the Player

You can display the Grading, Curves and Secondaries colour grading menus in the Player next to the image in the currently active playhead. This allows you to:

- Keep the Colour menus available even if you are accessing another menu.
- Display viewing options such as split-screen view on the second head of the graphics card.
- Use the mouse cursor to access the HDSDI head and draw shapes that will appear on the broadcast monitor.

For details on assigning shots to playheads, see [Viewing Reference Images](#) (page 2013).

### To display Colour menus in the Player:

- 1 Press F7.

The Colour menus appear alongside the image, and are disabled in the main user interface.

**NOTE** The Hue cube of the Diamond Keyer does not appear in this view mode.

## GPU Acceleration

Processing with the Graphics Processing Unit (GPU) is available for certain features and is faster than processing with the Central Processing Unit (CPU).

Support for GPU acceleration depends on the version of the NVIDIA graphic card that is installed on your system. The following configurations are supported for GPU acceleration.

| Configuration | Feature available?            |
|---------------|-------------------------------|
| FX5800        | Yes                           |
| FX5600        | Yes                           |
| FX5500        | Yes (except Noise plugin 3.1) |

#### **WARNING**

Due to the enhancements in the GPU, we do not recommend using Lustre to render grades created in Lustre 2011 or earlier if you are looking for pixel accuracy rendering.

GPU acceleration is available for the following features:

- Playback of cached degrained frames
- 1D or 3D on calibration LUTs
- Animated or still repositions (including rotations)
- Animated or still input primary grading
- Input and output primary grading with RGB, hue and light saturation (LS) curves
- Secondary grading with RGB curves
- Secondary grading with hue curves
- Secondary black clip/reference and white clip/reference in Linear mode
- Secondary key cleanup and shrink
- Imported mattes for secondaries
- Gamma and contrast adjustments to secondaries in Linear mode
- Low, mid, and high adjustments to secondaries
- Input and render/output LUT
- Lustre Sparks plugins:
  - Blur mix
  - Glow
  - Noise plugin 3.1
  - Printbleach

**NOTE** A performance hit can occur when using the Lustre Sparks plugins.

For more information about these features, see:

- [Primary Colour Grading](#) (page 2101).
- [Colour Grading RGB and Hue Curves](#) (page 2117).
- [Creating Lustre Sparks Effects](#) (page 2199).

GPU acceleration is also available for certain secondary grading features with up to 48 secondary layers enabled. You can apply, and optionally animate, each of the following secondary grading features and continue to use GPU acceleration:

- Primary grading inside and outside geometries, including adjustments to overall brightness, contrast, hue, and saturation
- Softness, Colour, and Opacity slider values for geometries, with Softer and Variable optionally enabled
- Key-in shapes based on hue, luminance, and saturation, and refined by tolerance and softness range definition
- Key and geometry blurs

**NOTE** A performance hit can occur when using the geometry blur.

- Multiple point changes for geometries

For more information about these features, see [Secondary Colour Grading](#) (page 2126).

When GPU acceleration is enabled, the histogram, vectorscope, and waveform monitors do not dynamically update. They retain the colour distribution of the image before GPU was enabled.

The following parameters cannot be accelerated by the GPU. These parameters are processed by the CPU instead.

Lustre Sparks plugins:

- Add noise
- Blur
- Defocus
- Directional blur
- Field zoom
- Gold
- Noise plugin 2
- Noise plugin 3
- Silver

---

**NOTE** If GPU acceleration is enabled and Lustre encounters a shot with features that cannot be processed by the GPU, the CPU is used for the shot. The GPU button remains enabled, but is greyed out until you navigate to the next shot in the timeline that contains features available for GPU acceleration.

---

**To enable GPU acceleration:**

- 1 Do one of the following:
  - Click GPU.
  - Press  $\gamma$ .

A GPU flag appears in the upper-right section of the Player.

**NOTE** GPU acceleration only works in progressive scan mode. Before you render a project, you need to switch the scan type to interlaced (located in the Setup > Grade menu).

#### To disable GPU acceleration:

1 Do one of the following:

- Click GPU.
- Press Y.

GPU acceleration is disabled.

## GPU Auto Switch

By default, when you use a feature that is not supported by GPU (while in GPU acceleration mode) it automatically switches to CPU processing mode. The GPU button is greyed out in the user interface to show you that this feature is not GPU compatible. You can prevent the switch to CPU mode by disabling the GPU Auto Switch feature, see [Display & Interface Settings](#) (page 1805). When you disable the GPU Auto Switch button, you can only see features which are supported by GPU (when GPU acceleration is enabled). To see all of the features, you have to disable the GPU button.

## Colour Grading With the Control Surfaces

The control surfaces facilitate colour grading work by accelerating interactivity with the shots. You can use control surfaces to perform many colour grading tasks. The dials and trackballs give you precise control over the colour effects you create.

## Viewing Multiple Shots

You can view multiple shots in the Player while you work. These views are useful when you want to compare shots in a cut to ensure continuity, match colours, or view a group of shots in which the colour grading parameters you are modifying are ganged. See [Using Dual View](#) (page 2029) and [Using Multi View](#) (page 2031).

## Reference Images

You can view a reference image while you work. For example, use a reference image to visually compare the current shot to another when you develop a continuity grade. Reference images are stored in the frame buffer and are loaded from your cut or from the Grade bin. You can only have one reference image stored in the frame buffer at a time. You can switch between different reference images to ensure continuity and consistency throughout the project. See [Viewing Reference Images](#) (page 2013).

## Viewing Proxies

After you generate proxies, you can view proxies while you colour grade your shots. It is useful to view proxies if interaction slows down. This can occur when you perform secondary colour grading on high-resolution images because a large amount of processing is required to display the result at full resolution.

Proxy view is set on a shot-by-shot basis. To view proxies, you must first generate them. See [Generating and Viewing Proxies](#) (page 2271).

**To view proxies:**

- 1 Do one of the following:
  - On the function control surface for the Autodesk control surface, press the Proxy button.
  - On the Tangent CP100 control surface, press the Resolution button.
  - Press F9.
  - Click the Resolution button.

The full-resolution image in the Player is replaced by the proxy (half-resolution) image. Use the same procedure to toggle between the full-resolution image and the proxy.

**NOTE** If you have not generated a proxy for the shot, an X will appear in the Player.

## Analysing the Image

While you colour grade, you can use different tools to view and analyse colours. Use the Analyse tools to view the colour distribution in the current frame. Use the Pixel Analyser to sample the image to compare colour values used in the input (original) and output (result) images.

## Sampling Colour Values

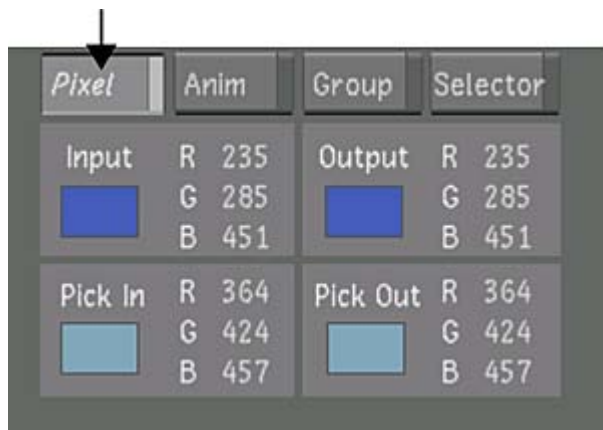

When you generate mattes, modify shots, or match colours between shots, you can sample the current image in the Player. When you sample the image, the input and output colour values are displayed in the Pixel Analyser.

The sample will appear in the Curves menu so you can view input colour values when you refine the image. R, G, and B colour values are plotted separately on the RGB curves while the combined RGB colour value is plotted on the Hue, Saturation, Lightness, and Luminance curves.

When you create a key, you must sample the image to set tolerance and softness values. See [Creating a Secondary by Keying a Range of Colours](#) (page 2159).

**To sample colour values:**

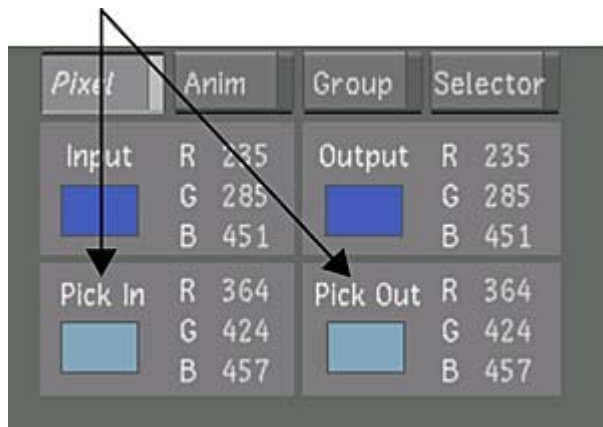

- 1 Select the frame in the shot you want to sample.
- 2 Click Pixel to display the Pixel Analyser.

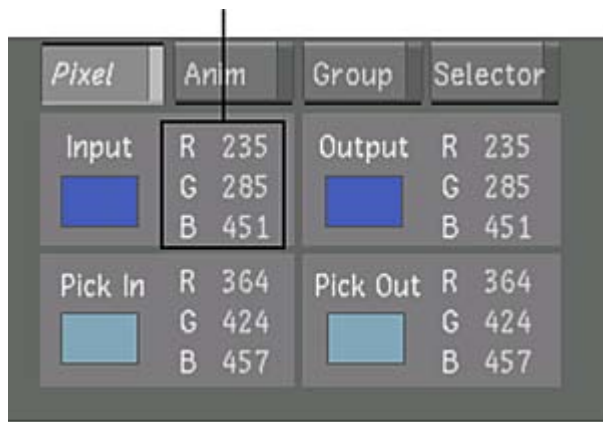

3 In the Player, do one of the following:

- Drag the image to sample a single pixel in the image. You can drag through the image until you locate the pixel you want to sample.
- Alt-click to sample an average taken from a range of colours in the image.

The sample appears in the Pixel Analyser.

4 (Optional) Press E to change the display value. You can display the colour in three different formats: colour, F-stop/float value, or high dynamic range (HDR).

| Display Value      | Description                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Colour             | Displays the colour value for all types of media.                                                                                                                          |
| F-stop/Float value | F-stop is only applicable for 10-bit media (whereas the 8 and 16-bit media retains the colour value). Float value is only applicable for the Input value of OpenEXR media. |
| HDR                | Displays the colour input value from -1 to 3 for OpenEXR media. For the other media, the colour value is from 0 to 1.                                                      |

**NOTE** For OpenEXR media the F-stop value is replaced by the media's float value and the HDR range is only applicable to the Input value. The Input HDR range is from -1 to 3 for OpenEXR media, but for all other media the range is from 0 to 1.

## Viewing Colour Distribution

There are a variety of Analyse tools that you can use to view the colour distribution in the current frame. Analyse tools are useful when you want to determine the original structure of the image and see how a grade transforms the colour space.

You can display up to three Analyse tools at one time. Use these tools to help match colours, view the colour distribution, adjust shadows and highlights, and ensure that broadcast and other standards are met. You can display the following Analyse tools while you colour grade.

**Histogram** Displays the distribution of image pixels across the luma range for the R, G, and B channels.

**Waveform monitor** Displays the R, G, B channels separately or together as a waveform.

**Vectorscope** Displays the distribution of image pixels across luma and hue ranges.

The Analyse tools show the changes you make to the colour content in a shot. Each tool is dynamically updated to reflect your changes as you modify the image.

**NOTE** The histogram, vectorscope, and waveform monitor do not dynamically update if GPU acceleration is enabled. They retain the colour distribution of the image prior to GPU being enabled.

### To view colour distributions:

- 1 Display up to three Analyse tools to view the colour distribution of the image.

| Press: | To display:                     |
|--------|---------------------------------|
| Alt+1  | The RGB waveform monitor.       |
| Alt+2  | The RGB histogram.              |
| Alt+3  | The luminance waveform monitor. |
| Alt+4  | The vectorscope.                |

**TIP** You may need to move the shot in the Player up in order to see the Analyse tools below it.

**(a)** Waveform monitor (with RGB channels displayed separately) **(b)** Histogram **(c)** Waveform monitor (with RGB channels displayed together)

**NOTE** Right-clicking over any of these monitoring tools either zooms you in, or adjusts the tool's luminance value.

### To view the RGB histogram for two images simultaneously:

- 1 Press F5.  
The last used view is displayed—either Dual View or Multi View. Dual View displays two frames at the same time while Multi View displays the entire frame of one or more shots.
- 2 If Multi View is displayed, press F4 to activate Dual View.  
The current frames on Playheads A and B are displayed either horizontally or vertically, depending on the last displayed orientation.
- 3 Press F1 or select A from the Playhead button and then select the shot in the Storyboard.  
The shot you are working on is assigned to Playhead A.
- 4 Press Alt+2 to display the histogram for the shot assigned to Playhead A.
- 5 Press F2 or select B from the Playhead button.  
The shot is assigned to Playhead A.
- 6 Press Alt+2 to display the histogram for the shot assigned to Playhead B.

## Saving and Loading Presets Using the Presets Lists

To increase the efficiency and speed of the colour grading process, you can save a limited set of the colour grading parameters that you plan to reuse on a regular basis. These predefined settings, or presets, are saved on a menu-by-menu basis and are stored in the Presets lists.

### Saving Presets

Save settings from the current Colour menu to a preset. You can save settings to the following Presets lists:

- Grade presets
- Curves presets
- Geometry presets
- Gmask raw import
- Tracker presets
- Key presets
- Degrain presets

---

**NOTE** Saving to a preset saves the settings currently displayed in the Player. For example, if you save to a preset in the middle of a colour dissolve or animation, this timeline position is saved to the preset file. Saving to a preset is a good way to save and load animation keyframes.

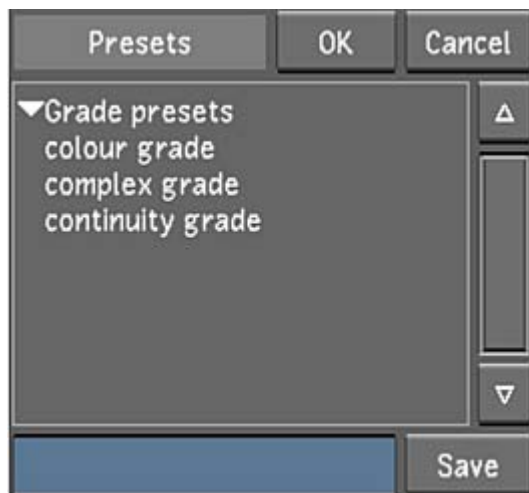

---

**To save a preset:**

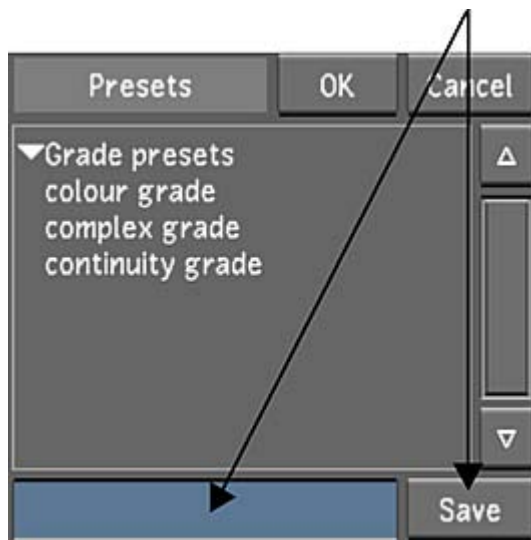

- 1 Click the Presets button in the Colour menu or right-click Grading, Curves, or Secondaries.

**NOTE** You can also right-click the Hue, Luminance, or Saturation button in the HLS Keyer as well the Presets colour buttons in the Diamond Keyer.

The affiliated Presets list appears. For example, if you right-clicked the Grading menu, the Grade presets list appears.

- 2 In the Colour menu, make any necessary modifications to the settings to create the colour look you want.
- 3 In the Presets Name field, enter a name for the preset, and then click Save.

**NOTE** Spaces are not permitted in naming conventions. It is recommended that underscores be used instead of spaces when working on either Linux or Windows.

The settings in the current menu are saved to the preset. The preset appears in the Presets list.

**TIP** To save the settings to an existing preset, select the preset in the Presets list.

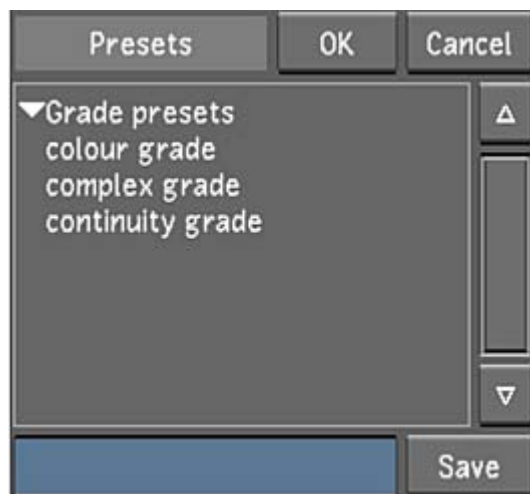

## Loading Presets

Increase efficiency by loading presets to the current shot when you want to reuse Colour menu settings. Preview the effect a preset will have on a shot before you apply the settings.

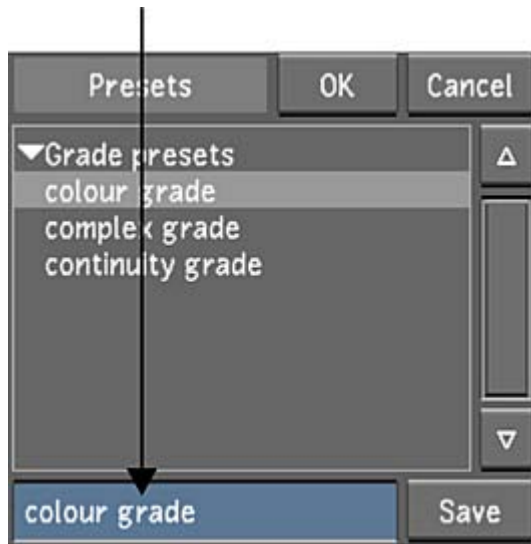

**To load a preset from a Presets list:**

- 1 Click the Presets button in the Colour menu or right-click Grading, Curves, Secondaries, Degrain, or the Keyer.

The affiliated Presets list appears. For example, if you right-clicked the Grading menu, the Grade presets list appears.

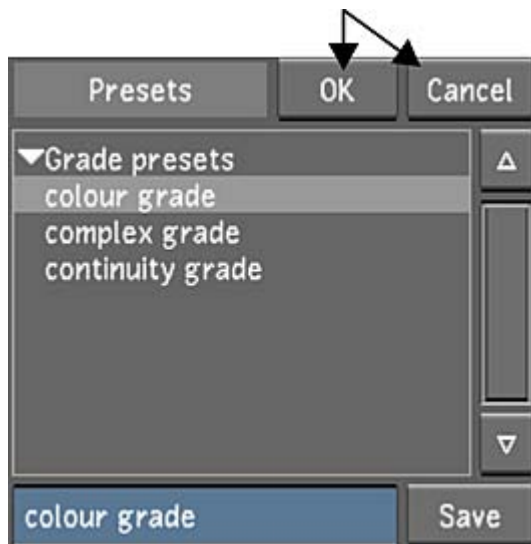

- 2 Select a preset in the list.

The image in the Player is updated with the settings from the preset so that you can preview the effect.

- 3 Do one of the following:
  - Click OK to apply the settings.

The settings are applied to the image and the Colour menu. The other Colour menus are unaffected.
  - Click Cancel to revert to the previous settings in the Colour menu.

## Colour Grade Animation

Use the Animation controls to animate colour grades. You can animate any parameter from the Colour menus except those in the Curves menu. For example, animate a colour grade to convey a change in the ambient light. To access the Animation controls, click the Anim button. See [Animation](#) (page 2214).

## Grade Bin Storage

During the colour grading process, use the Global Grade bin or Scene Grade bin as a framestore for reference images and as a scratch pad for grades. Grade settings are stored in the Grade bins on a shot-by-shot basis. See [Using Grade Bins](#) (page 1865) and [Using the Expanded Grade Bin](#) (page 1873).

## Colourist Multi-Layer Timeline

The colourist multi-layer timeline allows you to perform limited editing functions within the Colour menu. Grading information (a selection of a shot's grading information or all of the grading information) can be copied from one shot to another or to several others.

---

**NOTE** The functions in the colourist multi-layer timeline are not accessible if your timeline is in sort mode. See [Timeline Sort Mode](#) (page 2033).

---

## Accessing the Colourist Timeline Menu

To edit shots in the colourist timeline view, you need the Timeline menu.

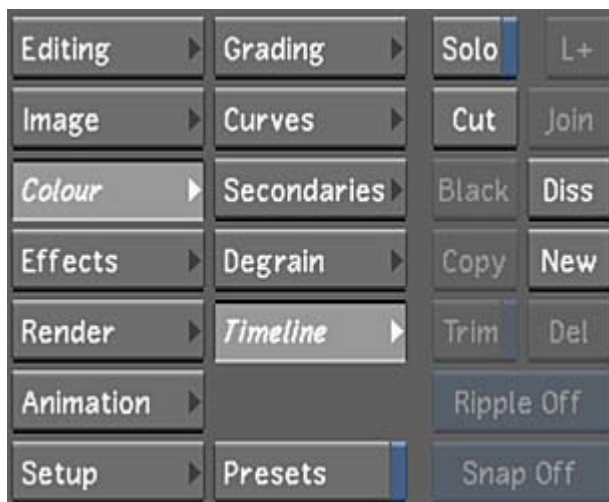

To access the colourist timeline menu:

- 1 In the Main menu, click Colour.
- 2 Click Timeline.

The colourist timeline menu appears.

The timeline is made up of the following buttons.

**Solo** Within a multi-layer timeline, Solo mode displays the layer which the Focus point is positioned on. The Storyboard is updated to only display the shots in the soloed layer. When Solo mode is disabled, the top layer, by default, is displayed in the Storyboard and Player.

---

**NOTE** If you are using the solo function as a method to create editorial or grade version, please keep in mind that the status is not part of the grade file data structure. Therefore, this state will not be saved upon restarting Lustre.

---

**Cut** Adds a splice at the positioner location on the focused layer.

**Diss** Adds a dissolve at the positioner location on the focused layer.

**New** Copies the current element to the next available top layer with grade data.

For more information about the multi-layer timeline, see [Multi-Layer Timeline](#) (page 1974).

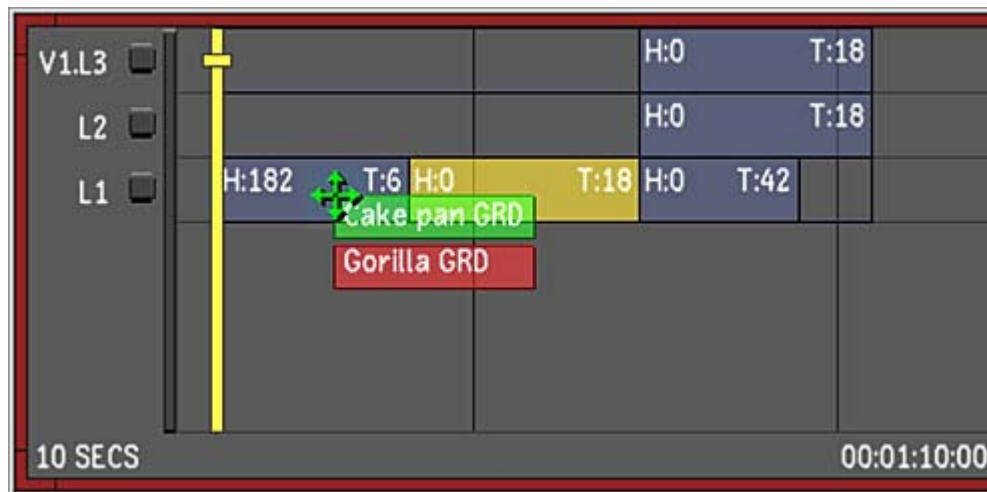

## Copying Grading Information in the Colourist Timeline

There are several procedures for copying grading information using the colourist timeline. You can easily drag and drop all or a selection of grading information from shot to shot (or to multiple shots). You can also drag and drop grading information from multiple shots to an equal number of shots.

**To copy all grading information from one shot to another:**

- 1 In the colourist multi-layer timeline, hold down the **Ctrl** key and drag from the graded shot to the destination shot.

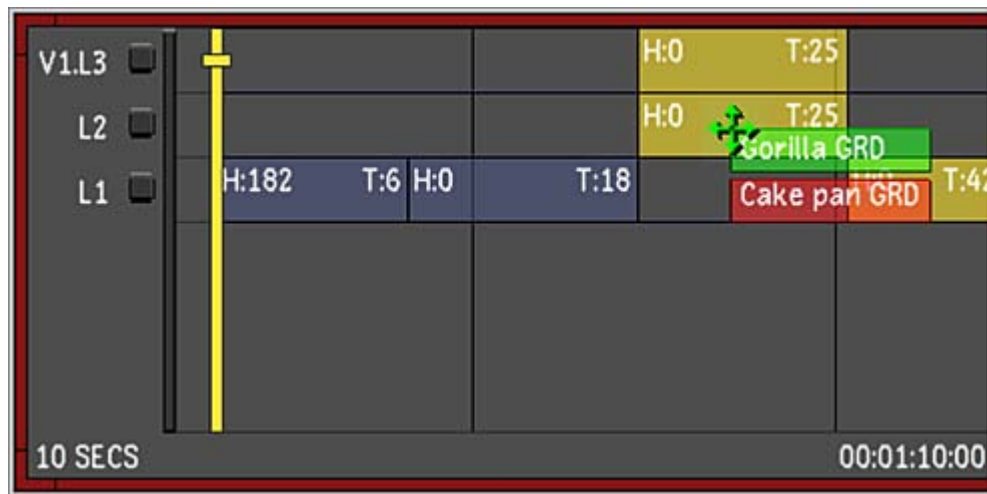

When you move your mouse over a shot, a green indicator displays the graded shot's name. A red indicator displays the destination shot name.

- 2 Drop the selection when the cursor is over the desired destination shot.  
The entire shot's grading information is copied to the destination shot.

**To copy all grading information from one shot to multiple shots:**

- 1 In the colourist multi-layer timeline, create a timeline selection of shots to which you wish to copy grading information. See [Selecting Elements](#) (page 1980).
- 2 Hold down **Ctrl** and **Shift** and drag from the graded shot to any of the selected shots.  
When you move your mouse over a shot, a red indicator displays the destination shot name.

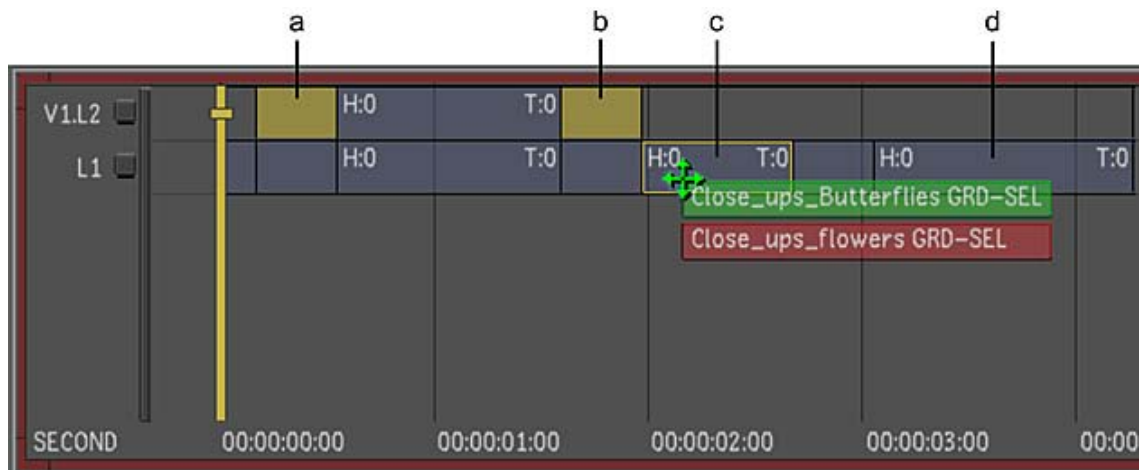

- 3 Drop the selection when the cursor is over any destination shot that is in your selection. The entire shot's grading information is copied to the selected shots.

**To copy all grading information from multiple shots to a different set of shots:**

- 1 In the colourist multi-layer timeline, select two or more shots with the grades you wish to copy. See [Selecting Elements](#) (page 1980).
- 2 Hold down the **Ctrl** and **Shift** keys and drag the first shot in the selection to the first destination shot to be graded.

When you move your mouse over a shot, a green indicator displays the shot name and a red indicator displays the destination shot name.

**(a) First graded shot selection (b) Second graded shot selection (c) First destination shot (d) Second destination shot**

- 3 Drop the selection when the cursor is over the first destination shot. The grading of each shot is applied to a corresponding destination shot. In the example above, if you drag a broken selection of the first and third shot and drop it on the fifth shot in another layer, then the fifth and seventh shot in that layer will be graded, respectively.

**To copy a defined selection of grading information from one shot to another:**

- 1 Using the various grading tools, grade a shot to your satisfaction.

- 2 In the Timeline menu, enable the Selector button.

- 3 Specify what parameters to copy:
  - To select all the channels in a directory, select the directory.
  - To select specific channels in a directory, expand the directory and select any of its channels.

The channels within selected directories become bold white.

- 4 Hold down the `Ctrl` and `Alt` keys and left-click+drag from the graded shot to the desired destination shot.

A green indicator displays the graded shot's name. A red indicator displays the destination shot's name when you move your mouse over a shot.
- 5 Release the `Ctrl` and `Alt` keys and mouse button when the cursor is over the destination shot.

The grade is copied to the destination shot.

**To copy a defined selection of grading information from one shot to multiple shots:**

- 1 Using the various grading tools, grade a shot to your satisfaction.
- 2 In the colourist multi-layer timeline, create a timeline selection of shots to which you wish to copy grading information. See [Selecting Elements](#) (page 1980).
- 3 In the Timeline menu, enable the Selector button.

- 4 Specify what parameters to copy:
  - To select all the channels in a directory, select the directory.
  - To select specific channels in a directory, expand the directory and select any of its channels.

The channels within selected directories become bold white.

- 5 Hold down **Ctrl**, **Shift**, and **Alt** and left-click+drag from the graded shot to any of the selected shots. A green indicator displays the graded shot's name. A red indicator displays the destination shot's name when you move your mouse over a shot.
- 6 Release the **Ctrl**, **Shift**, and **Alt** keys and mouse button when the cursor is over any destination shot in your selection. The grade is copied to the destination shot selection.

## Primary Colour Grading

Primary colour grading is applied to the entire image and is used to obtain an overall colour look. With primary colour grading, you modify the primary colour channels (red, green, and blue) independently. Although you can manipulate these colour channels simultaneously, the modifications you make to one colour channel will not depend on the pixel intensity of the other colour channels.

When you perform primary colour grading, you can develop a continuity grade to create a consistent colour look for shots at the beginning of the colour grading process, and then perform any final adjustments to readjust the colour look and complete the colour grade at the end of the process.

You perform primary colour grading in either Log mode or Linear mode. In Log mode, you can modify brightness, contrast, pivot point, and saturation. In Linear mode, you can modify lift, gain, gamma, saturation, and contrast values, as well as clamp minimum and maximum luminance values.

---

**TIP** For faster playback on shots with input primary grading applied, enable GPU processing by clicking the GPU button. See [GPU Acceleration](#) (page 2086).

---

---

**WARNING** The Histogram, Waveform, and Vectorscope functions do not update when GPU processing is enabled.

---

## Accessing the Grading Menu

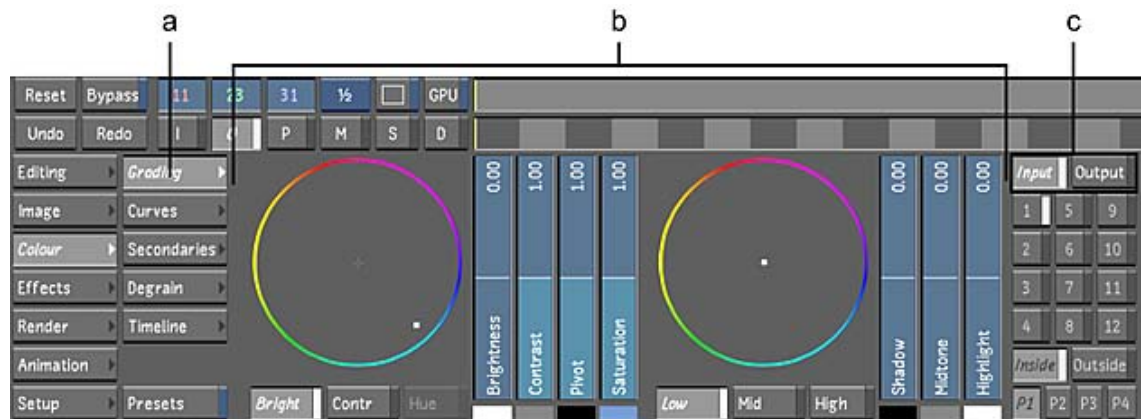

Primary colour grading is done from the Grading menu.

To access the Grading menu:

- 1 Do one of the following:
  - In the Main menu, click Colour and then Grading.

- Press F7. See [Displaying Colour Menus in the Player](#) (page 2085).

The Grading menu appears.

(a) Grading button (b) Grading menu (Log mode) (c) Input and Output buttons

- 2 Enable one of the following buttons.

**Input** Enables input primary grading. Use it to perform primary colour grading at the beginning of the colour grading process.

**Output** Enables output primary grading. Use it to perform primary colour grading at the end of the colour grading process, that is, after RGB and Hue modifications, as well as selective grading have been performed.

**NOTE** The Hue setting is only enabled for selective colour grading.

## Logarithmic Mode: Modifying the Brightness

When you modify brightness, colours appear to emit more or less light. You can modify brightness across the entire image or just in the shadows, midtones, and highlights. You can also view and make printer light adjustments. Reset the brightness settings to their original values at any time.

(a) Printer light settings (b) Brightness slider (c) Brightness controls for shadows, midtones, and highlights (d) Brightness Balance wheel and button

If you want to modify R, G, B curves individually and within a particular range, use the RGB curves. See [Modifying Red, Green, and Blue Channels](#) (page 2119).

## Modifying Brightness in the Entire Image

You can increase or decrease colour brightness across the entire image. Use the Brightness slider to modify the brightness of the red, green, and blue levels uniformly. Use the Brightness Balance wheel to balance colours, remove or add a colour cast, create a sense of time, or create ambience. When you use the Brightness Balance wheel, you modify RGB levels proportionally without changing the overall brightness. For example, if you drag the Brightness Balance wheel toward blue, blue will appear to emit more light while red and green will appear to emit less; the image may therefore develop a blue cast.

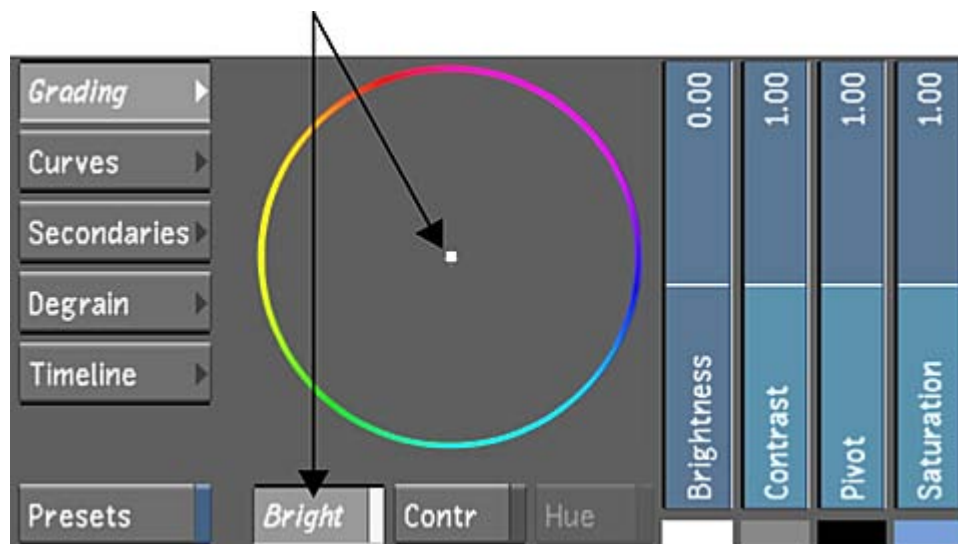

---

**NOTE** When you use a slider or colour balance wheel to colour grade a shot, the colour range is limited by the control (the edge of the colour wheel, for example). Use either the Autodesk control surface or the Tangent CP100 control surface to reach the full spectrum of colour.

---

To modify the brightness in the entire image:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Modify the overall brightness:
  - To increase the overall brightness in the image, drag the Brightness slider up.  
The colours in the image appear to emit more light. The printer light settings are also updated to reflect your changes.
  - To decrease the overall brightness in the image, drag the Brightness slider down.  
The colours in the image appear to emit less light.
- 3 To balance the colours in the image, create ambience, or develop a colour cast, enable Brightness and then drag the Brightness Balance wheel towards the colour you want to increase in the image. For example, to create a cooler image, drag toward blue; to create a warmer image, drag toward red.

The colours are balanced in the image without affecting the overall brightness. The printer light settings are also updated to reflect your changes.

**TIP** When you click on the printer lights, the printer light values are replaced by values based on the center point of the colour wheel.

- 4 Make adjustments to the image using the Brightness slider and Brightness Balance wheel until you are satisfied with the results.

**TIP** When working with any of the vertical sliders in the Grading menu, refer to their numerical values in order to make more precise adjustments. The default value for each of the sliders reflects the mid-point in the range of available values. For example, the Brightness slider has a range of -25 to 25, and a default mid-point value of 0. The Contrast slider, on the other hand, has a range of 0 to 2, making for a mid-point default value of 1.

## Adjusting Printer Lights for Primary Grading

You can make printer light adjustments to the entire image when you want to grade your shots according to printer lights and fstops. You can adjust the level of the overall colour brightness or the level of the RGB/CMY values independently. You can then send the printer light settings to the film lab for processing. Printer light steps are set in the Display & Interface page of the user configuration. See [Display & Interface Settings](#) (page 1805).

**NOTE** Hotkeys for printer light adjustments only work in Log mode.

**To modify brightness by printer lights:**

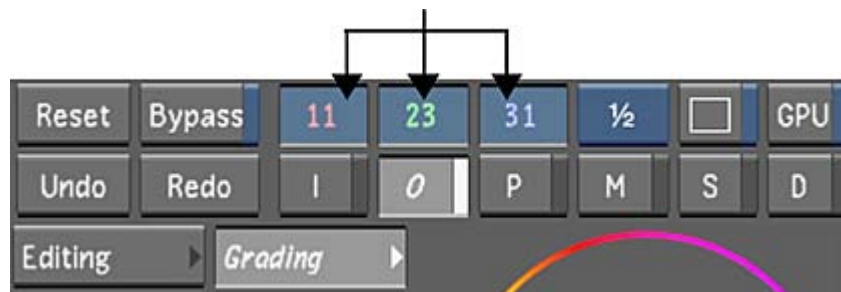

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Use the following keypad hotkeys to make printer light adjustments to the image.

| Press:            | To:                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------|
| + (plus sign)     | Increase overall brightness by one step. Press <code>Shift++</code> (+) to increase overall brightness by a half step. |
| Enter             | Decrease overall brightness by one step. Press <code>Shift+Enter</code> to decrease overall brightness by a half step. |
| NumLock           | Increase red brightness by one step. Press <code>Shift+NumLock</code> to increase red brightness by a half step.       |
| 7                 | Decrease red brightness by one step. Press <code>Shift+7</code> to decrease red brightness by a half step.             |
| / (divide sign)   | Increase green brightness by one step. Press <code>Shift+ /</code> to increase green brightness by a half step.        |
| 8                 | Decrease green brightness by one step. Press <code>Shift+8</code> to decrease green brightness by a half step.         |
| * (multiply sign) | Increase blue brightness by one step. Press <code>Shift+*</code> to increase blue brightness by a half step.           |

| Press:         | To:                                                                                                                |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| 9              | Decrease blue brightness by one step. Press <code>Shift+9</code> to decrease blue brightness by a half step.       |
| 4              | Increase cyan brightness by one step. Press <code>Shift+4</code> to increase cyan brightness by a half step.       |
| 1              | Decrease cyan brightness by one step. Press <code>Shift+1</code> to decrease cyan brightness by a half step.       |
| 5              | Increase magenta brightness by one step. Press <code>Shift+5</code> to increase magenta brightness by a half step. |
| 2              | Decrease magenta brightness by one step. Press <code>Shift+2</code> to decrease magenta brightness by a half step. |
| 6              | Increase yellow brightness by one step. Press <code>Shift+6</code> to increase yellow brightness by a half step.   |
| 3              | Decrease yellow brightness by one step. Press <code>Shift+3</code> to decrease yellow brightness by a half step.   |
| - (minus sign) | Reset overall brightness.                                                                                          |

The printer light settings for the R, G, and B values are updated to reflect your changes.

**NOTE** Printer light settings do not include any modifications you make to brightness in the shadows, midtones, or highlights. See [Modifying Brightness in the Shadows, Midtones, and Highlights](#) (page 2105).

**TIP** When you click on the printer lights, the printer light values are replaced by values based on the center point of the colour wheel. If you then right-click one of the colour wheel values, the calculator appears in the UI, allowing you to enter a value.

## Modifying Brightness in the Shadows, Midtones, and Highlights

You can increase or decrease the brightness in the shadows, midtones, or highlights. Use the Shadow, Midtone, or Highlight slider to modify the brightness of the red, green, and blue levels uniformly. Use the Low, Mid, or High Balance wheel to balance colours by modifying RGB levels proportionally.

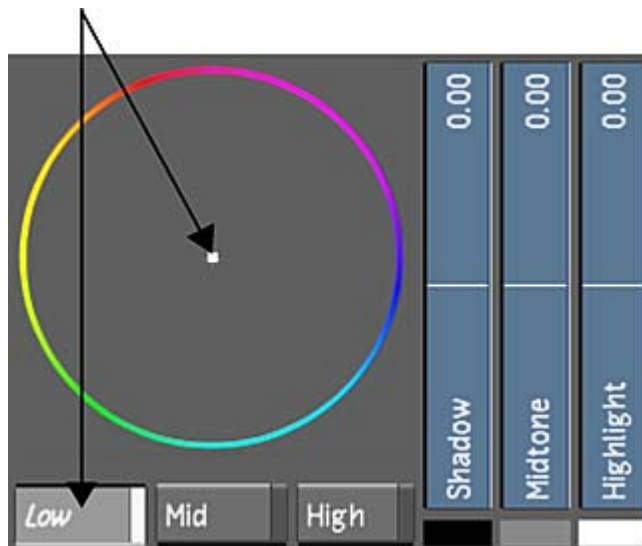

---

**NOTE** When you modify brightness in the shadows, midtones, or highlights, your changes are not reflected in the printer light settings.

---

**To modify the brightness in the shadows, midtones, and highlights:**

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Adjust the overall brightness:
  - To adjust the overall brightness in the shadows, drag the Shadow slider. Drag up to increase brightness. Drag down to decrease brightness.
  - To adjust the overall brightness in the midtones, drag the Midtone slider. Drag up to increase brightness. Drag down to decrease brightness.
  - To adjust the overall brightness in the highlights, drag the Highlight slider. Drag up to increase brightness. Drag down to decrease brightness.
- 3 Balance the brightness of colours:
  - To balance the brightness of the colours in the highlights, enable High and then drag the High Balance wheel toward the colour you want to increase in the image.
  - To balance the brightness of the colours in the midtones, enable Mid and then drag the Mid Balance wheel toward the colour you want to increase in the image.
  - To balance the brightness of the colours in the shadows, enable Low and then drag the Low Balance wheel toward the colour you want to increase in the image.

## Resetting Overall Brightness

You can reset the image brightness using the keypad hotkey.

**To reset Brightness settings:**

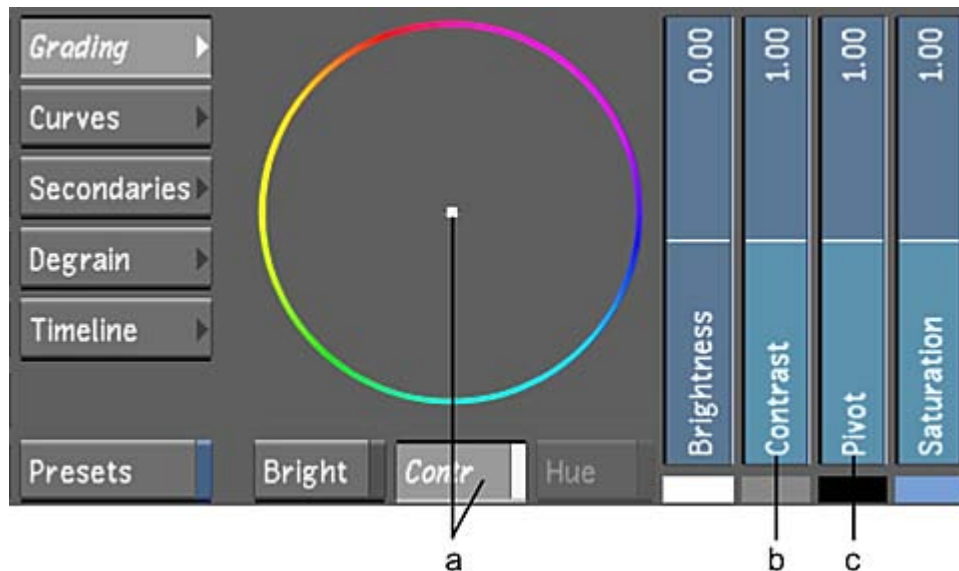

- 1 Press – (minus sign) on the keypad.

The Brightness slider and Brightness Balance wheel are reset to their default settings. Printer light settings are also reset and the image reverts to its original printer light settings.

**NOTE** Modifications you made to the image using the Brightness controls for shadows, midtones, and highlights are not reset to their default values. See [Resetting Parameters](#) (page 1849).

## Logarithmic Mode: Improving Contrast

Poor image contrast can be caused by various factors. For example, when you remove a colour cast from a shot, the shot may become washed out. Washed out images usually occur when image contrast and saturation levels are too low. To complete the task of balancing the colours in the shot, use the Contrast controls to correct poor contrast. When you correct contrast, you can also set the pivot point and saturation levels. See [Setting the Pivot Point](#) (page 2108) and [Modifying Saturation](#) (page 2109).

(a) Contrast Balance wheel and button (b) Contrast slider (c) Pivot slider

**NOTE** When you use a slider or colour balance wheel to colour grade a shot, the colour range is limited by the control (the edge of the colour wheel, for example). Use the Autodesk control surface or the Tangent CP100 control surface to reach the full spectrum of colour. You can also use the standard Lustre calculator to extend beyond the UI colour range. To access the calculator, click on the printer lights and then right-click one of the colour wheel values.

## Modifying Image Contrast

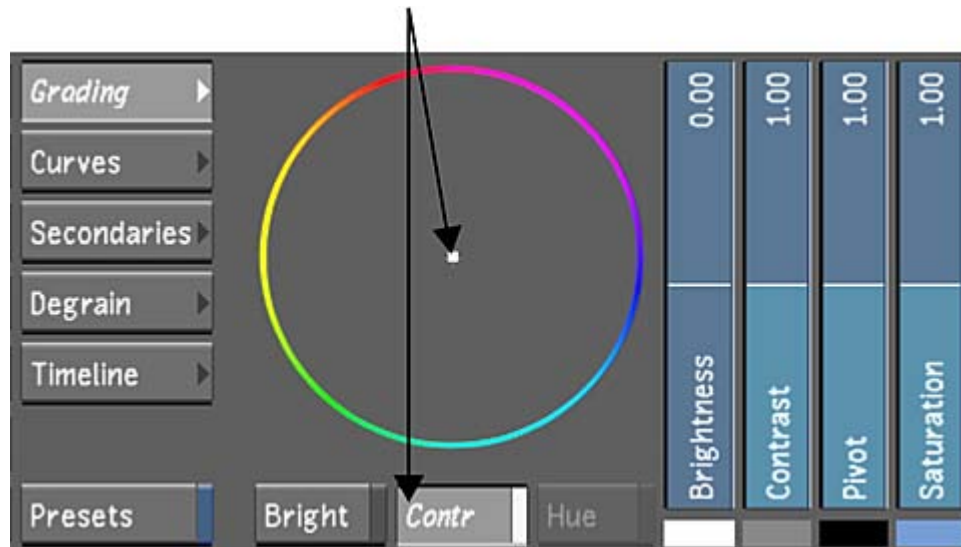

Improve image contrast by modifying the film gamma with the Contrast slider. Use the Contrast Balance wheel to increase the contrast of any channel while decreasing the contrast of other channels. These changes in contrast are relative to the pivot point.

**NOTE** To see how balancing the contrast works, view the histogram. Press **Alt+2** while modifying the contrast balance and the pivot point.

**WARNING** The Histogram, Waveform, and Vectorscope functions do not update when GPU processing is enabled.

### To improve image contrast:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Modify the contrast:
  - To increase the contrast in the image, drag the Contrast slider up.
  - To decrease the contrast in the image, drag the Contrast slider down.
- 3 To increase contrast in a range of colour in the image, enable Contrast and then drag the Contrast Balance wheel towards the colour.

The colour you drag toward increases in contrast while the opposing colours decrease in contrast. The overall image contrast remains the same.

**NOTE** The pivot point is the point around which the contrast balanced. See [Setting the Pivot Point](#) (page 2108).

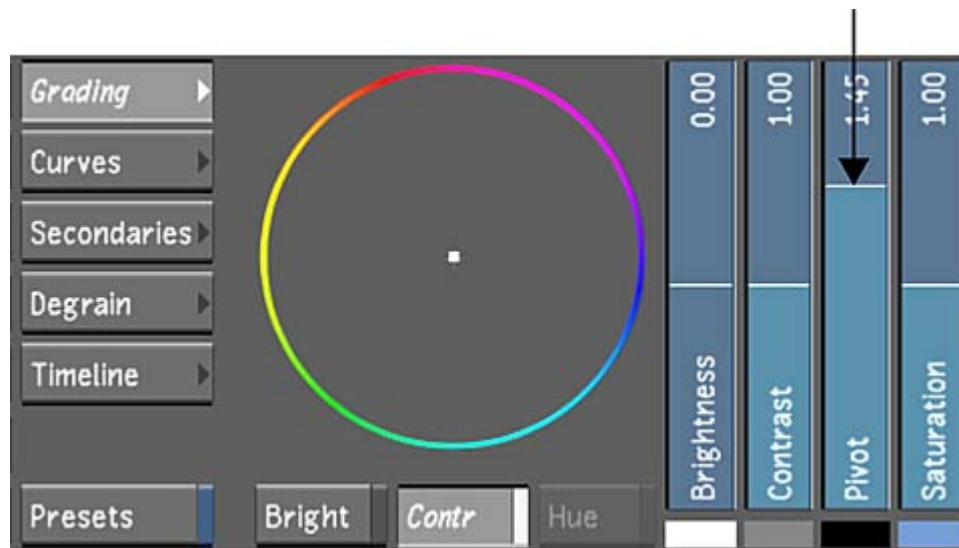

- 4 Make adjustments to the image using the Contrast slider and Contrast Balance wheel until you are satisfied with the results.

## Setting the Pivot Point

You can set the pivot point for contrast. The pivot point is the anchor around which contrast is scaled. By default, the pivot point is set to the midpoint in the image. You can move the pivot point to scale the contrast around the image highlights or shadows.

### To set the pivot point:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Drag the Pivot slider to move the anchor around which the contrast is modified. Drag up to modify contrast around highlights. Drag down to modify contrast around shadows.

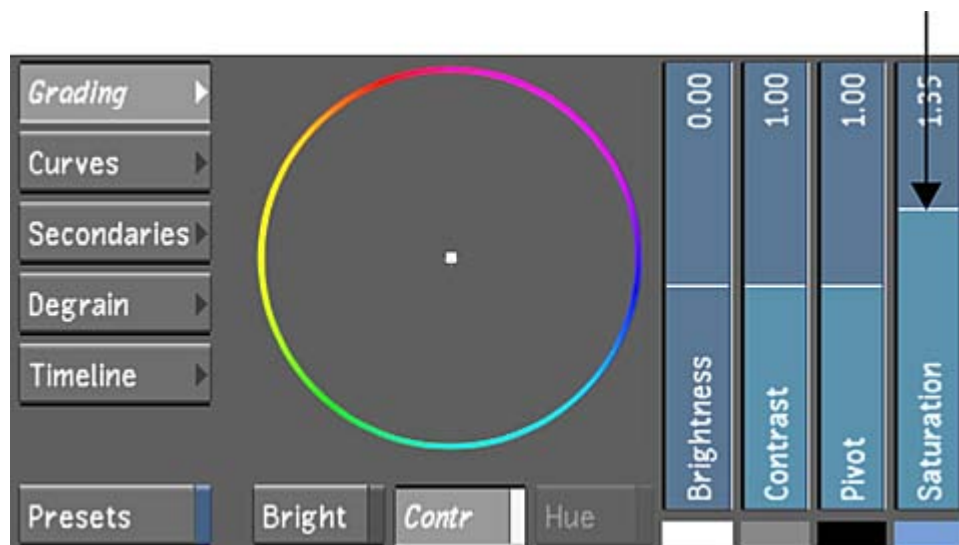

## Modifying Saturation

Control the image's colour intensity by modifying saturation levels.

To modify the saturation level:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Modify the saturation:
  - To increase the saturation in the image, drag the Saturation slider up.
  - To decrease the saturation in the image, drag the Saturation slider down.

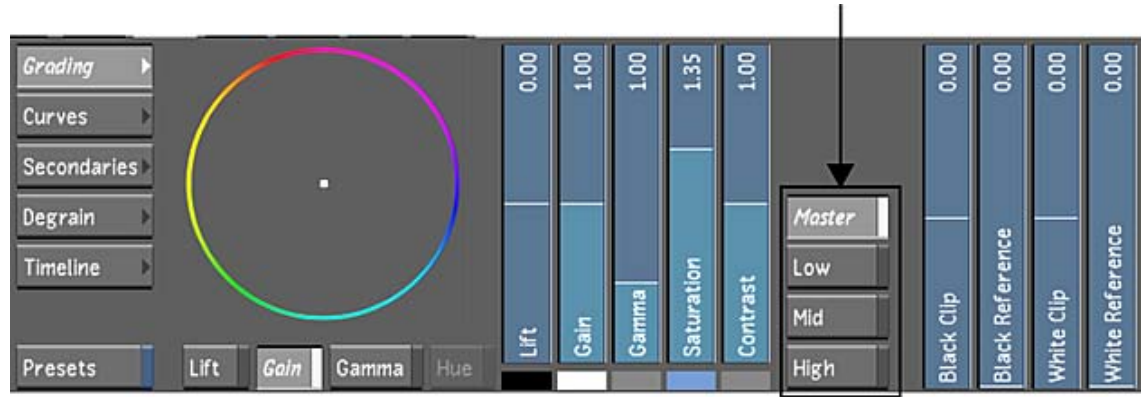

# Linear Mode: Selecting Levels of the Image

You can modify lift, gain, gamma, and saturation in the low, mid, and high levels of the image, or across the entire image. Select the range you want to modify while performing primary colour grading. You can also define values to clamp minimum and maximum luminance values.

**NOTE** You can use the Tangent CP100 control surface when you want to colour grade the entire image, not an individual level. You can use the Autodesk control surface for either the entire image or an individual level.

## To select a level of the image for colour grading:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Enable the appropriate button to select the entire image or a level of the image for primary colour grading.

| Enable: | To perform primary colour grading on: |
|---------|---------------------------------------|
| Master  | The entire image.                     |
| Low     | The low levels of the image.          |
| Mid     | The mid levels of the image.          |
| High    | The high levels of the image.         |

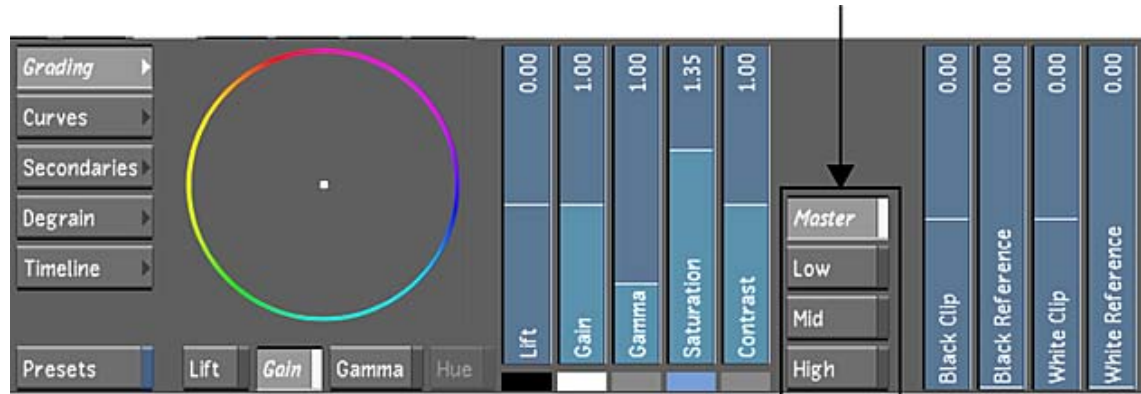

# Linear Mode: Modifying Lift

You can lift colour values in a selected range or in the entire image, and then offset ranges of colour. Changes in lift mostly affect black level. Although lift affects the entire image or image level, visually, it mostly affects the shadows.

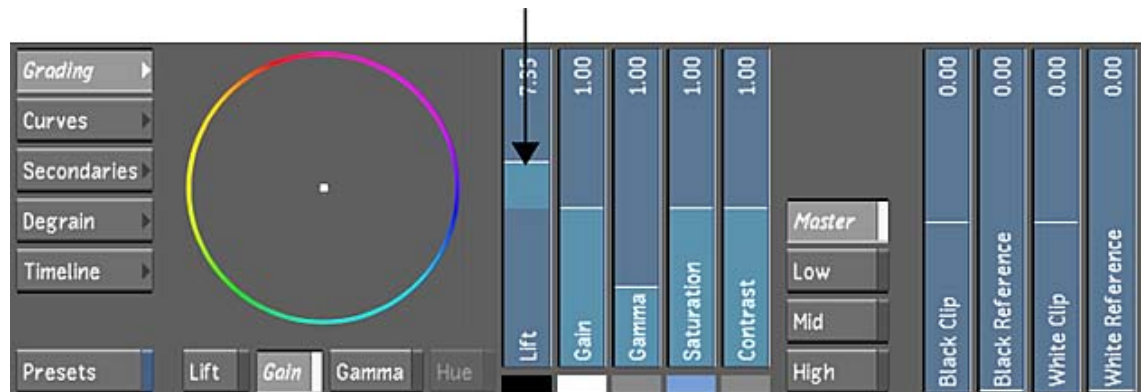

**NOTE** When you use a slider or colour balance wheel to colour grade a shot, the colour range is limited by the control (the edge of the colour wheel, for example). Use the Autodesk control surface or the Tangent CP100 control surface to reach the full spectrum of colour.

**To lift colour values:**

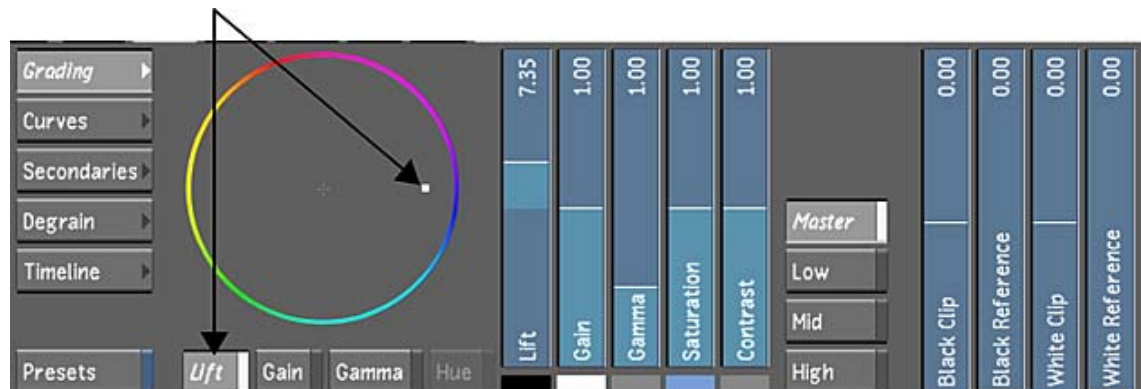

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Select the image level you want to modify.

- 3 Modify the black levels:
  - To increase the black level, drag the Lift slider up.
  - To decrease the black level, drag the Lift slider down.

- 4 To offset the colours while maintaining the overall luminance, enable Lift and then drag the Lift Balance wheel towards a colour.

The selected colour is lifted while other colours in the image are offset to compensate for the change in luminance.

## Linear Mode: Modifying Gain

You can boost image colours in the highlights of the selected range or entire image. Changes in gain mostly affect the highlights and do not change the black point of the image. Gain is similar to brightness in Log mode.

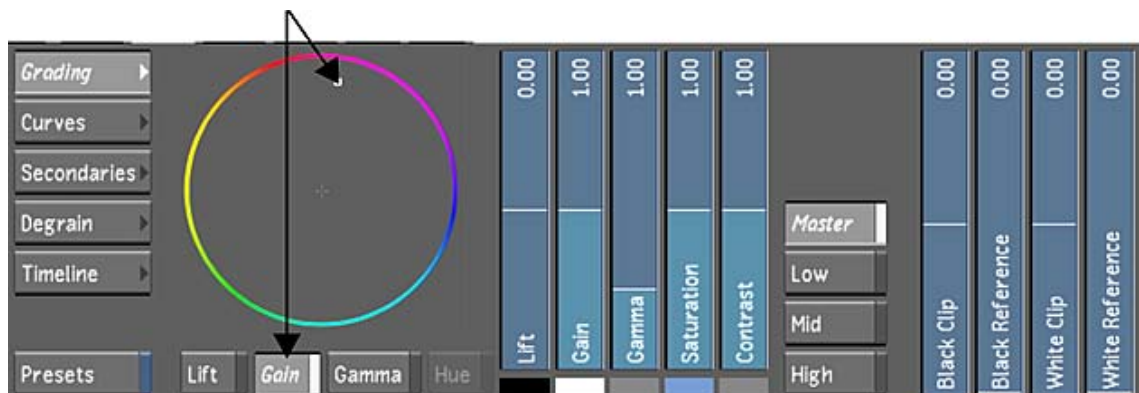

---

**NOTE** When you use a slider or colour balance wheel to colour grade a shot, the colour range is limited by the control (the edge of the colour wheel, for example). Use the Autodesk control surface or the Tangent CP100 control surface to reach the full spectrum of colour.

---

To modify gain:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Select the image level you want to modify.
- 3 Modify the image colours:
  - To increase image colours uniformly, drag the Gain slider up.
  - To decrease image colours uniformly, drag the Gain slider down.
- 4 To offset the colours while maintaining the overall gain, enable Gain and then drag the Gain Balance wheel towards a colour you want to boost.

The selected colour is boosted while other colours in the image are offset to compensate for the change in gain.

## Linear Mode: Modifying Gamma

You can adjust the grey values of an image by adjusting gamma. This allows you to brighten or darken the image and modify the gamma level without greatly affecting the shadows and highlights.

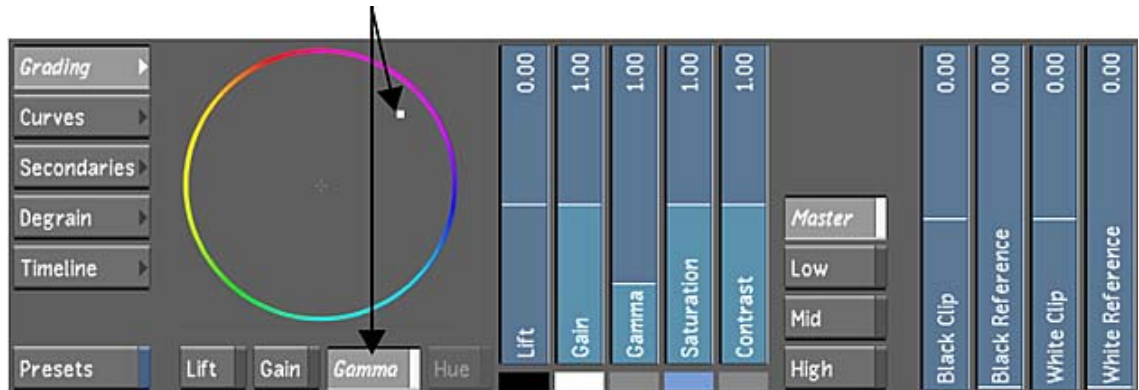

---

**NOTE** When you use a slider or colour balance wheel to colour grade a shot, the colour range is limited by the control (the edge of the colour wheel, for example). Use the Autodesk control surface or the Tangent CP100 control surface to reach the full spectrum of colour.

---

### To modify gamma:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Select the range you want to modify.
- 3 Do one of the following:
  - To decrease contrast, drag the Gamma slider up.
  - To increase contrast, drag the Gamma slider down.
- 4 To balance the colours while maintaining the overall gamma level, enable Gamma and then drag the Gamma Balance wheel towards a colour.

The amount of the selected colour is increased in the image while the overall gamma level is maintained. The middle of the image curve is the most affected.

**NOTE** Select Low, Mid, or High to further differentiate between the areas of the image that are affected.

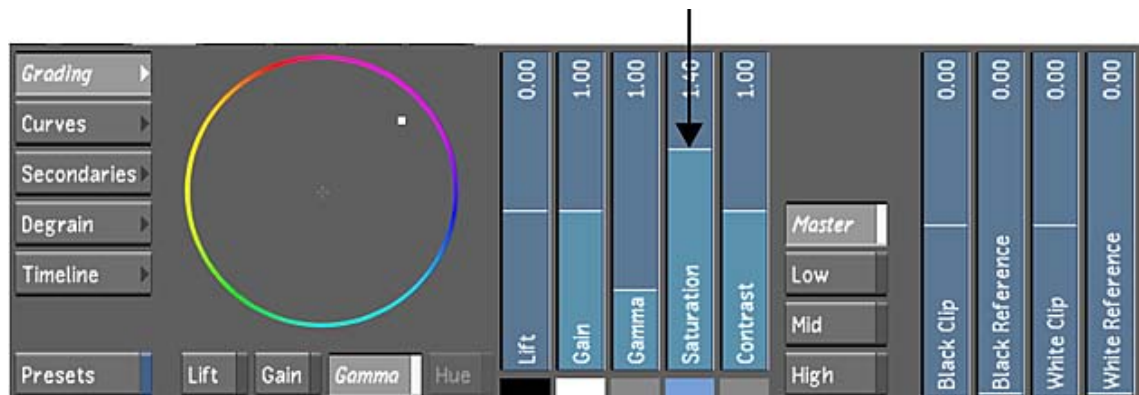

## Linear Mode: Modifying Saturation

Control the image's colour intensity by modifying the saturation levels.

### To modify image saturation:

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Modify the image saturation:
  - To increase image saturation, drag the Saturation slider up.
  - To decrease image saturation, drag the Saturation slider down.

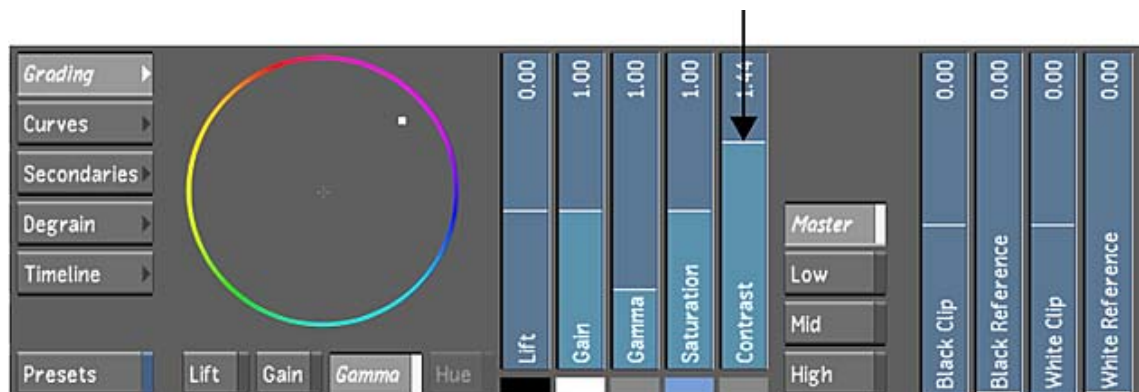

## Linear Mode: Modifying Contrast

As in Log mode, you can complete the task of balancing the shot's colours by modifying the contrast. With the Contrast slider, you can change the image's Linear luminance curve to a film-contrast-like S curve.

**To modify image contrast:**

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.
  - To make final adjustments to the primary colour grade, click Output.
- 2 Modify the image contrast:
  - To increase image contrast, drag the Contrast slider up.
  - To decrease image contrast, drag the Contrast slider down.

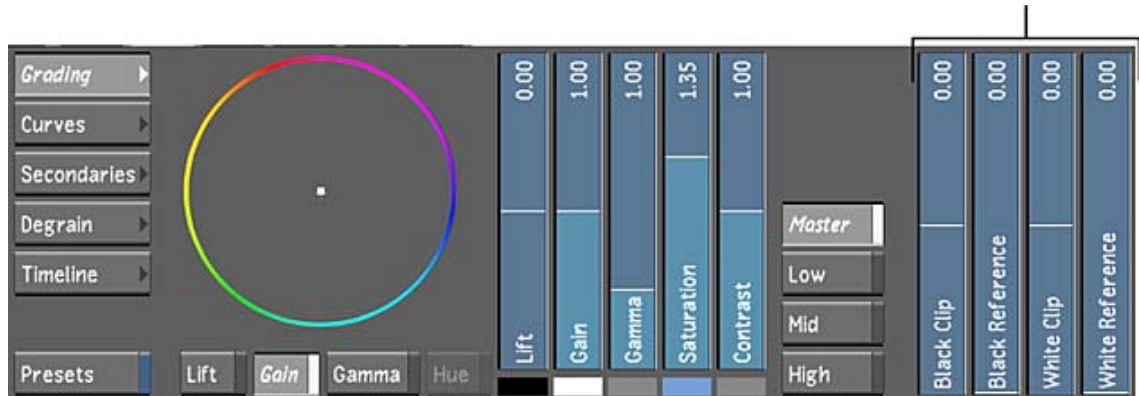

## Linear Mode: Setting Black Clip and White Clip

You can define values to clamp minimum and maximum luminance values using the clip and reference sliders.

**To clamp minimum and maximum luminance values:**

- 1 Indicate whether this is the initial or final primary grade:
  - To work on the initial primary colour grade, click Input.

- To make final adjustments to the primary colour grade, click Output.
- 2 Modify the clip and reference values using the following sliders.
  - Black Clip** Determines the extent to which values will be smoothed out in the shadows.
  - Black Reference** Defines the range of values in the shadows where the Black Clip will be effective.
  - White Clip** Determines the extent to which values will be smoothed out in the highlights.
  - White Reference** Defines the range of values in the highlights where the White Clip will be effective.

## Matching Colours

Use the Match feature to match a sample from one shot to other shots to improve continuity between shots in a scene. You can match highlights, shadows, or overall saturation. You can also use Match when you want to match colours such as the colour of the sky or skin tone.

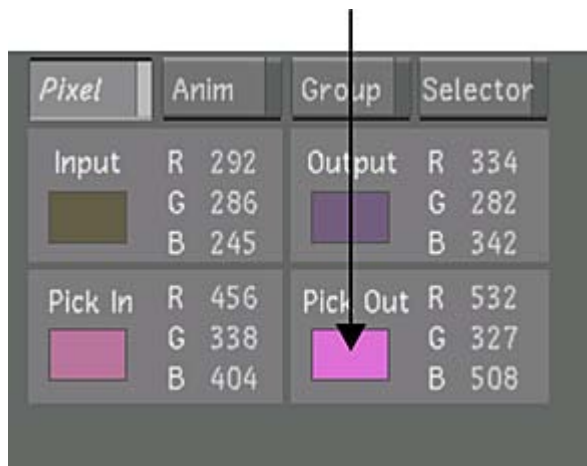

### To match colours:

- 1 In the Grading menu, click Input.
- 2 Show the clips you want to match in the Player. Press F3 to display Multi View and then set the number of viewers. See [Setting the Viewing Options](#) (page 2027).
- 3 Sample the image you want to use as reference. This is the shot to which other clips are matched. Sample an area that is predominantly black, white, or contains a wide spectrum of colours.

| You can:   | To:                                                                                                                           |
|------------|-------------------------------------------------------------------------------------------------------------------------------|
| Click      | Sample a single pixel in the image. You can drag through the image until you locate the pixel you want to sample, then click. |
| Shift-drag | Sample an average taken from a range of colours in the image.                                                                 |

The sample appears in the Pixel Analyser.

**NOTE** You can only sample the original image in the viewer. You cannot sample images that are loaded to the frame buffer. In order for sampling to function, geometries cannot be displayed. Be sure to disable the Show button in the Secondaries menu.

- 4 Sample the colours in the shot you want to match. Try to match whites with whites, blacks with blacks, or select a broad range from both images to match saturation.

| You can:        | To:                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Alt-click       | Sample an individual pixel and set the Brightness Balance wheel to match the reference sample. You can drag through the image until you locate the pixel you want to sample, then Alt-click.                        |
| Shift+Alt-drag  | Sample an average taken from a range of colours in the image and set the Brightness Balance wheel to match the reference sample.                                                                                    |
| Ctrl-click      | Sample an individual pixel and set the Brightness Balance wheel and Brightness slider to match the reference sample. You can drag through the image until you locate the pixel you want to sample, then Ctrl-click. |
| Shift+Ctrl-drag | Sample an average taken from a range of colours in the image and set the Brightness Balance wheel and Brightness slider to match the reference sample.                                                              |

The sampled colours in the second shot are matched to the reference image.

- 5 Continue matching other shots to the reference image.
- 6 To refine the result, use other controls in the Grading menu and then reuse the Match feature.

## Autograding Shots

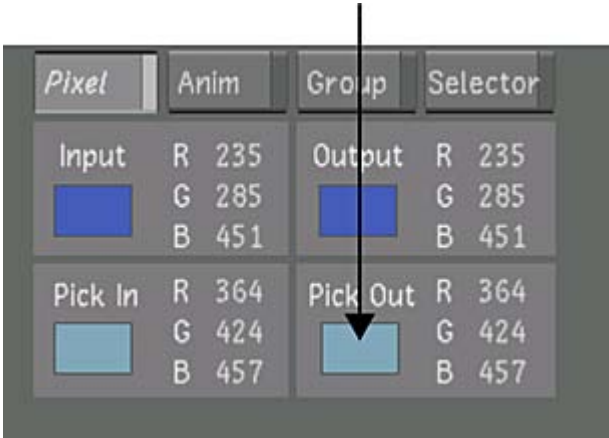

From the Grading menu, you can automatically colour grade a shot based on sampled pixels. Autograding balances the colours according to the Brightness Balance wheel—the sampled pixels are changed to a more neutral colour. For example, if you sample an area that contains more blue than any other colour, yellow (the colour that is opposite on the colour wheel) is added to the image. To properly autograde a shot, sample an area of the image that should be neutral or have no hue cast. Sample blacks, whites, or greys.

**To autograde a shot:**

- 1 Sample an area of the image that should be neutral.

| You can:   | To:                                                                                                                           |
|------------|-------------------------------------------------------------------------------------------------------------------------------|
| Click      | Sample a single pixel in the image. You can drag through the image until you locate the pixel you want to sample, then click. |
| Shift-drag | Sample an average taken from a range of colours in the image.                                                                 |

The sample appears in the Pixel Analyser.

- 2 Press / (forward slash).

The entire image is autograded according to the sample. The colours are rebalanced as shown on the Brightness Balance wheel.

# Colour Grading RGB and Hue Curves

When you want to colour grade a specific range of colour without generating a key, you can modify the RGB and Hue curves. The RGB curves are inserted in the processing pipeline in two places—after the initial primary colour grade and after the addition of any Sparks effects. Sparks are inserted after secondary colour grading. The Hue curves are inserted in the processing pipeline in one place—after the initial primary colour grade. RGB and Hue curves can also be applied to secondary colour grades.

The RGB curves consist of red, green, blue, and RGB curves. Modify these curves when you want to remap colour values for the red, green, and blue channels individually or together. The Hue curves consist of Hue, Lightness, Saturation, and Luminance curves. Modify these curves when you want to perform hue shifts, lighten colours in the image, and suppress or saturate a particular range of colour or luminance area.

You can also plot colours and add vertices to the curves so that you can remap any value in the colour range precisely.

For information on secondary colour grading, see [Secondary Colour Grading](#) (page 2126). The Luminance curve can only be modified on the Curves menu.

**TIP** For faster playback on shots with input RGB and Hue curve modifications, enable GPU processing by clicking the GPU button. See [GPU Acceleration](#) (page 2086).

## Accessing the Curves Menu

Use the Curves menu to modify RGB and Hue curves.

To access the Curves menu:

- 1 Do one of the following:
  - In the Main menu, click Colour and then Curves.
  - Press F7. See [Displaying Colour Menus in the Player](#) (page 2085).

The Curves menu appears.

(a) Curves button (b) Curves menu (c) RGB and Hue curve buttons (d) Sampled colour values (e) Input and Output buttons (f) Secondary layers

- 2 Enable one of the following buttons.

**Input** Enables RGB and Hue curve modification for primary colour grading performed prior to secondary colour grading.

**Output** Enables RGB curve modification for primary colour grading performed after secondary colour grading and the creation of Sparks effects.

**Secondary layer** Enables a layer for RGB and Hue curve modification for secondary colour grading.

**NOTE** Hue curves are not functional when the Output button is enabled.

## Plotting Colour Values when Adjusting Curves

Plot the colour value of any sample on RGB and Hue curves. While you make adjustments, you can plot colours as often as necessary to isolate the colours you want to modify.

To plot colour values when adjusting curves:

- 1 Indicate the colour grading stage at which the curve modification is being applied:
  - To work on the initial primary grade, click Input.
  - To make final adjustments to the primary grade, click Output.
  - To make curve modifications for secondary colour grading, enable a secondary layer.
- 2 In the Player, sample the colour you want to use as reference. Click the image to sample a single pixel. You can drag through the image until you locate the pixel you want to sample, and then click. On the RGB curve, red, green, and blue vertical lines appear, representing the red, green, and blue colour channels.

On the Hue curves, a single vertical line appears, representing the colour on the hue spectrum.

- 3 To zoom in on a curve using rectangle zoom, drag a selection box around the desired area while pressing **Alt**, and then release the mouse.

The area of the curves contained by the selection box now occupies the entire Curve canvas.

- 4 To zoom in on a curve using proportional zoom, press **Alt** while dragging right or left with the right mouse button.

The aspect ratio of the Curve canvas is maintained while zooming in and out.

## Modifying Red, Green, and Blue Channels

Modify the RGB, red, green, or blue curves to fine-tune the colour grade. When you modify the RGB curve, the red, green, and blue channels are adjusted equally. When you modify the red, green, or blue curve, only the selected colour channel is adjusted. You can add vertices to a curve to refine your adjustments.

**To modify the red, green, blue, or RGB curve:**

- 1 Indicate the colour grading stage at which the curve modification is being applied:
  - To work on the initial primary grade, click **Input**.
  - To make final adjustments to the primary grade, click **Output**.
  - To make curve modifications for secondary colour grading, enable a secondary layer.
- 2 Click **RGB** to display the RGB curves.

- 3 Show the curve you want to modify by clicking the button corresponding to the colour of the curve. The selected curve is highlighted.

**NOTE** To display the RGB curve, click the white button.

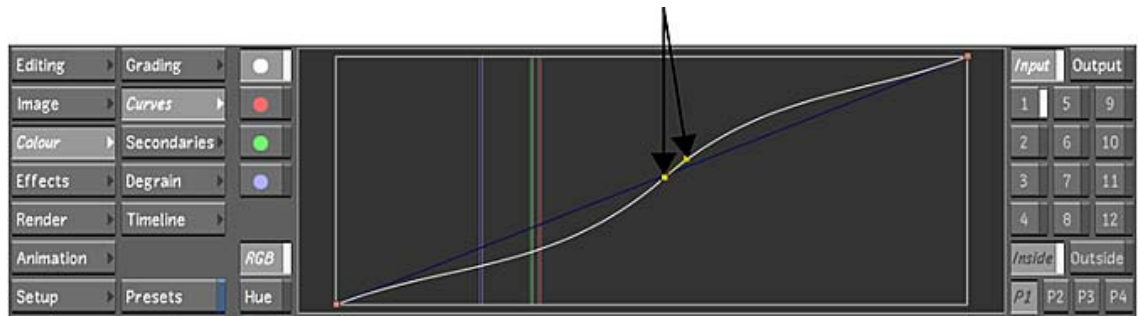

- 4 Sample the colour you want to use as a reference for your adjustments. See [Plotting Colour Values when Adjusting Curves](#) (page 2118).  
Red, green, and blue vertical lines representing the colour channels are plotted on the curve.
- 5 To add a vertex to the curve, place the mouse cursor over the area on the curve where you want to add the vertex and press A. To lock the curve in place while adding a vertex, press **Shift+A** on the curve.

- 6 Click a vertex to display its tangent handle and then drag the handle to adjust the curve. You can also adjust the curve by dragging the vertex.

- 7 Modify the curve until you are satisfied with the results:
  - To select a vertex, click it. To select several vertices, draw a selection box around them.
  - To move one or several selected vertices, drag a selected vertex. To restrict vertex movement to the Y axis, press **Shift** while moving the mouse. To restrict vertex movement to the X axis, press **Shift+Alt** while moving the mouse.
  - To delete vertices, select them and then press **D**.

## Modifying Hue, Saturation, Luminance, and Lightness

Modify curves to adjust the hue, saturation, luminance, and lightness of an image. You can:

- Perform hue shifts.
- Suppress or saturate colour ranges.
- Suppress or saturate luminance ranges.
- Lighten or darken colour ranges.
- Add vertices to the curves to refine your adjustments.

## Shifting Hue

Shift the hue of the entire image or a range of colour in the image.

To perform a hue shift:

- 1 Indicate the colour grading stage at which the curve modification is being applied:
  - To work on the initial primary grade, click **Input**.
  - To make curve modifications for secondary colour grading, enable a secondary layer.
- 2 Click the **Hue** button located below the **RGB** button, and then click the upper **Hue** button to display the Hue curve.

The Hue curve is plotted to the Hue spectrum.

- 3 Sample the colour you want to use as a reference for your adjustments. See [Plotting Colour Values when Adjusting Curves](#) (page 2118).  
A vertical line representing the reference colour is plotted on the Hue curve.
- 4 Drag vertices up or down to shift the hue of the colour displayed in the hue spectrum.

The hue of the selected colours moves through the hue spectrum as you drag.

**TIP** You can also select a vertex to use tangent handles to adjust the curve.

- 5 Modify the curve until you are satisfied with the results:
  - To select a vertex, click it. To select several vertices, draw a selection box around them.
  - To move several selected vertices, select them and then drag one. To restrict vertex movement to the Y axis, press *Shift* while moving the mouse. To restrict vertex movement to the X axis, press *Shift+Alt*.
  - To add a vertex to the curve, place the mouse cursor over the area on the curve where you want to add the vertex and then press *A*.
  - To lock the curve in place while adding a vertex, press *Shift+A* on the curve.
  - To delete vertices, select them and then press *D*.

## Saturating and Suppressing Colours

You can adjust the purity of colours in the image by modifying the saturation. You can suppress or saturate colours in a range or across the entire image.

**To saturate and suppress colours in the image:**

- 1 Indicate the colour grading stage at which the curve modification is being applied:
  - To work on the initial primary grade, click *Input*.
  - To make curve modifications for secondary colour grading, enable a secondary layer.
- 2 Click *Hue* and then click *Sat* to display the Saturation curve.

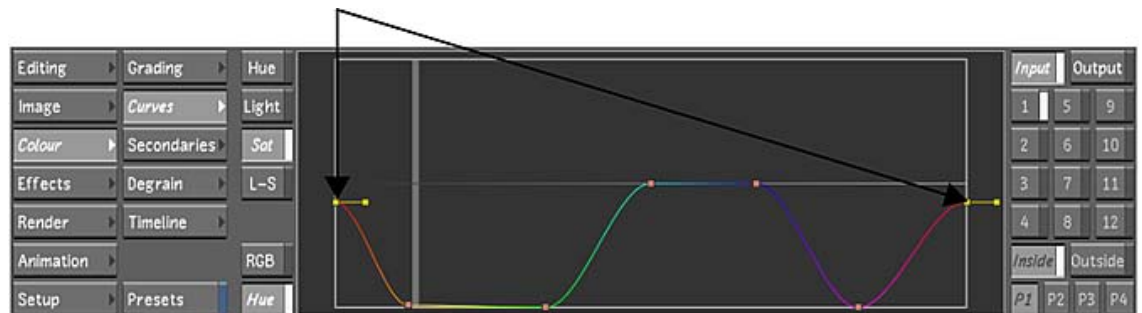

The Saturation curve is plotted to the hue spectrum.

- 3 Sample the colours you want to use as a reference for your adjustments. See [Plotting Colour Values when Adjusting Curves](#) (page 2118).

A vertical line representing the reference colour is plotted on the Saturation curve.

- 4 To select a vertex, click it. To select several vertices, draw a selection box around them.
- 5 Saturate or suppress the colour:
  - To saturate the colour displayed in the hue spectrum, drag selected vertices up.
  - To suppress the colour displayed in the hue spectrum, drag selected vertices down.

**TIP** You can also select a vertex to use tangent handles to adjust the curve.

- 6 To move several selected vertices, select them and then drag one. To restrict vertex movement to the Y axis, press **Shift** while moving the mouse. To restrict vertex movement to the X axis, press **Shift+Alt**.

**TIP** To create a greyscale image, select all the vertices and then drag them all the way down. You can then drag vertices up to saturate isolated ranges of colour.

- 7 To add a vertex to the curve, place the mouse cursor over the area on the curve where you want to add the vertex and then press **A**. To lock the curve in place while adding a vertex, press **Shift+A** on the curve.

- 8 To delete vertices, select them and then press D.
- 9 Edit the curve until you are satisfied with the results.

## Modifying Image Luminance

The Luminance curve represents the gamut of light from black to white. Use the Luminance curve to saturate or desaturate different luminance areas by adding or removing hue from black and white points. Like any other curve, you can add points to refine ranges of an effect.

**To suppress or saturate luminance areas in the image:**

- 1 Indicate the colour grading stage at which the curve modification is being applied:
  - To work on the initial primary grade, click Input.
  - To make curve modifications for secondary colour grading, enable a secondary layer.
- 2 Click Hue and then click L-S to display the Luminance curve.

The Luminance curve is plotted to the hue spectrum.

- 3 Sample the luminance areas you want to use as a reference for your adjustments. See [Plotting Colour Values when Adjusting Curves](#) (page 2118).  
A vertical line representing the reference colour is plotted on the Luminance curve.
- 4 To select a vertex, click it. To select several vertices, draw a selection box around them.
- 5 Saturate or suppress the luminance area:
  - To saturate the luminance area displayed in the hue spectrum, drag selected vertices up.
  - To suppress the luminance area displayed in the hue spectrum, drag selected vertices down.

**TIP** You can also select a vertex to use tangent handles to adjust the curve.

- 6 To move several selected vertices, select them and then drag one. To restrict vertex movement to the Y axis, press Shift while moving the mouse. To restrict vertex movement to the X axis, press Shift+Alt.

- 7 To add a vertex to the curve, place the cursor over the area on the curve where you want to add the vertex and then press A. To lock the curve in place while adding a vertex, press **Shift+A** on the curve.
- 8 To delete vertices, select them and then press **D**.
- 9 Edit the curve until you are satisfied with the results.

## Modifying Image Lightness

Increase or decrease the lightness in specific colour ranges or across the image.

To modify image lightness:

- 1 Indicate the colour grading stage at which the curve modification is being applied:
  - To work on the initial primary grade, click **Input**.
  - To make curve modifications for secondary colour grading, enable a secondary layer.
- 2 Click **Hue** and then click **Light** to display the Lightness curve.

The Lightness curve is plotted to the hue spectrum.

- 3 Sample the colours you want to use as a reference for your adjustments.  
A vertical line representing the reference colour is plotted on the Lightness curve.
- 4 To select a vertex, click it. To select several vertices, draw a selection box around them.
- 5 Modify the lightness:
  - To increase the lightness of the colour displayed in the hue spectrum, drag selected vertices up.
  - To decrease the lightness of the colour displayed in the hue spectrum, drag selected vertices down.

**TIP** You can also select a vertex to use tangent handles to adjust the curve.

- 6 To move several selected vertices, select them and then drag one. To restrict vertex movement to the Y axis, press **Shift** while moving the mouse. To restrict vertex movement to the X axis, press **Shift+Alt**.
- 7 To add a vertex to the curve, place the cursor over the area on the curve where you want to add the vertex and then press **A**. To lock the curve in place while adding a vertex, press **Shift+A** on the curve.
- 8 To delete vertices, select them and then press **D**.
- 9 Edit the curve until you are satisfied with the results.

## Secondary Colour Grading

In Lustre, you perform secondary colour grading on shots. With secondary colour grading, you isolate and then colour grade colour ranges and objects in your shots. Secondaries are defined by a combination of keys and geometries—keys to isolate colours and geometries to isolate objects or areas in the image. To colour grade an object that moves through time, you can animate the associated geometry using trackers.

---

**NOTE** Trackers are used for precise secondary animation; however, when a tracker is not required, keyframes are predominantly used to animate secondaries.

---

Secondary colour grading is done in the middle of the colour grading process—after the first modifications you make to RGB and Hue curves and before applying Sparks. In Log mode, you can modify brightness, contrast, and hue. In Linear mode, you can modify lift, gain, gamma, and hue.

---

**NOTE** If you create effects for your image using Sparks, they are processed after secondary colour grading. See [Creating Lustre Sparks Effects](#) (page 2199).

---

You can create and colour grade up to 48 unique secondary layers for each shot. However, you can toggle the secondary layers on and off and view the results in the Player. You can save key presets, geometry presets, and de grain presets. You can also import garbage mask setups, tracker data, and stabilizer data from other Autodesk products.

Secondaries are included in the processing pipeline. With the Geom button activated, you can use the colour grading controls in the Grading menu to perform secondary colour grading to the area defined by the key and geometry.

---

**TIP** GPU acceleration makes faster playback available for certain secondary grading features. See [GPU Acceleration](#) (page 2086).

---

---

**NOTE** The histogram, waveform, and vectorscope monitors do not dynamically update when GPU acceleration is enabled. They retain the colour distribution of the image prior to GPU acceleration being enabled. See [Viewing Colour Distribution](#) (page 2092).

---

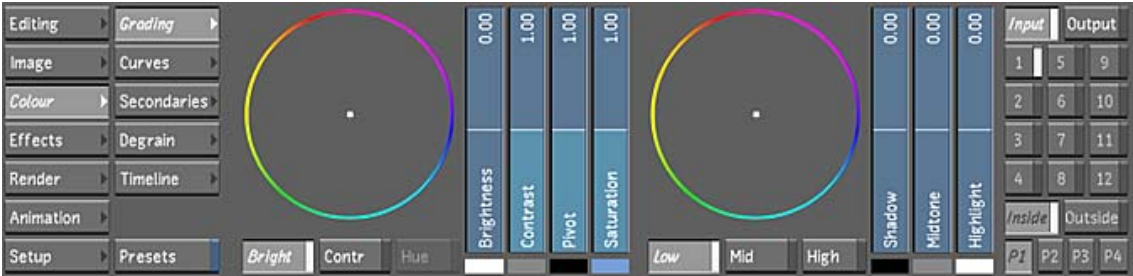

# Accessing Secondary Grading Menus

You perform secondary colour grading with the Secondaries and Grading menus.

To access the menus for secondary colour grading:

- 1 Do one of the following:
  - In the Main menu, click Colour.
  - Press F7. See [Displaying Colour Menus in the Player](#) (page 2085).

The Colour menu appears.

- 2 Click one of the following buttons.

**Secondaries** Displays the Secondaries menu, where you have access to the geometry, keyer, presets, secondary layers, and tracker panels. See [The Secondaries Menu](#) (page 2127).

**Grading** Displays the Grading menu. Once geometries have been created, use the Grading menu for secondary colour grading. In Log mode, make adjustments to brightness, contrast, saturation, and hue. In Linear mode, make adjustments to lift, gain, hue, gamma, and saturation. Use logical operations to link geometries across secondaries. See [Primary Colour Grading](#) (page 2101).

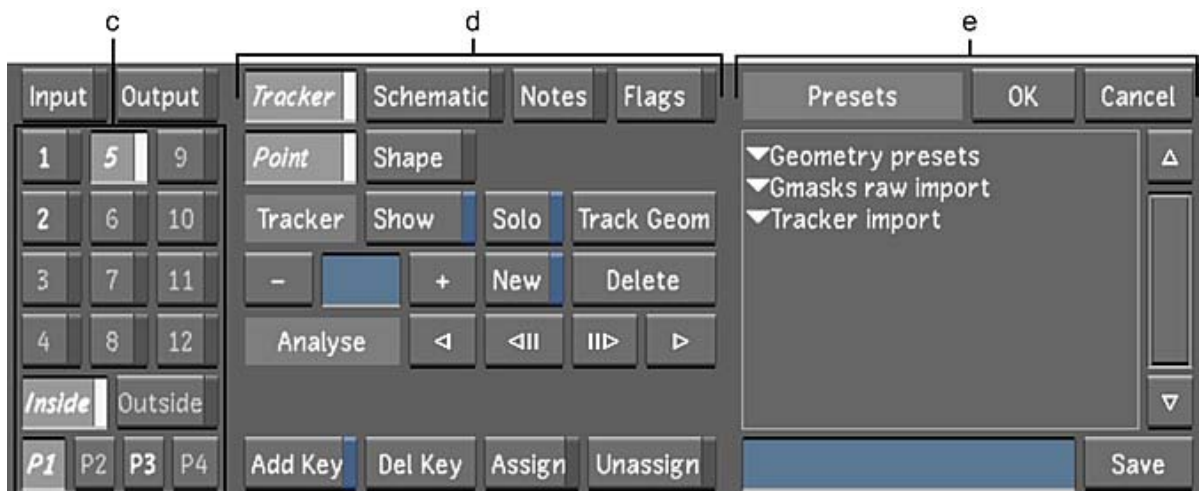

**NOTE** You can also modify RGB and Hue curves for secondaries using the Curves menu. For information, see [Colour Grading RGB and Hue Curves](#) (page 2117).

## The Secondaries Menu

The Secondaries menu allows you to create and track geometries to isolate objects or areas within the shot, and create keys to isolate ranges of colour. You are then able to use logical operations to link geometries across secondaries. The following is a breakdown of the Secondaries menu.

(a) Geometry panel (b) HLS and Diamond Keyer panel (c) Secondary Layers panel (d) Shape and Point Tracker panel (e) Presets panel

**Geometry panel** Creates geometries of various shapes in order to isolate objects or areas within a shot. Once a geometry has been graded, you can modify the softness, colour, opacity, and blur of the geometry to acquire a certain effect. See [About Geometries](#) (page 2134).

**HLS and Diamond Keyer panel** Extracts a key to isolate a colour within your shot. See [Creating a Secondary by Keying a Range of Colours](#) (page 2159).

**Secondary Layers panel** Creates up to 48 layers of secondary grading for each shot. See [Secondary Layers](#) (page 2128).

**Shape and Point Tracker panel** Tracks either objects or points throughout a shot. See [Shape Tracker](#) (page 2182) and [Animating the Point Tracker](#) (page 2187).

**Presets panel** Lists the previously saved geometry, gmask raw, tracker, and key presets that allows you to increase the efficiency and speed of the colour grading process. See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

## Secondary Layers

The secondary layers panel allows you to create up to 48 secondaries to be applied to each shot in your project. Once a secondary layer is selected, you can choose whether or not to apply the grading changes to the shot.

(a) Secondary layers (b) Secondary layer pages (c) Secondary layers within the F7 mode (d) Secondary layer pages within the F7 mode

**Secondary Layer buttons** There are 48 secondary layers that can be used to contain your secondary grading information. When a layer is selected, you are able to modify the grading applied to that layer. When a layer is activated, the grading is applied to the shot and is visible within the Player. Only one layer can be selected for editing at one time, but you can activate up to 48 layers at one time. There are 12 secondary layers on each page and there are four pages of secondary layers.

**Inside button** When selected, the secondary grading is applied inside the geometry. This is the default. In order to view the grading, make sure the button is activated (i.e., the text is white). If not, right-click the button to activate it. See [Colour Grading Inside and Outside Secondaries](#) (page 2133).

**Outside button** When selected, the secondary grading is applied outside of the geometry. In order to view the grading, make sure the button is activated (i.e., the text is white). If not, right-click the button to activate it. See [Colour Grading Inside and Outside Secondaries](#) (page 2133).

**Secondary Layer Page buttons** When a page is selected, it displays the 12 secondary layers associated with that page (e.g. P1 displays layers 1-12, P2 displays layers 13-24, etc.). If a page number is highlighted but not selected, it lets you know that there are active secondary layers on that page.

## Secondary Layer Hotkeys

The following is a list of the secondary layer hotkeys. Refer to the Autodesk Control Surface User Guide [Adding Secondary Layers](#) (page 2513) for a list of the control panel hotkeys. These hotkeys can be used wherever the secondary layer panel is visible on the user interface.

**NOTE** These hotkeys cannot be used with the secondary option within the Effects menu.

| Press:               | To:                                                      |
|----------------------|----------------------------------------------------------|
| 1 to 0, -, =         | Select a secondary layer (1-12, 13-24, 25-36, or 37-48). |
| \                    | Activate/deactivate the selected secondary layer.        |
| Ctrl+(1, 2, 3, or 4) | Select the secondary layers page 1, 2, 3, or 4.          |

| Press:                             | To:                                                                                                                         |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Scroll Lock                        | Cycle through all the activated secondary layers.                                                                           |
| Ctrl-click secondary layer button  | Copy the grading information from the current menu (e.g., Grading, Curves, or Secondaries) to the selected secondary layer. |
| Shift-click secondary layer button | Copy all the colour grading information to the selected secondary layer.                                                    |

## Selecting and Activating Secondary Layers

When a secondary layer is selected, you can edit that layer. You can then toggle the activation of the secondary layer and view the results in the Player. Only one layer can be selected at a time for editing, but up to 48 layers can be activated and displayed within the Player.

**To select and activate a secondary layer:**

- 1 Click the layer number button. The grey bar on the side changes colour to show that a layer has been selected.

**NOTE** Click on another layer number to select another layer to edit.

- 2 Right-click the selected layer number to activate it. The number on the secondary button becomes white and all the changes applied to that layer are now visible within the Player.

To deactivate the layer, right-click the layer number button again. The number on the secondary button goes from white to grey to indicate that it is no longer activated. The layer is then bypassed in the processing pipeline.

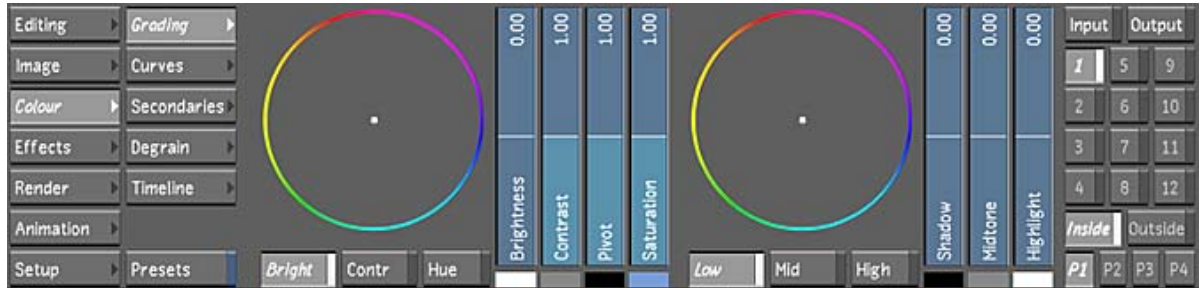

**NOTE** If you do not activate the layer, you can manipulate the geometry while keeping the colour correction hidden.

(a) Selected and activated secondary layer (b) Activated and unselected secondary layer (c) Current secondary layer page with activated layer(s) (d) Secondary layer page with activated layer(s)

## Colour Grading Secondaries

Use the colour grading controls in the Grading menu to perform secondary colour grading on your shots. Once the layer has been selected in the Secondaries menu, switch to the Grading menu and perform secondary grading, either in Logarithmic or Linear mode, just as you would for a primary grade.

To perform secondary colour grading:

- 1 In the Secondaries menu, right-click a secondary layer to activate it.

- 2 Define the area to be selectively colour graded by creating a key, adding one or more geometries, or combining a key with one or more geometries. See [About Geometries](#) (page 2134) and [Creating a Secondary by Keying a Range of Colours](#) (page 2159).

If you are colour grading geometries, enable Geom. This ensures that the colour correction will be applied selectively, rather than to the whole image.

- 3 Click Grading to display the Grading menu.
- 4 Perform colour grading as you would for a primary grade. See [Primary Colour Grading](#) (page 2101).

## Shifting Hue

You can shift the hue of the area defined by a secondary using the Hue Rotator.

To shift the hue:

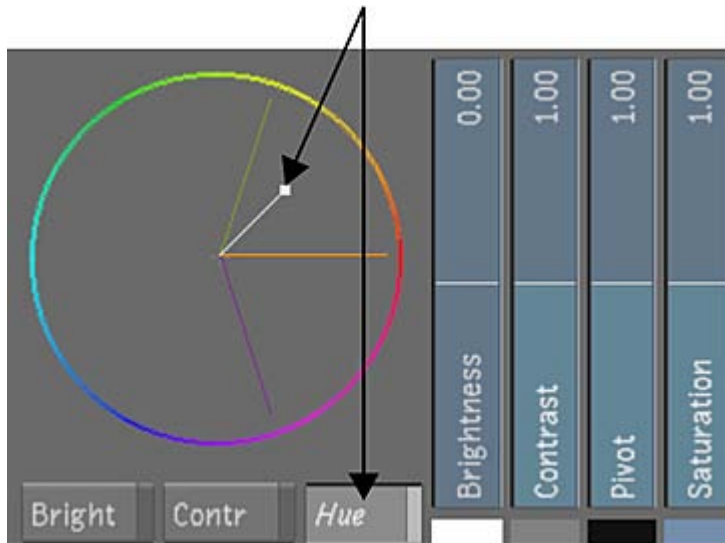

- 1 In the Secondaries menu, right-click a secondary layer to activate it.

- 2 Define the area to be selectively colour graded by creating a key, adding one or more geometries, or combining a key with one or more geometries.
- 3 If you are colour grading geometries, enable Geom. This ensures that the colour correction will be applied selectively, rather than to the whole image.

- 4 Click Grading to display the Grading menu.
- 5 Click Hue and then drag the Hue Rotator to shift the hue. To shift the hue clockwise through the hue spectrum, drag right. To shift the hue counter-clockwise, drag left.

## Adjusting Printer Lights for Secondary Grading

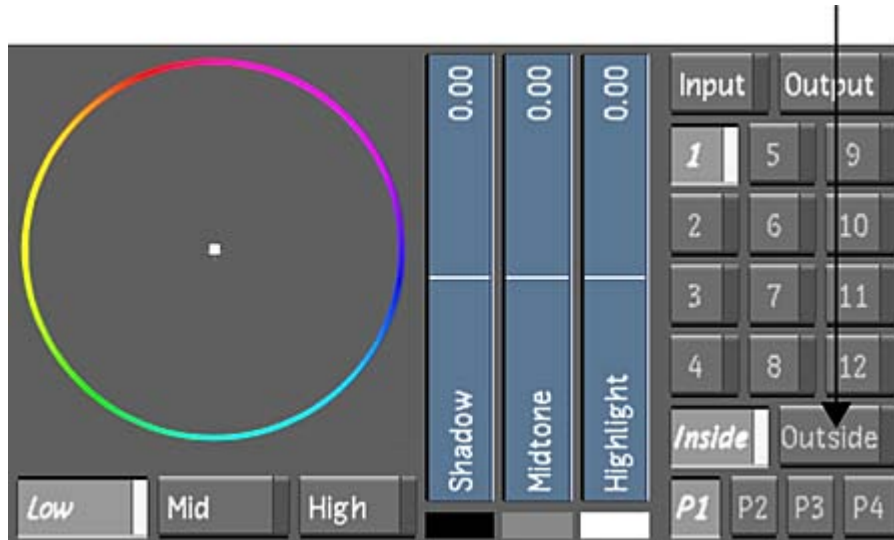

You can make printer light adjustments to secondaries just as you would to primary colour grades. See [Adjusting Printer Lights for Primary Grading](#) (page 2104).

## Colour Grading Inside and Outside Secondaries

Secondaries can have unique colour grades applied both inside and outside a defined shape. The secondary's default state is the inside.

**To grade a secondary and its surrounding area:**

- 1 Colour grade the secondary.
- 2 In the secondary layers panel, click Outside to switch out of inside colour grading mode.

- 3 Right-click Outside to activate the outside colour grading mode.

**NOTE** Selecting Inside or Outside allows you to colour grade the inside or outside area of the secondary. If you do not activate either button, its colour grade will be hidden in the Player.

If gradients are used to define the shape, the appropriate blend will be applied between the shapes.

## Copying Shapes and Grades

You can speed up the secondary colour grading process by copying a shape, or a shape with its parameters, from one secondary to another. This functionality is useful when colour grading the same shape(s) across several secondaries.

**To copy a shape from one secondary to another:**

- 1 Click Secondaries to display the Secondaries menu.
- 2 In the Player, select the shape's axis.
- 3 Hold down the **Ctrl** key while clicking a new secondary.  
The new secondary is enabled and the shape appears in the same position as on the previous secondary.

**To copy a shape and selected parameters from one secondary to another:**

- 1 Click Secondaries to display the Secondaries menu.
- 2 In the Player, select the shape's axis.
- 3 Click Selector and choose the parameters to be copied.

- 4 Shift-click the new secondary.

The new secondary is enabled and the shape with its parameters appears in the same position as on the previous secondary.

## Applying a Secondary Colour Grade to the Entire Image

Once a secondary has been graded, you can test how the secondary grade would look like as a primary grade.

**To view a secondary's colour grading as a primary colour grade:**

- 1 In the Secondaries menu, deactivate Geom and the keyer.

**NOTE** To reapply the secondary colour grade, enable the Geom button again.

## About Geometries

Geometries are spline-based objects you draw directly on a shot or an image. When performing secondary colour grading, you can create geometries to isolate particular objects or areas in the image to include with, or exclude from, the secondary colour grade.

You can include multiple geometries with each secondary.

Once geometries have been added, you can:

- Resize, reposition, and rotate them.
- Modify the softness, colour, opacity, and blur values of areas isolated by geometries.
- Parent multiple shapes to an axis.
- Change the priority order.
- Show or hide geometries in the Player.
- Invert geometries.
- Delete or reset geometries.
- Link geometries using logical operations from the previous secondary layer to the next one.
- Animate and track geometries.

Geometries are useful in many colour grading situations, from selectively colour grading large objects like the sky to small objects like a person's eyes. When you want to colour grade an object that moves through the shot, you can use the tracker to make a geometry follow the moving element. See [Animating the Point Tracker](#) (page 2187).

You can work with tangents and vertices to modify, scale, and rotate a geometry around its axis. You can also use the axis of the geometry to move it around the image. You can add and delete axes, and use one axis to move multiple geometries.

**NOTE** Field-based projects viewed on the data monitor will demonstrate a half-pixel downshift. Geometries added to the image will also display this downshift.

## Accessing the Geometry Controls

To draw geometries, you work with the Secondaries menu.

To access the Geometry controls:

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

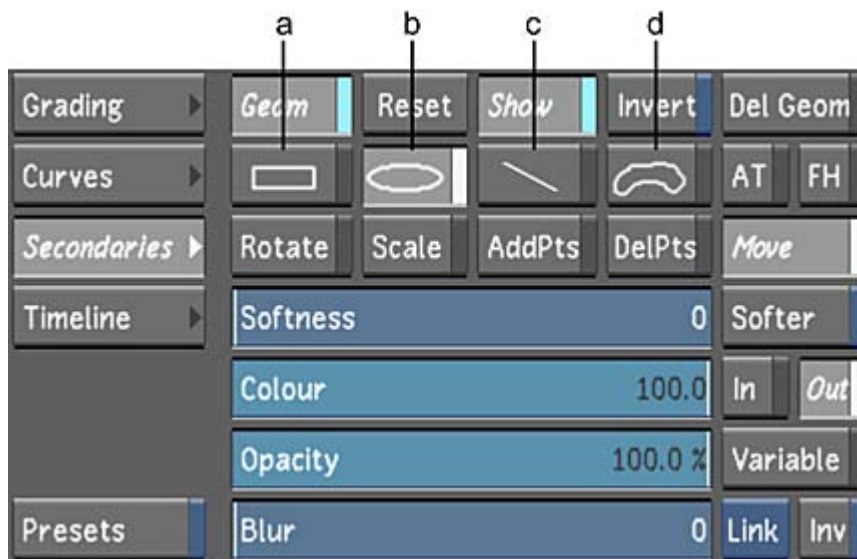

- 2 Enable Show.

If a geometry exists, it is displayed in the Player.

- 3 Enable a geometry.

(a) Rectangle geometry (b) Circle geometry (c) Split screen geometry (d) Free-form (bezier) geometry

**NOTE** The Keyer picker is automatically deactivated when a geometry is being created.

## Drawing Basic Geometries

For each secondary, you can draw multiple rectangles or circles to isolate parts of the shot or image for secondary colour grading. Basic geometries can also be converted into free-form (Bezier) shapes.

To draw a rectangle or a circle:

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

- 2 Enable Show.

If a geometry exists, it is displayed in the Player.

- 3 Enable either the rectangle or the circle shape.

- 4 Draw the shape on the image. In the Player, drag to set the initial dimensions for the geometry. The geometry appears in the Player.

**NOTE** To add more than one of the same basic shape to a secondary, you must enable the shape each time.

- 5 (Optional) To resize the geometry, drag vertices or a vertex point. To scale it, drag the Z-axis.
- 6 (Optional) To convert a basic shape to a free-form (Bezier) shape, right-click the shape in the Player.

## Drawing Free-Form Geometries

For each secondary layer, you can draw multiple free-form (Bezier) geometries to isolate parts of the shot or image for secondary colour grading. When you draw a free-form geometry, you can draw point-to-point using the Free-Form (Bezier) button, use Auto-Tangent mode or Freehand mode, or manually add vertices and tangents.

To manually draw a free-form geometry:

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

- 2 Enable Show.

If a geometry exists, it is displayed in the Player.

- 3 Enable the Free-Form (Bezier) button.

**NOTE** To add more than one of the same free-form shape to a secondary, you must enable the Free-Form shape button each time.

- 4 Make sure that the FH (freehand) button is disabled.

- 5 In the Player, click the image to set the first vertex.
- 6 Click again to add the second vertex.
- 7 To extend the tangents of a vertex and create a smooth curve, drag when you add a vertex.
- 8 Continue adding vertices and create the geometry.
- 9 To close the free-form geometry, click the first vertex.

Image courtesy of Hungarian Academy of Film & Theatre, 3rd year

To draw a free-form geometry using AutoTangent mode:

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

- 2 Enable Show.

Any pre-existing geometries will be displayed in the Player.

- 3 Enable the Free-Form (Bezier) button.

**NOTE** To add more than one of the same free-form shape to a secondary, you must enable the Free-Form shape button each time.

- 4 Enable AT (auto tangent).

- 5 In the Player, click the image to set the first vertex.
- 6 Click again to add the second vertex.  
As you move from one vertex to the next, the tangents are automatically interpolated to create a smooth curve between vertices.
- 7 Continue clicking the image to add vertices and create the geometry.
- 8 To close the free-form geometry, click the first vertex.

Image courtesy of Hungarian Academy of Film & Theatre, 3rd year

**To draw a free-form geometry using Freehand mode:**

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

- 2 Enable Show.

Any pre-existing geometries will be displayed in the Player.

- 3 Enable the Free-Form (Bezier) button.

**NOTE** To add more than one of the same free-form shape to a secondary, you must enable the Free-Form shape button each time.

- 4 Enable FH (freehand).

- 5 In the Player, click and drag on the image to draw the geometry.  
The vertices and tangents of the geometry are automatically added as you drag the mouse. The optimal number of vertices is used to create the smoothest curve.
- 6 To close the free-form geometry, release the mouse.

## Modifying Geometries

Once you finish drawing a basic or free-form geometry, you can modify its shape, position, and appearance. You can:

- Reposition axes.
- Adjust tangents and vertices.

- Apply transformations.
- Apply constant or variable softness.
- Apply a blur filter.
- Adjust the colour transparency.

---

**TIP** To modify the geometry's parameters without the colour correction being visible, right-click the geometry's layer number button. To re-display the colour correction, right-click the button again.

---

## Moving Axes

An axis can be moved from its default central position within the geometry. This affects how a geometry will behave when you scale or rotate it.

**To move an axis:**

- 1 Press **Alt**, right-click the axis, and drag it to another position.

## Adjusting Tangents and Vertices

Adjust the shape of a geometry by manipulating its tangents and vertices. You can:

- Modify the position of vertices and tangents.
- Add and remove vertices and tangents.
- Break tangents.

### Moving Vertices and Tangents

In the Player, you can move vertices and tangents to adjust the shape of a geometry.

**To move vertices and tangents:**

- 1 If you are working with a basic shape, right-click it in the Player to convert it to a free-form geometry.
- 2 In the Secondaries menu, enable Move.

- 3 Do any of the following:
  - To move a vertex, drag it in the Player.
  - To move multiple vertices, drag from anywhere on the screen without vertices. Then draw a selection box around the vertices you want to move and drag them in the Player.

**TIP** To deselect multiple vertices, click away from the selected ones.

- To modify the shape or curve of a side, move the adjacent tangents. Drag a tangent handle to change its position.

### Adding and Removing Vertices

You can add and remove vertices from a geometry. When you add or remove a vertex, the curve is redrawn according to the change of shape.

#### To add vertices:

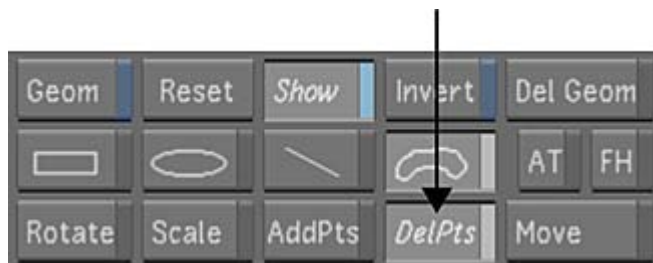

- 1 If you are working with a basic shape, right-click it in the Player to convert it to a free-form geometry.
- 2 In the Secondaries menu, enable Add Pts.

- 3 In the Player, move the mouse over the mask border of the geometry you want to modify. The current position on the geometry is highlighted.
- 4 Click the geometry where you want to add a vertex. The vertex is added to the geometry.

#### To remove vertices:

- 1 In the Secondaries menu, enable Del Pts.

- 2 In the Player, move the mouse over the mask border of the geometry you want to modify. The current vertex on the geometry is highlighted.
- 3 Click the highlighted vertex. The vertex is deleted from the geometry. The shape of the geometry is adjusted according to the change.

### Breaking and Repairing Tangents

You can separate two tangent handles (*break* the tangent) and move them separately. You can also repair broken tangents.

#### To break and repair tangents:

- 1 To break and move a tangent handle, **Ctrl**-click the tangent handle and drag it.

- 2 To repair a broken tangent handle, Ctrl-click it.

## Transforming Geometries

You can apply transformations to change the position and size of a geometry. You can:

- Move geometries.
- Rotate geometries.
- Scale geometries.

**To move a geometry:**

- 1 In the Secondaries menu, enable Move.

- 2 In the Player, drag the axis of the geometry you want to move.
- 3 To lock the geometry to the X- or Y-axis when you move it, you can drag from the arrowheads of the X- or Y-axis.

**To rotate a geometry:**

- 1 Do one of the following:
  - In the Player, right-click the axis and hold down the right mouse button while dragging.
  - In the Secondaries menu, enable Rotate. Then, in the Player, drag the axis of the geometry you want to rotate.

#### To scale a geometry:

- 1 In the Secondaries menu, enable Scale.

- 2 In the Player, drag along the axis of the geometry in the direction you want to scale.

| Drag the:         | To scale the geometry: |
|-------------------|------------------------|
| X-axis            | Along the X-axis.      |
| Y-axis            | Along the Y-axis.      |
| Global Scale axis | Along the Z-axis.      |

**TIP** You can drag the Z-axis to scale a geometry in any transformation mode—in Rotate, Move, or Scale mode.

## Transforming All Geometries With the Secondaries Master Axis

You can transform all geometries simultaneously in the Animation Editor, using the Master Axis. The Master axis affects all geometries on all secondaries for the current shot. You can:

- Move all geometries.
- Rotate all geometries.
- Scale all geometries.

#### To use the Master Axis:

- 1 Access the Animation menu.
- 2 Expand the Secondaries folder.  
The first entry in the Secondaries folder is the Master Axis.
- 3 Expand the Master Axis folder.

- 4 Select the parameter you want to modify.
- 5 Add a keyframe at the desired frame, by clicking Add.
- 6 Select the keyframe and set the its value in the Curve Editor.

## Applying Softness to Geometries

You can increase and decrease the softness range to soften the edges of geometries. You can set the softness of the mask edge using:

- Constant softness.
- Variable softness to vary the softness range for different parts of the mask.

### Applying Constant Softness

You can apply a constant range of softness to the edge of a geometry on a secondary. You can apply constant softness to the inside or outside of the mask border. You do not need to convert a basic shape to a free-form geometry in order to apply constant softness.

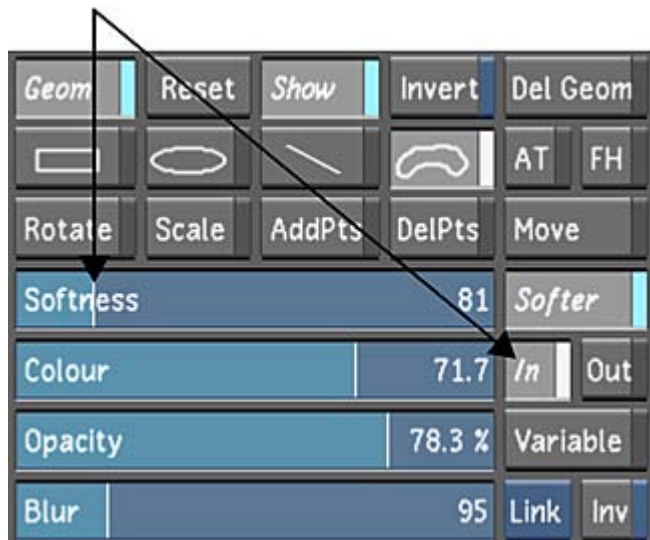

**To soften the edges of the geometry:**

- 1 Do one of the following:
  - In the Player, select a geometry.
  - From the Axes list, select a geometry or its axis.

- 2 In the Secondaries menu, do one of the following:
  - To apply softness to the inside of the mask border, enable In, and then drag the Softness slider. Drag right to increase softness. Drag left to decrease softness.
  - To apply softness to the outside of the mask border, enable Out, and then drag the Softness slider. Drag right to increase softness. Drag left to decrease softness.

The softness level set by the Softness slider is applied to the geometry.

### Applying Variable Softness

You can apply variable softness to the edges of one or more geometries to customize the softness at different parts of the mask. Variable softness has two softness borders, one inside and one outside the mask border. It also includes inner and outer softness vertices for each regular mask vertex.

**(a) Outer softness border (b) Inner softness border (c) Softness vertices (d) Mask border**

You can customize the softness at different parts of the mask by adjusting the distance of each softness vertex from the mask border—you set a softness value based on each vertex in the shape.

Variable softness can only be applied to free-hand geometries, or to basic geometries that have been converted to a free-form geometry.

To apply variable softness to the edges of the geometry:

- 1 Do one of the following:
  - In the Player, select a geometry.
  - From the Axes list, select a geometry or its axis.

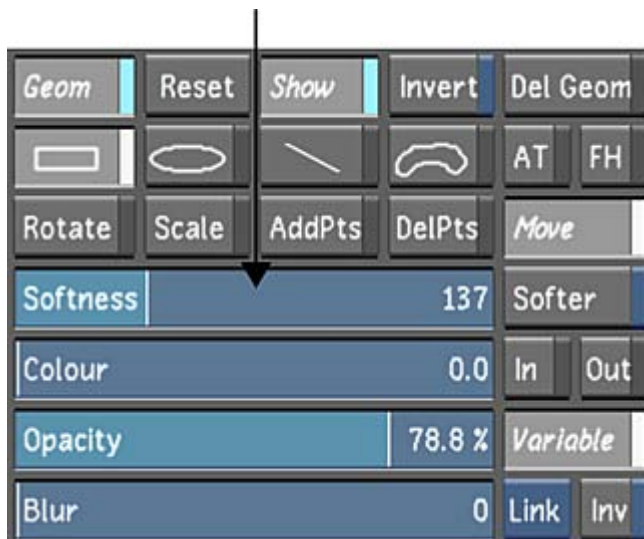

- 2 In the Secondaries menu, enable Variable.

Softness is applied inside and outside the mask border.

- 3 Drag the Softness slider. Drag right to increase softness. Drag left to decrease softness.

The softness level set by the Softness slider is applied to the geometry.

- 4 Drag the vertices and tangents to adjust the shape and vary the softness at the edges of the geometry. See [Adjusting Tangents and Vertices](#) (page 2141).

## Blurring Geometries

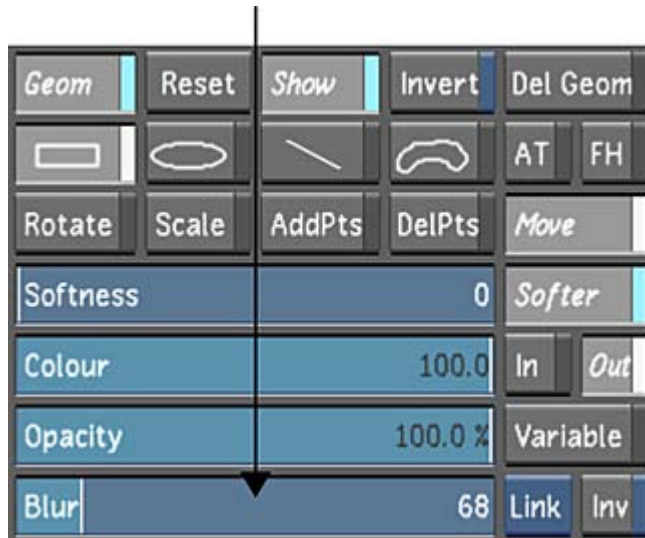

You can apply a Gaussian blur to soften all geometries on the current secondary layer.

To apply a Gaussian blur:

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

- 2 Drag the Blur slider. Drag right to increase the blur. Drag left to decrease the blur.

## Setting the Colour and Opacity of Geometries

You can adjust the colour and opacity of a geometry to affect the output image.

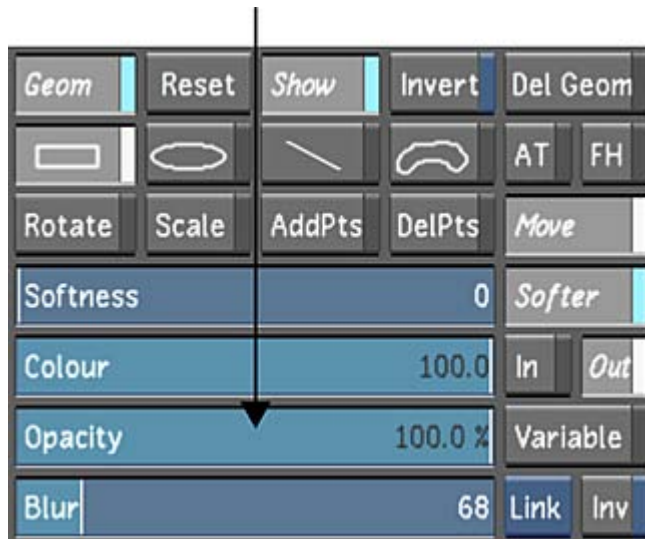

If you are applying only one geometry or several non-overlapping geometries to a secondary, modify either the colour or opacity to adjust the matte—in this case, colour and opacity will have the same effect on the image. If you are applying several overlapping geometries to a secondary, modify both colour and opacity to adjust the matte—colour will set the intensity of the colour of the geometry, whereas opacity will set the transparency, creating a blend between the overlapping geometries.

To set the colour and opacity of a geometry:

- 1 Do one of the following:
  - In the Player, select a geometry.
  - From the Axis list, select a geometry or its axis.

- 2 In the Secondaries menu, drag the Opacity slider to adjust the transparency of the mask.

The Opacity slider defines the blend between overlapping geometries. A value of 50% is a 50/50 blend. A value of 100% shows the exact colour of the geometry. A value of 0% shows what is behind the selected geometry.

- 3 To set the intensity of the colour of the geometry, drag the Colour slider to set a colour value between 0% and 100%. A value of 50% means the area is 50% grey.

## Adjusting the Colour and Opacity of a Matte Overlay

You can change the way a matte is displayed to help you easily view the isolated colour. The colour and opacity of the unselected region in a matte can be easily modified by adjusting the Matte Overlay parameters.

To adjust the colour and opacity of a matte overlay:

**NOTE** This procedure will not affect the output image.

- 1 Select and then right-click a secondary on which a matte is present.
- 2 Depending on your user settings, press F11 once or twice to enable the Matte view. See [Display & Interface Settings](#) (page 1805).
- 3 In the Setup menu, select Interface to display the Matte Overlay panel.

**NOTE** The default values are displayed.

- 4 Drag the Opacity slider as well as the R, G, and B sliders to adjust the opacity and colour of the unselected region. See [Matte Overlay Settings](#) (page 1836).

Secondary view (default)

Secondary view (adjusted)

---

**TIP** Click Reset twice if you wish to reset the sliders to their default values.

---

## Adding a Split Screen

The split screen feature lets you divide the screen in two in order to apply separate colour gradings to each half of the image.

Split screens can be moved and rotated.

**To add a split screen:**

- 1 In the Secondaries menu, right-click a secondary layer button to activate it.

- 2 Enable the Split Screen button.

- 3 In the Player, click where you would like the split screen applied.  
The split screen is applied horizontally in the spot where you clicked. You can now colour grade this part of the image.

Image courtesy of Technicolor (formerly Toybox)

- 4 To grade the other half of the split screen, enable Outside (see [Colour Grading Inside and Outside Secondaries](#) (page 2133)).
- 5 To move the split screen up or down, click and drag the split screen's axis.
- 6 To rotate the split screen, do one of the following:
  - Enable Rotate and then drag the axis.
  - Right-click the axis and drag.

## Adding and Deleting Axes

By default, every geometry you draw has an axis. Each geometry and its axis are displayed in the Player.

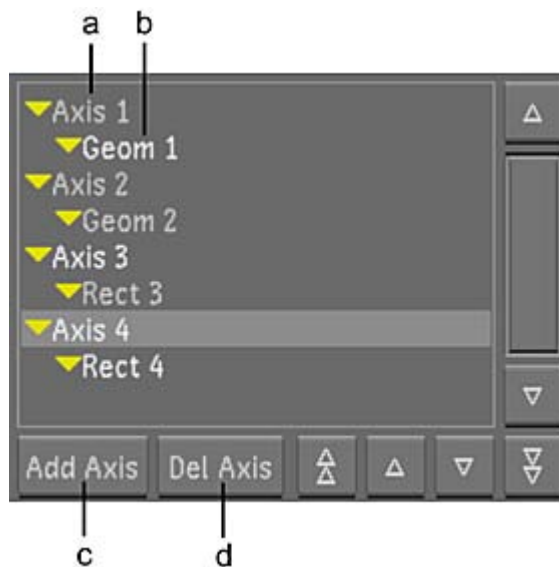

**(a) Geometry axis**

You use the Axes list to add and delete axes, as well as parent multiple axes to a master axis. You use the schematic view to create parent/child connections among shapes and axes.

A parent axis allows you to move, scale, rotate, and track multiple geometries.

## The Axes List

The Axes list appears in almost all Lustré menus and provides a list view of geometries and their axes.

**(a) Axis (b) Geometry (c) Add Axis button (d) Del Axis button**

When you select the axis or the geometry in the Axes list, it is also selected in the Player. The inverse is also true.

#### To create a parent axis:

- 1 In the Axes list, select the axis you want to parent. To select multiple axes, Shift-click each axis.
- 2 Click Add Axis.

The axes you selected are now parented to a new master axis.

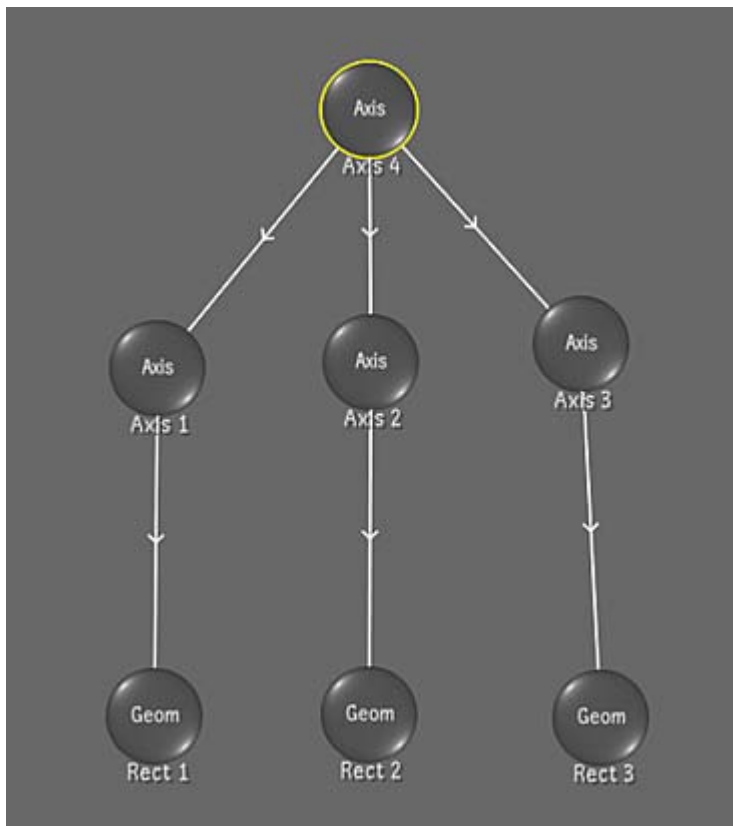

#### To delete an axis:

- 1 In the Axes list, select the axes you want to delete. To select multiple axes, Shift-click each axis.
- 2 Click Del. Axis.

The axis is deleted from the Player and the Axes list.

## Schematic View

As an alternative to using the Axes list to view the axis hierarchy and create parent axes, you can use the schematic.

The schematic appears in the Player and allows you to parent shapes and axes in any combination you like. For example, a shape could parent an axis, or vice versa.

Creating a master axis and using it to parent multiple axes simultaneously is performed the same way as when using the Axes list. However, in the schematic, you can also make connections one at a time.

---

**NOTE** Axes cannot be deleted in the schematic.

---

**To create parent/child connections using the schematic:**

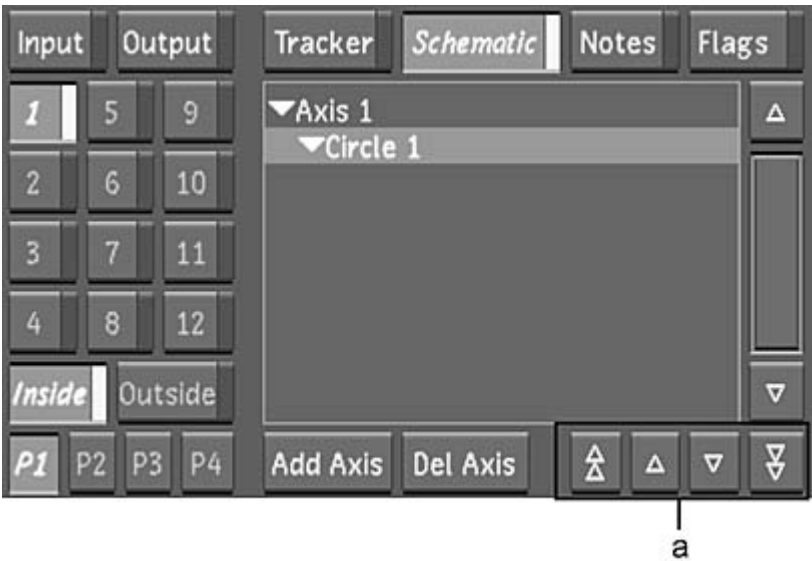

- 1 Press the tilde key (~) to switch to a schematic view of the axis hierarchy.  
**NOTE** To pan within the schematic, hold down the middle mouse button and drag.
- 2 To connect one item to another, click just inside the border of the parent object and drag to the intended child object. The connection is represented by a white line (yellow when selected), with the hierarchy indicated by an arrow that points away from the parent object and towards the child.  
**NOTE** To move an item, click in its centre and drag. To break a link, drag a red line across the connection line.
- 3 Switch back to default view by pressing ~ again.  
The changed hierarchy is displayed in the schematic.

**Changing the Priority Order of Geometries**

When you create several free-form geometries on a secondary layer, you can change the order in which they are drawn, or layered in the scene. This affects the resulting image because a geometry with a higher priority has precedence over one with a lower priority. You can use the priority order to create complex colour effects involving multiple geometries.

**To set the priority of a mask:**

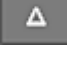

- 1 Select the geometry.
- 2 Enable Schematic to display the priority order buttons.

(a) Priority order buttons

- 3 Do any of the following.

|                                                                                     |                       |
|-------------------------------------------------------------------------------------|-----------------------|
| Click:                                                                              | To move the geometry: |
|  | To the top layer.     |

| Click:                                                                            | To move the geometry: |
|-----------------------------------------------------------------------------------|-----------------------|
|  | To the bottom layer.  |
|  | Down one layer.       |
|  | Up one layer.         |

## Showing and Hiding Geometries

You can show or hide geometries after you create them. Geometries that are hidden do not appear in the Player, but are applied to the secondary—depending on which logical operation you use.

**To show a geometry:**

- 1 In the Secondaries menu, enable Show.

**To hide a geometry:**

- 1 Disable Show.

## Inverting Geometries

You can invert geometries on the current secondary layer.

**To invert geometries:**

- 1 In the Secondaries menu, enable Invert.

## Deleting Geometries and Resetting Secondaries

Delete geometries one at a time from a secondary, or reset the secondary to delete all geometries simultaneously.

**To delete a geometry:**

- 1 In the Secondaries menu, enable Del Geom.

- 2 In the Player, select the geometry.  
The selected geometry is deleted.
- 3 Select the geometry's axis.  
The selected axis is deleted. Once both the axis and geometry have been deleted, the secondary colour grade is applied to the entire image.

---

**NOTE** You can also delete geometries and their axes from the Axes list. To delete a geometry or axis, select it in the Axis list (or *Shift*-click to select several), and then click Del. Axis.

---

**To reset a secondary:**

- 1 In the Secondaries menu, enable a Secondary button.
- 2 Do one of the following:
  - To clear all geometries from the layer and apply the secondary colour grade to the entire image, click the Reset button in the Secondaries menu and then click again to confirm.

- To clear all geometries from the layer without applying the secondary colour grade to the entire image, click the Reset button in the main menu.

## Linking Geometries across Secondary Layers

You can link geometries from the previous secondary layer to the current secondary layer by selecting an option from the Link option box, located in the Secondaries menu. Use the Link option box when you have already applied a key, a geometry, or both to the current secondary layer.

---

**NOTE** You can use the Link option box without applying any key or geometry to the current secondary layer.

---

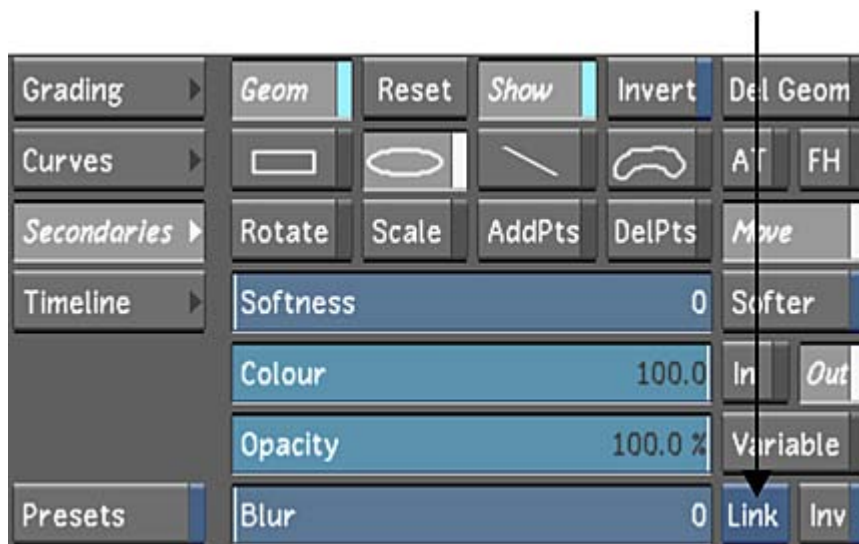

When you use the Link option box, a logical operation is applied to determine how the geometries from the previous layer are combined with the key and geometries on the current secondary layer, and what areas of the image are colour graded. Depending on what you want to accomplish with the secondary, you can use a logical operation to add or exclude the inside of the geometries from the previous layer to the key and geometries on the current secondary layer, or intersect the geometries with the current secondary layer. You can also invert the geometries from the previous layer using the Invert button.

**To combine geometries from the previous secondary layer with the current secondary layer:**

- 1 Make sure you have multiple secondary layers containing keys and geometries, and then in the Secondaries menu, enable the secondary you want to work on.

**NOTE** The previous secondary layer must have some sort of mask applied—it can be a key, a geometry, or both.

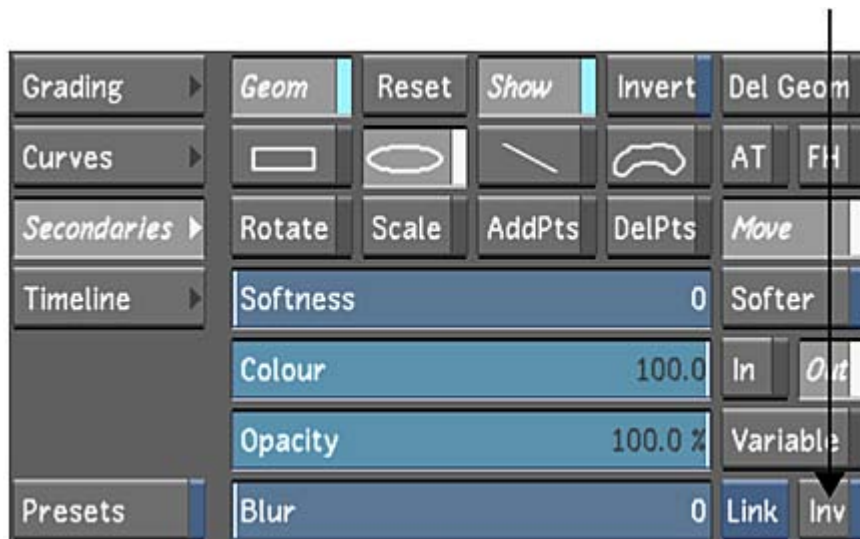

- 2 Select a logical operation from the Link option box. The logical operation you select determines what is colour graded by the current secondary.

| Select:                                                                             | To:                                                    |
|-------------------------------------------------------------------------------------|--------------------------------------------------------|
|    | Add the current secondary to the previous one.         |
|    | Subtract the current secondary from the previous one.  |
|  | Intersect the current secondary with the previous one. |

**NOTE** If you do not want to apply a logical operation, select the Link option.

- 3 To invert the previous selection, enable Inv.

When you invert geometries from the previous secondary layer, the logical operation you choose will combine the invert of the geometries from the previous secondary layer with the current one.

# Creating a Secondary by Keying a Range of Colours

You can create secondaries by defining transparent regions in a shot, based on a specific range of colour. This process is known as *keying*.

When you extract a key to isolate a colour, you can view it in the Player. Keys are based on the chrominance and luminance of a selected colour from the original image. Once you have selected a colour, you then set the tolerance and softness ranges by sampling the original image. Tolerance defines how similar luminance and chrominance values will be keyed (made transparent) in the secondary. A higher tolerance setting extracts a broader range of luminance and chrominance values, while a lower setting extracts a narrower range, leaving the rest of the image untouched. Softness defines how similar luminance and chrominance values are softened (made partially transparent) for the secondary. A higher softness setting extracts a broader range of luminance and chrominance values, while a lower setting extracts a narrower range, leaving the rest of the image untouched. You can soften the edge of a key to blend the secondary colour grading with the rest of the image.

Keys are, by default, based on original scans, bypassing any input primary colour grading. This allows you to modify an image upstream of any secondary without changing the key. For example, after you key a secondary, you can safely perform a hue shift from the Curves menu. The key, based on the original image colour, is unaffected. To base a key on colour corrected sources, enable the Src: Prim (Source Primary) button.

For extracting keys to isolate colours, Lustre provides two keyers that work independently of one another:

- The Hue, Luminance, and Saturation (HLS) Keyer, which is used to extract a key based on the softness and tolerance of the hue, luminance, and saturation channels of the source image. See [Using the Hue, Luminance, and Saturation \(HLS\) Keyer to Extract a Key](#) (page 2159).
- The Diamond Keyer, which is used to extract a key based on the chrominance range and luminance levels of the source image. See [Using the Diamond Keyer to Extract a Key](#) (page 2167).

## Using the Hue, Luminance, and Saturation (HLS) Keyer to Extract a Key

With the HLS Keyer, you can extract a key based on hue, luminance, and saturation channels. You can use one or more of these channels to create a key.

You can also use previously saved keyer presets. See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

Once you have extracted a key, you can modify a key by adjusting the Master Tolerance and Master Softness sliders or by using the Add/Remove Softness and Tolerance buttons. You can further modify a key using the Cleanup, Shrink, and Blur parameters.

Before extracting a key, you can modify the source image by using the Input Transform Log to Lin and Soften options. See [Tools Settings](#) (page 1811).

**NOTE** To disable the HLS Keyer at any time, right-click on the Keyer option box.

Use the following workflow to extract a key for colour isolation.

| Step:                                                                   | Refer to:                                                                   |
|-------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| 1. Determine which channels you want to use in a key.                   | See <a href="#">Setting Keying Parameters in the HLS Keyer</a> (page 2160). |
| 2. Select the colour that you want to key.                              | See <a href="#">Sampling a Colour in the HLS Keyer</a> (page 2161).         |
| 3. View your secondary to determine the range of colour you have keyed. | See <a href="#">Viewing Secondaries in the HLS Keyer</a> (page 2163).       |

| Step:                                                                                                                 | Refer to:                                                                     |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|
| 4. Set the tolerance to widen or narrow the range of luminance and chrominance values to extract in a key.            | See <a href="#">Setting the Tolerance Range in the HLS Keyer</a> (page 2164). |
| 5. Set the softness to widen or narrow the range of luminance and chrominance values to extract at the edge of a key. | See <a href="#">Setting the Softness Range in the HLS Keyer</a> (page 2166).  |
| 6. Blend the light and dark edges of a key by shrinking, eroding, or blurring the edges of a key.                     | See <a href="#">Modifying the Edges of the Key</a> (page 2177).               |
| 7. Clean up a key for colour grading.                                                                                 | See <a href="#">Removing Stray Pixels from a Key</a> (page 2178).             |
| 8. Increase or decrease the softness of pixels that are in the tolerance range.                                       | See <a href="#">Sharpening a Key Source Image</a> (page 2178).                |

The following procedures are not essential for extracting a key. You can perform these procedures at any time after extracting a key.

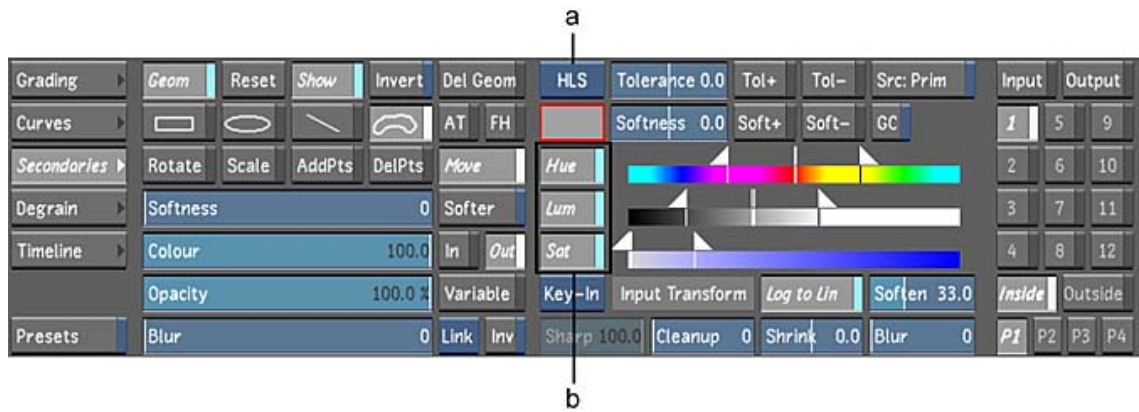

| Step:                                                           | Refer to:                                                        |
|-----------------------------------------------------------------|------------------------------------------------------------------|
| 1. Remove colours that you do not want to include in a key.     | See <a href="#">Inverting Keys</a> (page 2179).                  |
| 2. Exclude a key that you do not want to appear in a secondary. | See <a href="#">Excluding Keys from Secondaries</a> (page 2179). |

## Setting Keying Parameters in the HLS Keyer

You need to determine which channels (hue, luminance, and saturation) you will use to extract your key.

**To set keying parameters:**

- 1 In the Colour menu, click Secondaries.  
The Secondaries menu appears.
- 2 Click the Keyer option box to toggle to the HLS Keyer.  
The HLS Keyer appears in the Secondaries menu.

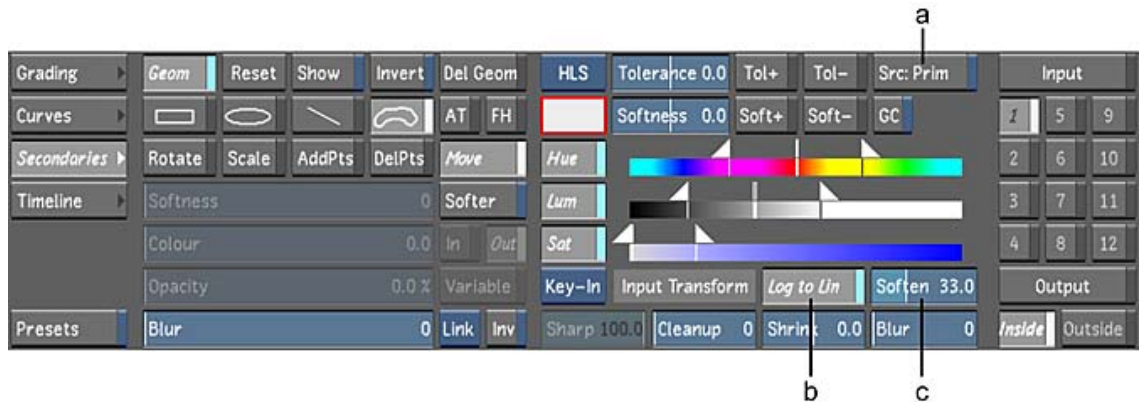

(a) Keyer option box (b) Hue, luminance, and saturation buttons

- 3 To select the basis of a key, enable one, two, or all three of the channels. Channel selection depends on what you want to base your key on: chrominance, luminance, or a combination of both.
  - To extract a key based on the hue of the selected colour range, enable Hue. To exclude hue from a key, disable Hue.
  - To extract a key based on the luminance of the selected colour range, enable Lum. To exclude luminance from a key, disable Lum.
  - To extract a key based on the saturation of the selected colour range, enable Sat. To exclude saturation from a key, disable Sat.

**NOTE** Chrominance is comprised of both the Hue and Saturation channels.

- 4 Enable the Source Primary button to use primary grading results as the input to the keyer.

**NOTE** When Src: Prim is disabled, the raw scan is used as the input to the keyer, effectively bypassing any input LUTs and primary grading that has been applied to your shot.

(a) Source Primary button (b) Log to Lin button (c) Soften slider

- 5 Enable the Log to Lin button. See [Tools Settings](#) (page 1811).
- 6 Adjust the Soften slider. See [Tools Settings](#) (page 1811).

## Sampling a Colour in the HLS Keyer

The typical way to extract a key is to sample a pixel or an average colour in the image using the colour picker. You can also use predefined colour grading parameters, called presets, by right-clicking the Hue, Luminance, or Saturation button. See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

**To sample a colour:**

- 1 Set the view mode to Output. You can click the O button.

**NOTE** Pressing F12 to set the view mode to Output only works from Matte view.

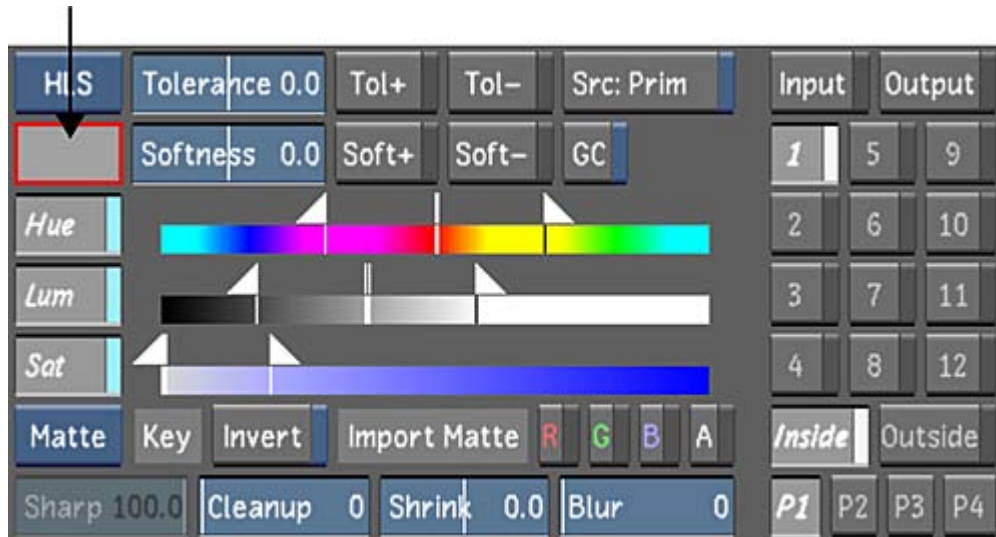

- 2 In the Secondary layers panel, activate a secondary layer.

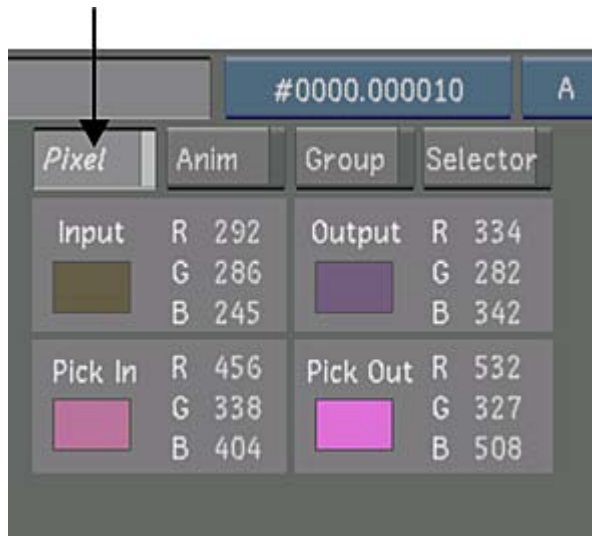

**NOTE** If you do not activate the secondary layer, the colour pot will not be updated with your colour sample.

- 3 Right-click the Keyer option box to enable the HLS Keyer.  
The letters in the Keyer option box turn bright white indicating that the HLS Keyer is enabled.
- 4 Click the colour pot.  
The HLS Keyer is enabled and the colour pot is outlined in red, indicating that it is in use.

- 5 Click Pixel to enable the Pixel Analyser.

- 6 Set the Log to Lin parameter. See [Tools Settings](#) (page 1811).
- 7 Adjust the Soften slider. See [Tools Settings](#) (page 1811).
- 8 Sample the image:
  - To sample a single pixel, click and drag in the image until you locate the pixel you want to sample. As you drag, the colour of the current pixel appears in the Pixel Analyser. When you locate the pixel you want to sample, release the mouse.
  - To sample an average taken from a range of colours in the image, **Alt**-drag the image in the Player.

The cursor changes to a colour picker when you move it over the image in the Player. When you release the mouse, the centre tolerance and the initial softness and tolerance ranges are set for the channels that are enabled. The colour pot displays the sampled colour.

- 9 Click the colour pot again to finish defining the colour.

## Viewing Secondaries in the HLS Keyer

Once you have sampled a colour for a key, you can view the resulting secondary in the Player. You can view a key in Secondary view or Matte view by toggling the **F11** key. Secondary view displays the keyed out colour as is; unsampled colours are overlayed with a uniform colour by default. Matte view displays the alpha channel, a black and white template indicating which parts of the image are transparent (black), and which are opaque and selected (white).

To view a secondary:

- 1 Select the secondary you want to view.
- 2 Display the image in Secondary view by pressing F11.

In Secondary view, the colour that is keyed out in the current secondary is unchanged; unsampled colours are overlaid with a uniform colour by default. See [Matte Overlay Settings](#) (page 1836).

- 3 Press F11 to display Matte view. See [Display & Interface Settings](#) (page 1805).

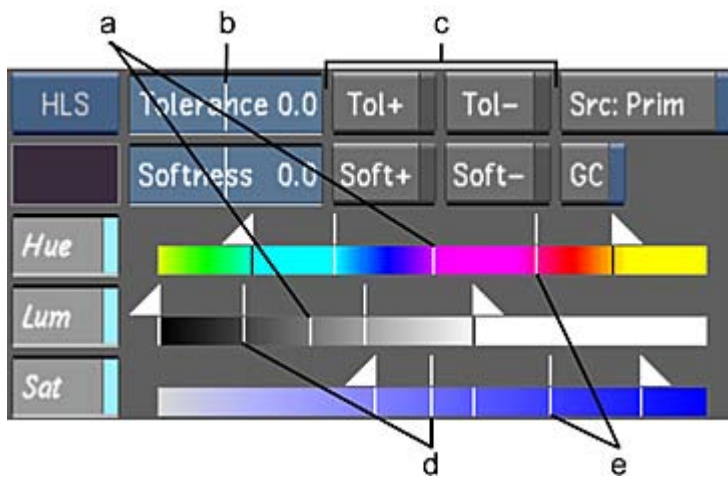

In Matte view, the white parts of the matte represent the selected colours which can be colour graded. The black parts represent the unselected colours in the secondary. Greys indicate the zone of softness.

## Setting the Tolerance Range in the HLS Keyer

You can set the tolerance range of colours to be fully keyed (transparent) and to remove unwanted greys from a key. The maximum and minimum tolerance values define the range of colours included in the secondary. The closer a pixel matches the key colour, the greater its transparency. Conversely, the less a pixel matches the key colour, the greater its opacity.

To set the tolerance, you can use the colour picker, the Master Tolerance slider, or the Tolerance Range indicators. With the colour picker and the Master Tolerance slider, you set the tolerance range for hue, luminance, and saturation together. With the Tolerance Range indicators, you set the tolerance range for hue, luminance, and saturation individually.

(a) Centre Tolerance indicators (b) Master Tolerance slider (c) Add Tolerance/Remove Tolerance buttons (d) Minimum Tolerance Range indicators (e) Maximum Tolerance Range indicators

#### To set the tolerance range using the colour picker:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.
- 2 In the Secondaries menu, enable the Add Tolerance or Remove Tolerance button beside the Master Tolerance slider to increase or decrease tolerance.
- 3 Click and drag in the image to include it in the tolerance range. Alt-drag in the image to select a larger area.  
The tolerance is modified.

#### To set the tolerance range using the Master Tolerance slider:

**NOTE** The Master Tolerance slider controls the position of all of the sliders in all of the channels (even when they are not enabled).

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.
- 2 Set the tolerance range:
  - To increase tolerance, drag the Master Tolerance slider to the right.
  - To decrease tolerance, drag the Master Tolerance slider to the left.

When you release the slider, the tolerance is modified and the slider returns to its original position.

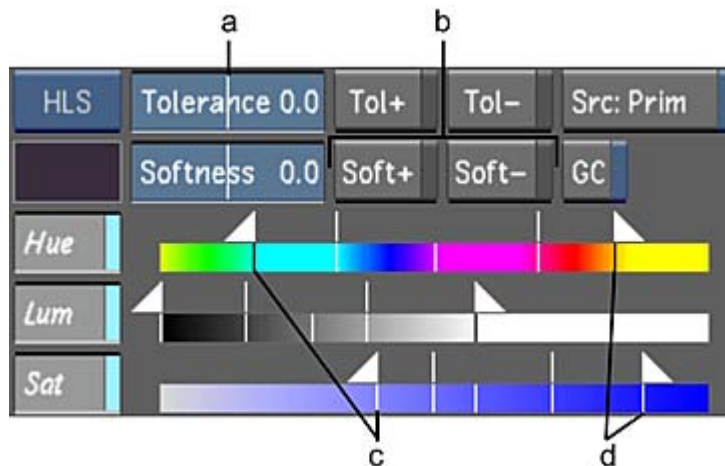

#### To set the tolerance range for the hue, luminance, or saturation channel:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.
- 2 For the hue, luminance, or saturation channel, set the centre tolerance value using the Centre Tolerance indicator. The Centre Tolerance indicator acts as a reference point for the tolerance range. Make sure to place your cursor directly over the indicator and then drag it to the left or right.  
When you move the Centre Tolerance indicator, the other indicators move as well—the softness and tolerance ranges are shifted.
- 3 For the hue, luminance, or saturation channel, set the minimum value for the tolerance range using the Minimum Tolerance Range indicator. Drag the indicator to the left to increase tolerance. Drag the indicator to the right to decrease tolerance.
- 4 For the hue, luminance, or saturation channel, set the maximum value for the tolerance range using the Maximum Tolerance Range indicator. Drag the indicator to the left to decrease tolerance. Drag the indicator to the right to increase tolerance.

## Setting the Softness Range in the HLS Keyer

Once you have set the tolerance range, you can then set the softness range. Softness sets the range of colours to make semi-transparent and can create a softer key. Use softness to create a more natural and softer look when applying secondary colour correction.

To set the softness of a key, you can use the colour picker, the Master Softness slider, or the Softness Range indicators. With the colour picker and the Master Softness slider, you set the softness range for hue, luminance, and saturation together. With the Softness Range indicators, you set the softness range for hue, luminance, and saturation individually.

(a) Master Softness slider (b) Add Softness/Remove Softness buttons (c) Minimum Softness Range indicators (d) Maximum Softness Range indicators

### To set the softness range using the colour picker:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.  
In Matte view, you can see the modifications you make to the softness. You can toggle between Matte view and Secondary view while you fine-tune a key.
- 2 In the Secondaries menu, enable the Add Softness or Remove Softness button to increase or decrease the softness.
- 3 Click and drag an area of the image. Alt-drag in the image to select a larger area.  
The softness is modified.

### To set the softness range using the Master Softness slider:

**NOTE** The Master Softness slider controls the position of all of the sliders in all of the channels (even when they are not enabled).

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.  
In Matte view, you can see the modifications you make to the softness. You can toggle between Matte view and Secondary view while you fine-tune a key.
- 2 Set the softness range:
  - To increase softness, drag the Master Softness slider to the right.
  - To decrease softness, drag the Master Softness slider to the left.

When you release the slider, the softness is modified and the slider returns to its original position.

**To set the softness range for the hue, luminance, or saturation channel:**

- 1 View the secondary in the Player. Press **F11** to toggle between Matte view and Secondary view.  
In Matte view, you can see the modifications you make to the softness. You can toggle between Matte view and Secondary view while you fine-tune a key.
- 2 For the hue, luminance, or saturation channel, set the minimum value for the softness range using the Minimum Softness Range indicator. This controls the minimum softness of edges between the image and the key colour. Drag the indicator to the left to increase the softness range. Drag the indicator to the right to decrease the softness range.
- 3 For the hue, luminance, or saturation channel, set the maximum value for the softness range using the Maximum Softness Range indicator. This controls the maximum softness of edges between the image and the key colour. Drag the indicator to the left to decrease the softness range. Drag the indicator to the right to increase the softness range.

**Using the Diamond Keyer to Extract a Key**

The Diamond Keyer provides comprehensive controls to set the key colour, as well as the chrominance range and luminance levels for softness and tolerance on the hue cube. You can set these by using sliders and numeric fields, or by sampling colours in the image.

With the Diamond Keyer, you can extract a key based on a preset red, green, blue, cyan, magenta, or yellow colour, or on a sampled colour. You can also use previously-saved keyer presets. See [Saving and Loading Presets Using the Presets Lists](#) (page 2094). By manipulating the chrominance Softness and Tolerance Diamonds, which define the boundaries of the chrominance range for softness and tolerance on the hue cube, you can quickly and easily isolate the colour for which you want to extract a key.

You can modify a key by adjusting the luminance levels using the Luminance gradient controls and by adjusting the chrominance range and luminance levels using the Add/Remove Softness and Tolerance buttons. You can further modify a key using the Sharpness, Cleanup, Shrink, and Blur parameters.

**NOTE** To disable the Diamond Keyer at any time, right-click on the Keyer option box.

Before extracting a key, you can modify the source image by using the Input Transform Log to Lin and Soften options. See [Tools Settings](#) (page 1811).

Use the following workflow to extract a key for colour isolation.

| Step:                                                                                  | Refer to:                                                                         |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| 1. Access the Diamond Keyer.                                                           | See <a href="#">Accessing the Diamond Keyer</a> (page 2168).                      |
| 2. Select the colour that you want to key.                                             | See <a href="#">Sampling a Colour in the Diamond Keyer</a> (page 2169).           |
| 3. View your secondary to determine the range of colour to key.                        | See <a href="#">Viewing Secondaries in the Diamond Keyer</a> (page 2171).         |
| 4. Set the luminance levels and chrominance range for tolerance to extract in the key. | See <a href="#">Setting the Tolerance Range in the Diamond Keyer</a> (page 2172). |
| 5. Set the luminance levels and chrominance range for softness to extract in the key.  | See <a href="#">Setting the Softness Range in the Diamond Keyer</a> (page 2174).  |

| Step:                                                                                             | Refer to:                                                         |
|---------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| 6. Blend the light and dark edges of a key by shrinking, eroding, or blurring the edges of a key. | See <a href="#">Modifying the Edges of the Key</a> (page 2177).   |
| 7. Remove stray pixels from a key to clean it up for colour grading.                              | See <a href="#">Removing Stray Pixels from a Key</a> (page 2178). |
| 8. Increase or decrease the softness of pixels that are in the tolerance range.                   | See <a href="#">Sharpening a Key Source Image</a> (page 2178).    |

The following procedures are not essential for extracting a key. You can perform these procedures any time after extracting a key.

| Step:                                                           | Refer to:                                                        |
|-----------------------------------------------------------------|------------------------------------------------------------------|
| 1. Remove colours that you do not want to include in the key.   | See <a href="#">Inverting Keys</a> (page 2179).                  |
| 2. Exclude a key that you do not want to appear in a secondary. | See <a href="#">Excluding Keys from Secondaries</a> (page 2179). |

# Accessing the Diamond Keyer

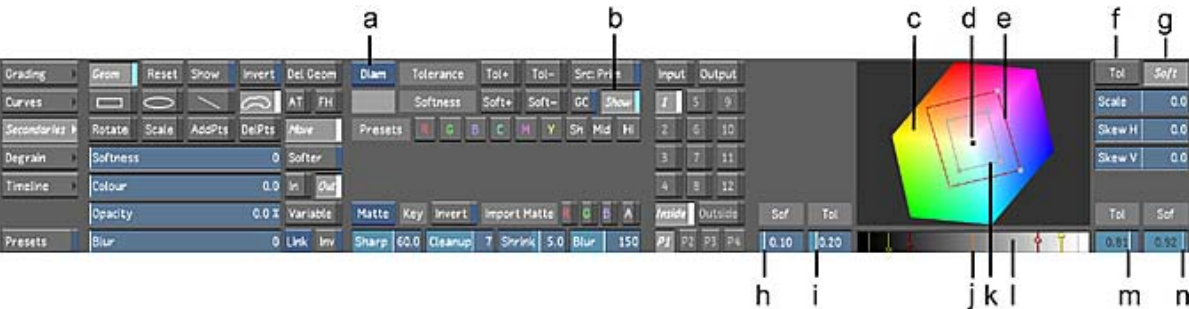

Use the comprehensive controls in the Diamond Keyer to extract a key.

To access the Diamond Keyer:

- 1 In the Secondaries menu, toggle the Keyer option box to access the Diamond Keyer.

The Diamond Keyer interface appears.

**NOTE** Disable the Show button to display the Shape Tracker, Schematic, Notes, Flags, Pixel, Animation, Group, and Selector panels.

(a) Keyer option box (b) Show Diamond Keyer (c) Hue cube (d) Sampled pixel (e) Chrominance Softness Diamond (f) Chrominance Tolerance Diamond selector (g) Chrominance Softness Diamond selector (h) Minimum Luminance slider for softness (i) Minimum Luminance slider for tolerance (j) Luminance level of sampled pixel (k) Chrominance Tolerance Diamond (l) Luminance gradient (m) Maximum Luminance slider for tolerance (n) Maximum Luminance slider for softness

The Diamond Keyer interface is made up of the following elements.

**Keyer option box** Toggles to display the HLS Keyer or the Diamond Keyer. The default keyer is configured in the user settings. See [Tools Settings](#) (page 1811).

**Show** Displays the Diamond Keyer. Disable to display the Shape Tracker, Schematic, Notes, Flags, Pixel, Animation, Group, and Selector menus.

**Hue cube** Representation of the colour space in which you perform colour isolation for the extraction of a key.

**Sampled pixel** Black dot represents the sampled colour on the hue cube.

**Chrominance Softness Diamond** Used to set the chrominance range for softness.

**Chrominance Tolerance Diamond selector** Selects the chrominance Tolerance Diamond for scaling and skewing.

**Chrominance Softness Diamond selector** Selects the chrominance Softness Diamond for scaling and skewing.

**Minimum Luminance slider for softness** Used to set the minimum luminance levels for softness.

**Minimum Luminance slider for tolerance** Used to set the minimum luminance levels for tolerance.

**Luminance level of sampled pixel** Orange bar represents the luminance level of the sampled pixel in the Luminance gradient.

**Chrominance Tolerance Diamond** Used to set the chrominance range for tolerance.

**Luminance gradient** Displays the level of luminance for the sampled pixel and the Minimum and Maximum luminance levels for tolerance and softness.

**Maximum Luminance slider for tolerance** Used to set the maximum luminance level for tolerance.

**Maximum Luminance slider for softness** Used to set the maximum luminance level for softness.

## Sampling a Colour in the Diamond Keyer

The typical way to extract a key is to sample a pixel or an average colour in the image using the colour picker. Lustre also provides colour presets as a starting point for the key. You can also use previously saved keyer presets. See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

**To sample a colour:**

- 1 Set the view mode to Output. You can click the O button.

**NOTE** Pressing F12 to set the view mode to Output only works from Matte view.

- 2 In the secondary layers panel, activate a layer.

**NOTE** If you do not activate the secondary layer, the colour pot will not be updated with your colour sample.

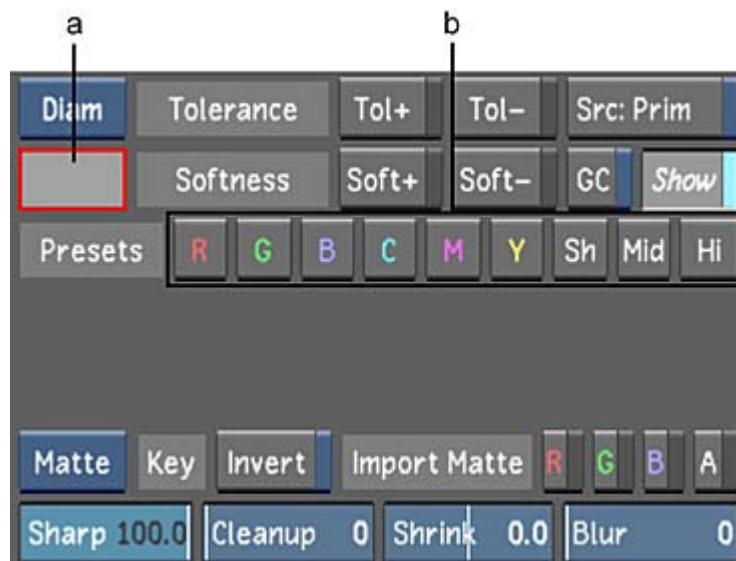

- 3 Right-click the Keyer option box to enable the Diamond Keyer.  
The letters in the Keyer option box turn bright white indicating that the Diamond Keyer is enabled.
- 4 Enable the Source Primary button to use primary grading results as the input to a key.

**NOTE** When Src: Prim is disabled, the raw scan is used as the input to the keyer, effectively bypassing any input LUTs and primary grading that have been applied to your shot.

(a) Source Primary button (b) Log to Lin button (c) Soften slider

- 5 Enable the Log to Lin button. See [Tools Settings](#) (page 1811).
- 6 Adjust the Soften slider. See [Tools Settings](#) (page 1811).
- 7 To sample a colour, do one of the following:
  - Click the colour pot.  
The colour pot is outlined in red.
  - Click a Presets option.  
The colour presets allow you to quickly select a starting point for your key. The R, G, B, C, M, and Y colour presets position the chrominance Tolerance and Softness Diamonds in the corresponding regions of the hue cube. The Sh (shadow), Mid (midtones), and Hi (highlights) presets select luminance ranges along the luminance axis.

(a) Colour pot (b) Presets options

## 8 Sample the image:

- To sample a single pixel, click and drag in the image until you locate the pixel you want to sample. As you drag, the colour of the current pixel appears in the colour pot. When you locate the pixel you want to sample, release the mouse.
- To sample an average taken from a range of colours in the image, **Alt**-drag the image in the Player.

The cursor changes to a colour picker when you move it over the image in the Player. When you release the mouse, the initial chrominance range is set for softness and tolerance on the hue cube, and the colour pot displays the sampled colour.

**NOTE** The chrominance of the sampled colour is represented by a black dot on the hue cube and the luminance of the sampled colour is represented by an orange bar in the Luminance gradient.

## 9 If the colour pot is enabled, click it again to finish defining the colour.

# Viewing Secondaries in the Diamond Keyer

Once you have sampled a colour for the key, you can view the resulting secondary in the Player. You can view the key in Secondary view or Matte view by toggling the **F11** key. Secondary view displays the keyed out colour as is; unsampled colours are overlayed with a uniform colour by default. Matte view displays the alpha channel, a black and white template indicating which parts of the image are transparent (black), and which are opaque and selected (white). The white parts of the image can be colour graded.

## To view a secondary:

- 1 Select the secondary you want to view.
- 2 Display the image in Secondary view by pressing **F11**.

In Secondary view, the colour that is keyed out in the current secondary is unchanged; unsampled colours are overlayed with a uniform colour by default. See [Matte Overlay Settings](#) (page 1836).

- 3 Press F11 to display Matte view.

In Matte view, the white parts of the matte represent the selected colours that can be colour graded. The black parts represent the unselected colours in the secondary. Greys indicate the zone of softness.

## Setting the Tolerance Range in the Diamond Keyer

You can set the tolerance for a range of colours to be fully keyed (transparent) and to remove unwanted greys from the key. You can modify the chrominance and luminance levels for tolerance across the entire image or just in the shadows, midtones, and highlights. The Tolerance Diamond defines the range of colours included in the secondary.

To set the chrominance range for tolerance, you can manipulate the Tolerance Diamond or sample the chrominance and luminance of the image using the Add Tolerance and Remove Tolerance buttons. You can also use the Minimum and Maximum Luminance sliders to set the luminance levels for tolerance.

**To set the chrominance range for tolerance by moving and modifying the Tolerance Diamond:**

- 1 View the secondary in the Player. Press F11 to toggle to Secondary view.  
In Secondary view, you can see the effect of the modifications you make to the chrominance range for tolerance while you fine-tune the key.
- 2 Click and drag the Tolerance Diamond or click and drag a vertex of the Tolerance Diamond.

**NOTE** If the Tolerance Diamond vertex is too small to drag with the mouse, you can use the scale and skew controls to expand the diamond. See [Using the Scale and Skew Controls in the Diamond Keyer](#) (page 2176). You can also zoom in and out on the hue cube. Right-click and drag to the right to zoom in or drag to the left to zoom out. The Tolerance Diamond is red when selected and grey when unselected.

(a) Tolerance Diamond vertex

The chrominance range for tolerance is modified.

**To set the luminance levels and chrominance range for tolerance using the Add/Remove Tolerance buttons:**

- 1 View the secondary in the Player. Press F11 to toggle between Secondary view and Matte view.
- 2 In the Secondaries menu, enable the Add Tolerance or Remove Tolerance button to increase or decrease the chrominance and luminance levels for tolerance.

(a) Add Tolerance and Remove Tolerance buttons

- 3 Click or drag in the image. Alt-drag in the image to select a larger area.  
The chrominance range and luminance levels for tolerance are modified.

**To set the luminance levels for tolerance using the Minimum and Maximum Luminance sliders:**

- 1 View the secondary in the Player. Press F11 to toggle to Matte view.  
In Matte view, you can see the effect of the modifications you make to the luminance levels for tolerance while you fine-tune the key.
- 2 Drag the Minimum and Maximum Luminance sliders (next to the Luminance gradient) to set the luminance levels for tolerance.

(a) Minimum Luminance slider for tolerance (b) Luminance gradient (c) Maximum Luminance slider for tolerance

**NOTE** As you move the Minimum and Maximum Luminance sliders for tolerance, the luminance levels are represented in the Luminance gradient by corresponding red markers.

The luminance levels for tolerance are modified.

## Setting the Softness Range in the Diamond Keyer

Once you have set the tolerance range, you can then set the softness range. Softness sets the range of colours to make semi-transparent and creates a softer key. Use softness to create a more natural and softer look when applying secondary colour correction.

To set the chrominance range for softness, you can manipulate the chrominance Softness Diamond. You can use the Add Softness and Remove Softness buttons to set the chrominance range and luminance levels for softness. You can also use the Minimum and Maximum Luminance sliders to set the luminance levels for softness.

**To set the chrominance range for softness by moving and modifying the Softness Diamond:**

- 1 View the secondary in the Player. Press F11 to toggle to Secondary view.  
In Secondary view, you can see the effect of the modifications you make while you fine-tune the key.
- 2 Click and drag the Softness Diamond or click and drag a vertex of the Softness Diamond.

**NOTE** If the Softness Diamond vertex is too small to drag with the mouse, you can use the scale and skew controls to expand the diamond. See [Using the Scale and Skew Controls in the Diamond Keyer](#) (page 2176). You can also zoom in or out on the hue cube. Right-click and drag to the right to zoom in or drag to the left to zoom out. The Softness Diamond is red when selected and grey when unselected.

(a) Softness Diamond vertex

The chrominance range for softness is modified.

**To set the chrominance range and luminance levels for softness using the Add Softness and Remove Softness buttons:**

- 1 View the secondary in the Player. Press F11 to toggle between Secondary view and Matte view.
- 2 In the Secondaries menu, enable the Add Softness or Remove Softness button to increase or decrease the chrominance range and luminance levels for softness.

(a) Add Softness and Remove Softness buttons

- 3 Click or drag in the image. Alt-drag in the image to select a larger area.  
The chrominance and luminance levels for softness are modified.

**To set the luminance levels for softness using the Minimum and Maximum Luminance sliders:**

- 1 View the secondary in the Player. Press F11 to toggle to Matte view.  
In Matte view, you can see the effect of the modifications you make while you fine-tune the key.
- 2 Drag the Minimum and Maximum Luminance sliders (next to the Luminance gradient) to adjust the luminance levels for softness.

(a) Minimum Luminance slider for softness (b) Luminance gradient (c) Maximum Luminance slider for softness

**NOTE** As you move the Minimum and Maximum Luminance sliders for softness, the luminance levels are represented in the Luminance gradient by corresponding yellow markers.

The luminance levels for softness are modified.

## Using the Scale and Skew Controls in the Diamond Keyer

With the Scale control, you can scale the chrominance Softness and Tolerance Diamonds to increase or decrease the range of colour to isolate. With the Skew controls, you can skew the chrominance Softness and Tolerance Diamonds horizontally and vertically relative to the orientation of the selected diamond to increase or decrease the range of colour to isolate.

**NOTE** To zoom in or out on the hue cube, right-click and drag to the right to zoom in or drag to the left to zoom out.

(a) Tolerance and Softness selectors (b) Scale slider (c) Skew Horizontal slider (d) Skew Vertical slider (e) Horizontal control vertices (f) Vertical control vertex

### To scale the range of colour:

- 1 View the secondary in the Player. Press F11 to toggle to Secondary view.  
In Secondary view, you can see the effect of the modifications you make while you fine-tune the key.
- 2 Click the Tolerance button or Softness button to select the Tolerance Diamond or Softness Diamond.
- 3 Drag the Scale slider to the left or to the right to decrease or increase the range of colour to isolate.

### To skew the range of colour horizontally:

- 1 View the secondary in the Player. Press F11 to toggle to Secondary view.  
In Secondary view, you can see the modifications you make to the chrominance range while you fine-tune the key.
- 2 Click the Tolerance button or Softness button to select the Tolerance Diamond or Softness Diamond.
- 3 Depending on the orientation of the diamond, drag the Skew slider to the left to horizontally decrease the range of colour to isolate or to the right to horizontally increase the range of colour to isolate.

### To skew the range of colour vertically:

- 1 View the secondary in the Player. Press F11 to toggle to Secondary view.  
In Secondary view, you can see the modifications you make to the chrominance range while you fine-tune the key.
- 2 Click the Tolerance button or Softness button to select the Tolerance Diamond or Softness Diamond.
- 3 Depending on the orientation of the diamond, drag the Skew slider to the left to vertically decrease the range of colour to isolate or to the right to vertically increase the range of colour to isolate.

## Modifying the Edges of the Key

You can shrink, erode, or blur the edges of a key. Shrink a key to remove pixels from the edge of the key. Erode a key to blend the light and dark edges. Blur a key to apply a softening filter to its edge.

---

**NOTE** The following steps apply to both the HLS and Diamond Keyers.

---

### To shrink or erode the edge of the key:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.
- 2 Fine-tune the edge of the key:
  - To shrink the edge of the key, drag the Shrink slider to the left.
  - To erode the edge of the key, drag the Shrink slider to the right.

### To blur the edge of the key:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.
- 2 Drag the Blur slider to the right.

The edge of the key is softened.

Before

After

Images courtesy of Hungarian Academy of Film & Theatre, 3rd year

## Removing Stray Pixels from a Key

When you extract a key, pixels in other parts of the image may be included. You can remove these stray pixels from the key to clean it up for colour grading.

---

**NOTE** The following steps apply to both the HLS and Diamond Keyers.

---

To remove stray pixels:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.
- 2 Drag the Cleanup slider to the right to apply a median filter to remove stray pixels.

## Sharpening a Key Source Image

Sharpen a key source image to increase or decrease the softness of only the pixels that are within the chrominance and luminance range for tolerance.

---

**NOTE** This procedure applies to the Diamond Keyer only.

---

To sharpen a key:

- 1 View the secondary in the Player. Press F11 to toggle between Matte view and Secondary view.

- 2 Drag the Sharpness slider to adjust softness and reduce noise if the matte appears grainy.

## Inverting Keys

Invert a key when it is easier to exclude rather than include colours in a secondary.

---

**NOTE** The following steps apply to both the HLS and the Diamond Keyers.

---

To invert a key:

- 1 In the Secondaries menu, toggle the Matte/Key-in option box to display the Key Invert panel, and then enable Invert.

The area of the key that was opaque becomes transparent and the area that was transparent becomes opaque.

## Excluding Keys from Secondaries

You can exclude keys from secondaries. When you exclude a key from a secondary that includes a geometry, only the geometry is colour graded.

---

**NOTE** The following steps apply to both the HLS and the Diamond Keyers.

---

To exclude a key from a secondary:

- 1 In the Secondaries menu, select and then right-click the Secondary button that contains the key you want to exclude.

If a key is included with the secondary, the keyer is enabled.

**TIP** Click M in the View Mode buttons and then toggle the F11 key to display the Matte view.

- 2 Right-click the Keyer option box to disable the current Keyer.

**NOTE** The HLS and Diamond Keyer letters turn from bright white to faded white, indicating that the keyer is disabled.

The key is excluded from the colour grade. The whole image or the areas defined by a geometry will be colour graded by the secondary.

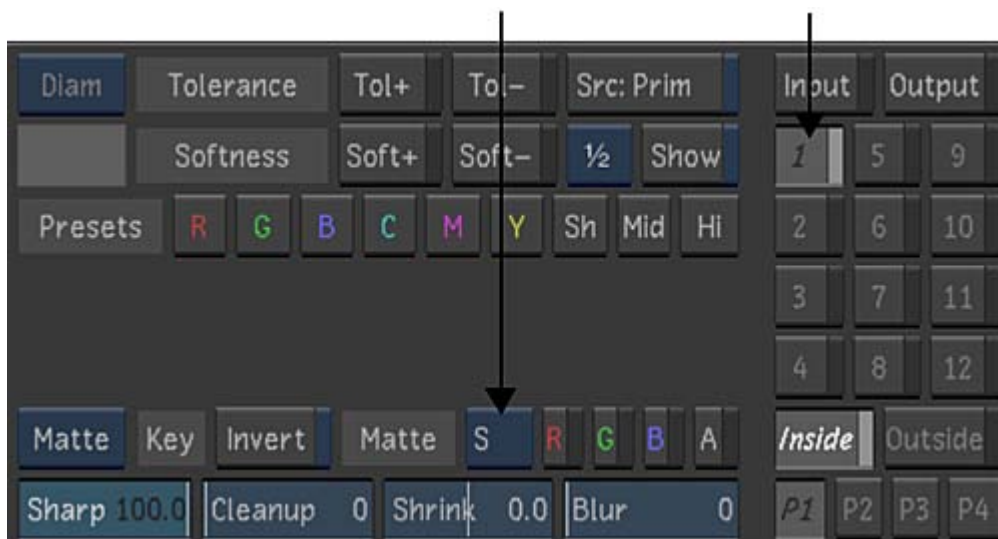

## Saving and Loading Key Presets

You can save user-defined keys, or previously saved keyer presets. You can then quickly load them to the current shot for comparison. See [Saving and Loading Presets Using the Presets Lists](#) (page 2094).

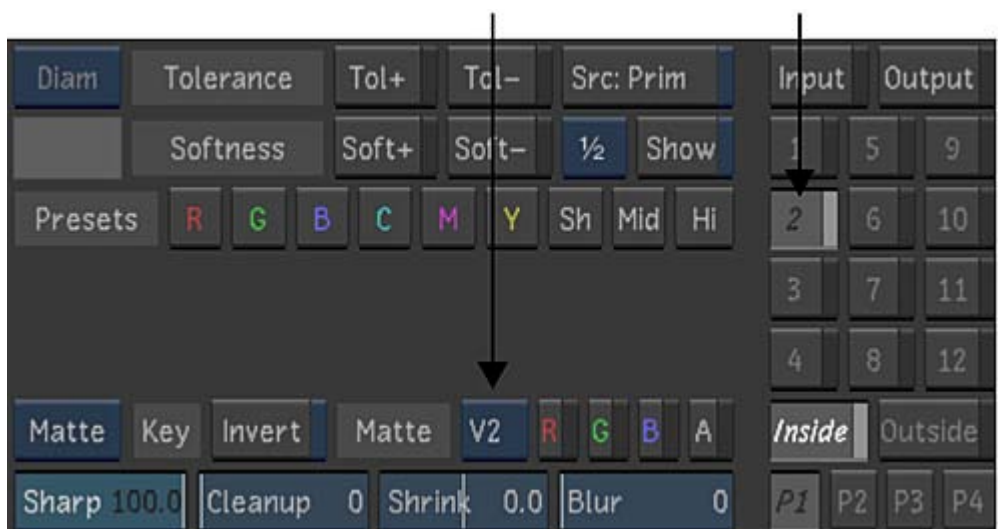

## Working with Mattes

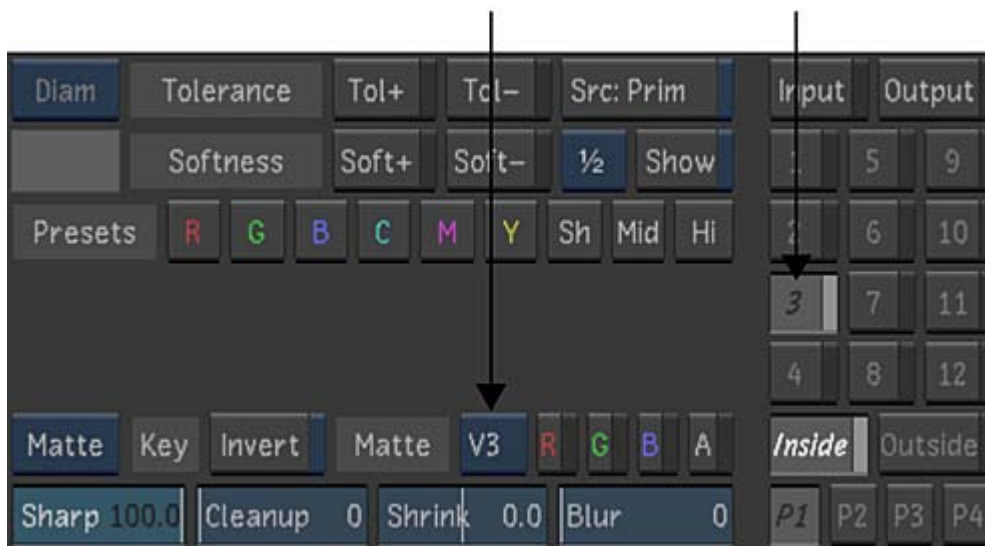

In the following screenshot, the matte on the secondary track is applied to the first secondary colour grading layer.

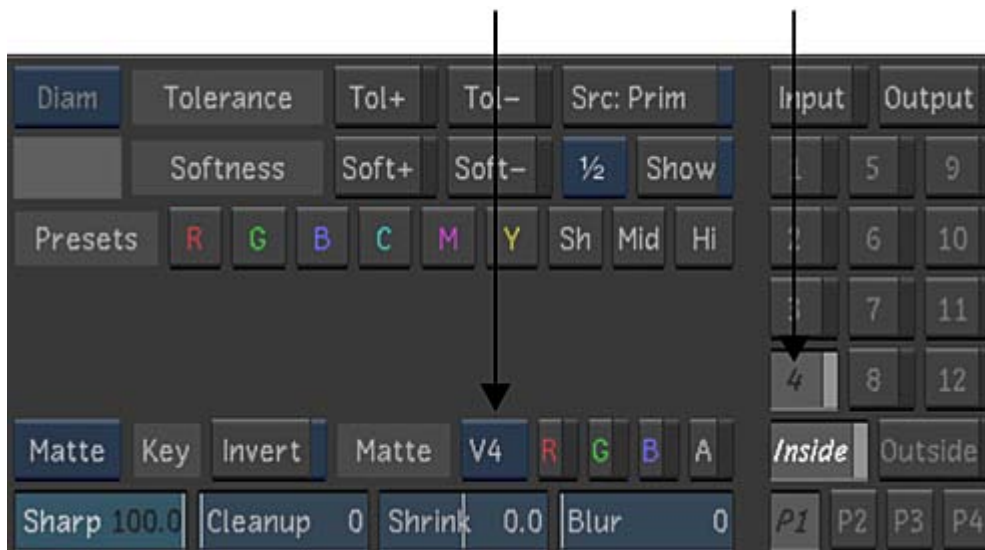

In the following screenshot, the matte on the V2 track is applied to the second secondary colour grading layer.

In the following screenshot, the matte on the V3 track is applied to the third secondary colour grading layer.

In the following screenshot, the matte on the V4 track is applied to the fourth secondary colour grading layer.

---

**NOTE** If the matte you are using does not contain an alpha channel, the alpha button is not available.

---

**NOTE** Playback performance may vary based on the number of active mattes, file formats, resolution, storage bandwidth and type of project. For example, if you have two matte tracks in a matte container that are both being used on secondaries, three playback streams of media are required. You may not achieve real-time playback based on storage bandwidth, graphics card processing, etc. Performance may also be compromised if you are working with dissolves or stereoscopic timelines.

---

## Shape Tracker

The Shape Tracker tool is a 2-dimensional tracking device that allows you to track objects within your shot. It allows you to create a geometry around the object you want to track, analyse the object through the shot, and then grade the geometry.

To use the Shape Tracker you need to define a region of interest (ROI) by drawing a geometry around the object you want to track. The area inside this geometry is where Lustre searches for trackable points. This group of trackable points is called a point cloud. By tracking a cloud instead of a single point, Lustre can track shapes through translation, rotation, and scaling.

In order to track a shape properly, the ROI needs to be large enough so there are enough trackable points in the point cloud. If the ROI is large enough, the object in the shot will be tracked properly. If the object you want to track is small and does not contain enough trackable points, you need to link the smaller graded geometry to a larger tracked geometry.

## The Shape Tracker Panel

To track 2D shapes within a shot, you need to enable the Shape Tracker tool and create an ROI.

**To access the Shape Tracker panel and create an ROI:**

- 1 In the Main menu click Colour.
- 2 Click Secondaries.

The Secondaries menu with the Shape Tracker panel appears.

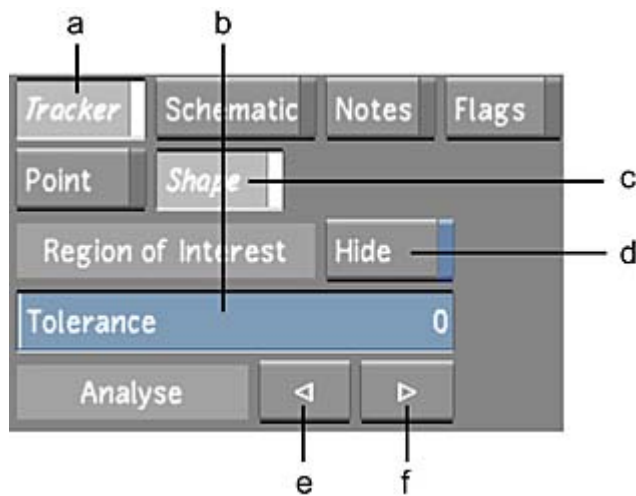

**NOTE** When the Diamond Keyer is selected, disable the Show button to display the Shape Tracker panel (as well as the Schematic, Notes, Flags, Pixel, Animation, Group, and Selector panels).

### Parts of the Shape Tracker

The Shape Tracker is made up of the following components.

**(a) Tracker button (b) Tolerance slider (c) Shape button (d) Hide button (e) Analyse backward button (f) Analyse forward button**

**Tracker button** Enables the tracking option (Point Tracker or Shape Tracker).

**Tolerance slider** Defines the tolerance level of the Shape Tracker analysis. The range is from 0 to 10.

A tolerance level of 0 (low tolerance) means the object that is being tracked does not change in shape throughout the shot. If an external object passes in front of the tracked object, a low tolerance ensures that the motion of the external object does not get tracked through the analysis.

A tolerance level of 10 (high tolerance) means the object which is being tracked has a slight change in shape throughout the shot. For example, there is slight 3D movement from the shape. If you have set the tolerance level to high, external objects that pass in front of the tracked object may be included in the analysis.

**Shape button** Enables the Shape Tracker tool.

**Hide button** When enabled, it hides the selected geometry and grading (if applicable). You can also use the hotkey, left **Ctrl+H**, to hide and show the geometry.

**Analyse backward button** When selected, the Shape Tracker analyses the object within the selected ROI from your insertion point to the beginning of the shot.

**Analyse forward button** When selected, the shape tracker analyses the object within the selected ROI from your insertion point to the end of the shot.

## Tracking an Object using Shape Tracker

There are two ways to use the Shape Tracker. If you can create a large enough ROI around the object you want to track, you can use the Shape Tracker to track the object and then grade the same geometry. If the object you want to track and grade is small and it does not have enough trackable points to use the Shape Tracker effectively, you need to track a larger ROI, create a graded geometry of the smaller object, and link the ROI geometry to the graded geometry.

The following procedure is used when the object has a large enough ROI to track.

**To track an object within a shot:**

- 1 Make sure you are on the first frame of where you want the tracking to start.
- 2 In the Secondaries menu, right-click a secondary layer to activate it.

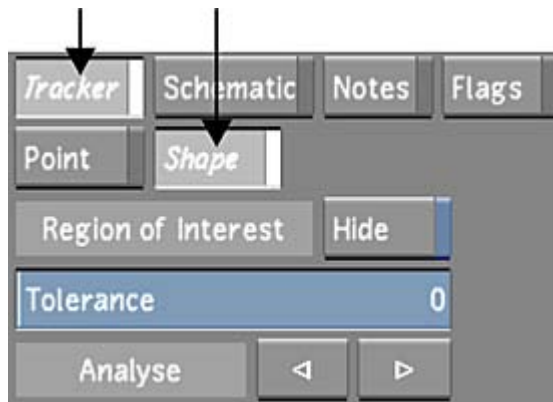

- 3 Click Show

- 4 Enable the Shape Tracker tool by clicking on Tracker and Shape.

- 5 Create an ROI by drawing either a basic or free-form geometry around the object you want to track. See [Drawing Basic Geometries](#) (page 2136) and [Drawing Free-Form Geometries](#) (page 2136).

**NOTE** Make sure your ROI is as large as possible, without including too many non-rigid shapes, in order to give Shape Tracker a sufficient area to analyse.

- 6 Make sure the geometry you want to track is selected.  
The axis of the geometry should be yellow.
- 7 Set the tolerance slider between 0-10.
- 8 Click the analyse backward, or analyse forward button, to analyse the shot segment.  
When the analysis is complete, you can grade the geometry.

**NOTE** If the analysis stops before the end of the shot or it does not begin at all, the ROI area may be too small to track. Refer to the following procedure below.

The following procedure is used if the object you want to track is small and does not contain enough trackable points.

**To track a small object that does not contain enough trackable points:**

- 1 Make sure you are on the first frame of where you want the tracking to start.
- 2 In the Secondaries menu, right-click a secondary layer button to activate it.

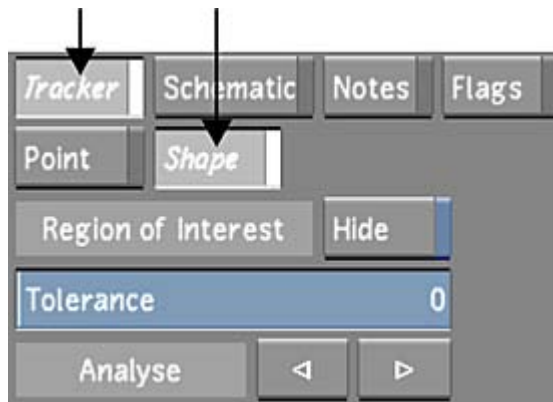

- 3 Click Show.

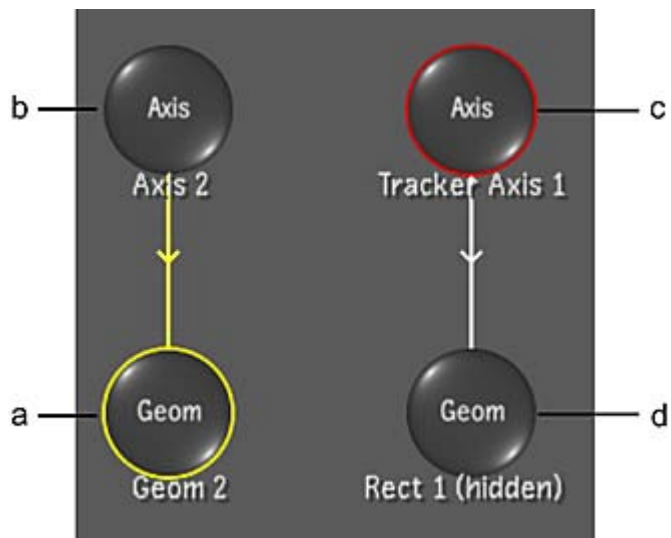

- 4 Enable the Shape Tracker tool by clicking on Tracker and Shape.

- 5 Create an ROI by drawing a basic geometry around a large area in the shot. See [Drawing Basic Geometries](#) (page 2136).

**NOTE** Depending upon your shot, the large ROI area may or may not contain the smaller object you want to track.

- 6 Make sure the geometry you want to track is selected.  
The axis of the geometry should be yellow.
- 7 Set the tolerance slider between 0-10.
- 8 Click the analyse backward, or analyse forward button, to analyse the shot segment.  
The analysis is now complete.
- 9 Click Hide.  
The tracked geometry is now hidden.
- 10 Create a geometry around the object you want to grade.
- 11 Grade this new geometry.
- 12 Press ~ (the tilde key) to enter the Schematic view.  
You should see the axis and geometry of the tracked shape and the graded shape.

(a) Geometry of graded shape (b) Axis of graded shape (c) Axis of ROI (d) Geometry of ROI

- 13 Position your cursor over the edge of the circle representing the ROI axis and left-click and drag a line to the edge of the circle representing the graded shape axis.

The graded shape is now linked to the ROI and therefore follows its tracked path.

- 14 Press ~ to return to the Player view.

## Animating the Point Tracker

Point Tracker is a useful tool for tracking points through a shot. In situations where tracking a point cloud is impossible, Point Tracker provides an excellent alternative. For example, if Shape Tracker's ROI provides no rigid shapes to track, Point Tracker's ability to track a point remains the best choice. With Point Tracker, you can animate a geometry by applying tracking data to it. Users can assign one or several trackers to a geometry. This is useful when you want a geometry to follow a moving element in a shot. With Point Tracker, you can:

- Animate the position of an entire geometry without changing its shape by assigning a tracker to the geometry's axis.

- Animate the shape of a geometry by assigning a tracker to each vertex. If you are animating a basic geometry, convert it to a free-form geometry first.

When you apply tracking data to a geometry, only the axis or the position of the vertices is animated. Because you can assign multiple trackers to a geometry, you can assign trackers to both its axis and vertices.

Tracking data appears in the Channel Editor. Tracking data for each tracker is contained in a Trackers directory of the channel hierarchy. Use the channel hierarchy to select the tracker and then modify the tracking data. In the channel hierarchy, the channels for each tracker appear.

| Tracker Channel | Description                                                 |
|-----------------|-------------------------------------------------------------|
| Ref X           | The point being tracked on the X-axis                       |
| Ref Y           | The point being tracked on the Y-axis                       |
| Track X         | Last tracked (or current) tracker position along the X-axis |
| Track Y         | Last tracked (or current) tracker position along the Y-axis |

You can also animate the softness of geometries and the position of their individual vertices using the Animation controls. See [Animation](#) (page 2214).

The Point Tracker is further improved with sub-pixel accuracy. Subsequently, any subtle movement (including movements less than a single pixel in dimension) can now be analysed and written to the Lustre Animation Channel.

## Animating the Position of Geometries

You can animate the position of geometries by defining a Point Tracker and assigning it to the axis of the geometry.

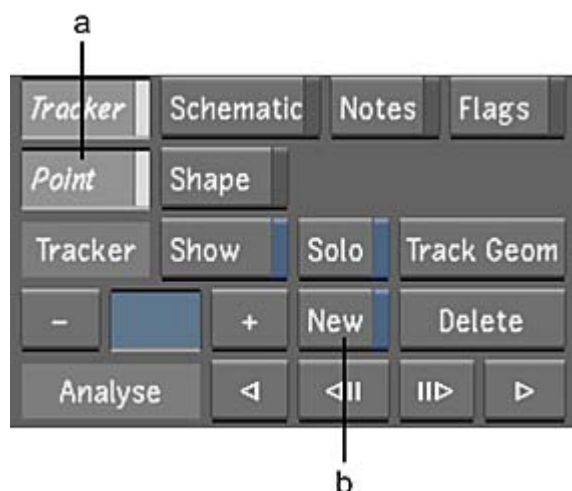

**To animate the position of a geometry with the Point Tracker:**

- 1 In the Secondaries menu, activate the secondary layer button that contains the geometry you want to track.
- 2 Click Show.

- 3 The Point Tracker option should already be enabled by default.

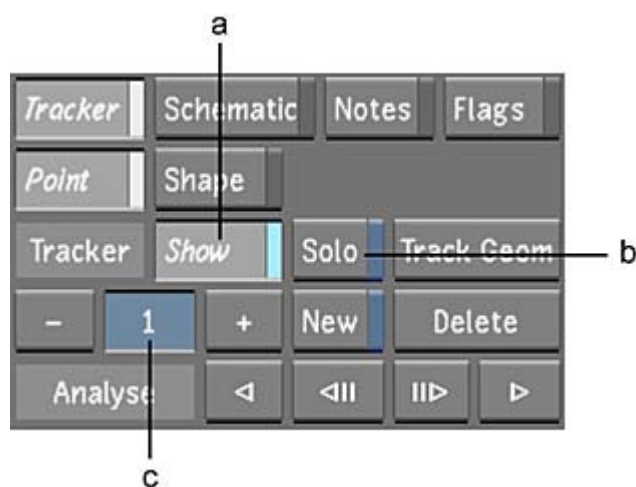

**NOTE** When the Diamond Keyer is selected, disable the Show button (beneath the Source Primary button) to display the Tracker panel.

(a) Point Tracker button (b) New button

- 4 Enable a new tracker by clicking New.
- 5 In the Player, go to the frame where you want to start tracking, and then click a tracking point in the image.

In the Player, the tracker is assigned to, and positioned over, the tracking point. A tracker number is assigned to the tracker and the tracker is set to On.

(a) Tracker status (b) Solo/Gang button (c) Tracker list

When a tracker is on, it is displayed in the Player and can be analysed.

- 6 Disable the Solo/Gang button to select Solo mode.  
In Solo mode, only the current tracker is analysed.
- 7 Use the Analyse buttons to analyse the shot:
  - To track the tracking point forward in time, click the Analyse Forward buttons.
  - To track the tracking point backward in time, click the Analyse Backward buttons.

(a) Analyse Backward buttons (b) Analyse Forward buttons

The system analyses the image and generates tracking data. For each frame in the shot, the position of the tracking point is displayed in the Player. The current position of the tracking point is highlighted in magenta.

- 8 Enable Assign.

- 9 In the Player, click the geometry's axis.

The tracker is assigned to the geometry's axis or vertex.

- 10 If the tracker loses the tracking point, click the image to stop the process, and then use the Step Backward or Step Forward button in the Player controls to return to the last frame that was correctly tracked.
- 11 In the Player, do any of the following:
- To resize the tracker, modify the Match area (magenta rectangle) and Search area (yellow rectangle) by dragging the vertices of the rectangles.
  - To reposition the tracker, drag the centre point of the tracker.
  - To reposition the tracker and reference point, middle-click and drag the centre point of the tracker.

**TIP** You can reposition the tracker and reference point when the reference point moves off-screen.

- 12 Continue using the Analyse buttons to analyse the shot.

- 13 To manually add or reposition a tracking point, go to the frame where you want to modify the tracking data, enable Add Key, and then click a tracking point in the image.

The position of the tracking point is displayed in the image.

- 14 To manually delete the position of a tracking point, go to the frame where you want to remove the tracking data, and then click Del Key.

The tracking data is deleted.

**NOTE** Linear interpolation is used to set the tracking position for frames without tracking data. For these frames, the previous defined tracking position and the next defined position are used to interpolate the tracking position.

## Animating the Shape of Geometries with the Point Tracker

You can use the Track Geom button to animate the shape of a geometry when using Point Tracker. When you animate the shape of a geometry, the vertices of the geometry change position as the moving elements in the shot are tracked.

When you use Track Geom, a Point Tracker is simultaneously assigned to each vertex in the current geometry. You then analyse the shot to generate the tracking data.

**To animate the shape of a geometry:**

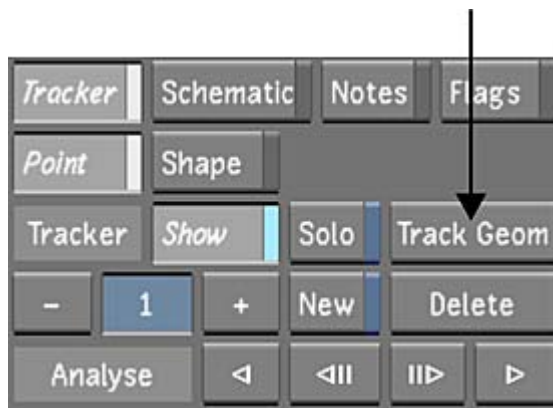

- 1 If working with a basic shape, right-click it in the Player to convert it to a free-form geometry.
- 2 In the Secondaries menu, activate the secondary layer button that contains the geometry you want to track.
- 3 Enable Show.

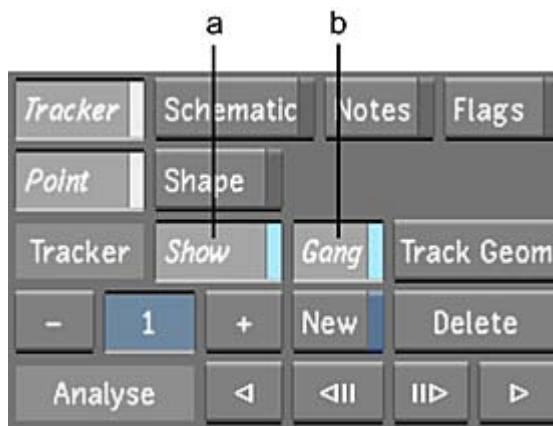

The geometries are displayed in the Player.

- 4 Go to the frame where you want to start tracking.
- 5 Select the geometry you want to track. In the Player, draw a selection box around the geometry to select all vertices on the shape. Alternatively, click a vertex to select it.
- 6 Click Track Geom.

**NOTE** When the Diamond Keyer is selected, disable the Show button (beneath the Source Primary button) to display the Tracker panel.

In the Player, a Point Tracker is assigned to, and positioned over, each vertex on the shape. A tracker number is assigned to each tracker. Gang mode is selected and the Point Trackers are turned on.

**(a)** Tracker status **(b)** Gang mode

When a Point Tracker is on, it is displayed in the Player and can be analysed. When Gang mode is selected, all Point Trackers assigned to the geometry (and any others included in the gang) will be analysed simultaneously.

**NOTE** If other Point Trackers exist, they will be turned off and hidden so as not to be included in the gang. However, if they are assigned to another geometry, their tracking data will still be applied.

- 7 Use the Analyse buttons to analyse the shot:
  - To track the tracking point forward in time, click the Analyse Forward button.
  - To track the tracking point backward in time, click the Analyse Backward button.

(a) Analyse Backward buttons (b) Analyse Forward buttons

The system analyses the shot and generates the tracking data.

- 8 If the Point Tracker loses the tracking point, click the image to stop the process, and then use the Step Backward or Step Forward button in the Player controls to return to the last frame that was correctly tracked.
- 9 In the Player, do any of the following:
  - To resize the tracker, modify the Match area (magenta rectangle) and Search area (yellow rectangle) by dragging the vertices of the rectangles.
  - To reposition the Point Tracker, drag the centre point of the tracker.
  - To reposition the Point Tracker and reference point, middle-click and drag the centre point of the tracker.

**TIP** You can reposition the Point Tracker and reference point when the reference point moves off-screen.

- 10 Continue using the Analyse buttons to analyse the shot.
- 11 To manually add or reposition a tracking point, go to the frame where you want to modify the tracking data, enable Add Key, and then click a tracking point in the image.

The position of the tracking point is displayed in the image.

- 12 To manually delete the position of a tracking point, go to the frame where you want to remove the tracking data, and then click Del Key.

The tracking data is deleted.

**NOTE** Linear interpolation is used to set the tracking position for frames without tracking data. For these frames, the previous defined tracking position and the next defined position are used to interpolate the tracking position.

## Assigning and Unassigning Point Trackers to Geometries

You can assign Point Trackers to, or unassign Point Trackers from, geometries at any time after you create them.

You can assign a Point Tracker to the axis of any geometry when you want to animate the entire geometry with or without changing its shape. You can also assign a Point Tracker to a vertex of a geometry when you want part of the edge of the geometry to change as it tracks a moving element in the shot. However, if you want to assign Point Trackers to all the vertices in a geometry, use Track Shape. See [Animating the Shape of Geometries with the Point Tracker](#) (page 2190).

**To assign a Point Tracker to a geometry:**

- 1 In the Secondaries menu, activate the secondary layer button that contains the geometry you want to track.
- 2 Enable Show.

The geometry is displayed in the Player.

- 3 Do one of the following:
  - Add a new Point Tracker.
  - Click the + or - button to select a Point Tracker from the Tracker list. Make sure the tracker is set to On and is in Solo mode.

The current Point Tracker is displayed in the Player.

- 4 Enable Assign.

- 5 In the Player, do one of the following:
  - To animate the entire geometry without changing its shape, click the geometry's axis.
  - To animate a single vertex in a geometry, click the vertex.

The Point Tracker is assigned to the geometry's axis or vertex.

**NOTE** You cannot assign a Point Tracker to more than one point on a geometry. If the tracker is already assigned to a vertex or axis on the geometry, you must unassign it.

**To unassign a Point Tracker from a geometry:**

- 1 Select the shot that contains the tracking data.
- 2 In the Secondaries menu, enable Show.

The geometry is displayed in the Player.

- 3 Click the + or - button to select a Point Tracker from the Tracker list. Make sure the tracker is set to On and is in Solo mode.

The current tracker is displayed in the Player.

- 4 Enable Unassign and then click the vertex or axis to which you assigned the tracker.

The Point Tracker is unassigned to the vertex but remains in the Tracker list.

## Soloing and Ganging Point Trackers

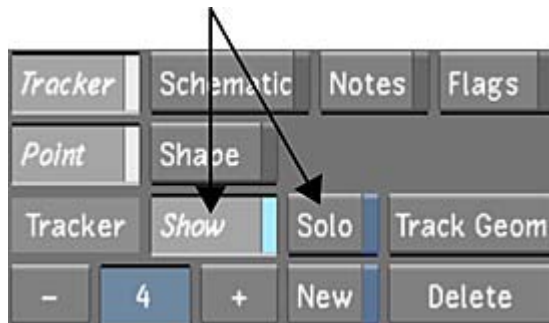

You can solo or gang Point Trackers. Solo a Point Tracker when you want to view and generate tracking data for the current tracker only. Gang Point Trackers when you want to view and generate tracking data for multiple Point Trackers at the same time.

**To solo a Point Tracker:**

- 1 Click the + or - button to select a Point Tracker from the Tracker list.

- 2 Make sure the Point Tracker is set to On and is in Solo mode.

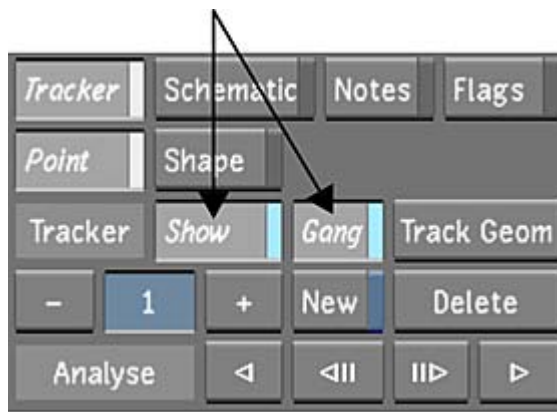

Only the current Point Tracker is displayed in the Player.

#### To gang Point Trackers:

- 1 Click the + or - button to select a Point Tracker from the Tracker list.

- 2 Make sure the tracker is set to On and is in Gang mode.

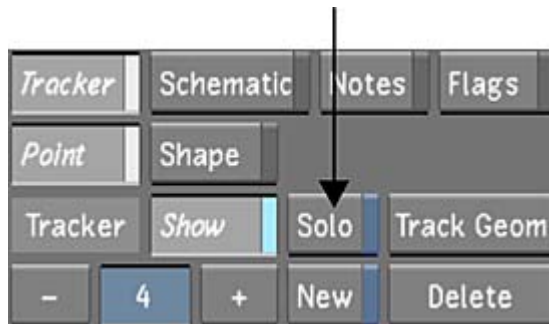

- 3 Repeat steps 1 and 2 for all the Point Trackers you want to add to the gang.  
The ganged trackers that are set to On are displayed in the Player and can be analysed as a group.

## Deleting Point Trackers

You can delete Point Trackers from a shot.

**To delete a Point Tracker:**

- 1 Select the shot that contains the tracking data.
- 2 In the Secondaries menu, select Solo mode.

When you use Solo mode, only the current Point Tracker is displayed in the Player. If the tracker does not appear, set the tracker to On.

- 3 Click the + or - button to scroll to the Point Tracker you want to delete.

If the current Point Tracker is on, it is displayed in the Player.

- 4 Click Delete.

The Point Tracker is deleted.

## Loading Tracker and Stabilizer Data from Autodesk Applications

You can load tracker and stabilizer data created with other Autodesk products (Flint®, Flame®, Inferno®, Fire®, Smoke®, and Autodesk Combustion®) into Lustre. To import tracker and stabilizer data, you must export it from the applicable Autodesk product as a raw setup file, and then save it in the *C:\Program Files\Autodesk\<version number>\settings\geompresets* folder (Windows), or in the */usr/autodesk/<version number>/settings/geompresets* directory (Linux).

---

**NOTE** You must create the *geompresets* directory manually to store your raw setup files. However, if you have created a preset, the *geompresets* directory is automatically generated.

---

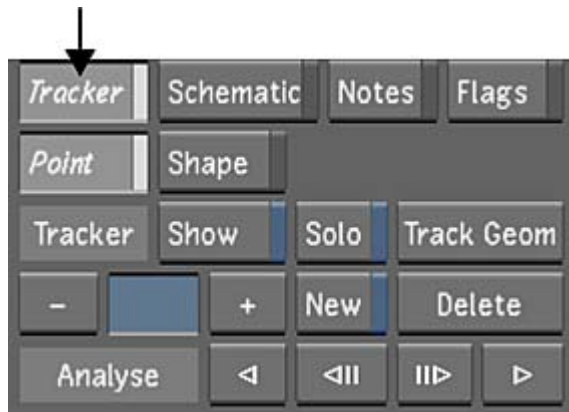

### To load tracker or stabilizer data:

- 1 Save a tracker or stabilizer raw setup file from the applicable Autodesk product.
- 2 Do one of the following:
  - If using the Windows version of Lustre, store the raw setup file in the *C:\Program Files\Autodesk\<version number>\settings\geompresets* folder.
  - If using the Linux version of Lustre, store the raw setup file in the */usr/autodesk/<version number>/settings/geompresets* directory.
- 3 In the Secondaries menu, enable the secondary layer button that contains the geometry you want to track.
- 4 Enable Show.

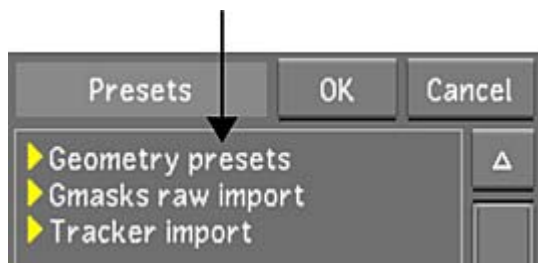

The geometries are displayed in the Player.

- 5 Click Tracker.

- 6 Click Point.
- 7 Click Presets to display the Presets list.

- 8 Expand Tracker import, and then select the tracker or stabilizer file.
- 9 Click OK.

The tracker appears in the Player and can be assigned to the points or axes of geometries.

## Loading Garbage Mask Setups from Autodesk Applications

You can load garbage mask setups created with other Autodesk products (Flint, Flame, Inferno, Fire, and Smoke) to use as geometries in Lustre. To import a garbage mask setup, you must export it from the applicable Autodesk product as a raw setup file, and then save it to the Lustre program directory. You can then load the garbage mask setup to the current secondary for use as a geometry.

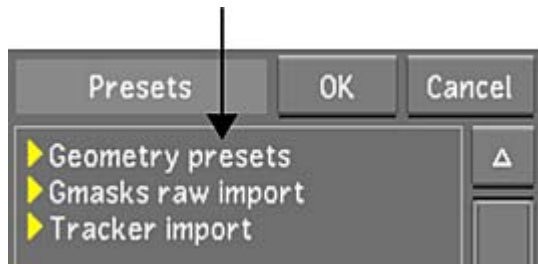

---

**NOTE** You must create the *geompresets* directory manually to store your raw setup files. However, if you have created a preset, the *geompresets* directory is automatically generated.

---

### To load a garbage mask setup:

- 1 Export a raw setup file from the applicable Autodesk product.
- 2 Do one of the following:
  - If using the Windows version of Lustre, store the raw setup file in the *C:\Program Files\Autodesk\<version number>\settings\geompresets* folder.
  - If using the Linux version of Lustre, store the raw setup file in the */usr/autodesk/<version number>/settings/geompresets* directory.
- 3 Click Presets to display the Presets list.

- 4 Expand Gmasks raw import, and then select the raw setup file.
- 5 Click OK to load the garbage mask setup.  
The geometry appears in the Player.

## Creating Lustre Sparks Effects

You can apply effects to your shots using Lustre Sparks plugins created by Autodesk or third-party developers. These plugins are image processing effects that you can add to individual shots. You can apply up to six effects to the same shot.

Lustre Sparks plugins occupy a specific, fixed spot in the processing pipeline in Lustre— between the secondary and output colour grading. You can therefore create them anytime and the effect will be the same. It is suggested to add them after the secondary grading process so that you can see the effect on the graded shot.

Lustre Sparks plugins are integrated into the application and function in the same way as any effect in Lustre. For example, as with colour grading effects, you can apply a plugin created on one shot to another shot. When you save the grade, plugin data is saved with colour grading data in the grade file. Likewise, Lustre Sparks plugins are rendered with all other effects in the processing pipeline and are reset in the same way as other effects.

## Installing Lustre Sparks Plugins

Lustre Sparks plugins are installed automatically during Lustre installation. They are included with all Lustre configurations, as well as with all render components, including the Linux render farm package for background rendering.

---

**NOTE** You can modify plugin parameters on the Master Station or the Lustre HD Station. On the Lustre Station, you can only view the plugins.

---

All Lustre Sparks plugins reside in the plugins directory. If developing your own plugins, you must place them in the plugins directory and they must have a \*.dll extension. If running the Windows version of Lustre, save your plugins in the *C:\Program Files\Autodesk\<version number>\plugins* folder. If running the Linux version of Lustre, save your plugins in the */usr/autodesk/<version number>/plugins* directory.

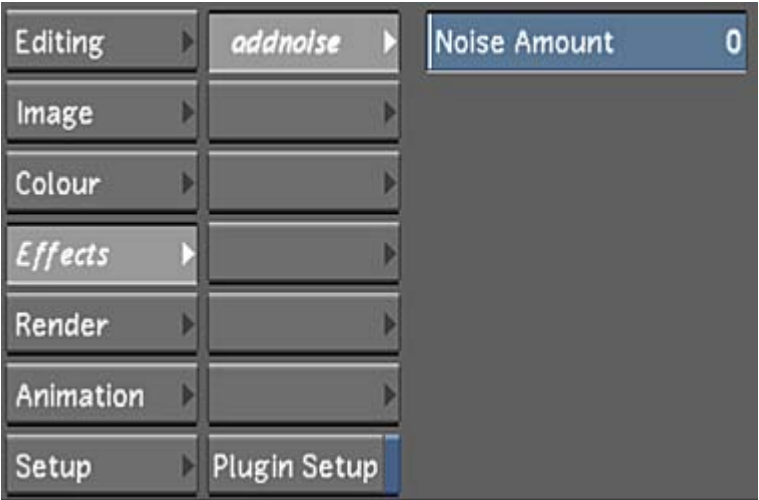

Removing a Lustre Sparks plugin consists of deleting it from the plugins directory.

For details on developing Lustre Sparks plugins, see [Developing Lustre Sparks Plugins](#) (page 2214).

## Lustre Sparks Plugin Descriptions

There are several Lustre Sparks plugins that are included with Lustre. These plugins, and their parameters, are described in the following sections.

**Add Noise** Grain-type plugin that you can use for adding random noise to an image. Use the Noise Amount parameter to adjust the amount of noise added to the shot.

**Blur Mix** Blur-type plugin that performs a multiply mix between the original image with the blurred image. You can also use this plugin to sharpen or tint an image.

| Use:    | To:                                                                                                                                                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Defocus | Set the amount of blur.                                                                                                                                                                                                                                         |
| Aspect  | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur.                                                                                                                                  |
| Mix     | Adjust the amount of mix between the original image and the unblurred image.<br>By default, this value is set to 1. If you set the value to zero, no mix occurs and you see only the original image.<br>Setting the mix to a negative value sharpens the image. |
| Boost   | Multiply key values when using the plugin on a secondary key. This allows you to visually grow your key by increasing the range of the key value.                                                                                                               |

| Use:      | To:                                         |
|-----------|---------------------------------------------|
| Red Mix   | Adjust the red gain of the blurred image.   |
| Green Mix | Adjust the green gain of the blurred image. |
| Blue Mix  | Adjust the blue gain of the blurred image.  |

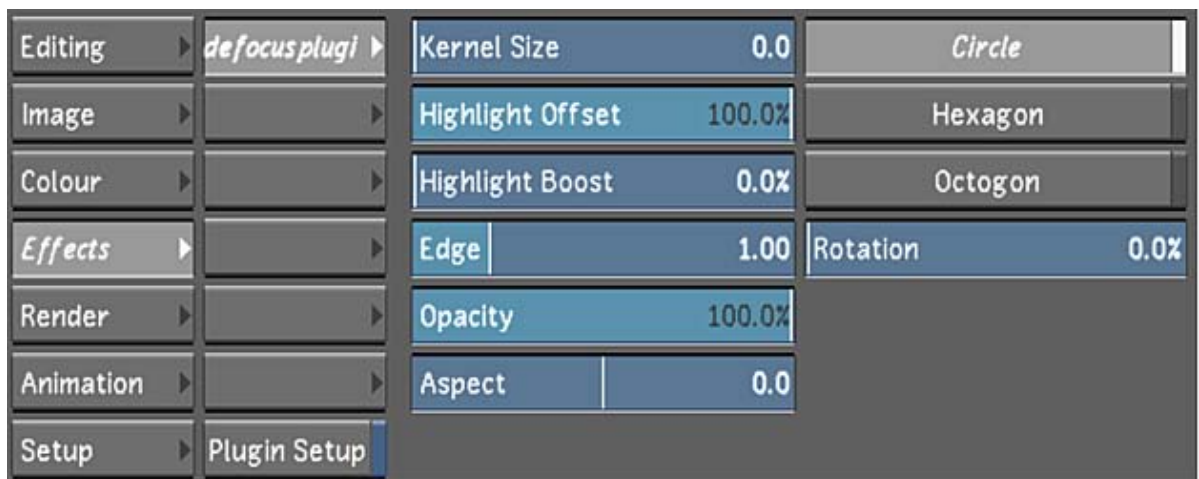

**Blur** Simple blur plugin using a high-speed algorithm.

| Use:        | To:                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| Kernel Size | Adjust the amount of blur.                                                                                                     |
| Aspect      | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur. |

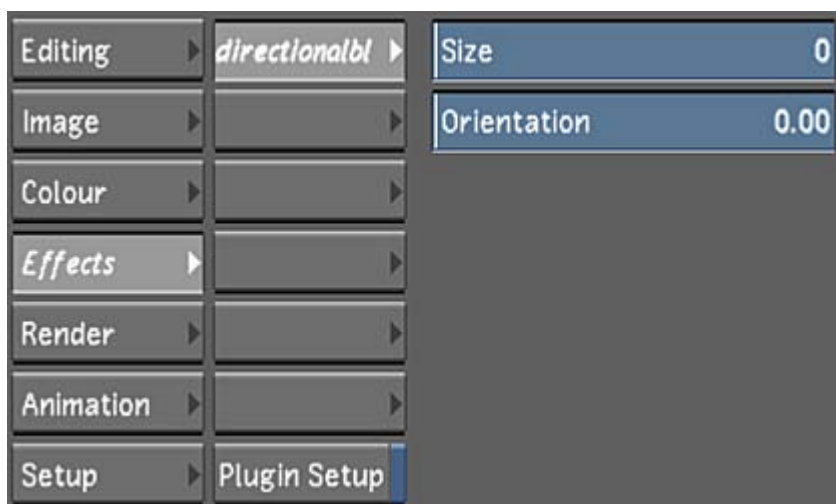

**Defocus** Blur-type plugin that simulates a camera out-of-focus effect. Along with the blur parameters, this plugin includes variable iris types, additional highlight controls, as well as a control for softening the edge of a secondary.

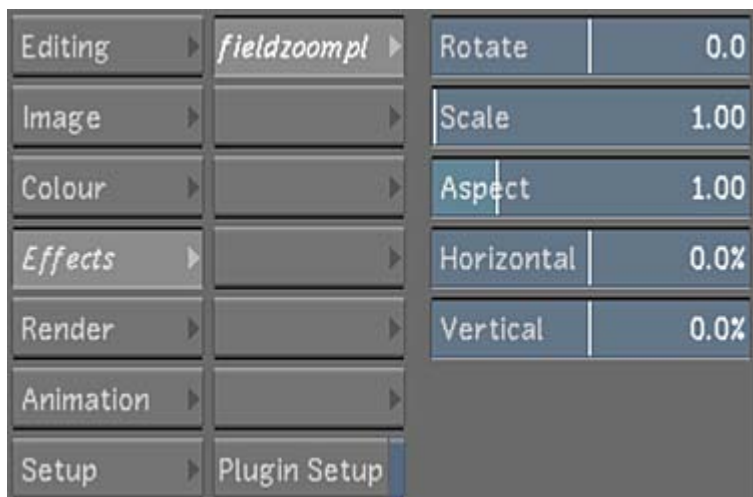

| Use:                     | To:                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Kernel Size              | Set the amount of the camera defocus.                                                                                          |
| Highlight Offset         | Offset the highlight range.                                                                                                    |
| Highlight Boost          | Increase the highlight range.                                                                                                  |
| Edge                     | Adjust the edge softness of a matte when using this plugin with a secondary.                                                   |
| Opacity                  | Change the opacity of the image. By adding transparency, you see through to the original image.                                |
| Aspect                   | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur. |
| Circle, Hexagon, Octagon | Specify the shape of the plugin matrix (or camera iris) used to calculate how the defocus is applied.                          |
| Rotation                 | Rotate the plugin matrix (or iris).                                                                                            |

**Directional Blur** Simple directional blur along a specified direction.

| Use:        | To:                               |
|-------------|-----------------------------------|
| Size        | Adjust the amount of blur.        |
| Orientation | Change the direction of the blur. |

**Field Zoom** Pan, scan, scale, and rotate interlaced footage. The parameters in this plugin work in the same way as the tools in the Image > Reposition menu, except that they are applied to individual fields instead of the entire frame. This yields a smooth image from interlaced footage even after repositioning.

| Use:       | To:                                           |
|------------|-----------------------------------------------|
| Rotate     | Rotate the fields.                            |
| Scale      | Resize the fields.                            |
| Aspect     | Adjust the aspect ratio of the fields.        |
| Horizontal | Adjust the horizontal position of the fields. |

| Use:     | To:                                         |
|----------|---------------------------------------------|
| Vertical | Adjust the vertical position of the fields. |

**Glow** Blur-type plugin that can be used by itself or combined with a secondary key.

| Use:      | To:                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Defocus   | Adjust the amount of blur.                                                                                                                        |
| Aspect    | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur.                    |
| Mix       | Adjust the amount of mix between the original image and the blurred image.                                                                        |
| Boost     | Multiply key values when using the plugin on a secondary key. This allows you to visually grow your key by increasing the range of the key value. |
| Red Mix   | Adjust the red gain of the blurred image.                                                                                                         |
| Green Mix | Adjust the green gain of the blurred image.                                                                                                       |
| Blue Mix  | Adjust the blue gain of the blurred image.                                                                                                        |

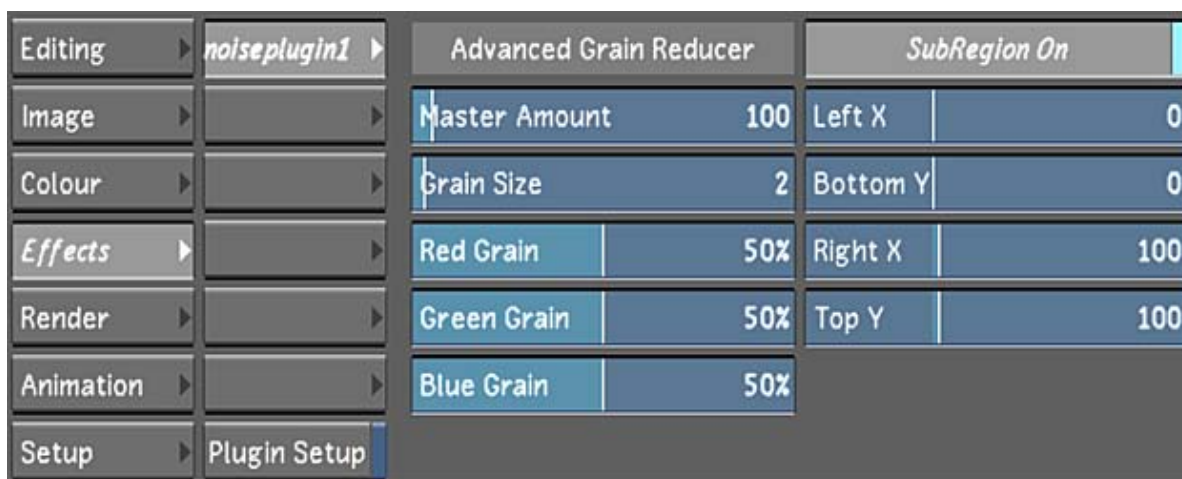

**Gold** Blur-type effect that allows you to soften and tint an image. The defocused and coloured image is multiplicatively combined with the original image to create a coloured soft-filter look.

| Use:        | To:                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Kernel Size | Adjust the amount of blur.                                                                                                                          |
| Aspect      | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur.                      |
| Hue Value   | Set the hue that is used to tint the image.                                                                                                         |
| Amount      | Adjust the amount of the selected hue.                                                                                                              |
| Mix         | Adjust the amount of mix between the original image and the blurred, tinted image. The other parameters have no effect until you set the Mix value. |
| Brightness  | Adjust the brightness of the tinted image.                                                                                                          |

**Noise Plugin 1** This grain-type plugin is a first generation advanced noise reducer that uses a spatial filter with detail preservation control. It is useful for grain, noise, or detail reduction. During playback, this plugin updates dynamically as you adjust the values, so you can see how the grain removal works in context of the shot.

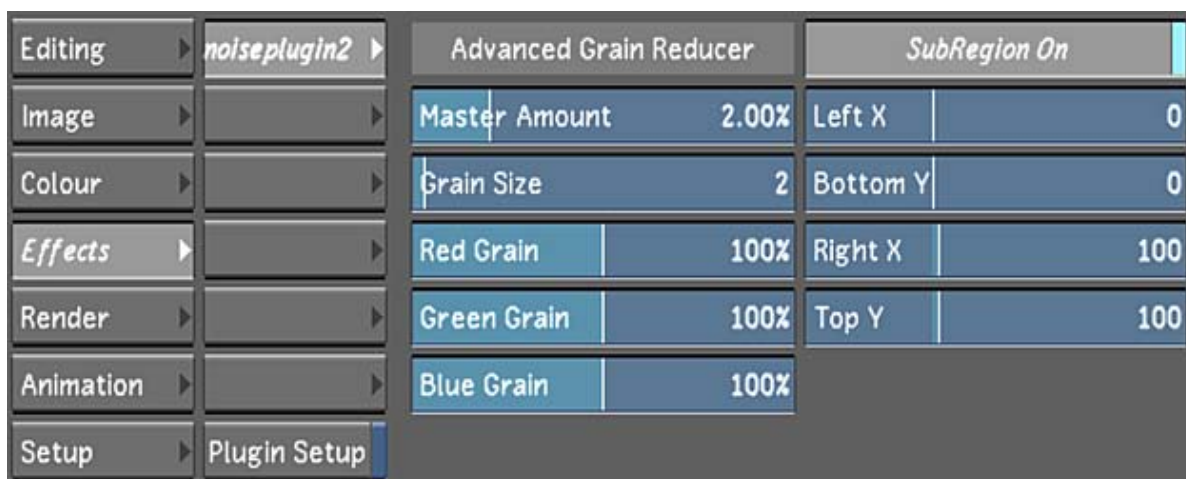

If the plugin processing slows down image playback, you can restrict grain reduction to a subregion of the frame.

| Use:                             | To:                                                                                                                                                                                                                                           |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master Amount                    | Set how much the grain is reduced. The default value (or less) generally produces a good result for grain removal.                                                                                                                            |
| Grain Size                       | Set the size of grain that is reduced.                                                                                                                                                                                                        |
| Red Grain                        | Independently adjust grain removal on the red colour channel.                                                                                                                                                                                 |
| Green Grain                      | Independently adjust grain removal on the green colour channel.                                                                                                                                                                               |
| Blue Grain                       | Independently adjust grain removal on the blue colour channel.                                                                                                                                                                                |
| SubRegion On                     | Restrict the grain setting to the subregion defined by the bounding box.<br>Right-click in the subregion to drag it to another position.<br>Adjust the size of the subregion by clicking and dragging a corner of the subregion bounding box. |
| Left X, Bottom Y, Right X, Top Y | You can adjust the size of the subregion bounding box by adjusting these parameters.                                                                                                                                                          |

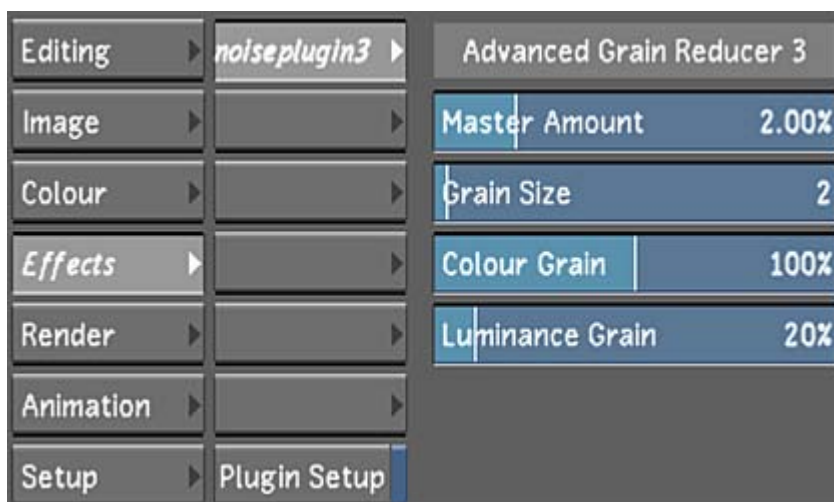

**Noise Plugin 2** This grain-type plugin is a second generation advanced noise reducer that uses a spatial filter with detail preservation control. It is useful for grain, noise, or detail reduction. During playback, this plugin updates dynamically as you adjust the values, so you can see how the grain removal works in context of the shot.

If the plugin processing slows down image playback, you can restrict grain reduction to a subregion of the frame.

| Use:                             | To:                                                                                                                                                                                                                                           |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master Amount                    | Set how much the grain is reduced. The default value (or less) generally produces a good result for grain removal.                                                                                                                            |
| Grain Size                       | Set the size of grain that is reduced.                                                                                                                                                                                                        |
| Red Grain                        | Independently adjust grain removal on the red colour channel.                                                                                                                                                                                 |
| Green Grain                      | Independently adjust grain removal on the green colour channel.                                                                                                                                                                               |
| Blue Grain                       | Independently adjust grain removal on the blue colour channel.                                                                                                                                                                                |
| SubRegion On                     | Restrict the grain setting to the subregion defined by the bounding box.<br>Right-click in the subregion to drag it to another position.<br>Adjust the size of the subregion by clicking and dragging a corner of the subregion bounding box. |
| Left X, Bottom Y, Right X, Top Y | You can adjust the size of the subregion bounding box by adjusting these parameters.                                                                                                                                                          |

**Noise Plugin 3** This grain-type plugin is a third generation advanced noise reducer that uses a spatial filter with detail preservation control. You can control luminance and colour noise processing separately.

| Use:            | To:                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------|
| Master Amount   | Set how much the grain is reduced. The default value (or less) generally produces a good result for grain removal. |
| Grain Size      | Set the size of grain that is reduced.                                                                             |
| Colour Grain    | Adjust grain reduction on colour grain only.                                                                       |
| Luminance Grain | Adjust grain reduction on luminance grain only.                                                                    |

**Noise Plugin 3.1** This grain-type plugin is a third generation advanced noise reducer that uses a spatial filter with detail preservation control. It is useful for colour noise processing, and allows you to specify whether processing should occur in the shadows, midtones, or highlights. During playback, this plugin updates dynamically as you adjust the values, so you can see how the grain removal works in context of the shot. It is the fastest of the four noise plugins available in Lustre.

If the plugin processing slows down image playback, you can restrict grain reduction to a subregion of the frame.

| Use:                             | To:                                                                                                                                                                                                                                           |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Master Amount                    | Set how much the grain is reduced. The default value (or less) generally produces a good result for grain removal.                                                                                                                            |
| Grain Size                       | Set the size of grain that is reduced.                                                                                                                                                                                                        |
| Colour Grain                     | Adjust grain reduction on colour grain only.                                                                                                                                                                                                  |
| Shadow Grain                     | Adjust grain reduction in the shadows only.                                                                                                                                                                                                   |
| Midtone Grain                    | Adjust grain reduction in the midtones only.                                                                                                                                                                                                  |
| Highlight Grain                  | Adjust grain reduction in the highlights only.                                                                                                                                                                                                |
| SubRegion On                     | Restrict the grain setting to the subregion defined by the bounding box.<br>Right-click in the subregion to drag it to another position.<br>Adjust the size of the subregion by clicking and dragging a corner of the subregion bounding box. |
| Left X, Bottom Y, Right X, Top Y | You can adjust the size of the subregion bounding box by adjusting these parameters.                                                                                                                                                          |

**Print Bleach** Blur-type plugin that creates an effect similar to the chemical print bleach process. This plugin increases contrast for the shadows while desaturating the image. When you use this plugin, you first set a mix value so that you mix the image onto itself, and then you blur and brighten the underlying layer.

| Use:       | To:                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------|
| Blur       | Adjust the amount of blur. The blur parameter has no effect until you set the mix parameter.                                   |
| Aspect     | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur. |
| Mix        | Change the amount of the mix. By increasing the mix value, you increase the contrast and decrease the saturation of the image. |
| Brightness | Adjust the amount of brightness of the blurred image. The brightness parameter has no effect until you set the mix parameter.  |

**Silver** Blur-type effect that mixes a black-and-white (desaturated) image with the original image creating a soft-filtered look.

| Use: | To:                                                                                          |
|------|----------------------------------------------------------------------------------------------|
| Blur | Adjust the amount of blur. The blur parameter has no effect until you set the mix parameter. |

| Use:   | To:                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------|
| Aspect | Adjust the orientation of the blur. A negative value produces a horizontal blur and a positive value produces a vertical blur. |
| Mix    | Adjust how much the black and white image is mixed with the original. Use a negative value to give your image a silver look.   |

## Creating an Effect with a Lustre Sparks Plugins

Load and use Lustre Sparks plugins from the Effects menu. You can load up to six plugins at a time.

Each plugin has various parameters that you set to create the desired effect. Apply the effect to the whole shot, or an area of a shot defined by a secondary. You can animate the effect to make it change over time. You can also create an effect using a single or multiple plugins on the same shot. The order of the plugin in the menu will affect the final result, as they are processed sequentially starting with the plugin at the top of the menu and continuing down.

**To load a plugin and create an effect:**

- 1 In the Storyboard, select the shot to which you want to apply the effect.
- 2 From the Main menu, click Effects to display the Effects menu.
- 3 Enable Plugin Setup.

A list of the available plugins is displayed.

**(a) Blank plugin buttons**

- 4 Click the blank button in which to load the plugin.
- 5 Select a plugin from the Available plugins list.

The plugin is loaded and its name appears on the selected button. The plugin parameters appear to the right of the button.

**TIP** You can also replace a loaded plugin with another by loading the second plugin into the button used by the first. In this case, the settings of the replaced plugin are deleted.

- 6 Set the parameters as needed.

The parameters are applied to the entire shot and the image is dynamically updated to reflect the changes.

- 7 If you wish, modify the effect by repeating the previous steps on the shot with other plugins.

#### To apply an effect to an area defined by a secondary:

- 1 In the Storyboard, navigate to the shot you are applying the effect on.
- 2 Create one or more secondaries for the shot to which you want to add an effect.
- 3 In the Main menu, click Effects to display the Effects menu.
- 4 Select a blank plugin button and choose a plugin from the Available plugins list.
- 5 Select a secondary layer that corresponds to the secondary you want to use:
  - Right-click the Secondary slider to display the calculator and enter the number of the secondary layer.
  - Click and drag within the Secondary slider to select the secondary layer.

**NOTE** The Field Zoom plugin does not allow you to select a secondary layer.

- 6 Enable the Use Secondary Mask button.  
The plugin is applied to the area defined in the secondary layer.
- 7 Set the parameters as needed.

### To animate an effect:

- 1 Place the positioner on the frame where you want the effect to start.
- 2 Enable AutoK.  
The AutoK button turns yellow.

- 3 In the Main menu, click Effects to display the Effects menu.
- 4 Make sure the plugin you want to animate is selected.  
The plugin name on the button is highlighted and italicized and its parameters appear to the right of the buttons.

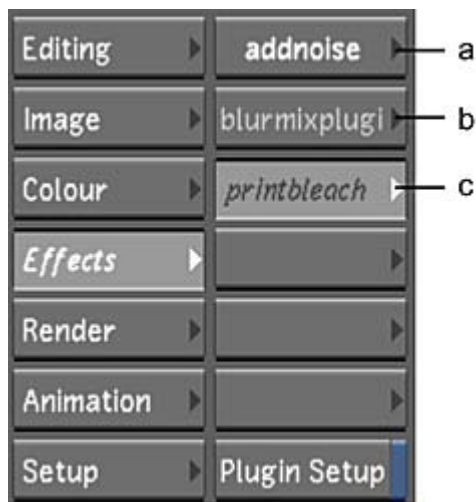

- 5 Set one or more of the parameters.  
As soon as you change a parameter, a blue line in the Shot timebar appears indicating a keyframe.
- 6 Move the positioner to the next frame where you want to set another keyframe and adjust one or more of the parameters. Continue to add keyframes as needed.

## Disabling and Re-enabling Lustre Sparks Plugins

You can disable and re-enable loaded Lustre Sparks plugins. Disabling a plugin allows you to temporarily view the shot without the effect while retaining the settings.

### To disable and re-enable a plugin:

- 1 Right-click the plugin button to toggle between disabling and re-enabling the plugin.  
When the plugin is disabled, the text on the button is grey. When the plugin is enabled, the text on the button is white.

(a) Enabled plugin (b) Disabled plugin (c) Selected and disabled plugin

## Developing Lustre Sparks Plugins

An application programming interface (API) is available to third-party developers for creating Lustre Sparks. The API is provided on the Lustre CD. If you are interested in developing commercial Lustre Sparks, you must apply to the system Sparks program. To request an application, send an e-mail to [sparks@lustrer.com](mailto:sparks@lustrer.com) and indicate your interest in developing specifically for Lustre. For more information, see the *Plugin Reference Guide*.

## Animation

In Lustre, you create animations with the Channel Editor by making channel values change over time. When you set values for a channel, they are plotted on a curve in the Channel Editor. This curve maps frame numbers (time) on the horizontal axis and channel values on the vertical axis.

When you explicitly set a channel value at one frame, you are creating a keyframe. If you set more than one keyframe, the values between the keyframes are automatically calculated, creating an animation curve. This is called interpolation. You can customize the shape of the animation curve to control how quickly and by how much the parameters change.

By controlling interpolation and keyframes, you can create complex animations involving numerous variable parameters. For example, you can animate primary and secondary colour as well as Sparks effects (such as a blur). You can also make a dull stationary shot dynamic and therefore more visually interesting using frame positioning and scaling.

Once you create an animation, you can use the Track Editor to adjust animation timing or duration without changing the keyframe values.

## Accessing the Channel Editor

Use the animation curves in the Channel Editor to create animations.

**To access the Channel Editor:**

- 1 In the Main menu, click Animation.  
The Channel Editor appears.

(a) Channel hierarchy (b) Animation Curves window (c) Animation controls (d) Channel Display buttons

The Channel Editor is made up of the following elements.

**Channel hierarchy** Use to select the folders and channels to animate. You can also refer to the Channel hierarchy to quickly see what channels contain keyframes.

**Animation Curves window** Use to create and view animation curves, adjust interpolation, and add, edit, or delete keyframes. The [Track Editor](#) (page 2242), used to adjust animation timing, appears in place of the Animation Curves window when you select the Tracks option in the Display option box.

**Animation Controls and Animation Options** Use to switch between animation modes, select and view channels, and control interpolation.

## Animation Curves Window

You perform most animation operations in the Animation Curves window.

(a) Start of current shot (b) Positioner (c) End of current shot (d) Animation curve (e) Trimmed frames

The Animation Curves window is made up of the following elements.

**Current Frame positioner** A vertical yellow line represents the current frame position.

**Start and end of current shot** Vertical thick grey lines represent the start and end of the current shot. If the shot is trimmed, the trimmed handles are greyed out.

**Trimmed frames** If you trimmed frames from the current shot, these frames are greyed out before or after the shot.

**Animation curves** Selected curves are white. Deselected curves are black.

## Navigating in the Animation Curves Window

Using the Animation Curves window, you can go directly to any frame for the current shot, or you can go directly to previous or next keyframes. The Current Frame positioner always moves to reflect your new frame position in the current shot.

### To move to any frame in the Animation Curves window:

- 1 Drag in the Shot timebar to scrub between frames in the current shot.  
The Current Frame positioner moves in sync with the timebar positioners.

**TIP** You can also use the playback controls to navigate through the Animation Curves window.

### To move between keyframes:

- 1 Do one of the following:
  - Click Next to move to the next keyframe.
  - Click Previous to move to the previous keyframe.

(a) Previous button (b) Next button

## Displaying Curves in the Animation Curves Window

Use the buttons to the left of the Animation Curves window to change its display.

### To view the entire channel range between keyframes in the Channel Editor:

- 1 Click Range.  
All keyframes are loaded into the Animation Curves window.

### To view all animated curves in the Channel Editor:

- 1 Click AllCrv.  
All animated channels appear in the Animation Curves window.

### To view the selected curve in the Channel Editor:

- 1 In the Channel hierarchy, select the animated channels.
- 2 Click SelCrv.  
The selected curves are loaded into the Animation Curves window.

To view the selected keyframes in the Channel Editor:

- 1 In the Animation Curves window, select the keyframes. See [Selecting Keyframes](#) (page 2227).
- 2 Click SelPts.

The animation curves are scaled so that the selected keyframes fill the Animation Curves window.

## Panning and Zooming the Animation Curves Window

You can pan and zoom the Animation Curves window using the mouse. Do this when you need to see a part of the window that is not visible.

To pan the Animation Curves window:

- 1 Middle-click and drag to pan the Animation Curves window view horizontally or vertically.

To zoom the Animation Curves window view:

- 1 Do one of the following:
  - To zoom horizontally, hold down the right mouse button and drag to the right to increase the zoom factor and to the left to decrease it.
  - To zoom vertically, hold down the right mouse button and drag up to increase the zoom factor and down to decrease it.

**TIP** Hold down **Alt** while dragging to centre the zoom at the point where you began dragging.

## Channel Hierarchy

Use the Channel hierarchy to select the channels to animate. In the following example, Green Gain is selected. You can then set keyframes for this channel and create an animation. See [Animating with Keyframes](#) (page 2219).

Channels are grouped together in folders. When you select a folder, all its channels are selected and all its curves appear in the Animation Curves window. You can also expand a folder and select a single channel.

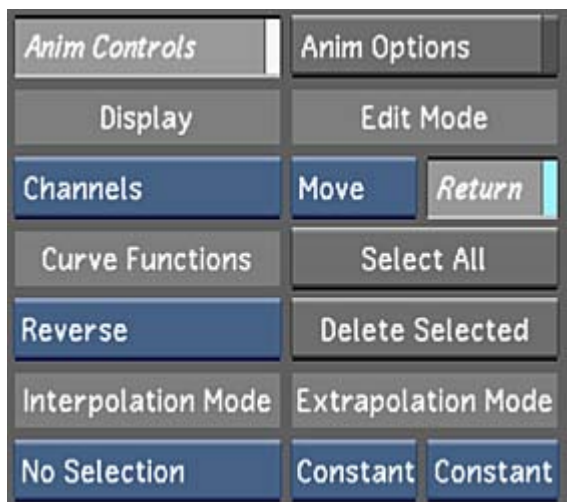

(a) Collapsed folder (b) Expanded folder (c) Selected channel (d) Deselected folder

## Animation Controls

Use the Animation controls to modify channels. The settings are displayed when the Anim Controls toggle button is enabled in the Animation editor or the Dissolve editor (some options are unavailable in the Dissolve editor).

**Display box** Toggle between displaying the Channel Editor view (Curve in previous versions of Lustre) or in Track Editor view (Timeline in previous versions).

#### NOTE

In the Dissolve editor, only the Channels display is available.

**Tools box** Select how you want to modify keyframes:

| Select:    | To:                      |
|------------|--------------------------|
| Add (A)    | Add a keyframe.          |
| Move (M)   | Move a keyframe.         |
| Delete (D) | Delete a keyframe.       |
| Break      | Break a tangent.         |
| Repair     | Repair a broken tangent. |

**Return button** Modify a keyframe and return to Move mode.

**Curve Functions box** Apply a curve function to the current channel. Options are:

- Tangent R/L
- Tangent L
- Translate X
- Translate Y
- FrameSnap
- Simplify
- Jitter
- Average
- Reverse
- Invert

**Select All button** Selects all keyframes on the current channel.

**Delete Selected button** Deletes selected keyframes from the current channel.

**Interpolation Mode box** Select how the curve between keyframes is shaped: as a Constant, Linear, Hermite or Bezier curve; Mixed is displayed only when a selection contains keyframes with different interpolations; Natural is available only when importing timelines with dissolves from Wiretap server.

**Extrapolation Mode box** Select the shape of the curve before and after the first and last keyframes.

## Animation Options

Use the Animation Options to determine the way in which the animation channels function. The settings are displayed when the Anim Options toggle button is enabled. The default settings for these options are set in the Animation panel of the [Tools Settings page](#) (page 1811) (some options are unavailable in the Dissolve editor).

## Animating with Keyframes

To create an animation, you select channels with animatable parameters, and then you add keyframes at points in time where the parameters change. The following procedure outlines the basic steps required to create an animation.

**To create an animation:**

- 1 In the Channel hierarchy, select the channel or parent folder you want to animate. See [Selecting Channels](#) (page 2220).
- 2 Move the positioner to the frame you wish to mark as a keyframe and then add a keyframe. See [Adding Keyframes](#) (page 2220).
- 3 Set the value by dragging the keyframe or by using the individual controls in the appropriate tool.
- 4 Set the interpolation and extrapolation (if needed) for the keyframe. See [Setting Interpolation](#) (page 2222) and [Setting Extrapolation](#) (page 2224).
- 5 Move to the next frame and add another keyframe.
- 6 Set the keyframe value at the new position.
- 7 Make any additional modifications to the animation curve.

- 8 Move to the start of the shot and play the animation.
- 9 If necessary, use the Track Editor to adjust the animation timing. See [The Track Editor](#) (page 2242).

## Selecting Channels

To create an animation, you select channels with animatable parameters, and then you add keyframes at points in time for which the parameters change. You select animation channels in the Channel hierarchy. Once you select a channel, its curve appears in the Animation Curves window.

**To select a channel:**

- 1 In the Main menu, click Animation.
- 2 In the Channel hierarchy, expand a folder and click a channel to select it. To select all channels in the folder, select the folder.

**NOTE** You can also select a channel in the Animation Curves window by clicking the inactive curve. You can see inactive curves in the Animation Curves window only when the Hide Inactive Curves button in the Animation Options panel is disabled.

(a) Select folder (b) Selected channel (c) Deselected channel

Selected channels are highlighted.

- 3 Click a selected channel to deselect it.

**NOTE** Deselecting a channel does not change the selection state of that channel's keyframes.

## Adding Keyframes

You can add keyframes at any point in your animation curves. There are three methods of adding keyframes:

- Add a single keyframe to the selected channel(s) at the current position.
- Interactively add keyframes to any point on the selected curves. There must be at least one keyframe on a channel before you can interactively add keyframes.
- Set keyframes automatically when you adjust a parameter in any menu. For example, set up an animation directly in the Colour menu and then fine-tune the animation curve in the Animation Curves window.

**To add a keyframe:**

- 1 In the Channel hierarchy, select the channel to which you want to add a keyframe.
- 2 Move the positioner to the frame you wish to mark as a keyframe.
- 3 Click Add.

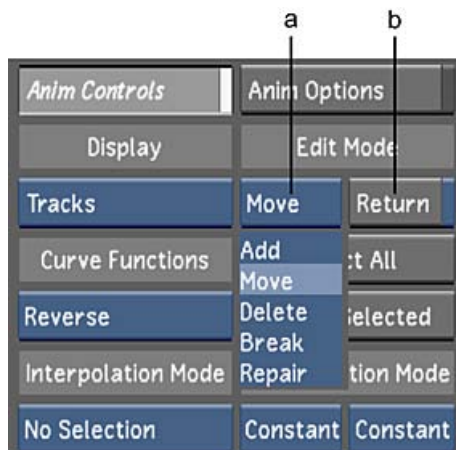

When you add a keyframe to a channel, an orange indicator appears to the left of the channel in the Channel hierarchy.

- 4 Set the channel value as needed by dragging the keyframe.

Once you add keyframes to a shot, blue markers appear in the Shot timebar indicating the location of the keyframes.

#### To add multiple keyframes interactively:

- 1 You must explicitly add one keyframe using the Add button or Autokey before you can add keyframes interactively in Add mode.
- 2 Display the Animation controls.

(a) Edit Mode option box (b) Return toggle button

**NOTE** If Return mode is enabled, you are returned to Edit mode after adding one keyframe.

- 3 In the Channel hierarchy, select the channel to which you want to interactively add keyframes.
- 4 In the Animation controls, select Add in the Edit Mode option box.
- 5 Move the mouse cursor over the animation curve.  
Keyframes appear as you approach each frame.
- 6 Click the animation curve to add a keyframe at that frame.

**NOTE** The new keyframe is automatically set to Bezier interpolation.

Once you add keyframes to a shot, markers appear in the Shot timebar indicating the location of the keyframes.

To add keyframes in Autokey mode:

- 1 Enable AutoK.

**NOTE** Autokey is available from all menus in Lustre.

- 2 Access the tool you want to use to create the animation. For example, in the Main menu, click Colour, and then click Grading.
- 3 Move the Shot timebar to the frame where you want to add a keyframe.
- 4 Adjust the colour parameters.  
A keyframe is added automatically to the channels you modified.
- 5 Move to another frame and adjust the colour parameters and set another keyframe.
- 6 Keep adjusting colour as needed.  
Once you have added keyframes to a shot, blue markers appears in the Shot timebar indicating the location of the keyframes.

## Setting Interpolation

Interpolation defines the shape of an animation curve between keyframes. You can choose from the following interpolation settings depending on how you want the channel values to change over time.

**Linear** Joins keyframes with a straight line.

**Constant** Produces a square curve. The value of one keyframe is held at a constant value until the next keyframe. This setting can produce abrupt changes between keyframes.

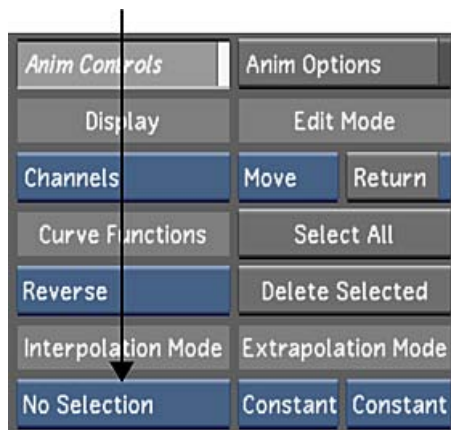

**Hermite and Bezier** Produces a smooth curve with a smooth transition between keyframes. Each keyframe on the animation curve has an associated tangent handle. You can change the shape of the animation curve by dragging the tangent handle. Bezier requires fewer keyframes than Hermite to produce a similar curve. This is because there are two tangents at each keyframe: one incoming, one outgoing.

**NOTE** You can create animation curves with mixed interpolation types.

**To set the interpolation type for a keyframe:**

- 1 [Display the Channel Editor](#) (page 2214).
- 2 Select the keyframe for which you want to set the interpolation.
- 3 In the Animation controls, select the type of curve from the Interpolation Mode option box.

To create an animation curve with mixed interpolation:

- 1 Create an animation with at least four keyframes. Do not worry about the interpolation setting at this point.
- 2 [Display the Channel Editor](#) (page 2214).
- 3 Make sure you are in Move mode and then select the first keyframe. See [Editing Keyframes](#) (page 2227).
- 4 Select Constant to set the interpolation for the first keyframe to Constant.
- 5 Select the second keyframe.
- 6 Select a different interpolation mode, such as Linear.
- 7 Select the third keyframe, and then select a different mode, such as Bezier.

Your animation curve may resemble the following.

## Setting Extrapolation

Extrapolation defines the shape of the animation curve outside the keyframes. You can set up a cycle in which channel values change repeatedly in the same manner over time. You can set the extrapolation before the first keyframe separately from the extrapolation after the last keyframe.

You can specify how keyframes are extrapolated using the following settings.

**Constant** Creates an extrapolated animation curve that stays at the same value as the first or last keyframe.

**Linear** Creates an animation curve that changes in a linear fashion before the first or after the last keyframe.

**Repeat** Creates a mirror image of the animation curve before the first or after the last keyframe.

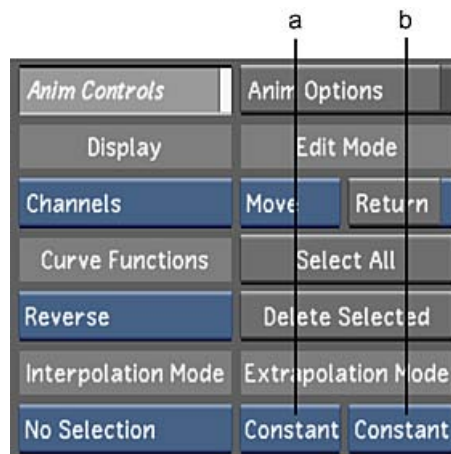

**Cycle** Creates a pattern of repeating keyframes before the first of after the last keyframe.

**To set the extrapolation type for a channel:**

- 1 Select the keyframe for which you want to set the extrapolation.
- 2 Click Animation.
- 3 Enable the Animation Controls panel.
- 4 In the Extrapolation Mode panel of the Animation controls, do any of the following:
  - In the PreType controls, click one extrapolation type button to set the extrapolation before the first keyframe.
  - In the PostType controls, click one extrapolation type button to set the extrapolation after the last keyframe.

(a) PreType Extrapolation option box (b) PostType Extrapolation option box

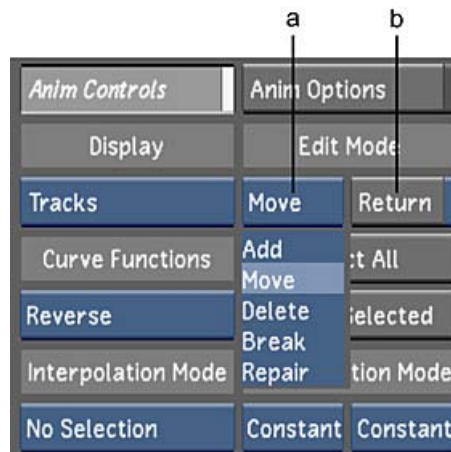

## Editing Keyframes

As you create animations, you may need to edit keyframe values, modify animation curves, and manipulate keyframes. Make sure that you are in the appropriate Edit mode when selecting and editing keyframes.

**NOTE** You cannot edit keyframes in Add mode or Delete mode.

To enable Edit mode:

- 1 Click Animation.
- 2 In the Animation controls, select Add, Move, Break or Repair from the Edit Mode option box.

(a) Edit Mode option box (b) Return toggle button

**NOTE** To return to Move mode after editing a keyframe, enable the Return toggle button.

## Selecting Keyframes

You need to select keyframes in order to edit them. You can select one keyframe at a time, marquee select a group of keyframes, or select all keyframes in a given channel.

Selected keyframes are yellow. Unselected keyframes are red.

**To select a keyframe:**

- 1 In the Animation Curves window, position the cursor over the keyframe and click.

The keyframe is selected.

**To select multiple keyframes:**

- 1 In the Animation Curves window, click a keyframe to select it and then hold down **Ctrl** and click additional keyframes to add them to the selection.

**NOTE** To deselect a selected keyframe, hold down **Ctrl** and click the keyframe. This is useful when you make a marquee selection but you would like not to include one or more keyframes in the selection.

If you release the **Ctrl** key and then click a keyframe, this keyframe is selected and the previous selection is cleared.

To marquee select multiple keyframes:

- 1 In the Animation Curves window, drag to draw a marquee selection rectangle around the keyframes you want to select.

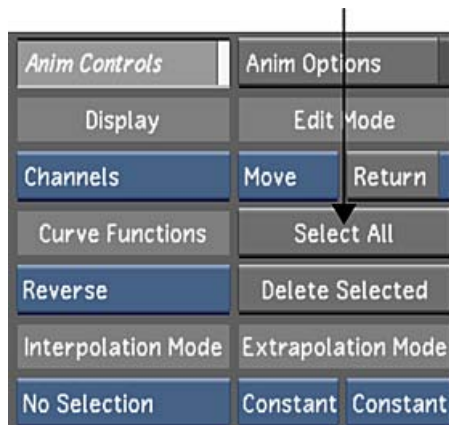

Keyframes inside the marquee selection are selected.

- 2 To zoom in on the selected area, hold down the **Alt** key when drawing the marquee selection.

To select all keyframes in the selected curve:

- 1 In the Animation Controls panel, click Select All.

## Modifying Your Animation

The rate at which your animation changes depends on the slope of the animation curve. A steep slope results in a more rapidly changing animation. A gradual slope represents a slower change in channel values over time. By changing the shape of the animation curve, you can modify the speed at which the animation occurs between keyframes. Although you can use Constant or Linear interpolation to create animations,

with Bezier and Hermite interpolation you have much more control over the shape of the animation curve, and therefore, the speed of the animation.

You can hide curves that are not selected. This can make it easier to manage your keyframes and modify animations.

**To modify the shape of an animation curve:**

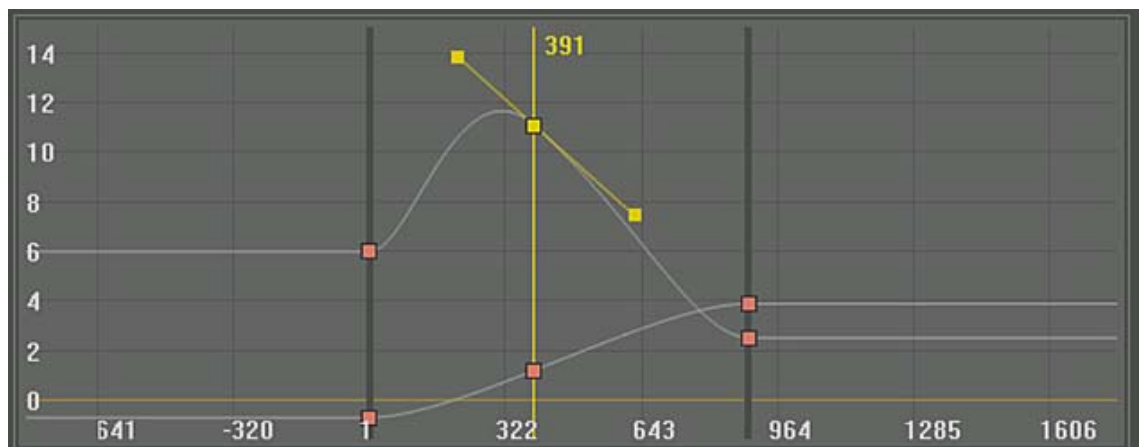

- 1 In the Channel hierarchy, select the animated channel you want to modify.
- 2 Click Range to view the entire curve between the first and last keyframes.

- 3 Select the first keyframe and set the interpolation to Bezier.  
A pair of Bezier tangent handles appear for the selected keyframe.

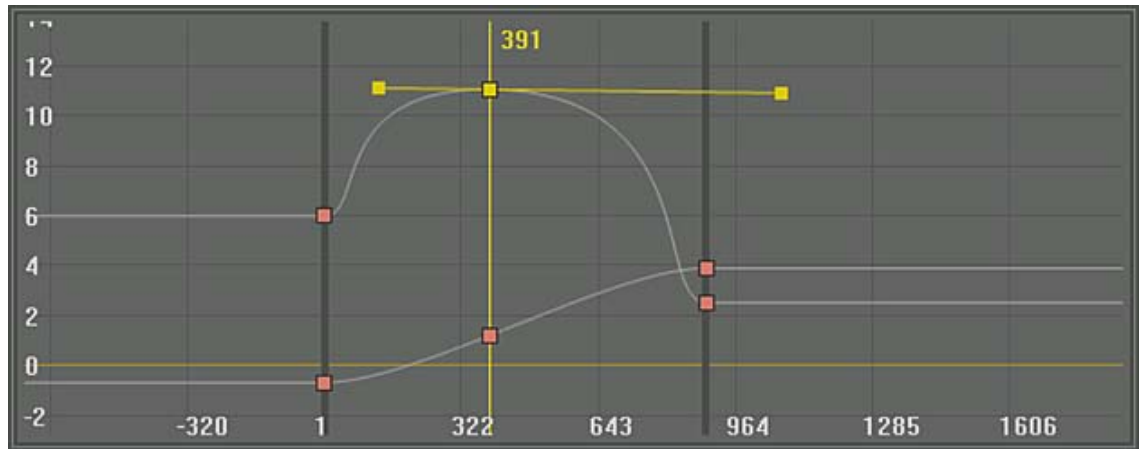

- 4 Drag one of the tangent handles.  
The shape of the curve changes as you move the tangent handle.

**NOTE** When you drag a tangent handle, its adjacent tangent handle moves in the opposite direction. If you want to move the tangent handles independently, you need to first break them. See [Breaking Tangent Handles](#) (page 2231).

- 5 You can lengthen a tangent handle independently without breaking the pair.

To hide curves that are not in use:

- 1 Enable the [Animation Options](#) (page 2219) panel.
- 2 Enable the Hide Inactive Curves toggle button.

## Synchronizing Keyframe Functionality

When you assemble with the Record base of assembly, dissolved shots become one shot on the timeline and the dissolve start and end points are automatically keyframed. The ACS Animation System option ensures consistent keyframe animation functionality between the control surface and the Lustre user interface. This means that if you modify colour settings that occur before the dissolve, the colour settings will fade into the next shot correctly whether you are using the control surface or the user interface.

To ensure consistent keyframe functionality between the control surface and the user interface:

- 1 Click Animation.
- 2 Enable the [Animation Options](#) (page 2219).
- 3 Enable the ACS Animation System button.

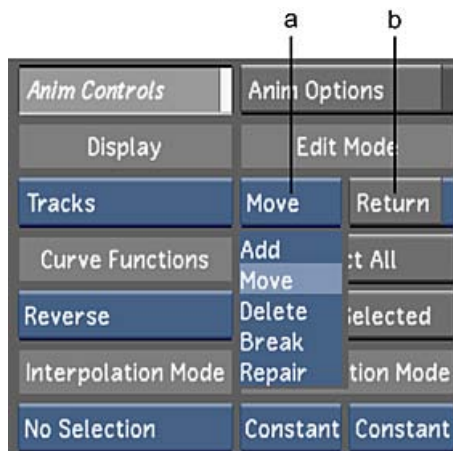

## Breaking Tangent Handles

Normally when you move one Bezier or Hermite tangent handle, the other moves in the opposite direction. You can break tangent handles so that you can adjust each tangent independently and create abrupt changes in your animation.

**To break a tangent handle:**

- 1 In the Edit Mode option box, select Move to select the keyframes you want to break. You can also click Select All to select all keyframes.

**(a)** Edit Mode option box **(b)** Return toggle button

- 2 In the Edit Mode option box, select Break.

**NOTE** If you want to break the tangents for more than one keyframe, disable Return. If Return mode is enabled, you are returned to Edit mode after performing one break operation.

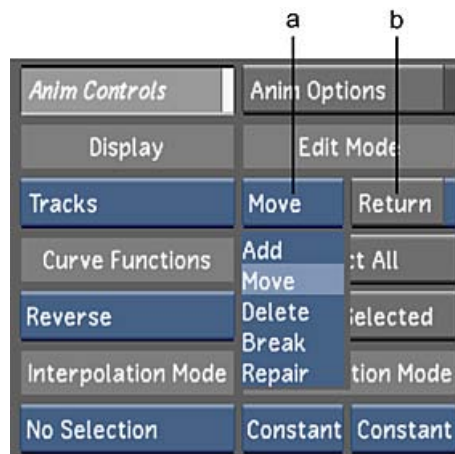

- 3 In the Animation Curves window, click and drag the selected tangent handle you want to break.
- 4 If Return mode is disabled, click additional keyframes to break the tangent handles and modify them as needed.

## Resetting Tangent Handles

Use Repair mode to reset broken tangent handles to an unbroken state.

**To reset broken tangent handles:**

- 1 In the Edit Mode option box, select Move to select the broken keyframes you want to repair. You can click the Select All button to select all keyframes.

(a) Edit Mode option box (b) Return toggle button

- 2 In the Edit Mode option box, select Repair.  
All broken tangent handles for the selected keyframes are restored to an unbroken state.

## Hiding Tangent Handles

You can hide tangent handles for keyframes that are not selected.

**To hide inactive tangent handles:**

- 1 Click Animation.
- 2 Enable the [Animation Options](#) (page 2219).
- 3 Enable the Hide Inactive Tangents toggle button.

## Applying Curve Functions to Keyframes

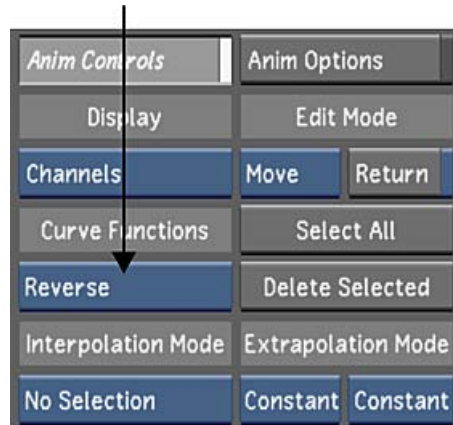

You can apply curve functions to keyframes, in the Animation Editor.

**To apply curve functions to keyframes:**

- 1 Click Animation.
- 2 In the Channel hierarchy, select the channel to which you want to apply a curve function.
- 3 Enable the Animation Controls panel.
- 4 In the Curve Functions option box, select the curve function you want to apply. Options are:
  - Tangent R/L
  - Tangent L
  - Translate X
  - Translate Y
  - FrameSnap
  - Simplify
  - Jitter
  - Average
  - Reverse

- Invert

The curve function is applied to the selected channel's keyframes.

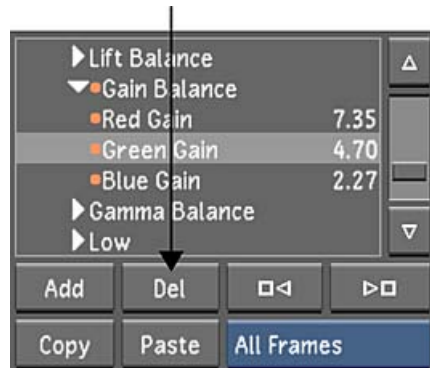

## Deleting Keyframes

You can delete keyframes when they are no longer needed. You can:

- Delete a single keyframe.
- Delete a selection of keyframes.
- Delete keyframes interactively, enabling you to click directly on keyframes in the Animation Curves window to delete them.

### To delete one keyframe:

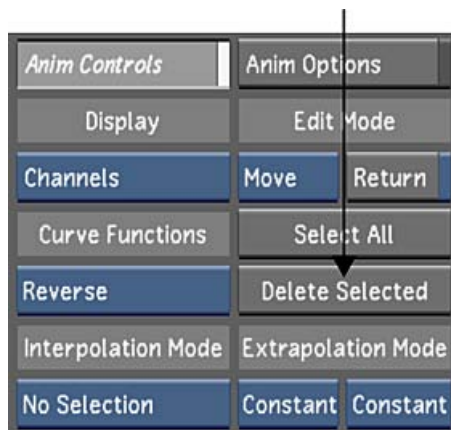

- 1 Scrub the positioner to the frame with the keyframe you want to delete.
- 2 Click the Delete button.

The selected keyframe is deleted.

### To delete a selection of keyframes:

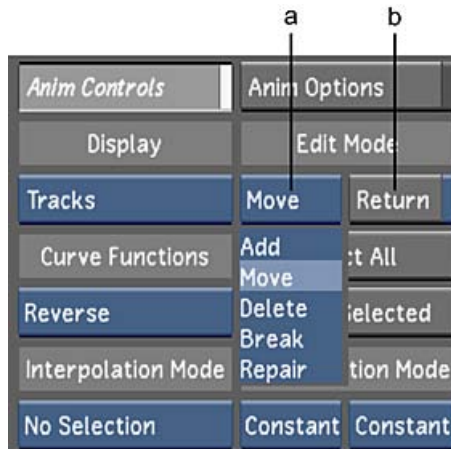

- 1 In the Tools box, select Move.
- 2 In the Animation Curves window, select the keyframes you want to delete.
- 3 Enable the Animation Controls.
- 4 Click Delete Selected and then confirm the deletion. You can also press `Delete`.

The selected keyframes are deleted.

**To delete multiple keyframes interactively:**

- 1 Enable the Animation Controls.
- 2 In the Tools box, select Delete.

**(a)** Edit Mode option box **(b)** Return toggle button.

**NOTE** Disable Return if you want to delete multiple keyframes. If Return mode is enabled, you are returned to Edit mode after deleting one keyframe.

- 3 In the Animation Curves window, click a keyframe to delete it.
- 4 You can click to delete as many keyframes as needed.

## Copying and Pasting Keyframes

Copying and pasting keyframes or a group of keyframes (animation curves) eliminates the need for manually duplicating your creative accomplishments. With copying and pasting, you only need to set up a keyframe or an animation curve once and then you can reuse it as many times as your project demands. With Lustre, you can easily copy a single keyframe or animation curves from a source channel or folder (group of channels) and paste them in a target channel or folder in the Channel hierarchy.

You can copy and paste any keyframe or animation curve from any channel to any other channel.

---

**NOTE** A red dot next to a channel or folder indicates keyframes or animation curves have been applied.

---

There are three different tools you can use to perform a copy and paste procedure:

- The user interface. See [About the Copy/Paste Keyframe Controls](#) (page 2236).
- Keyboard shortcuts. See [About Copy/Paste Keyboard Shortcuts](#) (page 2237).
- The Autodesk Control Surface (ACS). See the *Autodesk Control Surface User Guide*.

There are four main ways to copy and paste keyframes:

- On the current frame. See [Copying and Pasting Keyframes on the Current Frame](#) (page 2237).
- All of the keyframes in the shot. See [Copying and Pasting All Keyframes in a Shot](#) (page 2238).
- A manual selection of keyframes. See [Copying and Pasting a Selection of Keyframes](#) (page 2239).
- Over a selection of keyframes. See [Copying and Pasting Over a Selection of Keyframes](#) (page 2239).

In the case where you want to create a dissolve using keyframes, you can paste a sequence of keyframes that exceeds the target shot boundary.

See [Pasting a Keyframe Sequence That Exceeds a Shot Boundary](#) (page 2240).

## About the Copy/Paste Keyframe Controls

The Copy/Paste Keyframe controls are located in the Channel hierarchy, which is displayed in the user interface in all but the following menus:

- Editing > Timeline
- Editing > Capture
- Editing > Playout
- Colour > Timeline

The Channel hierarchy and Copy/Paste Keyframe controls do, however, remain operational, even though they are not displayed in these menus. Any Copy Keyframe actions and channel/folder selections you perform remain active, even after you leave the Channel hierarchy.

**(a) Copy/Paste Keyframe controls**

**Copy** Click to copy one or more keyframes to memory. The Copy function is dependent on what is selected in the Channel hierarchy, the location of the positioner, and whether One Fr or All Fr is enabled.

**Paste** Click to paste the copied keyframes held in memory. The Paste function is dependent on the location of the positioner, and whether or not keyframes are selected in the target channel or folder.

**Frame Selection option box** Select whether to copy the current keyframe present at the location of the positioner (One Frame) or all keyframes (All Frames) for a selected channel or folder.

**NOTE** If you manually select keyframes in the Channel Editor, you do not need to use the Frame Selection option box. Lustre automatically copies and pastes the selected keyframes.

## About Copy/Paste Keyboard Shortcuts

You can use the copy/paste keyboard shortcuts in any of Lustre's menus to copy and paste keyframes. For the procedures below, the following keyboard shortcuts can be used:

- CTRL (left) +C to copy keyframes
- CTRL (left) +V to paste keyframes

See [Animation](#) (page 2407) for a complete list of Animation keyboard shortcuts.

## Copying and Pasting Keyframes on the Current Frame

This procedure enables you to copy from the source only the keyframes on the current frame and paste them in the target where the positioner is located.

**To copy and paste only the keyframes on the current frame:**

- 1 Navigate to the shot from which you want to copy keyframes.
- 2 In the Channel hierarchy, select the source channel or folder whose keyframes you want to copy.

**TIP** If you want to view the entire range of keyframes for the selected channel or folder, click Range in the Animation > Curves menu.

- 3 Set the copy mode. Do one of the following:
  - In the Frame Selection option box, select One Frame.
  - Use the ACS.
- 4 Click the Next or Previous buttons to navigate to the keyframes that you want to copy.

(a) Previous button (b) Next button

The positioner moves to the next keyframe in the sequence.

- 5 When you have located the appropriate keyframes, do one of the following:
  - Click Copy.
  - Press `CTRL (left) +C`.
  - Use the ACS.
- 6 Navigate to the target shot and then place the positioner on the frame where you want to paste the keyframes.
- 7 In the Channel hierarchy, select the target channel or folder into which you want to paste the copied keyframes.

**NOTE** If there are keyframes present in a channel or folder at the location of the positioner, they will be overwritten.
- 8 Paste the keyframes held in memory. Do one of the following:
  - Click Paste.
  - Press `CTRL (left) +V`.
  - Use the ACS.

The shot is updated in the Player with the pasted keyframe data.

## Copying and Pasting All Keyframes in a Shot

Copying a sequence of keyframes and pasting it in a target that has no keyframes selected, overwrites any keyframe data that are present, beginning at the location of the positioner (for the length of the source sequence). For example, if the source sequence of keyframes is ten frames long, then only ten frames of keyframes are overwritten in the target, beginning at the location of the positioner.

---

**NOTE** Should the pasted keyframes extend beyond the target shot boundary, see [Pasting a Keyframe Sequence That Exceeds a Shot Boundary](#) (page 2240).

---

This procedure enables you to copy all of the keyframes in a shot for the selected source channel or folder, regardless of the location of the positioner, and paste them in a target channel or folder, starting from where the positioner is located.

**To copy and paste all of the keyframes in the shot for the selected channel or folder:**

- 1 Navigate to the shot from which you want to copy keyframes.
- 2 In the Channel hierarchy, select the source channel or folder whose keyframes you want to copy.
- 3 Set the copy mode. Do one of the following:
  - In the Frame Selection option box, select All Frames.
  - Use the ACS.
- 4 Copy all the keyframes. Do one of the following:
  - Click Copy.
  - Press `CTRL (left) +C`.
  - Use the ACS.
- 5 Navigate to the target shot and then place the positioner on the frame where you want to paste the keyframes.
- 6 Select the target channel or folder into which you want to paste the copied keyframes.

**NOTE** If there are keyframes present in a channel or folder at the location of the positioner, they will be overwritten.

- 7 Paste the keyframes held in memory. Do one of the following:
  - Click Paste.
  - Press `CTRL (left) +V`.
  - Use the ACS.

The shot is updated in the Player with the pasted keyframe data.

## Copying and Pasting a Selection of Keyframes

This procedure enables you to copy a manual selection of keyframes in a shot for the selected channel or folder.

**To copy and paste a selection of the keyframes in the shot for the selected channel or folder:**

- 1 Navigate to the shot from which you want to copy keyframes.
- 2 In the Channel hierarchy, select the source channel or folder whose keyframes you want to copy.
- 3 Click Range to view the entire range of keyframes for the selected channel or folder.
- 4 Select the keyframes you wish to copy. See [Selecting Keyframes](#) (page 2227).
- 5 Copy the selected keyframes. Do one of the following:
  - Click Copy.
  - Press `CTRL (left) +C`.
  - Use the ACS.
- 6 Navigate to the target shot and then place the positioner on the frame where you want to paste the keyframes.
- 7 Select the target channel or folder into which you want to paste the copied keyframes.

**NOTE** If there are keyframes present in a channel or folder at the location of the positioner, they will be overwritten.
- 8 Paste the keyframes held in memory. Do one of the following:
  - Click Paste.
  - Press `CTRL (left) +V`.
  - Use the ACS.

The shot is updated in the Player with the pasted keyframe data.

## Copying and Pasting Over a Selection of Keyframes

This procedure enables you to copy and paste keyframes over a selection of existing target keyframes while preserving unselected target keyframe(s).

**To copy and paste keyframes over a selection of keyframes:**

- 1 Navigate to the shot from which you want to copy keyframes.
- 2 In the Channel hierarchy, select the source channel or folder whose keyframes you want to copy.

- 3 Click Range to view the entire range of keyframes for the selected channel or folder.
- 4 Select the keyframes you wish to copy. See [Selecting Keyframes](#) (page 2227).
- 5 Copy the selected keyframes. Do one of the following:
  - Click Copy.
  - Press CTRL (left) +C.
  - Use the ACS.
- 6 Navigate to the target shot and then place the positioner on the frame where you want to paste the keyframes.
- 7 Select the target channel or folder into which you want to paste the copied keyframes.
- 8 In the Animation Curves window, manually select the keyframes that you want to overwrite with the copied keyframe data.
- 9 Paste the keyframes held in memory. Do one of the following:
  - Click Paste.
  - Press CTRL (left) +V.
  - Use the ACS.

In the Animation Curves window, unselected keyframe(s) are preserved, as seen in the following example.

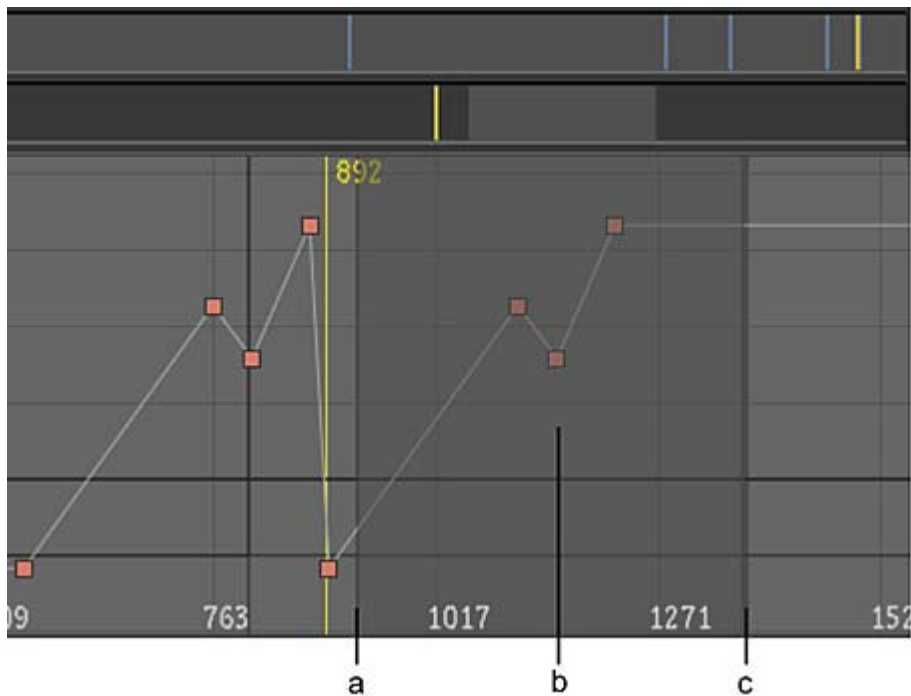

(a) Keyframe preserved

## Pasting a Keyframe Sequence That Exceeds a Shot Boundary

Pasting a keyframe sequence that extends beyond the boundary of the target shot can be really useful when creating a dissolve. See [Creating Dissolves](#) (page 1970).

The target shot can be shorter in length than the keyframe sequence due to its actual length or its having been trimmed. When you copy and paste a keyframe sequence that exceeds the boundary of the target shot that has been trimmed, the excess keyframes in the sequence are still pasted, but they appear in a greyed out area. The greyed out area represents the available handles of a trimmed shot and contains the “inactive” keyframes, as seen in the following example. This means the keyframes are available for creating a dissolve.

(a) Shot boundary (b) Excess keyframe data (c) Beginning of next shot

You can also paste a keyframe sequence to a target shot that is of equal or greater length and then manually trim the shot. The keyframes will still exist in the handles (greyed out area). The excess keyframes can also be viewed in the [Track Editor](#) (page 2242).

(a) Pasted keyframe sequence (b) Positioner (where first of copied keyframes is pasted) (c) Shot boundary

## Guidelines for Geometries, Point Trackers, and Effects Plugins

When copying and pasting keyframes for geometries, point trackers, and Effects plugins, you need to be aware of the following guidelines:

- When there are more source channels in the copy buffer than there are corresponding channels in the target, Lustre will match channels (in top-to-bottom order) with their corresponding target channels. Non-matching channels will not be pasted.
- Axes are not saved with absolute values; therefore, it is not possible to copy and paste an axis while maintaining its original position. If you perform such an action, you will have to manually modify the appropriate axis channel values.

## The Track Editor

Use the Track Editor to adjust animation timing after you create an animation. With the Track Editor, you can select and view all the keyframes and channels in your animation, but you do not see the animation curves. Instead, you see a track representation of each animation curve. Using the handles on the track, you can move the keyframes in time, but you cannot modify their value. This makes it easier to change animation timing to match on-screen occurrences.

In the Track Editor, channels are represented by horizontal bars called *tracks*. The channel name appears in the Channel hierarchy to the right of the Track Editor.

**(a)** Channel hierarchy **(b)** Track Editor **(c)** First keyframe in channel **(d)** A selected channel **(e)** Last keyframe in channel

The position and length of a track is determined by the first and last keyframes of the channel it represents. The track extends from the frame number of the first keyframe to the frame number of the last keyframe.

Light blue tracks represent selected channels. Dark blue tracks are for deselected channels. Grey tracks represent folders that contain at least one animatable channel.

Superimposed over each track are small orange squares that represent the position of the channel's existing keyframes. You can adjust the position of these keyframes without affecting their channel value.

## Accessing the Track Editor

Use the Track Editor to adjust animation timing for an existing animation.

**To access the Track Editor:**

- 1 Click Animation.
- 2 Enable the Animation Controls.
- 3 In the Display option box, select Tracks.

The Track Editor appears.

## Selecting Tracks

Before you can adjust an animation's timing, you must select the channel in the Channel hierarchy.

To select a channel in the Channel hierarchy:

- 1 [Display the Track Editor](#) (page 2242).
- 2 In the Channel hierarchy, either select a folder (to select all channels), or expand a folder and select individual channels.

Selected channels are light blue. Deselected channels are dark blue.

## Adjusting Animation Timing

Using the Track Editor, you can adjust a keyframe's timing without adjusting its value. You can also slide the entire animation ahead or back in time, and change the duration of an animation.

To adjust the timing for an entire channel:

- 1 [Display the Track Editor](#) (page 2242).
- 2 In the Channel hierarchy, select the channel you want to modify.  
The corresponding track in the Track Editor turns light blue and its keyframes appear.

**TIP** Click Range to see all three track handles.

- 3 In the Tools box, select Move.
- 4 Move the mouse over the centre light-blue handle. When the four-direction arrow cursor appears, drag to the left or right to slide the entire animation forward or backward in time.

**NOTE** Adjusting timing for a folder changes the timing for all channels in that folder.

To adjust keyframe timing:

- 1 [Display the Track Editor](#) (page 2242).
- 2 In the Channel hierarchy, select the channel you want to modify.  
The corresponding track in the Track Editor turns light blue and its keyframes appear.

- 3 In the Tools box, select Move.
- 4 Drag the keyframe to the left or right to slide the keyframe forward or backward in time.

**NOTE** Dragging a keyframe in the Track Editor does not change the channel value.

## Adjusting Animation Scaling

Using the Track Editor, you can independently modify the animation's start or end point. This changes the animation's overall duration and scales the keyframes. Dragging the start or end point compresses or stretches the keyframes in the selected channels. If you want to simply move the first or last keyframe to another point in time, drag the keyframe.

(a) Before scaling keyframes (b) After scaling keyframes

---

**NOTE** By repositioning the start or end point, you cannot delete any existing keyframes. This means that you can only adjust the start or end time as far as the adjacent keyframe.

---

### To adjust an animated channel's start or end point:

- 1 [Display the Track Editor](#) (page 2242).
- 2 In the Channel hierarchy, select the channel you want to modify.  
The corresponding track in the Track Editor turns light blue and its keyframes appear.
- 3 In the Tools box, select Move.
- 4 Select the first or last keyframe and drag it to change the start or end point of the animation.

**NOTE** Adjusting the timing for a folder changes the timing for all channels in that folder.

### To scale an animated channel's timing:

- 1 [Display the Track Editor](#) (page 2242).
- 2 In the Channel hierarchy, select the channel you want to modify.  
The corresponding track in the Track Editor turns light blue and its keyframes appear.
- 3 In the Tools box, select Move.
- 4 Move the mouse over the starting light-blue handle. When a two-directional arrow cursor appears, drag to the left or right to slide the start point forward or backward in time.

As you drag the handle, the keyframes in the track scale proportionally to the amount you move the handle.

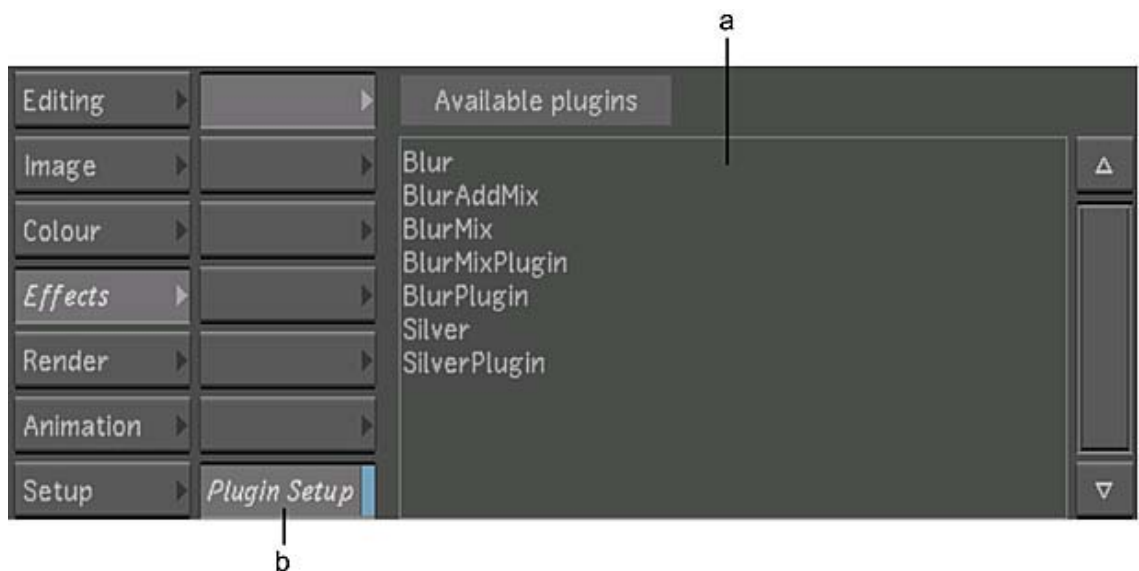

**NOTE** Adjusting the timing for a folder changes the timing for all channels in that folder.

## Animating in Other Menus

You can create animations directly in the other menu without having to access the Animation menu. For example, you can change the Grading settings directly in the Colour menu. In the following example, you create an animation using a blur plugin effect.

To create animations in the Effects menu:

- 1 Select a shot and scrub to the first frame.  
Click Effects, and then enable Plugin Setup.

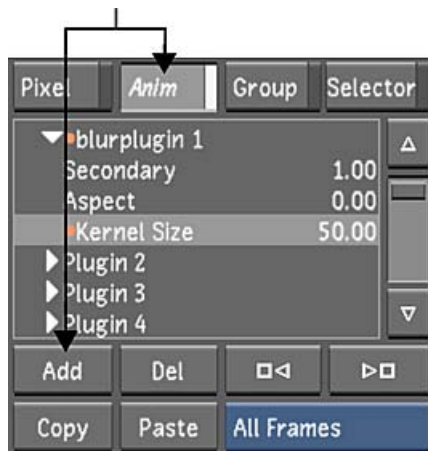

(a) Available plugins list (b) Plugin Setup button

The Available plugins list appears.

- 2 Select Blur from the plugin list, and then set the kernel Size to 50.

- 3 Click Anim, and then click Add.

A keyframe is added at the current frame. When adding keyframes in this way, the interpolation type is always set to Bezier. To change it, you have to use the Interpolation controls in the Animation menu.

- 4 Scrub to the last frame of the shot.
- 5 Set the Kernel Size to 0.
- 6 Click Add again to add another keyframe.
- 7 Scrub through the shot to see the animation.
- 8 To edit the shape of the animation curve, use the tools in the Animation menu. See [Modifying Your Animation](#) (page 2229).

## Undoing and Redoing Operations

When working in the Animation menu, you can undo and redo all operations except the following:

- Canvas pan and zoom changes
- Changes made using the Align options

# Stereoscopy

The Stereoscopy features of Lustre allow you to grade shots and see them in stereoscopic context. Stereoscopy allows you to take your shots and create the illusion of depth, within the image. In order to create this illusion of depth, you need to present each eye with a slightly different image. This is done by having two sets of footage or conformed timelines; one designated for the left point of view (Left Eye) and the other designated for the right point of view (Right Eye). Once you have one set of footage for the Left and Right Eye, you would use the encoding/decoding scheme to display the image. Encoding is done at the stereoscopic display level by the graphic SDI board and decoding is done by the glasses. This chapter shows you how to enable and use the Stereoscopy features.

## Creating a Stereoscopic Project

When you create a stereoscopic project, the Left and Right folders are automatically created in the Library for your stereoscopic footage. See [Project Settings](#) (page 1784)

It is also possible to enable Stereoscopy from a monoscopic project, in which case you need to do the following:

- Enable the Stereoscopy feature. See [Enabling Stereoscopy](#) (page 2247).
- Load your left and right eye footage into your timeline. See [Setting Up the Stereoscopic Footage](#) (page 2249).

## Enabling Stereoscopy

You can enable the Stereoscopy feature in one of the following ways:

- When you select your project settings before entering the Lustre application. See [Project Settings](#) (page 1784).
- By enabling the Stereoscopy button. See [Enabling the Stereoscopy Button](#) (page 2248).

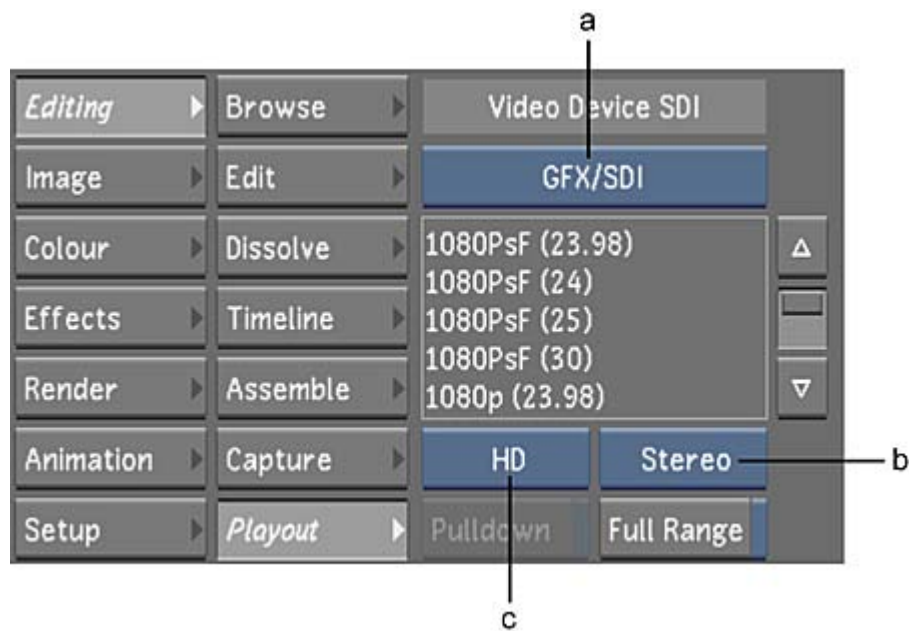

### Selecting a Raster for Stereoscopy

You want to only select a stereoscopic raster if you are connected to a proper stereoscopic device (e.g., Stereoscopy projectors (two projectors or one), or a 3D monitor). When you are playing out your footage to a dual link device, each eye is assigned to one link. The Left Eye always runs through the A Link and the Right Eye through the B Link. Refer to the *Autodesk Lustre Hardware Setup Guide*.

**To select a stereoscopic raster:**

- 1 Click Editing in the main menu and then click Playout.  
The Playout menu is displayed.
- 2 In the Video Device SDI group, toggle the Video/Graphics Raster button to display GFX/SDI, toggle the format option button to HD, toggle the link type button to Stereo, and select a Stereo raster from the list.

**NOTE** The GFX/SDI raster outputs in 8-bit range when you are working in Stereo mode.

(a) Video/Graphics Raster button (b) Link Type button (c) Format button

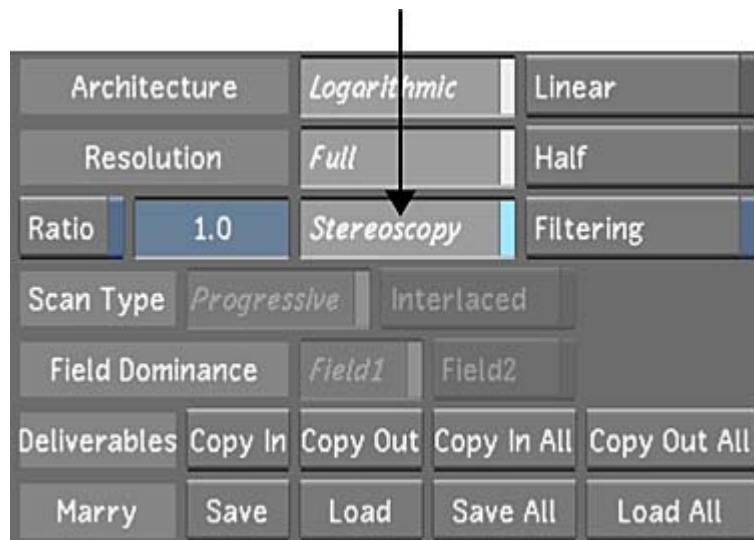

Stereoscopic outputs are now enabled.

### Enabling the Stereoscopy Button

You can disable and re-enable the Stereoscopy feature by using the Stereoscopy button. You would enable the Stereoscopy button when you are assembling an EDL independently for each eye to create a two-layer timeline. You would then convert it to a Stereo timeline.

To enable the Stereoscopy feature:

- 1 Click Setup in the main menu and then click Grade.  
The Grade menu is now displayed.
- 2 Enable the Stereoscopy button.

The Stereoscopy feature is now enabled.

- 3 (Optional) Click Editing and then click **Playout**. Within the **Playout** menu, select a raster from the **Video Device SDI** group

(a) Raster list

## Setting Up the Stereoscopic Footage

Once you have created a Stereoscopic project, a Library with Left and Right folders, as well as a stereo timeline with a left and right layer is automatically created.

---

**NOTE** The stereoscopic timeline is locked as follows:

- The top layer is the left eye.
  - The bottom layer is the right eye.
- 

**To load the stereoscopic footage to the timeline:**

- 1 Drag your stereoscopic footage from the folder location to the Library. See, [Loading Clips to the Library](#) (page 1917).
- 2 Select and drop the footage for the Left eye into the Storyboard.
- 3 Click on the L/R button to enable the Right eye.
- 4 Select and drop the footage for the Right eye into the Storyboard.

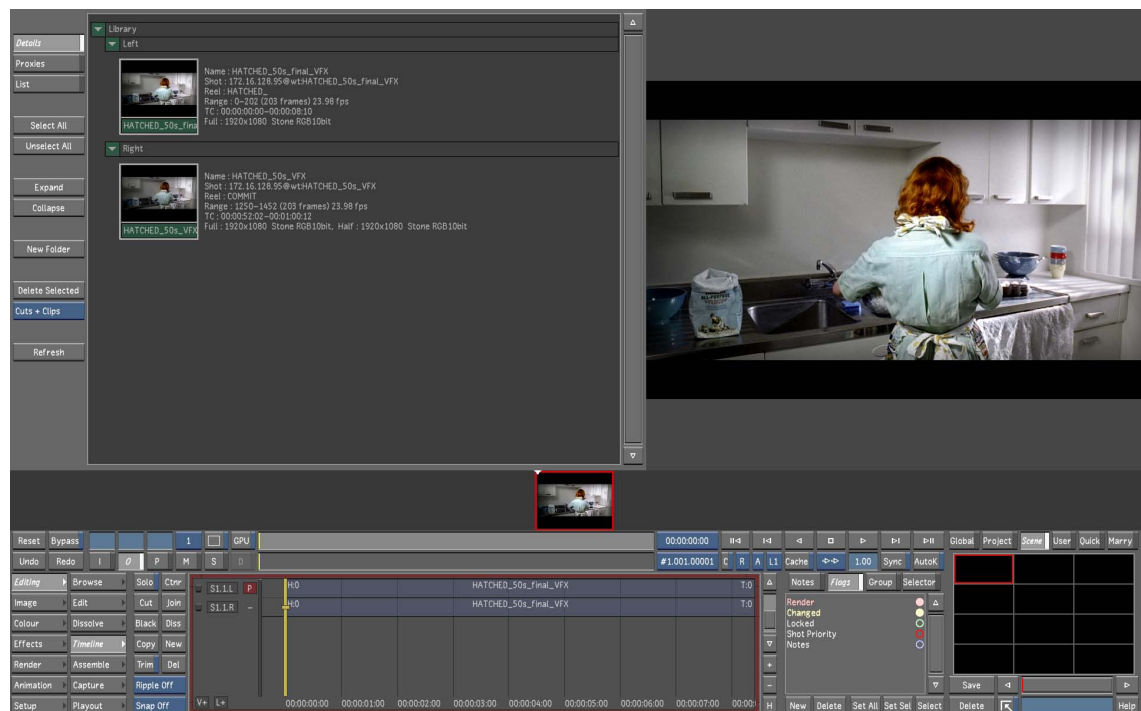

Image courtesy of EVN PRODUCTIONS

- 5 Save the new cut. See [Managing Cuts](#) (page 1819).

## Assembling a Stereoscopic EDL

Use an EDL to rebuild a timeline using the original footage that matches the edited timeline from the offline editing stage of post-production.

**To assemble a Stereoscopic EDL:**

**NOTE** This procedure is for every type of media except RED media.

- 1 Import the Left and Right Eye media that you want to assemble into its corresponding Left or Right folder within the Library.
- 2 Click Editing in the Main menu, and then click Assemble.  
The Assemble menu is displayed.
- 3 Select the EDL you want to load from the EDL list and then click Load EDL.
- 4 Click Match Media.
- 5 Click Assemble to conform the EDL.  
A stereoscopic EDL is created.

**To assemble a stereoscopic EDL for RED Stereo workflow:**

- 1 Import the Left and Right Eye media that you want to assemble into its corresponding Left or Right folder within the Library.
- 2 Click Setup in the Main menu, and then click Grade.  
Make sure the Stereoscopy button is disabled.
- 3 Click Editing in the Main menu, and then click Assemble.

- 4 Select the Right Eye EDL from the EDL list and click Load EDL.
- 5 Within the Library, select the Right Eye folder.
- 6 Enable the Use Selected Folder button.
- 7 Click Match Media and then click Assemble to conform the EDL.
- 8 Enable the To Layer button.
- 9 Repeat steps #4-7 for the Left Eye media.
- 10 Click Setup in the Main menu, and then click Grade.
- 11 Enable the Stereoscopy button and then save the cut.

## Repositioning the Left Eye and Right Eye

Repositioning is fully supported in a stereoscopic project. When Sync mode is enabled, you can reposition both eyes at the same time. (For example, the image in both eyes are offset horizontally by the same amount.)

You can also correct convergence discrepancies for the Left Eye and Right Eye by repositioning images at the same time in an equal and opposite manner. (For example, if you scale the image in the Left Eye to 0.80, the image in the Right Eye will be scaled to -1.20.)

You can converge two images using the repositioning options of the Autodesk Control Surface. See [Repositioning Shots](#) (page 2497) See the Autodesk Control Surface User Guide.

**TIP** When converging a shot, select the Blend option in Dual View to overlay the images in the Player. See [Viewing Stereoscopic Footage in Dual View](#) (page 2255).

**To converge Left Eye and Right Eye images:**

- 1 Enable Sync mode. See [Synchronizing the Left and Right Eye](#) (page 2256).
- 2 In the timeline, place the positioner over the two shots that you want to converge.
- 3 Display the Reposition menu. See [Accessing the Reposition Menu](#) (page 2061).
- 4 Enable Convergence.

**NOTE** In the Preview window of the Reposition menu, the image reference (i.e., the blue rectangle) is for the assigned eye only.

- 5 Use the Reposition sliders to converge the shots. The other eye will be offset in the equal and opposite manner.

# Using the Floating Window

When grading Stereo3D content, it may happen that certain elements of the scene are present in one eye but not the other. When this is the case, you can apply a Floating Window that crops part of Stereo3D content that is only displayed in one eye, preserving the 3D illusion.

Specifically, the Floating Window tool has two main uses:

- To manipulate the Z-axis position of the 3D scene, without changing the overall depth bracket of the scene.
- To shape and position a floating window to mask out elements in the 3D scene.

The Floating Window is accessed through the Image / Reposition menu. It is displayed by enabling the Floating Win button.

---

## NOTE

- Because the Floating Window affects both eyes simultaneously, the controls are greyed out unless Stereoscopy is enabled, in the Project Settings, and that Sync mode is enabled.
  - You must be viewing the Stereo3D footage on a 3D monitor or on a 2D monitor in Anaglyph mode, in order to view the results of the Floating Window properly.
- 

The controls allow you to position the corners of the floating window in Z-space. It also allows one, two or all four corners to be manipulated simultaneously.

There are 3 sets of parameters in the Floating Window menu:

- 1 The first set of controls consists of four numerical sliders labeled Top/Left, Top/Right, Bottom/Left and Bottom/Right.  
These controls allow you to "pull in" or "push out" the corresponding corner of the Floating Window. This translates to a black mask being drawn on the edges of the image in the left or the right eye. Depending on whether the slider value is positive or negative, they affect each eye's mask differently. For example:
  - Increasing the value of the Top/Left slider results in the Floating Window's corner being "pushed out" away from the viewer. The mask is applied on the left edge of the right eye in that case.
  - Decreasing the value of the Top/Left slider results in the Floating Window's corner being "pulled in" towards the viewer. When the values are negative, the corner is in theater space (i.e. virtually in front of the monitor) and a black edge becomes visible on the left edge of the left eye.
  - The other controls affect the Floating Window in the same way. Increasing the value of a slider "pushes out" the corresponding corner of the Floating window, whereas decreasing the value results in the corner being "pulled in".
- 2 The second set of controls will affect the Post-Render-Shift (PRS) value, which effectively displaces the whole scene (including the Floating Window) along the Z-axis.  
The PRS is implemented as a horizontal translation of one, or both eyes. You can select which eye remains fixed by selecting a value from the Align box. 'Align Left' applies the PRS entirely to the right eye, while Align Right applies it to the left eye and Center applies it to both eyes.  
Aux and Offset values are simply additive extensions of the PRS value. For example, if you have PRS=1, Offset=2 and Aux=4, the overall PRS value is 7. You can use Aux and Offset as Presets and enable or disable them using the corresponding Bypass button.
- 3 Lastly the Bypass buttons enable you to bypass specific parameters. The Link buttons allow you to link corners together, making it possible to modify more than a single Floating Window corner with a single slider. And the Reset buttons enable you to reset the values of the top (T), bottom (B), left (L) and right (R) parameters, respectively.

All the slider values can be animated.

| Floating Window |      |        |      |                |       |            |   |   |   |
|-----------------|------|--------|------|----------------|-------|------------|---|---|---|
| Top / Left      |      | 548.80 |      | Top / Right    |       | 0.00       |   |   |   |
| Bottom / Left   |      | 0.00   |      | Bottom / Right |       | 0.00       |   |   |   |
| PRS             | 0.00 | Aux    | 0.00 | Offset         |       | 0.00       |   |   |   |
|                 |      |        |      |                |       | Align Left |   |   |   |

| Link            | T    | B      | L    | R              | Reset | T          | B | L | R |

## Floating Window

**Top/Left field** Affects the displacement value of the Top/Left corner of the Floating Window. Increasing the value results in the Floating Windows's Top/Left corner being "pushed out" away from the viewer. Decreasing the value results in the Floating Window's Top/Left corner being "pulled in" towards the viewer.

**Bottom/Left field** Affects the displacement value of the Bottom/Left corner of the Floating Window. Increasing the value results in the Floating Windows's Bottom/Left corner being "pushed out", away from the viewer. Decreasing the value results in the Floating Window's Bottom/Left corner being "pulled in", towards the viewer.

**Top/Right field** Affects the displacement value of the Top/Right corner of the Floating Window. Increasing the value results in the Floating Windows's Top/Right corner being "pushed out", away from the viewer. Decreasing the value results in the Floating Window's Top/Top Right corner being "pulled in", towards the viewer.

**Bottom/Right field** Affects the displacement value of the Bottom/Right corner of the Floating Window. Increasing the value results in the Floating Windows's Bottom/Right corner being "pushed out", away from the viewer. Decreasing the value results in the Floating Window's Bottom/Right corner being "pulled in", towards the viewer.

## Post-Render Shift

**PRS field** Affects the horizontal translation offset value applied between the two shots in the scene. This parameter is relative to the setting if the Alignment box.

**Offset field** Affects the horizontal translation offset value applied between the two shots in the scene. This parameter is relative to the setting if the Alignment box.

**Aux field** Affects the horizontal translation offset value applied between the two shots in the scene. This parameter is relative to the setting if the Alignment box.

---

**NOTE** These three fields are additive. The offset applied to the scene is the sum of the values of these three fields.

---

## Bypass

**All button** Bypasses all Floating Window parameters.

**Window button** Bypasses the corner parameters of the Floating Window (Top/Left, Bottom/Left, Top/Right, Bottom/Right).

**Prs button** Bypasses the PRS parameter of the Floating Window.

**Offs button** Bypasses the Offset parameter of the Floating Window.

**Aux button** Bypasses the Aux parameter of the Floating Window.

## Link

**T button** Link the Top/Left and Top/Right parameters. When enabled, moving one slider affects both values.

**B button** Link the Bottom/Left and Bottom/Right parameters. When enabled, moving one slider affects both values.

**L button** Link the Top/Left and Bottom/Left parameters. When enabled, moving one slider affects both values.

**R button** Link the Top/Right and Bottom/Right parameters. When enabled, moving one slider affects both values.

## Reset

**T button** Reset the Top/Left and Top/Right parameters. The button resets both values regardless of whether they are linked or not.

**B button** Reset the Bottom/Left and Bottom/Right parameters. The button resets both values regardless of whether they are linked or not.

**L button** Reset the Top/Left and Bottom/Left parameters. The button resets both values regardless of whether they are linked or not.

**R button** Reset the Top/Right and Bottom/Right parameters. The button resets both values regardless of whether they are linked or not.

# Viewing From One Eye to the Other

As you are grading your Left and Right Eye footage, there is an easy way for you to switch the footage that is being displayed in the Player. The Left and Right Eye button allows you to switch between the footage with ease.

To switch the footage displayed in the Player from one eye to the other:

- 1 Do one of the following:
  - In the Player display controls, click on the Left/Right Eye (L/R) button.

**NOTE** This is the field 1 (F1)/field 2 (F2) button when you are not in Stereo mode. You can still check your field dominance when in Stereo mode by holding the Ctrl key and clicking on the Field 1/Field 2 buttons in the Setup/Grade menu.

- Press ; (semicolon).

If you are currently displaying the Right Eye timeline in the Player, the layer output selector is labelled R. When you click the R button, the layer output selector is now labelled L, the Left Eye is displayed in the Player, and the focus point is now on the Left Eye layer (and vice versa).

Switching the Player to display the Left or Right Eye footage does not affect what is playing out on the NVIDIA HDSDI output if you have selected a stereoscopic raster. If you have selected a mono (non-Stereo) raster, the layer (eye) you see on your monitor is what is displayed on your video output.

---

**NOTE** The position of the focus point is linked to the layer output selector.

---

## Viewing Stereoscopic Footage in Dual View

Once a stereoscopic project is enabled, you can display each eye at the current frame at the same time in Dual View mode. As in A/B mode, you can view the images side by side (2-up mode), or a portion of each image in the same viewer (Vertical Wipe and Horizontal Wipe modes).

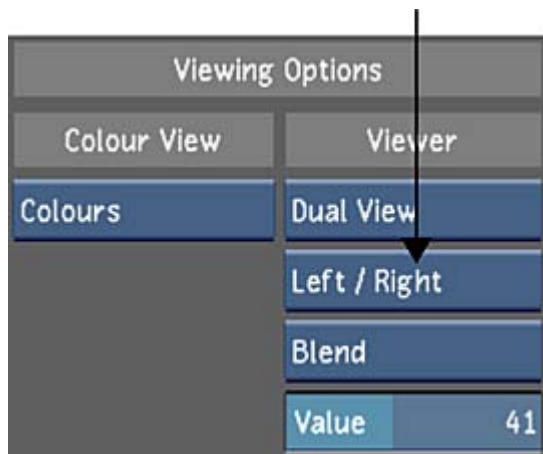

In a stereoscopic project, you can also view the Left Eye overlaid on the Right Eye, as a blended image.

To display the Dual View Blend mode:

- 1 Display the dual viewer. See [Using Dual View](#) (page 2029).

- 2 In the Dual View Display option box, select Left/Right.

- 3 Do one of the following:
  - Select Blend.
  - Press **Ctrl+F4** to cycle through display options until Blend is displayed.  
The viewer displays the image of the Right Eye overlaid over the Left Eye.

- 4 Set the Value slider to determine the percentage of opacity of the image in the Left Eye.

## Synchronizing the Left and Right Eye

Since the Player only displays either the Left Eye or Right Eye, it is difficult and tedious to edit and grade one eye and create the same changes for the other eye. An easy way for you to make sure any editing or grading is automatically applied from one eye to the other is by using the Sync option. When this feature is enabled, any editing or grading you do on one eye is applied to the other.

**To apply the editing and grading from one eye to the other:**

- 1 From the Player display controls, click Sync.

Now all editing and grading operations on one eye will be duplicated on the other.

The Sync option only works if you do not break the sync. For example, if you enable Sync and draw a geometry, whatever you do to that geometry on one eye will be duplicated on the other. The moment you disable the Sync option and change the geometry on one eye (e.g., colour, position, vertex, etc.), that geometry will never be synced again when you re-enable Sync.

---

**NOTE** If you only break sync with the colour grading, the rest of the geometry (i.e., position, vertex, etc.) will still be in sync once you re-enable the Sync option.

---

When you re-enable Sync mode, the grading data that was applied separately on each eye will be retained on each eye. Re-enabling Sync mode will not copy the grading back to the other eye.

## Editing the Stereoscopic Timeline

When the Sync button is enabled, all editorial operations (Cut, Trim, Copy, Delete, add a Dissolve, add black frames, Solo, etc.) and all structural operations (add a Track/Layer, add a Container, Collapse) are supported when working on stereoscopic timelines.

---

**NOTE** The sync button affects only the editorial operations. Structural operations are always performed in sync.

---

See [Synchronizing the Left and Right Eye](#) (page 2256).

## Stereoscopy and Matte Containers/Multi-Channel Clips

When working in a stereoscopic project, entering the matte container or multi-channel segment shows both left and right eye content.

See [Adding a Matte to a Matte Container](#) (page 1988).

## Swapping Left and Right Shots

Use the hotkeys ALT+L and ALT+R to swap all shots from one stereo eye to the other on the current layer. The layer indicator will not change location. It is also possible to swap shots on all layers of the primary video track with hotkeys CTRL+ALT+L and CTRL+ALT+R.

## Replacing Shots in a Stereo Timeline

When working on a Stereoscopic project, you can perform a shot replace that applies to both eyes at the same time.

---

**NOTE** In Stereo, you must replace the shot for both eyes. It is not possible to use Replace Shot for only one eye.

---

- 1 Load the Timeline you want to modify.
- 2 In the Library, hold SHIFT key and select the Left clip. A "L" icon appears on the top right side of the thumbnail.
- 3 Navigate the Library to find the Right clip, hold SHIFT key and select the Right clip. A "R" icon appears on the thumbnail. Release SHIFT key.
- 4 Move the selection over the Storyboard or Timeline segment you want to replace and click on the thumbnail.

Both Left and Right shots have been replaced with the selection and the grading on the original shots is preserved.

## Grading Stereoscopic Footage

When Sync mode is enabled, grading operations (including dragging and dropping) are applied to the respective destination eye. For example, grading data dragged from a Right Eye layer is always applied to a Right Eye destination layer, even if it is dropped on the Left Eye. See [Synchronizing the Left and Right Eye](#) (page 2256).

Shots can still be graded separately when Sync mode is disabled. After grading one eye, grading data can be copied to the other eye. See [Copying Elements](#) (page 1982). Separate grading can also be used to differentiate the grades on each eye.

During secondary colour grading, you can copy different grading data for each eye at the same time from one secondary layer to another, and the grading data for each eye that was applied when Sync mode was disabled will be copied to appropriate eyes.

# Working with Grade Files

In a stereoscopic project, grade files contain data for both the Left Eye and Right Eye.

In the Grade bin, each storage container can include Left Eye and Right Eye grading data. The thumbnail of the grade corresponds to the currently assigned eye. In the Grade view, the expanded Grade bin and its player demonstrate the same behaviour. See [Using Grade Bins](#) (page 1865) and [Using the Expanded Grade Bin](#) (page 1873).

Disable Sync mode to apply data from a grade file to only the assigned eye: only the grade data for the current eye will be applied. When Sync mode is on, data from a grade file is applied to both eyes: if the grades are different for each eye, each grade is applied to the appropriate eye. See [Synchronizing the Left and Right Eye](#) (page 2256).

## Bypassing Menu Parameters of an Eye

You can use the Bypass button to view the original shot of one eye or both eyes. See [Bypassing Menu Parameters](#) (page 1850).

Bypass results depend on the state of the Sync mode. See [Synchronizing the Left and Right Eye](#) (page 2256).

| Set:          | To:                                                            |
|---------------|----------------------------------------------------------------|
| Sync mode on  | Display the original state of shots on the Left and Right Eye. |
| Sync mode off | Display the original state of shots on the assigned eye.       |

## Rendering Stereoscopic Footage

The procedure for rendering your stereoscopic footage is the same as for rendering normal shots (i.e., mono mode). See [Rendering Shots](#) (page 2259).

The differences in rendering stereoscopic shots are as follows:

- The shots are rendered out to the folder you specified when creating your project (see [Project Settings](#) (page 1784)), but the Left and Right Eye footage is separated into two folders labelled 'Left' and 'Right'.
- You have to render both Left and Right Eye shots together. You cannot render each eye individually.

Once the shots have been rendered, Stereoscopy must be enabled in order for you to view your rendered footage in print (P) mode.

# Rendering

Render individual shots, layer(s) in the timeline, or complete scenes in Lustre to create a new version of the footage with all colour grading, animation, repositioning, and dust removal data applied. Rendering is necessary for output and viewing both frames of interlaced footage at the same time. Furthermore, rendering 2K material with effects applied allows you to view your work in real-time.

### WARNING

Due to the enhancements in the GPU, we do not recommend using Lustre to render grades created in Lustre 2011 or earlier if you are looking for pixel accuracy rendering.

You can render anytime during a colour grading project. For example, you might want to render an interim version part way through a project to show to a client, in addition to rendering the final version. Lustre has several options to make this easier—you can render full- or half-resolution versions of the grade, apply an output LUT, and render to a number of different file formats, regardless of the format of the original.

There are also several methods available for rendering your scenes—using the Lustre Render menus, or using Autodesk Burn® for Lustre to take advantage of the processing power of other machines. You can also use Lustre ShotReactor to render shots as you work on the grade.

In Lustre, there are two methods available for viewing rendered versions. To view any shot that has been rendered to disk, use Print view mode. See [Setting the View Mode](#) (page 2016). To quickly render a temporary version for playback, use memory caching. Frames are rendered and cached to your computer's memory and then made available for playback. See [Caching Frames to Memory for Real-Time Playback](#) (page 2039).

For increased speed of interaction on unrendered footage throughout the course of a project, you can opt to work on 1K proxies of the original footage.

## Rendering Shots

You can use the Render menus to render your work. You can render selected shots, all shots in a cut, a specific layer in the multi-layer timeline, or the flattened result of a multi-layer timeline. To prepare for rendering, do the following:

- Specify the shots to render.
- Specify the layer to render.
- Set the resolution of the render files.
- Set resize options as needed.
- Specify the destination for the render files.
- Specify the output file format.
- Specify the file density (logarithmic or linear).
- (Optional) Change the output colour space or specify an output LUT.
- Set other options such as timecode burn-in and rendering with a viewing LUT.

## Specifying the Shots to Render

Renders are done on a shot-by-shot basis—you can render one shot, several selected shots, or all shots in a scene. To specify a shot for rendering, you flag it. You can flag shots manually or have Lustre automatically flag any shot to which changes have been applied. By default, all shots are automatically flagged for rendering.

A file containing rendering information is created and stored in the Library directory found under each scene directory. This file contains a line for each shot that includes the shot path and name and the number 0 or 1, which indicates if a render flag is set for the shot (1) or not (0). These files are named `<grade name>.render` and are updated each time the grade is saved. Other applications, such as the command line renderer or scripts, can read or bypass this file setting.

If you are rendering a multi-layer timeline and Solo and Mute mode are disabled, only the flagged shots in the flattened timeline will be rendered. If you are rendering a multi-layer timeline and Solo or Mute mode is enabled, only the flagged shots in the active layer(s) will be rendered.

A shot that is flagged for rendering is identified by a red square in the upper-left corner of the screen.

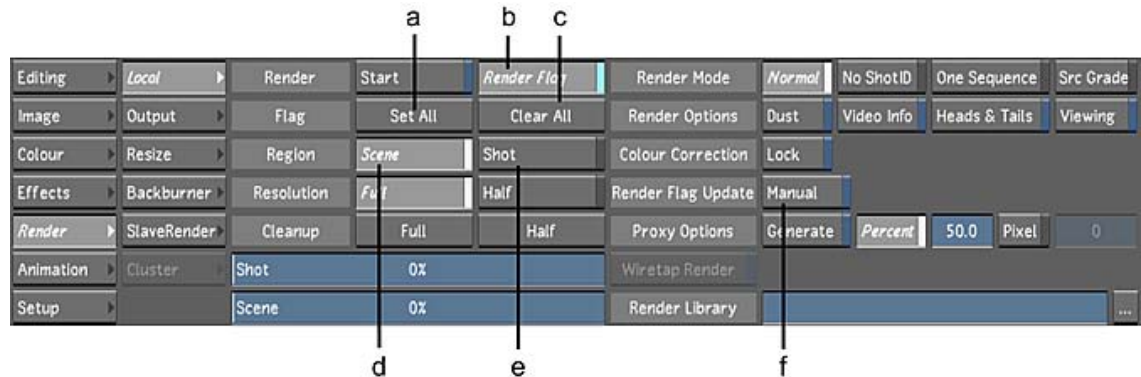

To flag shots, use the Render Local menu.

**To access the Render Local menu:**

- 1 In the Main menu, click Render, and then click Local.

The Render Local menu appears.

(a) Set All button (b) Render Flag button (c) Clear All button (d) Render Scene button (e) Render Shot button (f) Render Flag Update button

**NOTE** If using the Linux version of Lustre, the Cluster menu will be part of the Render menu. This is for use with Lustre on an Incinerator high-speed network. If applicable, refer to your *Autodesk Incinerator Installation and User Guide*.

**To manually flag one shot:**

- 1 Navigate to any frame in the shot.
- 2 Enable Render Flag.

**To manually flag all shots in the cut:**

- 1 Click Set All.  
The render flag is set for all shots in the cut and the Render Flag button is enabled.

**To manually clear one flag:**

- 1 Navigate to the shot.
- 2 Disable Render Flag.

**To clear all render flags:**

- 1 Click Clear All.

**NOTE** Render flags are not automatically cleared after rendering.

**To flag shots automatically:**

- 1 Enable Render Flag Update.  
Shots will be flagged for render immediately after any grading or other effect has been applied.

After you set your render flags, you can still choose to render just the current flagged shot or all flagged shots in the timeline.

To set the shots to be rendered:

- 1 Do one of the following:
  - Enable Scene to render all flagged shots in the cut.
  - Enable Shot to render the current flagged shot.

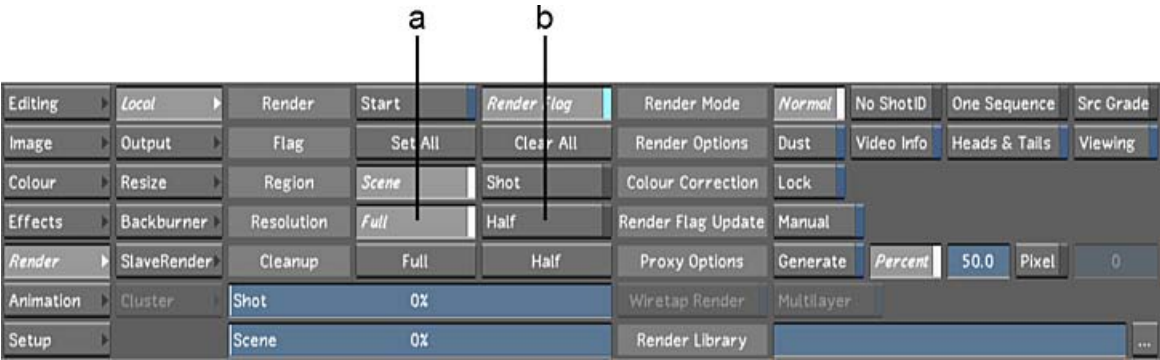

**NOTE** In both cases, rendering starts from the current frame and continues forward.

## Setting the Resolution for the Render

You can render your original shots at full resolution, which is the same resolution as the original footage, or at half resolution. You can also render resized shots at either full or half resolution. If you use half-resolution scans as the source, they can affect the quality of the output but are usually faster to process. You may opt to do this if you want a quick, intermediate render as opposed to a final quality render.

To set the resolution, use the controls directly below the image window.

**NOTE** The resolution parameter in the Render Local menu is the same as that found in the Grade menu and in the user interface controls directly below the image window.

(a) Full Resolution button (b) Half Resolution button

To set the output resolution for full- or half-resolution output:

- 1 Specify the output resolution you want to use by enabling the Full Resolution or Half Resolution toggle, below the Viewport.

To set the output resolution to a video format:

- 1 Specify the source resolution you want to use for your render files by enabling the Full Resolution or Half Resolution toggle, below the Viewport.
- 2 Select a video format in the Render Resize menu. See [Resizing Shots](#) (page 2261).

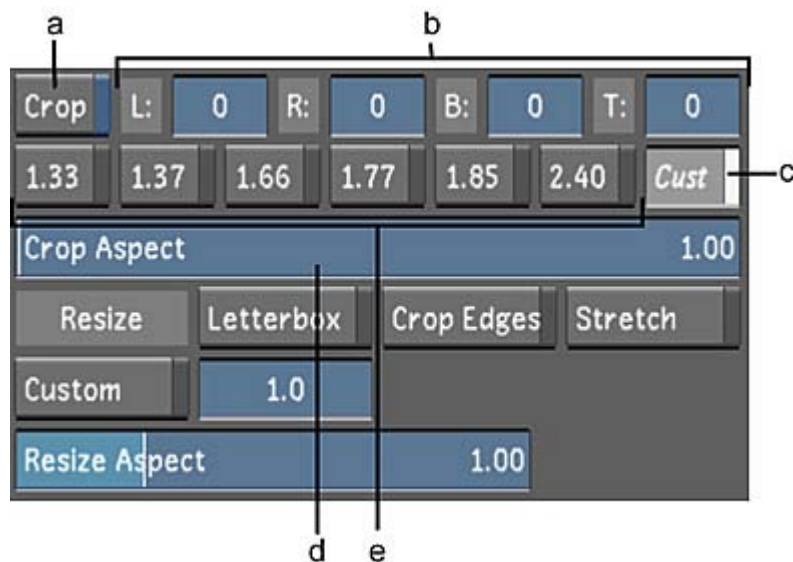

## Resizing Shots

Resize shots prior to rendering them to conform to a different destination output format. For example, if you plan on playing out a cut to a video format, use the controls in the Resize menu to select the appropriate video format and then render the cut at that format to use as the version you play out to a VTR. After you

| Select: | To:                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stretch | Stretch the original image to fit the specified output format. If the aspect ratio of the original image and final output format is different, the image is distorted. |

- 5 Set the crop size. Enable Crop and then do one of the following:
  - Enter custom crop values in the Left, Right, Bottom, and Top fields.
  - Enable one of the standard Crop Preset buttons.
  - Enable Cust and then use the Crop Aspect slider to set the aspect ratio of the crop.

(a) Crop button (b) Left, Right, Bottom, and Top fields (c) Cust (Custom) button (d) Crop Aspect slider (e) Crop Preset buttons

**NOTE** Cropping in Lustre affects both output resolution and how the source file is read. For example, if you crop a 2K (2048x1556) scan to 1:85, the render size becomes 2048x1107. Lustre also reads the scan more quickly since there are fewer lines of pixels to go through.

- 6 To proportionally scale the image, enable Cust and then enter a scaling value in the Cust field.
- 7 If needed, you can squeeze or stretch the image horizontally using the Resize Aspect slider. The Resize Aspect value you set is displayed in the field to the right of the slider.

## Specifying the Destination for Local Render Files

The render files are saved in the location specified in the Renders Full Home or Renders Half Home, in the Project Settings. The sub-folders are named according to the render mode used, (i.e. Normal, One Sequence, etc.), which Lustre automatically creates when you render your first shots.

You can use the default path structure defined in the RenderNaming section of the init.config file. Or you can customize your renders by modifying the fields in the Render Naming menu, in the Project settings.

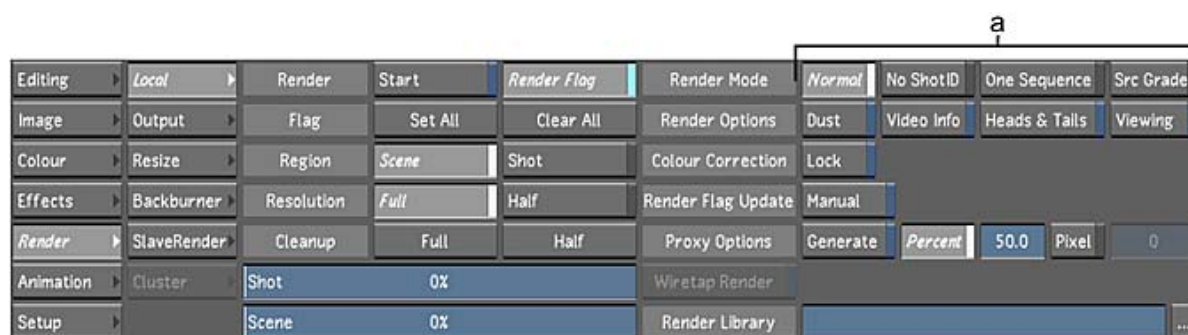

See

[Recommended Directory Structure for Projects](#) (page 1780).

[Render Naming Settings](#) (page 1793)

**NOTE** Dust removal render files created using the Rendering controls in the Dust menu are not saved with the rendered files. See [Rendering the Result](#) (page 2050).

You can specify how you want render files to be organized using the Render Place controls in the Render Local menu.

**(a) Render Place controls**

These controls affect the naming scheme of the render files, the location where they are saved, and the way that multiple instances of the same shot in the timeline are saved. For example, when Normal is selected, Lustre saves all the render files of each given shot to an individual folder based on the original filename and grade.

#### To set how render files are organized:

**NOTE** The following explains the render modes when using the DEFAULT render naming structure.

- 1 Enable Normal, No ShotID, One Sequence, or Src Grade.

**Normal** Individually graded shots are rendered to a folder called "Normal", in the Renders Home location and the UID is included in the filename.

Default render structure for Normal mode (ignore any line breaks):

```
[RENDERS_HOME]/Normal/[SCENE]/[GRADE_NAME]/[REEL_NAME]/
[RESOLUTION]/[UID]_[ORIGINAL_FILENAME]_[GRADE_NAME]
```

Black frames are rendered out to a separate folder in the Renders Home location.

**No ShotID** Individually graded shots are rendered to a folder called "NoShotID", in the Renders Home location.

Default render structure for No ShotID (ignore any line breaks):

```
[RENDERS_HOME]/NoShotID/[SCENE]/[GRADE_NAME]/[REEL_NAME]/
[RESOLUTION]/[ORIGINAL_FILENAME]_[GRADE_NAME]
```

Black frames are rendered to a separate folder in the Renders Home location.

**One Sequence** Individually graded shots are rendered as a single sequence in the Renders Home location. Black frames are rendered to the same single sequence in the same scene folder.

Default render structure for One seq mode (ignore any line breaks):

```
[RENDERS_HOME]/OneSequence/[SCENE]/[GRADE_NAME]/[RESOLUTION]
```

#### Src Grade

Individually graded shots are rendered to a folder called "SrcGrade" in the Renders Home location and UID is included in the filename.

When used locally, this render mode bypasses dissolve transitions and retime parameters. Dissolves become hard cuts and retimes are rendered with a default value of 100%.

This render mode is also used in Interoperability workflows. When rendering with a Wiretap path, Src Grade will retain transition effects and Timeline FX.

Black frames are rendered to a separate folder in the Renders Home location.

## Rendering the Multi-Layer Timeline

Lustre renders out what is displayed in the multi-layer timeline and Player, according to:

- Top vertical priority
- The presence or absence of priority shots and muted layers
- The Solo status

If Solo mode is disabled, Lustre renders the topmost layer by default. If there are gaps, Lustre takes into account top vertical priority behaviour and render out all the shots from the lower layers that are visible through the transparent gaps that are above.

If you do not want a shot in a lower layer to be rendered that is located beneath a gap, you can replace the gap with a virtual black clip. See [Adding a Virtual Black Clip using the Storyboard](#) (page 1974) and [Adding Black Media to the Timeline](#) (page 1983).

If you wish to render out the shots on a specific layer, you either must Solo the active layer, or Mute the unwanted layers. If there are gaps in this layer, the gaps are skipped by the rendering process .

If you wish to render out a shot that normally would not be rendered because top vertical priority renders out a shot on a different layer, you can use the shot priority function to prioritize this shot.

For more information, refer to the following links:

- [Top Vertical Priority](#) (page 2001)
- [Muted Layers](#) (page 2002)
- [Shot Priority](#) (page 2003)
- [Solo Mode](#) (page 2006)

### Rendering the Multi-Layer Timeline with Normal

When the Normal button is selected, Solo mode is disabled, and there are no muted layers, Lustre interprets gaps as being transparent and flattens layers in a top-down manner. Lustre renders out what is visible in the multi-layer timeline in accordance with top vertical priority. The individually graded shots with frames that are visible are rendered and saved to their own folder in the Renders Home location. If there are no shots beneath the gap, the rendering process skips the gap.

You can render one specified layer at a time by muting unwanted layers or soloing a desired layer. Lustre renders individually graded shots with frames that are visible as individual shots and saves them to their own UID directories in the Renders Home location.

### Rendering the Multi-Layer Timeline with No ShotID

Renders the same way as Normal mode. However, when rendering with No ShotID, you can render one layer only for each grade. Consequently, when rendering out L1 first, then rendering out L2 within the same grade, the L2 render overwrites the previous L1 render files.

To render out L2 without overwriting the previous L1 render, you can do one of the following:

- Save a new grade (i.e., grd02).

- Use Normal render mode.
- Add a UID token in the filename. See [Render Naming Settings](#)

### Rendering the Multi-Layer Timeline with One Sequence

When the One Sequence button is selected, Solo mode is disabled, and there are no muted layers, by default Lustre sees the gaps as transparent and flattens the layers in a top-down manner. Lustre renders out what is visible in the multi-layer timeline in accordance with top vertical priority. Lustre renders the individually graded shots with frames that are visible to the scene folder as a single sequence in the Renders Home location. If there are no shots beneath the gap, the gap is rendered as black to the same single sequence in the same scene folder.

When the One Sequence button is selected, you can render one specified layer at a time by soloing the desired layer or muting the unwanted layers. Lustre renders the individually graded shots with frames that are visible to the scene folder as a single sequence in the Renders Home location. Gaps are rendered as black to the same single sequence in the same scene folder.

---

**NOTE** When rendering with One Sequence, you can render one layer only for each grade. That is, if you render out L1 first, and then within the same grade renders out L2, the L2 render will overwrite the previous L1 render files. To render out L2 without overwriting the previous L1 render, you must save a new grade (grd02).

---

### Rendering the Multi-Layer Timeline with Src Grade

Src Grade works just like Normal render in that it renders each shot to its own folder under the SrcGrade directory and the rendering process will skip gaps if there are no shots beneath them. When this option is enabled, the rendering process bypasses any dissolve transitions and retime parameters. In other words, dissolves become hard cuts and retimes are rendered with a default of 100% value.

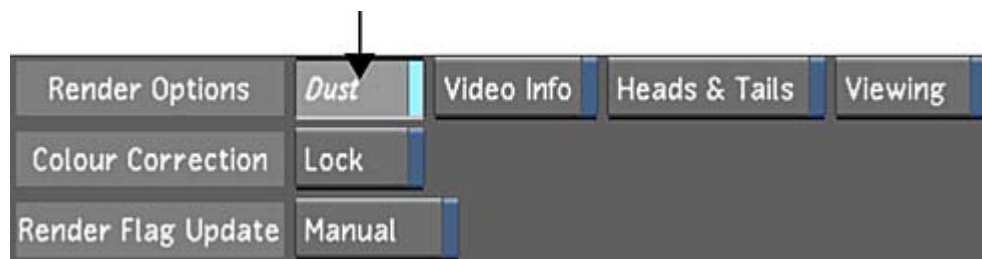

## Rendering Dust Metadata

You can render shots with or without dust metadata. This is a workflow decision. You can render dust metadata either from the Render Local menu or from the Image Dust menu. See [Rendering the Result](#) (page 2050).

To render shots with dust metadata, you must first use the dust removal tools to remove dust artefacts. See [Removing Dust](#) (page 2041).

**To render shots with or without dust metadata:**

- 1 In the Render Local menu, do one of the following:
  - To render shots without dust metadata, disable Dust.
  - To render shots with dust metadata, enable Dust.

## Burning Timecode into the Render

You have the option of burning the timecode into the render files. For example, burn a timecode into the black border of a letterboxed shot to identify the location of the shot.

To set timecode burn-in:

- 1 In the Render Local menu, enable Video Info.

## Rendering with the Viewing LUT

For linear work, you can render shots to 8-bit BMP files using the currently loaded viewing LUT with the Viewing option. Use this option when you want to render the image displayed in the monitor.

When this option is enabled, the output consists of exactly what you see on the monitor, namely, the image resulting from the applied monitor calibration setting, viewing LUT, and colour space settings applied in the Render Output menu.

When this option is disabled, the currently applied viewing LUT is not taken into account in the output image, and the files are rendered to the file format specified in the Render Output menu rather than to 8-bit BMP files.

For information on monitor calibration, see [Calibrating a Monitor](#) (page 1895). For information on output colour space settings, see [Setting Colour Space Options](#) (page 2269).

---

**NOTE** You can also render shots to DPX files with a viewing LUT applied. This is performed in the Render Output menu. See [Setting Colour Space Options](#) (page 2269).

---

To set rendering with the viewing LUT:

- 1 In the Render Local menu, enable Viewing.

## Rendering Head and Tail Frames

When rendering shots or timelines, you can render the grade on the head and tail frames. This can be useful if, for example, the graded shot needs to be changed to include a longer dissolve and requires additional frames.

---

**NOTE** Rendering the head and tail frames is only applicable to the Normal, No ShotID, and Src Grade rendering options.

---

**To render shots with head and tail frames:**

- 1 In the Render Local menu, enable Heads & Tails.

## Specifying the Output Format of the Render Files

You can render your shots to the same file format as the original footage or select a different one. By default, shots are rendered to the same format as the original footage. Currently supported formats are DPX and Cineon at 10 and 8 bits per channel, TIFF at 8 and 16 bits per channel, TARGA®, SGI, and BMP at 8 bits per channel and OpenEXR. When OpenEXR is set as the output format, the resulting files are encoded as single channel RGB OpenEXR 16-bit half float.

---

**NOTE** The ability to render OpenEXR files is only available on the Linux version of Lustre. Also, it is not possible to render OpenEXR files through BrowseD.

---

**To specify the output format:**

- 1 In the Main menu, click Render and then click Output.  
The Render Output menu appears.
- 2 Do one of the following:
  - To render to the same format as the originals, enable Same format as scans.
  - To render to another format, disable Same format as scans and select an output format from the list.

**NOTE** If you applied a colour transform that converts between integer and floating-point data or vice versa in the Transcode menu or elsewhere, you should disable Same format as scans and specify the output format manually.

---

**NOTE** If you output to a floating-point format, the float conversion LUT is applied to the output buffer for display. See [Calibration Settings](#) (page 1787).

---

## Setting Colour Space Options

You can convert the colour space of the output shots from Log to Lin or vice versa. Whether you are outputting in Log or Lin colour space, you have several options for setting a LUT or colour transform used on output. You can:

- Use the default colour mapping. The default mapping differs according to the grading architecture used on the project (as set in the Grade menu).

| Grading Architecture | Output Colour Space | Colour Mapping Applied       |
|----------------------|---------------------|------------------------------|
| Log                  | Log                 | None                         |
| Log                  | Lin                 | Standard log-to-lin (95-685) |
| Lin                  | Lin                 | None                         |
| Lin                  | Log                 | Standard lin-to-log (95-885) |

- Select an output LUT or colour transform.

The output colour space and colour mapping affect the image you see on the monitor. These settings are saved in the output buffer, which is applied to the output on the monitor before the viewing LUT and *monitor.calib* correction (if used) are applied.

## Specifying the Output Colour Space

### Using the Default Colour Mapping

- 1 Access the Render / Output menu.
- 2 From the Colour Space box, select either Logarithmic or Linear.  
You are set up to use the default colour mapping.

### Using a LUT or Colour Transform

- 1 Access the Render / Output menu.
- 2 From the LUT Type box, select 1D Lut, 3D Lut or Colour Transform.
- 3 Click Enable.
- 4 Select an item from the list, or click the Browse (...) button to locate and select a different LUT or colour transform.
- 5 Click the Enable LUT button.  
The selected LUT will be applied to your render.

To create a custom colour transform, see [Creating a Custom Colour Transform](#) (page 1928).

---

**NOTE** If you apply a colour transform that has floating-point inputs, the inverse float-conversion LUT is applied automatically first. See [Calibration Settings](#) (page 1787).

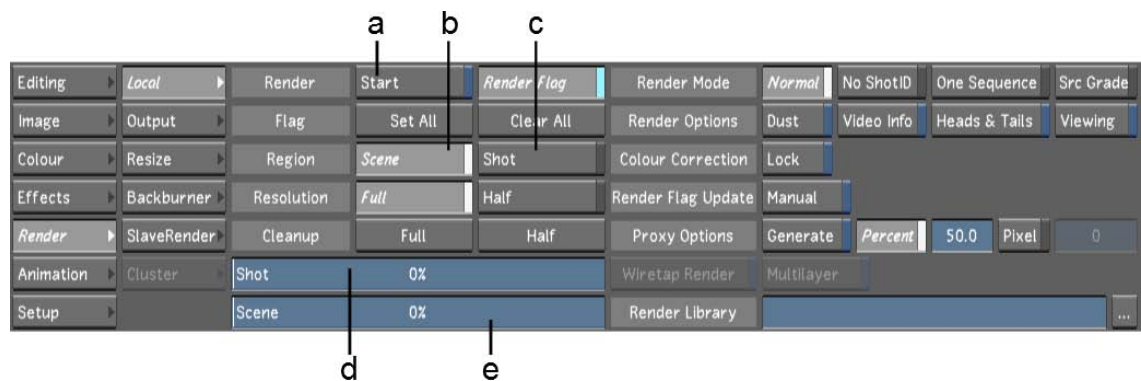

---

## Rendering the Selected Region

Once you have set all the rendering options, you can render flagged shots within a scene region using the Render Local menu, or just render one shot at a time by enabling the shot region.

**To render the selected region:**

- 1 Access the Render Local menu.

**(a) Start button (b) Region Scene button (c) Region Shot button (d) Shot progress bar (e) Scene progress bar**

- 2 Click Start.  
The render starts and its progress is shown in the Shot and Scene progress bars. The Start button label changes to Stop. When the Shot progress bar reaches 100% and the Render button is no longer highlighted (it again reads "Start"), the render is complete.
- 3 If needed, you can abort the process by clicking Stop.

# Generating and Viewing Proxies

When working with high-resolution material in Lustre installations that do not include Incinerator, the speed of interaction can decrease substantially as grading effects are added, compromising real-time playback. For faster interaction with the application, you can generate lower resolution proxies of your footage and perform the colour grading on the proxies. After the grading is complete, you can easily render the colour grading data to the full-resolution version.

If you plan on using proxies on a project, it is recommended that you generate them at the beginning of the project so that you will have them available when needed. Proxies are stored in a sub-directory of the scans directory, at the same directory level as that of the original footage.

You can specify the proxy generation filter by selecting the one you need in the Rendering menu. See [Rendering Settings](#) (page 1789).

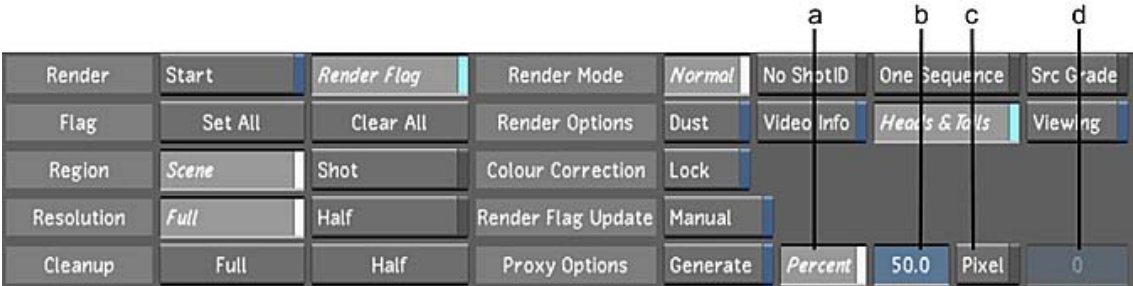

An alternative to generating proxies in Lustre is to create them using another means outside the application, and place them in a directory with a name composed of the resolution (for example, *1024x778*). See [Recommended Directory Structure for Projects](#) (page 1780).

**NOTE** Proxy generation differs from rendering a half-resolution render using the Half Resolution button in that grading and other effects data is not applied to proxies as it is when rendering the images.

**To generate proxies:**

- 1 Specify the proxy generation filter in the Rendering menu for the project configuration.  
To override the filter specified in the configuration file, enter the appropriate proxy generation filter in the Command Line Renderer. See [Command Line Renderer](#) (page 2280).
- 2 Load the scene and grade containing the cut for which you want to generate proxies. See [Selecting Scenes](#) (page 1816) and [Loading Grades for a Cut](#) (page 1823).
- 3 Navigate to the first shot in the cut for which you need proxies. You do not have to go to the beginning of the shot, as generation automatically starts at the first frame of the current shot.
- 4 In the Render Local menu, set the proxy size.

| Enable: | To enter:                                                   |
|---------|-------------------------------------------------------------|
| Percent | The size of the proxy as a percentage in the Percent field. |
| Pixel   | The width of the proxy in pixels in the Pixel field.        |

(a) Percent button (b) Percent field (c) Pixel button (d) Pixel field

Modifying a value in one field automatically updates the value in the other field.

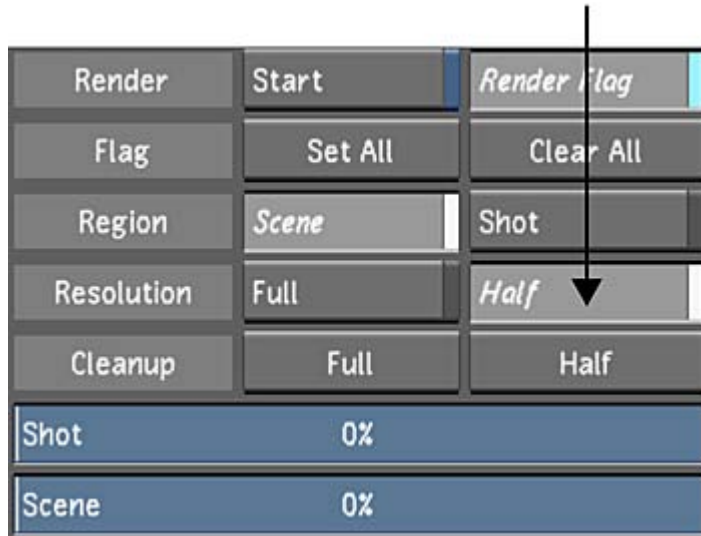

**NOTE** No other options in the Render Local menu affect generated proxies.

- 5 Click Generate.

The Generate button changes to a Stop button, and proxy generation starts at the first frame of the current shot. It continues through to the end of the cut unless you abort the process by clicking the Stop button.

#### To view proxies:

- 1 Do one of the following:
  - Enable the Half Resolution button in the Render Local menu or in the Grade menu.

- Set the Full/Half Resolution button to 1/2.

- Press F9.

**NOTE** An ungenerated proxy appears as a red X with a black background.

## Generating Proxies for Matte Media in Multi-Channel Clips and Matte Containers

It is now possible to generate proxy media for matte clips inside a Multi-Channel clip and Matte Container. When generating proxies, only the matte defined in the Multi-Channel clip & Matte Container (the S track) is generated. If you enable the Render/Proxy Options/All option, all mattes located inside the Multi-Channel clip/Matte Container are generated, including any shots located on any timeline layers of the primary video track.

#### To automatically generate matte proxies for the secondary track (S):

- 1 Access the Render/Local menu.
- 2 From the Proxy options section, enable Generate.

**To generate proxies for all mattes**

- 1 Access the Render/Local menu.
- 2 From the Proxy options section, enable Generate and All.

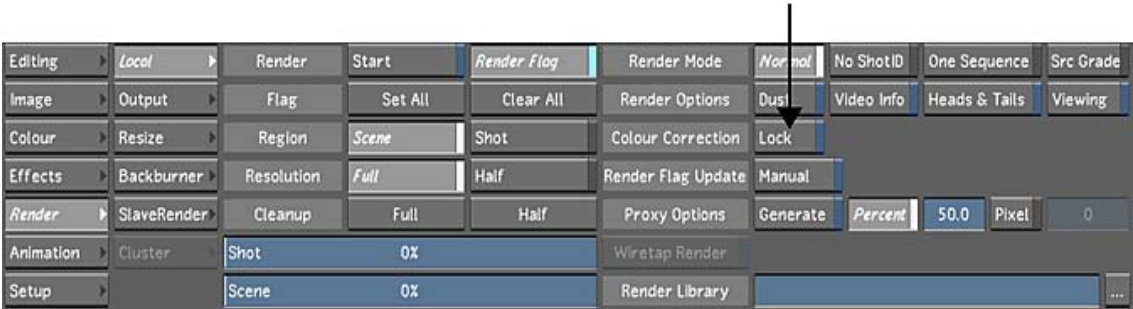

**Locking Colour Grading**

You can lock the colour grading on the current shot so that no colour changes can be made to the shot. This is useful to avoid accidental modification once the grading is complete. For example, you might want to lock the colour grading after it has received final client approval.

**NOTE** Sparks plugin effects are also locked, but dust removal is not.

**To lock colour grading:**

- 1 Navigate to the shot for which you want to lock the colour grading.
- 2 Do one of the following:
  - In the Render Local menu, enable the Colour Correction Lock button.

- Enable the Locked flag in the Flags section by right-clicking on the Locked flag. A filled green circle indicates that the flag is enabled. See [Flagging Shots](#) (page 1853).

The word “Locked” appears in the Printer Light fields and the shot can no longer be modified in any of the Colour menus until either the Lock button or Lock flag has been disabled.

**Cleaning Up Render Files**

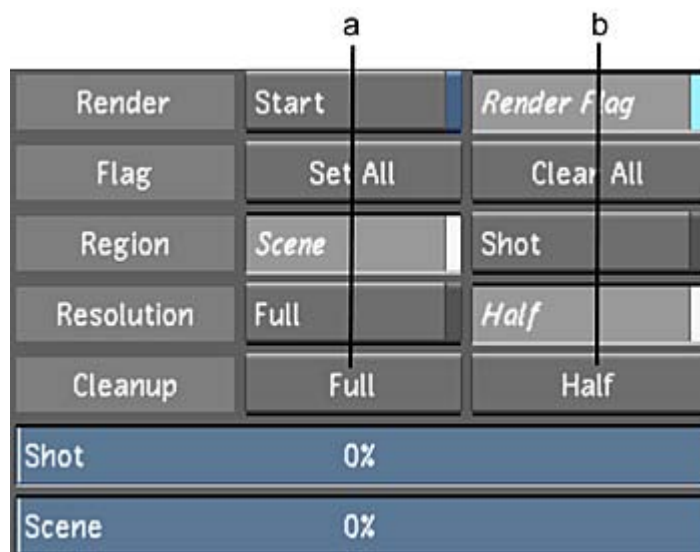

You can remove unneeded render files. Because renders are created separately for each grade (that is, grd01 to grd99), you may want to delete renders for grades that are not used anymore to free up storage.

**To remove unneeded render files:**

- 1 Load the grade that has associated unwanted render files. See [Loading Grades for a Cut](#) (page 1823).
- 2 In the Main menu, click Render, and then click Local to display the Render Local menu.
- 3 Do one of the following.

| Click:                   | To:                                                                |
|--------------------------|--------------------------------------------------------------------|
| Cleanup Full and confirm | Remove all full-resolution render files associated with the grade. |
| Cleanup Half and confirm | Remove all half-resolution files associated with the grade.        |

(a) Cleanup Full button (b) Cleanup Half button

## Rendering Shots as You Work

You can render shots as you work on them using Lustre ShotReactor locally or remotely. As you move from shot to shot in the timeline, the previous shot is rendered using the ShotReactor, making the rendering process invisible and hence does not interrupt your work. If several shots are changed before Lustre has had time to render the last one, the changed shots are sent to a job queue.

By default, ShotReactor is installed locally on your Lustre station.

To install ShotReactor on a remote server, see [Autodesk Flame Premium Install Guides](#).

---

### NOTE

- When rendering a multi-layer timeline, ShotReactor renders the shots that are visible from a flattened timeline, or the shots from the active layer in the multi-layer timeline, depending on the mode you are working in. For Solo mode, see [Multi-Layer Timeline](#) (page 1974) and for Mute mode, see [Muted Layers](#) (page 2002).
- Running a rendering service like ShotReactor on the creative workstation as a background task may impact interaction and playback performance, based on the resolution of your project, the configuration of the workstation, etc.

---

Files rendered with the ShotReactor are stored in the same directories as those used for renders created using the Render / Local menu. Directories are specified when you first create the project. To view the renders, use P (Print) view mode. See [Setting the View Mode](#) (page 2016).

---

**NOTE** For information on setting up the ShotReactor, refer to the *Autodesk Lustre Software Installation Guide* for your platform.

---

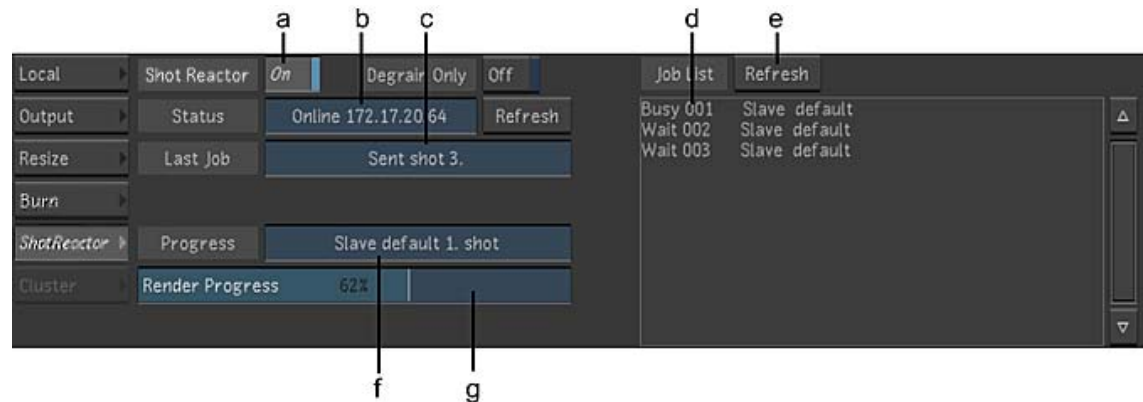

### To render shots with the ShotReactor:

- 1 Do one of the following:
- 2 To use ShotReactor locally, make sure the IP address is set to <localhost>, in the *init.config* file. This is the default setting.

- 3 To use ShotReactor on a remote machine, make sure the IP address field is set to the ShotReactor machine's IP address set to <localhost>, in the *init.config* file.

**NOTE** To render at full resolution, enable Renders Full Res in the Network Rendering page of the project configuration. See [Network Rendering Settings](#) (page 1799).

- 4 Start Lustre.
- 5 Access the Render / ShotReactor menu.

(a) ShotReactor On/Off button (b) Status field (c) Last Job field (d) Job List (e) Job List Refresh button (f) Progress field (g) Render progress bar

In the Status field, the status and IP address of the ShotReactor machine are displayed. If you are using ShotReactor locally, <localhost> is displayed in the Status field. This is the default setting.

**TIP** Click Refresh to update the Status field.

- 6 Set the ShotReactor On/Off button to On.  
The letters BR in the upper-left corner of the screen indicate that ShotReactor is activated.

- 7 In the Render / Local menu, specify the region to render. See [Specifying the Shots to Render](#) (page 2259).
- 8 When you want to render a shot with ShotReactor, modify a parameter and then move to the next shot.
- 9 To view the render status, display the ShotReactor menu.

The last job sent to the ShotReactor is displayed in the Last Job field. The last job sent is also the shot currently being rendered, and its name is displayed in the Progress field. The shot's render progress is indicated by the Render progress bar.

**TIP** The Render progress bar shows the shot's render progress as a percentage and updates every second. You can change the update interval using the Refresh in Seconds slider in the Network Rendering tab of the project configuration. See [Network Rendering Settings](#) (page 1799).

- 10 When you have finished, you can turn off rendering with ShotReactor by setting the ShotReactor On/Off button to Off.  
Any jobs remaining in the job queue are cancelled.

#### To play shots rendered by ShotReactor:

- 1 Navigate to a shot that has been rendered.
- 2 Enable P (Print) view mode.

- 3 Use the playback controls to play the shot.

**NOTE** If you have rendered files on the filesystem but Lustre does not “see” them, you can force a refresh by pressing **Shift** while enabling **P** in the user interface. The force refresh function is especially useful when background rendering processes are involved.

## Rendering with Burn for Lustre

Burn for Lustre allows you to render shots using Linux servers set up on the network, speeding up the rendering process and freeing up the Lustre stations. On a 2K film project, you might, for example, want to render half-resolution versions using the local machine and render 2K final versions using Burn for Lustre, as this takes much longer. Or, when you are satisfied with the grade of a reel, use the render farm to render 1K or 2K versions of it.

---

**NOTE** When rendering a multi-layer timeline, Burn only renders the flattened timeline. It does not take into account the Solo (see [Multi-Layer Timeline](#) (page 1974)) or Mute (see [Muted Layers](#) (page 2002)) status, since these modes are not saved in the grade.

---

Files rendered using Burn for Lustre are stored in the same directories as those used for renders created using the Render Local menu. Render directories are set up in the Render / Burn menu. See the *Autodesk Lustre Software Installation Guide* for your platform.

To view and manage jobs sent to the render farm, you use Autodesk Backburner™ Manager and Backburner Monitor.

## Remote Rendering with Burn and Wiretap

Burn for Lustre allows you to render footage stored in the local storage array, or footage imported via Wiretap, to a destination specified in the Burn Render Fulls Home. The destination could be the local storage array, shared network storage, or the Stone filesystem via Wiretap.

---

**NOTE** If rendering footage imported via Wiretap, the footage must be located on the Stone filesystem.

---

### Remote Rendering to the Local Storage Array or Shared Network Storage with BrowseD

Enter the Wiretap path in the Renders Full Home field in the Render / Burn menu. See [Submitting a Remote Render Job](#) (page 2277).

Example:

`BURN_PROJECT_HOME 192.23.200.76:/L:/lustre_project`

`BURN_RENDERERS_FULL_HOME 192.23.200.76:/L:/renders/full`

### Command Line Render

`./render -s <scene_name> -g <grd_name> -r <output_resolution> -i -1`

192.23.200.76:/L:/lustre\_project -2 192.9.200.19@wt:/stonefs/project/library -3  
192.23.200.76:/L:/renders/full

---

**NOTE** Use the -i option to render, taking trim information into account.

---

For more information, see [Command Line Renderer](#) (page 2280).

## Starting Backburner Manager

Before you can start a network render, you must start Backburner Manager on a Windows or Linux workstation designated as the Manager, and start Backburner server on each rendering server.

The Backburner Web Monitor has all the features of the Windows-based Backburner Monitor. The Backburner Web Monitor runs in a Web browser from any workstation on the network. You can use it to view and control jobs currently being processed. Jobs in the Distributed Queueing System can be stopped, restarted, reordered, archived, or removed. You can monitor the overall health of the Distributed Queueing System and identify any Render Nodes that are not working. See the *Autodesk Backburner User Guide*.

For details on starting and configuring Backburner Manager, see the Backburner Installation Guide.

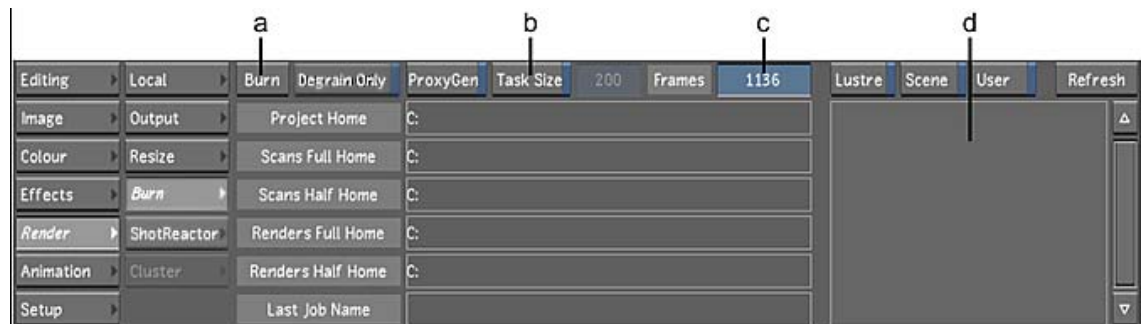

## Submitting a Remote Render Job

You can render one shot, several selected shots, or all shots in a scene using Burn for Lustre. Jobs are submitted from the Render / Burn menu, where you can also monitor job progress.

**To render a selected region using Burn for Lustre:**

- 1 Load the cut containing the shots you want to render. See [Managing Cuts](#) (page 1819).
- 2 Apply the required colour grading changes, and then save the grade.
- 3 If you do not wish to render out the entire sequence, flag the shots you wish to render. See [Flagging Shots](#) (page 1853).
- 4 Click Render and then click Burn.

The Render / Burn menu appears.

(a) Burn button (b) Task Size button (c) Frames field (d) Job list

- 5 If needed, change the size of the task (in number of frames) sent to individual Linux systems by enabling the Task Size button and then changing the value in the Task Size field.

**NOTE** It is recommended that you save the grade file before proceeding to the next step. If not, changes made in the Render menu might not be submitted to the render farm. Press **s** on the keyboard to save your changes.

6 Click Burn.

The job is submitted to Backburner, which then queues and distributes it to the render farm. The last successfully submitted job appears in the Last Job Name field. If the job submission was unsuccessful and nothing appears in the Last Job Name field, check for errors in the Lustre console. Otherwise, check for errors in the Backburner Monitor.

**NOTE** The total number of frames in the cut is displayed in the Frames field, for reference.

**To monitor job progress:**

- 1 In the Render / Burn menu, click Refresh.

- 2 All submitted jobs appear in the Job list. This is the same list of jobs shown in the upper-left panel of the Backburner Monitor. See [Monitoring the Render Tasks with Backburner Monitor](#) (page 2278).
- 3 To view a subset of the jobs, apply a filter to the job list by enabling one or more of the filter buttons above the job panel.

| Enable: | To view:                                                                                                 |
|---------|----------------------------------------------------------------------------------------------------------|
| Lustre  | Only jobs submitted from Lustre (as opposed to other Autodesk applications such as Flame or Combustion). |
| Scene   | Only jobs for the currently loaded scene.                                                                |
| User    | Only jobs submitted by the current user.                                                                 |

## Monitoring the Render Tasks with Backburner Monitor

During an active render session, you can use Backburner Monitor on any Windows workstation on the network to view and edit jobs that are in process or in the job queue.

**To start Backburner Monitor:**

- 1 On the workstation designated as the render monitor, choose Start | Programs | Autodesk | Backburner | monitor.

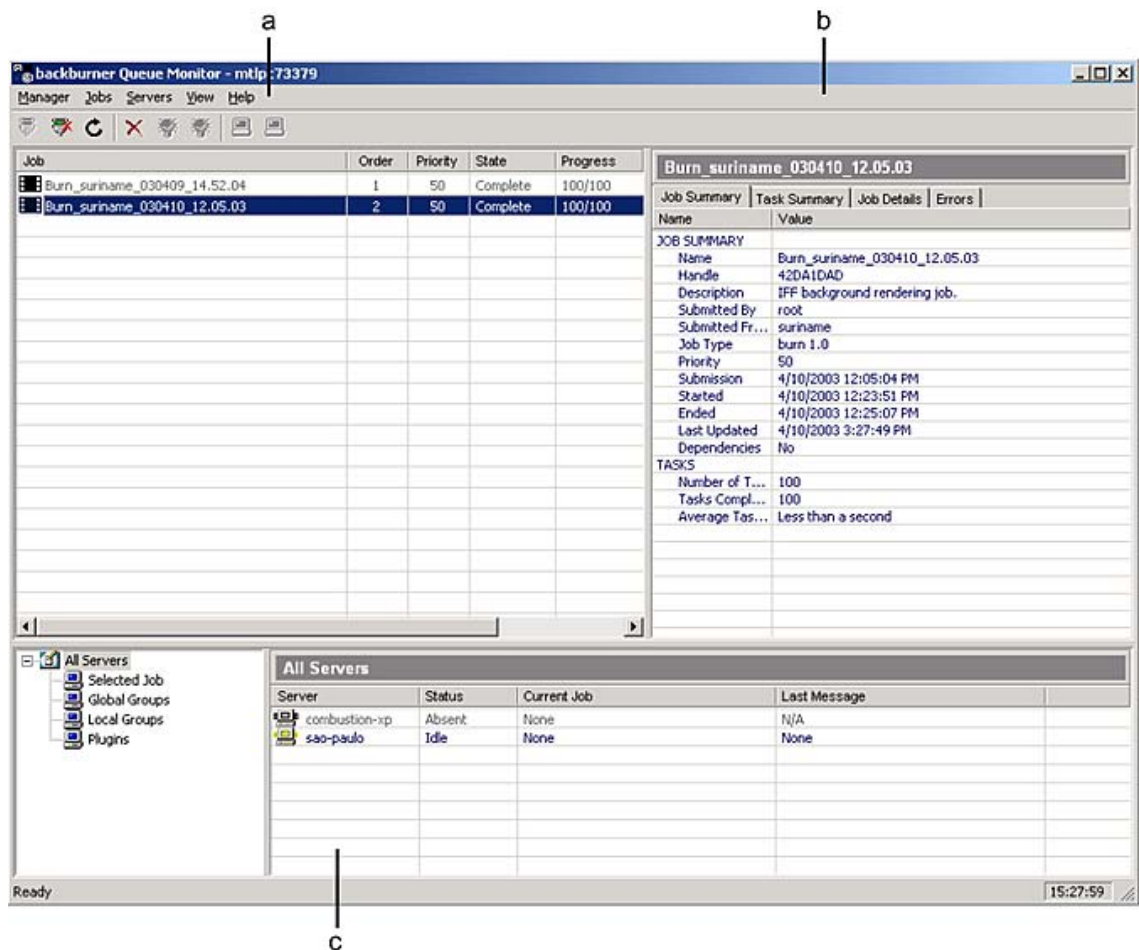

The Monitor window appears.

- 2 If no servers or data appear in the Backburner Queue Monitor, the Backburner Manager was not found with the current settings. Choose Manager | Connect to connect to the Backburner Manager.

The Connect to Manager dialog appears.

- 3 Enter localhost if you are using Backburner Monitor on the same workstation as Backburner Manager. Otherwise, enter the IP address of the workstation on which Backburner Manager is running. When Backburner Manager is found, its name appears in the title bar and the list of servers is updated.

(a) Job list (b) Job panel (c) List of servers

#### To view and edit jobs:

- 1 In the Job list, select a job.  
The columns in the Job list include Order, Priority, State, Progress, and Owner. The Job Summary, Task Summary, and Job Details panels are updated to reflect the selected job.
- 2 In the Job list, right-click a selected job to choose from a list of operations. For example, activate, suspend, delete, or restart the current job.

#### Monitoring Results Using rdesktop

You can access Backburner Monitor by running a Windows session on the Linux system using *rdesktop*—a remote desktop protocol client. The *rdesktop* application is an open source client for Windows NT® Terminal Server and Windows 2000 Terminal services. The *rdesktop* application displays your NT desktop on the Linux platform. For more information, see [GUID-690963B8-74BD-4190-BB0A-8869622C2ED](#).

#### Command Line Renderer

The Command Line Renderer allows you to render shots by entering a command in a Linux shell instead of using the Render / Burn menu.

**NOTE** Use the *bbserver.log* file describing the Command Line Renderer output to view error messages and other pertinent information.

Run the Command Line Renderer on the machine you want to render on. Files rendered using the Command Line Renderer are stored in the same directories as those used for renders created using the Render Local menu. Render directories are set up in the Project menu.

The Project Home directory must be specified when you use the Command Line Renderer. The Scans home and Renders home directories must also be specified if they are not sub-directories of the Project Home directory. You can specify these directories in two ways. You can either use the -1, -2, and -3 parameters in the command line, or you can set them as environment variables on the Linux server.

To use the Command Line Renderer, Burn for Lustre must be installed and licensed on each machine (node). For information, refer to the *Autodesk Lustre Software Installation Guide* for your platform.

## Command Line Renderer Syntax

The Command Line Renderer uses the following syntax:

**./render -s** <scene\_name> **-g** <grade\_name> **-o** <output\_file\_format> **-r** <output\_resolution>

**NOTE** This syntax example shows required parameters and modifiers when environment variables for project directory locations have been set on the local machine. For a complete list of parameters, refer to the following table.

| Par. | Modifier              | Description                                                                                                  | Req'd | Comments                                                                                                                  |
|------|-----------------------|--------------------------------------------------------------------------------------------------------------|-------|---------------------------------------------------------------------------------------------------------------------------|
| -s   | <scene_name>          | The name of the scene containing the grade and associated cut you want to render.                            | Yes   |                                                                                                                           |
| -g   | <grade_name>          | The name of the grade and associated cut you want to render.                                                 | Yes   |                                                                                                                           |
| -o   | <output_file_format>  | The file format of the render files. Valid modifiers: cin, dpx, tga, sgi, tif or bmp.                        | Yes   |                                                                                                                           |
| -r   | <output_resolution>   | The resolution of the render files. Valid modifiers: full, half.                                             | Yes   |                                                                                                                           |
| -1   | <video_format>        | Renders to a specified video format. Valid modifiers: HD, PAL, or NTSC.                                      | No    |                                                                                                                           |
| -1   | <project_home_folder> | The path and directory name of the Project Home directory, including the drive letter. Example: G:\ProjectAB | No    | Not required if set as environment variables on the local machine. See <a href="#">Project Configuration</a> (page 1776). |
| -2   | <footage_home_folder> | The path and directory name of the original footage directory, including the drive letter.                   | No    | Not required if set as an environment variable on the local machine.                                                      |

| Par. | Modifier                    | Description                                                                                                                                 | Req'd | Comments                                                                                                                |
|------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------------------------------------------------------------------------------------------------------------------|
| -3   | <renders_home_folder>       | The path and directory name of the render files directory, including the drive letter.                                                      | No    | Not required if set as an environment variable on the local machine.                                                    |
| -n   | <number_shots>              | The number of shots, starting from the first shot in the cut, to be rendered.                                                               | No    | Use only when rendering to Lustre ShotReactor.                                                                          |
| -f   | <first_frame<br>last_frame> | Renders a range of frames within the set of shots defined for rendering. Example: -f 120 340                                                | No    | Can be used to specify a new range when restarting a cancelled render.                                                  |
| -a   | <start_fr_no<br>end_fr_no>  | Renders a range of frames in the timeline, between the Start Frame number and End Frame number. Example: -a 140 480                         | No    | Do not use this parameter with other parameters that specify a subset of shots.                                         |
| -i   | None                        | Renders shots taking trim information into account.                                                                                         | No    |                                                                                                                         |
| -e   | <preset>                    | Name of output colour space preset, if used.                                                                                                | No    |                                                                                                                         |
| -t   | <number_of<br>_threads>     | Specifies the number of threads, or processors, used for processing. You can opt to use only one of two processors. Example: -t 1           | No    | On Linux machines, you must set this parameter to -t 2.                                                                 |
| -w   | None                        | Renders wedges to the same place.                                                                                                           | No    | Same as No Wedge option. See <a href="#">Specifying the Destination for Local Render Files</a> (page 2263).             |
| -q   | None                        | Renders to one sequence.                                                                                                                    | No    | Same as One Sequence option. If neither -w nor -q are specified, Normal is used. This parameter should be used with -i. |
| -p   | <part_of_<br>frame>         | Renders a fraction of the shots in the cut. Express the modifier as a fraction, for example, <1/4> would render the first 25% of the shots. | No    | You can use this parameter to divide the job between several machines.                                                  |
| -u   | None                        | Renders dust removal data.                                                                                                                  | No    |                                                                                                                         |
| -k   | None                        | Renders with timecode burned in.                                                                                                            | No    |                                                                                                                         |

| Par. | Modifier | Description                                                                                                    | Req'd | Comments                                            |
|------|----------|----------------------------------------------------------------------------------------------------------------|-------|-----------------------------------------------------|
| -L   | None     | Render using the Normal filter for reposition.                                                                 | No    | See <a href="#">Rendering Settings</a> (page 1789). |
| -M   | None     | Render using the Mitchell filter for reposition. There are three parameters (s = size; B = blur; C = ringing). | No    | See <a href="#">Rendering Settings</a> (page 1789). |
| -T   | None     | Render using the CatmullRom filter for reposition.                                                             | No    | See <a href="#">Rendering Settings</a> (page 1789). |
| -O   | None     | Render using the new type Lanczos3lobe filter for reposition.                                                  | No    | See <a href="#">Rendering Settings</a> (page 1789). |
| -d   | None     | Debug level.                                                                                                   | No    |                                                     |
| -h   | None     | Print help to command prompt window.                                                                           | No    | Use this parameter by itself. Example: render -h.   |

### Example of Use

**render -s alabama -g grd21 -o dpx -r half -i -q -1 g:/project1 -n 1**

Where **alabama** is the scene name, **grd21** is the grade name, **dpx** is the output format, and **g:/project1** is the Project Home directory as mapped from the local (rendering) machine.

### To render one or more shots with the Command Line Renderer in Windows:

- 1 Open a Command Prompt window on the machine on which you want to render the shots by choosing Start | Programs | Accessories | Command Prompt.
- 2 Go to the Lustre application directory by typing:  
**cd C:\Program Files\Autodesk\Lustre <version\_number>**  
where C is the local drive.
- 3 Enter the render command using the syntax provided in the previous table.

### To render one or more shots with the Command Line Renderer in Linux:

- 1 Open a Linux shell.
- 2 Go to the Lustre application directory by typing:  
**cd /usr/autodesk/lustre\_<version\_number>**
- 3 Enter the render command using the syntax provided in the previous table.

## Rendering Grades Created in Releases Prior to Lustre 2011 Extension 1

Due to the enhancements in the GPU, we do not recommend using Lustre to render grades created in Lustre 2011 or earlier if you are looking for pixel accuracy rendering.

To be able to render grades created before Lustre 2011 Extension 1 using the older HLS/Blur algorithm:

- 1 In a text editor, open the init.config configuration file.
- 2 Add the following keyword in the Miscellaneous section:

```
<GPUHLSKeyerBackwardCompatibility state= "On" />
```

- 3 Restart Lustre.
- 4 Load and render the grade.

#### NOTE

This keyword must be enabled in any init.config configuration file used by Lustre or Lustre render services (Lustre ShotReactor, Burn, etc). Also, verify that the keyword is disabled from init.config configuration files before creating new content in Lustre 2011 Extension 1. If not, all newly created grades will use the older HLS/Blur algorithm.

To disable the keyword:

- 1 Do one of the following:
  - Remove the keyword from the init.config configuration file
  - Set the keyword to:

```
<GPUHLSKeyerBackwardCompatibility state= "Off" />
```

#### NOTE

When using Incinerator, this keyword does not apply. Incinerator uses CPU rendering only and does not use the GPU to accelerate the keyers and Blur.

## Media Export (Linux Only)

### About Background Media Export

Lustre 2013 supports a media encoding service called Media Converter. The Media Converter allows Lustre to offload encoding tasks to Wiretap Gateway servers (Linux and Mac OS X). This means that you can continue working on your project while media files are being generated in the background, even if you are using your local Wiretap Gateway server. It offers the ability to encode streaming formats such as Quicktime, MFX, graphic files like Jpeg, DPX and Tiff. and audio files like AIFF, Wave and mp3. It also adds support for formats and codecs only available on specific operating systems (Apple ProRes) and leverages your networking infrastructure (InfiniBand, 10-Gig, etc). The tasks are managed by Backburner Manager, the Autodesk queue management system. This means that facilities can centralize the management of these tasks without disturbing the creative suite and use a web browser to monitor and edit the tasks.

The Media Export workflow in Lustre is based on Export Versions: export configurations that are linked to a grade. Consequently, all the exports you create can be recalled for future use. Numerous options are available to suit multiple file delivery workflows.

You can define the Wiretap Gateway server used for background media export. It can be local or remote. Unless otherwise specified, the default Wiretap Gateway Server is set to "localhost".

To set up a stand-alone Wiretap Gateway server for media encoding, see [Stand-Alone Wiretap Gateway Server Configuration for Media Encoding](#) (page 2298).

## Setting the Render Location during Project Creation

Define the location of the exported media files, in the Rendering tab, when you create the project or after the project is created in the Project Settings. The path can be local or remote.

- To export locally, set the path to:

/[PROJECT\_HOME]

- To export to a remote location, the path must be in the following format:

Remote\_Host\_Name@wtg:/[PROJECT\_HOME]

For example: Upton@wtg:/[PROJECT\_HOME]

## The Export Panel

The Export Panel is a sub-menu of the Render menu. It is divided into three sub-menus:

Sub-menu:	Description:
Format Options	Use to define file format options used for export, media location and the Wiretap Gateway Server used for the export tasks.
Resize	Use to define the output resolution and the Resize options of the exported media files.
LUT Options	Use to apply a LUT to the media files to be exported.

## Settings Common to the Three Export Sub-Menus

The first column of options, along with the Export Versions and Export Templates boxes, are common to all Export sub-menus.

**Media Origin:** Defines the type of media used for export. The options are:

- **Source Grade Renders:** Source Grade rendered files are used to create media files on a shot basis.
- **One Sequence Renders:** One Sequence rendered files are used to create one media file for the entire grade.
- **Original Media:** Uses the original media files for the export. No grades are applied.

**NOTE** Because the Export service requires media files to be saved to disk, you must render your grades in Lustre prior to exporting. If you set off an export prior to rendering you grades, Lustre automatically starts the rendering process in the mode corresponding to your export options (One Sequence or Source Grade) and exports the file once rendering is complete.

**Region:** Enable Scene to export the entire timeline or enable Shot to export only the current shot. Available when Media Origin is set to Source Grade rendered or Original Media.

**Media Selector:** Use to define attributes of the exported media. Options are:

- **Video Only:** Only video stream is exported.
- **Video & Audio:** Video and audio stream is exported.

- **Audio Only:** Only audio stream is exported.

**Export All Versions:** If you created multiple Export versions, enabling this option will add them all as jobs in the queue.

See [Export Versions](#) (page 2292).

**Export:** Click to start the Export tasks.

**Export Version:** Use to create, update, load and delete Export Versions.

You can create multiple Export Versions, with different export settings for the same grade. Export Versions contain all the data required to define an export job and are stored in the Library folder, alongside the grade metadata file. Export Versions are named after the grade they are associated to:

- grade01\_export01, grade01\_export02, etc.

You can add a comment to an Export Version, which appears alongside the export name:

- Export01 Final Version

See [Export Versions](#) (page 2292).

**File Naming:** Use tokens to define the filename of the exported file(s). The default value is [GRADE\_NAME] for One Sequence Renders and [ORIGINAL\_FILENAME]\_[GRADE\_NAME] for Source Grade Renders.

To create a folder, type a token in the file name field followed by "/". This creates a folder in the destination location.

The following tokens can be used:

- [PROJECT\_NAME]: The name of the current project.
- [PROJECT\_HOME]: The home folder of the project.
- [SCENE]: The current scene.
- [USER]: The current user settings.
- [GRADE\_NAME]: grd01 is the grade name.
- [GRADE\_NOTE]: Text data entered by user and appearing to the right of the grade in the grade list.
- [CUT]: The name of the cut.
- [UID]: The shot-based UID.
- [RESOLUTION]: The resolution of the exported media.
- [REEL\_NAME]: The reel/tape name of the source clip.
- [STEREO\_LAYER]: Left or Right.
- [ORIGINAL\_FILENAME]: The original file name of the source clip (without the file extension).
- [DATE]: Current date in YY\_MM\_DD format (i.e. 2011\_11\_29).
- [TIME]: Current job starting time in HH\_MM\_SS format (i.e. 22\_12\_10).
- [EXPORT\_VERSION]: Current export version name.
- [EXPORT\_NOTE]: Current export version note.

---

**NOTE** For file sequence exports, you can define the file padding value. If the selected file format is not a file sequence format, the padding field is greyed out.

---

**Destination:** Displays the destination folder for the exports, as defined by the project settings. You can change the destination folder by clicking on the browse button. When browsing for a destination folder, only Wiretap Gateway servers are displayed. You can select different Wiretap Gateway servers than your default server. The path must be in the following format:

[EXPORT\_HOST]@wtg/[PROJECT\_HOME]

Destination  ...

---

**NOTE** When you select a different Wiretap Gateway server, the Wiretap Gateway Server option field is updated. This action also refreshes the available codecs list.

---

Once you select a Wiretap Gateway server, you can select an existing folder or create a new one as your destination folder.

**Export Templates:** Use to save, load and delete Export Templates. An Export Template contains one or more Export Versions.

See [Export Templates](#) (page 2293).

## The Format Options Tab

Adjust the values in the Format Options tab to define your Wiretap Gateway server and the file format export options.

### Format Options Tab - Video Settings

**Video File Format:** Use to select the file type for the export of the video stream.

**Compression:** Displays the list of available codecs based on the selected Wiretap Gateway server. See [Wiretap Gateway Supported Media File Formats](#) (page 1902) for a complete list of supported media file formats.

---

**NOTE** The list only displays the available codecs that are compatible with the resolution, frame rate and bit depth of the current grade.

---

**Include YUV Headroom** Enable to include YUV headroom on export for Quicktime and MXF files.

**Profile:** You can select a pre defined profile for certain video file formats. Selecting a profile populates all the relevant parameters for the export.

Each codec can be configured to produce different results. Data rate, video range, etc. can be edited to account for many file delivery requirements. The codec profiles are located in:

`/usr/discret/mediconverter/2013.0.0/profiles/<file format>/<essence>/<compression>`

**File Format:**

- QuickTime
- MXF

**Essence:**

- Video
- Audio

**Compression:**

- The codec in question.

Each codec has a default value, located in the <default.xml> file.

**H264 Codec Profiles**

For H264, multiple preset profiles are available:

H264 Codec Profile:	Description:
Baseline_1SEG_384Kbits	H264_CIF 352x288 or 352x240 at 384 kbit/s, Baseline profile.
Baseline_3GP_256Kbits	H264_FLASH_LOWRES 320x240 at 300 kbit/s, Baseline profile.
Baseline_600Kbits	H264_BASELINE 320x240 at 600 kbit/s, Baseline profile.
Baseline_Adobe_300Kbits	H264_FLASH_LOWRES 320x240 at 300 kbit/s, Baseline profile.
Baseline_Apple_1_5Mbits	H264_iPOD Apple iPod, 320x240 at 1.5 Mbit/s, Baseline profile.
Baseline_Apple_400Kbits	H264_iPOD Apple iPod, 320x240 at 400 kbit/s, Baseline profile.
Baseline_Apple_600Kbits	H264_iPOD Apple iPod, 320x240 at 600 kbit/s, Baseline profile.
Baseline_Apple_970Kbits	H264_iPOD Apple iPod, 320x240 at 970 kbit/s, Baseline profile.
Baseline_CIF_600Kbits	H264_CIF 352x288 or 352x240 at 600 kbit/s, Baseline profile.
Baseline_RIM_12Mbits	H264_BASELINE 1920x1080 at 12 Mbit/s, Baseline profile.
Baseline_RIM_20Mbits	H264_BASELINE 1920x1080 at 20 Mbit/s, Baseline profile.
Baseline_RIM_4Mbits	H264_BASELINE 1920x1080 at 4 Mbit/s, Baseline profile.
HDTV_1080i_10Mbits	H264_HDTV_1080i 1920x1080 at 10 Mbit/s, High profile, interlaced.
HDTV_720p_8Mbits	H264_HDTV_720p 1280x720 at 8 Mbit/s, High profile.
High_1080i_6Mbits	H264_HIGH 1920x1080 at 6 Mbit/s, High profile, interlaced.

H264 Codec Profile:	Description:
High_AVC_HD_20Mbits	H264_AVCHD AVCHD, 1920x1080 at 20 Mbit/s, High profile, interlaced.
High_AVC_Intra_111Mbits	H264_INTRA_CLASS_100 AVC Intra Class 100, 1920x1080 at 111 Mbit/s, High 10 profile, interlaced.
High_AVC_Intra_54Mbits	H264_INTRA_CLASS_50 AVC Intra Class 50, 1440x1080 at 54 Mbit/s, High 10 profile, interlaced.
High_Blu_Ray_20Mbits	H264_BD_HDMV Blu-ray HD, 1920x1080 at 20 Mbit/s, High profile, interlaced.
High_Blu_Ray_8Mbits	H264_BD Blu-ray SD, 720x576 or 720x480 at 8 Mbit/s, High profile, interlaced.
High_Divx_2Mbits	H264_DIVX DivX+, 1920x1080 at 2 Mbit/s, High profile.
High_DVD_3Mbits	H264_DVD 720x576 or 720x480 at 3 Mbit/s, High profile, interlaced.
High_HD_DVD_20Mbits	H264_HD_DVD 1920x1080 at 20 Mbit/s, High profile, interlaced.
High_Microsoft_10Mbits	H264_SILVERLIGHT Microsoft Silverlight, 1920x1080 at 10 Mbits/s, High profile.
High_Microsoft_500Kbits	H264_SILVERLIGHT Microsoft Silverlight, 640x480 at 500 kbits/s, High profile.
Main_3Mbits	H264_MAIN 704x576 or 704x480 at 3 Mbit/s, Main profile.
Main_Adobe_670Kbits	H264_FLASH_HIGHRES 640x480 at 670 kbit/s, Main profile.
Main_Apple_1_8Mbits	H264_MAIN 1024x576 at 1.8 Mbit/s, Main profile.
Main_Apple_4_5Mbits	H264_MAIN 1280x720 at 4.5 Mbit/s, Main profile.
Main_D1_3Mbits	H264_D1 720x576 or 720x480 at 3 Mbit/s, Main profile, interlaced.
Main_Sony_2Mbits	H264_PSP_640x480 Sony PSP Level 3, 640x480 at 2 Mbit/s, Main profile.
Main_Sony_700Kbits	H264_PSP Sony PSP, 320x240 at 700 kbit/s, Main profile.
Main_Sony_900Kbits	H264_PSP_480x270 Sony PSP Level 2, 480x272 at 900 kbit/s, Main profile.
Main_SVCD_1_15Mbits	H264_SVCD 480x576 or 480x480 at 1.15 Mbit/s, Main profile, interlaced.

The H264 codec profiles are located in:

*/usr/discreet/mediacconverter/profile/quicktime/video/h264*

**NOTE** Some H264 codec profiles are also used by some Export Templates. Keep this in mind if you plan to modify some of the parameters within the codec profiles. Your changes will be reflected in the Export Templates.

## Format Options Tab - Audio Settings

**Audio File Type:** For streaming formats, like QuickTime and MXF, the Audio File Type menu is automatically set to the Video File Type. There may be situations in which you require a separate audio stream. For example, if you export the video stream as a DPX file sequence, you can select a standalone audio file format (.aiff, .wav, .mp3, etc.). [Wiretap Gateway Supported Media File Formats](#) (page 1902) for a complete list of supported media file formats.

**Compression:** Use to select the audio compression settings. Options are:

**Sampling:** Use to define the sampling frequency of exported audio files. Options are:

- Native
- 11Khz
- 22Khz
- 44.1Khz
- 48Khz

Lustre's behavior when exporting audio depends on the type of render mode selected. To export media files with audio, Lustre uses the grade-based audio file when the Media Origin is set to OneSequence. If you select Source Grade or Original Media and you are working with media files that contain audio media, such as Quicktime, MXF, R3D, the exported audio will come from the source media files.

**Profile:** When exporting Quicktime movies with PCM audio, you can select an audio encoding profile to define the bit depth and the bit ordering. The following profiles are available:

- 16-bit (LE)
- 16-bit (BE)
- 24-bit (LE)
- 24-bit (BE)
- 32-bit fp (LE)
- 32-bit fp (BE)

---

**NOTE** LE: little endian; BE: big endian. Endianness has no impact on performance, and little endian should work in most cases. Output in big endian mode if you expect compatibility issues with the target application / operating system.

---

### Summary:

- **Source Grade Renders:** Lustre uses the source audio of each clip for the render and re-encodes it to the selected format.
- **One Sequence Renders:** Lustre uses the timeline's audio and re-encodes it as one multi-channel audio track (the number of channels depends on the selected output format).
- **Original Media:** Lustre uses the source audio of each clip for the render and re-encodes it to the selected format.

---

## NOTE

- You must select an audio output format that supports the number of audio channels you are exporting. For example, if you are exporting a four channel audio file to mp3, channels 3 and 4 will be discarded during the encoding as the mp3 format only supports up to two channels.
  - When exporting audio, Lustre will re-encode to the bit depth of either your source audio or your timeline audio, based on your export mode, as long as the selected output format supports that bit depth. If it does not support the bit depth, the export defaults to a lower bit depth, supported by the selected output format.
- 

## The Resize Tab

Adjust the values in the Resize Options tab to define the destination resolution and the framing of the exported media.

**Output Resolution:** Use to define the output resolution, aspect ratio, bit depth and scan mode of the exported media.

**Resolution Field:** Use to set custom resolution values.

**Aspect Ratio Field:** Select from a list of preset aspect ratios or set your own value.

**Bit Depth Field:** Use to define the bit depth of exported media.

**Scan Mode Field:** Use to define the scan mode of exported media.

**Resize Options:** Use to define the Fit Method, Resize Filter type, the Precision and the Crispness/Softness of the exported media.

**Fit Method Box:** Use to select the Fit Method applied to exported media. Options are:

- Fill (the default option)
- Crop Edges
- Letterbox
- Center/Crop

**Resize Filter Type Box:** Use to select the Resize Filter type applied to exported media. Options are:

- Impulse
- Triangle
- Mitchell
- Bicubic
- Quadratic
- Gaussian
- Shannon
- Lanczos

**Aspect Button:** Enable to use non-square pixel formats. This option is automatically enabled when Fit Method is set to Crop Edges or Letterbox.

**Precision Field:** Use to set the frequency cut-off point used during the Resize.

**Crisp/Soft Field:** Use to set the amount of blur used during the Resize.

## The LUT Options Tab

Use the Render / Export / LUT Options menu to apply a LUT or colour transform to exported media.

**Enable:** Apply the selected LUT or colour transform when exporting.

**Output LUT type:** Select 1D LUT, 3D LUT, or Colour Transform.

**Output LUT list:** Select a LUT or colour transform to apply to exported media.

**Browse (...) button:** Press to open the file browser to navigate to a LUT or colour transform file.

**NOTE** The Wiretap Gateway supports Flame-compatible 1D and 3D LUT files only. Lustre-compatible 1D and 3D LUT files are not supported.

## Export Versions

Export Versions contain all the data required to define an export job and are stored alongside the grade metadata files.

You can create, update, load and delete Export Versions.

### To Create an Export Version

- 1 Define your export settings in the Export tabs.
- 2 Type a comment to identify your Export Version in the Export Version Comment field.
- 3 Click New.

Your Export Version is saved and displayed in the Export Version List.

### To Load an Export Version

- 1 Select the Export Version you want to load from the list.
- 2 Click Load.

Your Export Version is loaded and the export settings are updated.

### To Update an Export Version

- 1 Make sure the Export Version you want to update is loaded.
- 2 Modify the parameters as needed.
- 3 Click Save.

The Export Version is updated.

### To Delete an Export Version

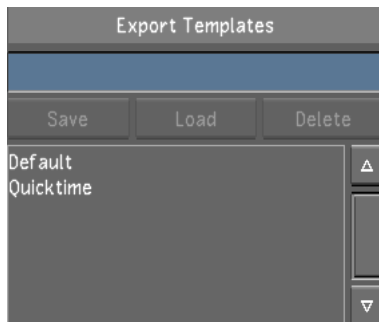

- 1 Make sure the Export Version you want to delete is loaded.
- 2 Click Delete.

Your Export Version is deleted.

## Using Export Templates

Use templates to automatically define one or multiple export versions. If for a given project you need to consistently provide the same file types, use Templates to easily create the required versions. You can create, update, load and delete Export Templates.

Export Templates contain one or more Export Versions. When you load an Export Template, the Export Versions contained within the template are appended to the currently displayed Export Versions. If you wish to overwrite the currently displayed Export Versions when you load your template, press the Alt key when clicking the Load button.

### **To Create an Export Template**

- 1 Make sure you have saved at least one Export Version.
- 2 Type a name to identify your Export Template in the Export Template Name field.
- 3 Click Save.

Your Export Template is saved and is displayed in the Export Template List.

### **To Load an Export Template (Append)**

- 1 Select the Export Template you want to load from the list.
- 2 Click Load.

Your Export Template is loaded and the Export Version list is updated.

### **To Load an Export Template (Overwrite)**

- 1 Select the Export Template you want to load from the list.
- 2 Hold the Alt key.
- 3 Click Load.

Your Export Template is loaded and the Export Version list is updated.

### **To Update an Export Template**

- 1 Make sure the Export Template you wish to update is loaded.
- 2 Modify the export parameters and save one or more new Export Versions.
- 3 Click Save.

The Export Template is updated to contain the new Export Versions.

### **To Delete an Export Template**

- 1 Make sure the Export Template you wish to delete is loaded.
- 2 Click Delete.

Your Export Template is deleted.

### **Preset Export Templates**

You can also choose from a list of preset export templates to use for the following applications and devices:

:

- Avid® Media Composer® software
- Apple® Final Cut Pro® application
- Adobe® Flash®
- Apple® iPod®
- Apple® iPad®
- Apple® iPad® 2
- Apple® iPhone®
- Apple® iPhone® 4
- Apple® iPhone® 4S

- Apple® iPod® Touch
- Apple® TV
- Apple® TV 2
- Blu-ray™
- BlackBerry® PlayBook™ tablet
- DivX®
- Microsoft® Silverlight®
- Sony® PSP®

Preset Export Template:	File Size Estimate (30 second clip with two audio tracks at 23.97 fps):
Apple_FinalCutpro_1080p_online	431M
Apple_FinalCutpro_1080p_online_444	906M
Apple_FinalCutpro_1080p_online_HQ	614M
Apple_FinalCutpro_1080p_online_HQ	210M
Apple_FinalCutpro_720p_online_444	462M
Apple_FinalCutpro_720p_online_HQ	319M
Apple_FinalCutpro_960p_offline	123M
Adobe_Flash_320x240_300Kbits	2.7M
Adobe_Flash_640x480_670Kbits	4.0M
Apple_iPad_1024x576_1_8Mbits	13M
Apple_iPad_1280x720_1_8Mbits	13M
Apple_iPhone_640x480_1_5Mbits	5.1M
Apple_iPod_320x240_600Kbits	3.7M
Apple_iPod_640x480_970Kbits	5.1M
Apple_TV_1280x720_4_5Mbits	13M
AVC_HD_1920x1080_20Mbits	76M
AVC_Intra_1440x1080_54Mbits	166M

Preset Export Template:	File Size Estimate (30 second clip with two audio tracks at 23.97 fps):
AVC_Intra_1920x1080_111Mbits	330M
Avid_MediaComposer_1080p_offline	141M
Avid_MediaComposer_1080p_online_10bit	648M
Avid_MediaComposer_1080p_online	648M
Avid_MediaComposer_720p_offline	220M
Avid_MediaComposer_720p_online	333M
Avid_MediaComposer_720p_online	333M
BlackBerry_PlayBook_1920x1080_12Mbits	11M
BlackBerry_PlayBook_1920x1080_20Mbits	11M
BlackBerry_PlayBook_1920x1080_4Mbits	11M
Divx_1920x1080_2Mbits	77M
HDTV_1080i_10Mbits	38M
HDTV_720p_8Mbits	35M

## Export Workflows

Example workflows used with the Background Media Export feature in Lustre 2013.

### Final Project Delivery Workflow

When your project is finished and ready to be digitally delivered, you can use the following workflow.

- 1 Render your project in One Sequence mode.
- 2 In the Render/Export menu, create a new Export version. **See** [Export Versions](#) (page 2292).
- 3 Set the Media Origin field to One Sequence Renders.
- 4 Set the Region field to Scene to export all shots.
- 5 If the sequence has audio media and that you want to be included in the export, enable the Video & Audio option.
- 6 Set the Video File Format and the Compression type or select a profile, if available.
- 7 If the Media Origin field is set to Audio & Video, set the Audio File Format and Compression type.
- 8 Define the File Name using tokens or an actual alphanumeric filename.
- 9 Define the Export Destination.

**10** Save your Export Version.

**11** Click Export.

The Export process is started and the resulting media - in this case one file sequence, with audio if selected - will be saved at your defined destination.

If the grade is not rendered before you click Export, Lustre warns you and automatically starts the render, and then the export.

If your workstation is setup with a Burn configuration, you can now send Media Export jobs without first having to render your grades in the foreground. Both processes take place in the background. After the grades are rendered, the Media Export jobs start. This allows you to send multiple jobs for Media Export without having to wait for foreground grade rendering. See [Remote Rendering with Burn and Wiretap](#) (page 2276).

If you need to deliver the same grade in other file formats, create a new Export Version and define the various parameters for the chosen file format.

If you want to export multiple versions, enable the Export All Versions option and press Export.

### **Production Dailies for Editorial Workflow**

When working with digitally acquired content like RED and ARRIRAW, post facilities are often asked to deliver graded production material to Editorial, often in various file formats. The following workflow can accommodate this situation.

- 1** Import the source clips you need to grade.
- 2** Create a new Cut and a new Grade.
- 3** Grade the content.
- 4** In the Render/Export menu, create a new Export version. **See** [Export Versions](#) (page 2292).
- 5** Set the Media Origin field to Source Grade Renders.
- 6** Set the Region field to Scene to export all shots.
- 7** If the sequence has audio media and that you want to be included in the export, enable the Video & Audio option.
- 8** Set the Video File Format and the Compression type or select a profile, if available.
- 9** If the Media Origin field is set to Audio & Video, set the Audio File Format and Compression type.
- 10** Define the File Name using tokens or an actual alphanumeric file name.
- 11** Define the Export Destination.
- 12** Save your Export Version.
- 13** Press Export.

The Export process is started and the resulting media - in this case the individual source clips that comprise your sequence, with audio if selected - will be saved at your defined destination.

If the grade is not rendered before you click Export, Lustre warns you and automatically starts the render, and then the export.

If you need to deliver the same grade in other file formats, create a new Export Version and define the various parameters for the chosen file format.

If you want to export multiple versions, enable the Export All Versions option and press Export

### **Media Conversion Workflow**

When you need to deliver media files of a given format into another one, with or without audio, the following workflow can accommodate this situation.

This workflow is similar to the Production Dailies for Editorial workflow but does not require media rendering since the exported media is not graded. Only the original media is exported.

The steps are identical to the Production Dailies for Editorial workflow except that you need to set the Media Origin to Original Media.

## Stand-Alone Wiretap Gateway Server Configuration for Media Encoding

To use a stand-alone Linux or Mac OSX remote Wiretap Gateway server for media encoding, follow the instructions below.

- 1 Install Backburner 2013.
  - Add the name of your Backburner Manager in `/usr/discreet/backburner/cfg/manager.host`. In most cases, the Backburner Manager to use is the one installed on your creative workstation.
  - Restart Backburner manager.
- 2 Install Wiretap Gateway 2013.
- 3 Restart the Wiretap Gateway Server.

## Media Export in Lustre with Incinerator

When using the Media Export feature in Lustre with Incinerator, it is important to keep certain considerations in mind.

The Incinerator configuration uses Browsed and Lustre Media Server (LMS) for media access over InfiniBand. In this configuration, the Backburner Manager runs on the LMS. You must configure the remote server (Linux / Mac OS X) to use the LMS as the Backburner Manager.

To speed up media transfers between the LMS and the Linux servers used for media export, make sure the Wiretap Gateway configuration file is set to use InfiniBand as the main network interface. To achieve this:

- 1 As root, open the following file: `/usr/discreet/wiretapgateway/cfg/wiretapgateway.cfg`.
- 2 Define the server IP address in the IP0 line: `IP0=10.0.10.1`
- 3 Save the file.
- 4 Restart the Wiretap Gateway server with the following command: `/etc/init.d/wiretapgateway restart`.

Your Wiretap Gateway server is now configured to use InfiniBand as the main network interface.

## Video Capture and Video Playout

During the colour grading process, you may need to capture or playout video and audio from, or record to, an external device, such as a VTR.

For example, you may receive an edited HD or SD video tape to grade with Lustre. Or, you may be given raw footage on video tapes and an EDL to auto-conform in Lustre, and then colour grade.

During capture, the files are created on-the-fly and are available after capturing is completed.

---

**NOTE** When capturing video from an HD or SD tape and converting to a DPX file, Lustre writes the SMPTE timecode to the DPX header. Once captured, the timecode appears as part of the DPX file information and is available for use in EDL assembly.

---

After grading a scene, you play it out to a VTR for client approval or for final delivery on HD or SD tapes.

**NOTE** The availability of SDI video rasters, which are required to control a VTR, depends on the type of license you have purchased. Contact Customer Support for details.

But before you can capture from, or play out to, an external device, you set up options such as the capture path, file type, and video resolution, as well as options for transferring shots between Lustre and a VTR.

## About Audio Tracks

When capturing and recording, you can transfer one video track and up to 16 audio tracks (eight tracks of DVS/AJA AES audio, or 16 tracks of embedded AJA audio). In Lustre, audio tracks are identified as A1 through A16. You can select non-consecutive tracks (for example, you can select tracks A1, A5, and A8).

You can capture, playback, and play out audio in two different ways:

- Audio embedded with video, coming from or going to the SDI connectors ('Embedded' option)
- Audio going through XLR cables from or to the DVS or AJA breakout box ('AES' option)

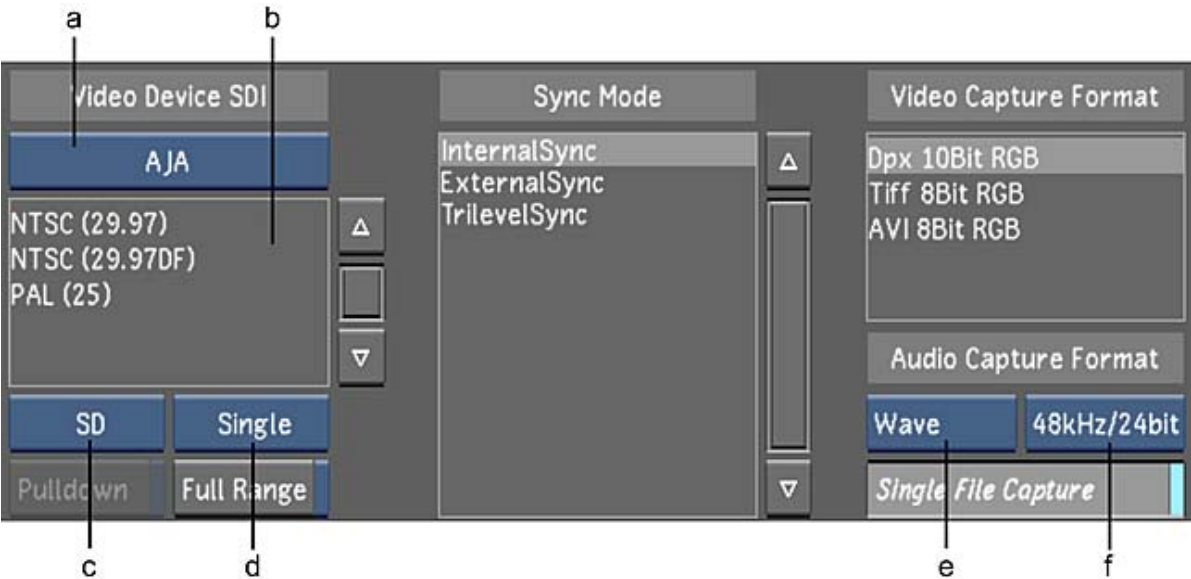

For more information on capturing, playing back, and playing out audio, see [Audio](#) (page 2347).

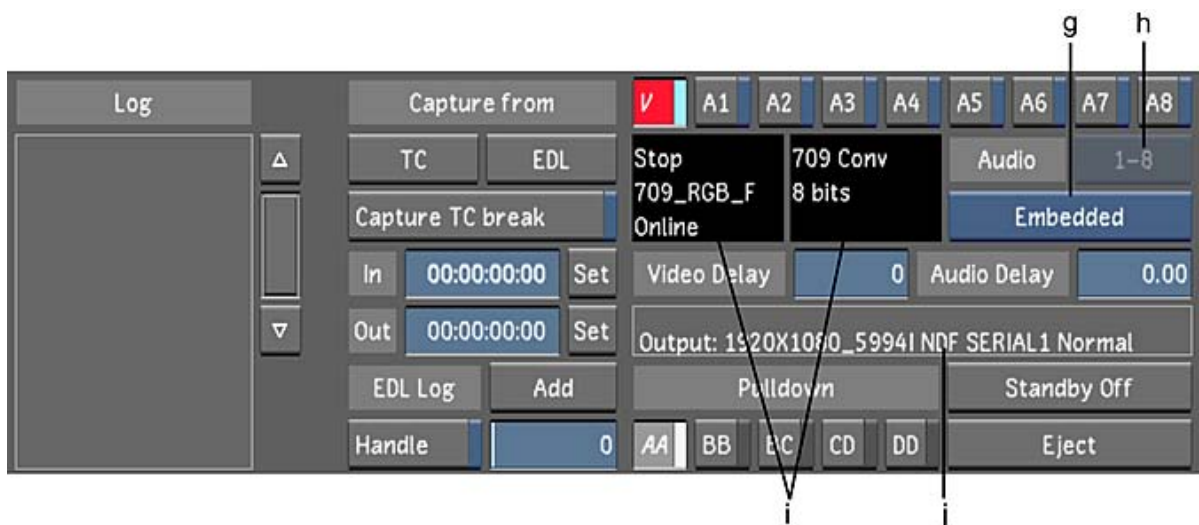

## Capture Menu Options

Use the Capture menu to perform your VTR capture operations.

**NOTE** Capture can only be done using the DVS or AJA video cards. The GFX/SDI options listed below are provided as reference only and should not be used during the capture.

The following three graphics represent the Capture menu.

Naming	
Home	C:\Footage\New\Projects\Project
Scene	scene01
Capture	capture
Tape	<TAPE>
Resolution	<RES>
File	<NUM7>.dpx

(a) Video/Graphics option box (b) Raster list (c) Format option box (d) Link Type option box (e) Audio File Type option box (f) Sampling Rate/Bit Depth option box (g) Audio Input button (h) Audio Track Selection option box (i) VTR Status panel (j) Capture Error status

**Video/Graphics option box** Toggle between the video card (AJA or DVS) and the graphics card (GFX/SDI). The Raster list is then populated with rasters for the selected card.

**WARNING** When capturing, do not select a raster for the GFX/SDI card. Doing so is not supported and can result in failed capture.

**Raster list** With a video card selected in the Video option box (AVIO), select one of the listed rasters to set the resolution and timing for capture. For more information about rasters, see [Supported Video SDI and GFX SDI Rasters](#) (page 2339).

**Format option box** Toggle to display only rasters belonging to a particular footage format in the Raster list.

Select:	To display:
SD	Standard definition rasters.
HD	High definition rasters.

Select:	To display:
Film	Film rasters.
Audio	Audio rasters (only applicable to GFX/SDI).

**NOTE** Enable an Audio Only raster when monitoring the GFX/SDI output and working with audio signal coming out of the AJA/DVS breakout box. This is similar to working with audio media or to using the LTC chase feature with a DVS.

**Link Type option box** Toggle to display only rasters belonging to a particular link type in the Raster list.

Select:	To display:
Single	The single link rasters.
Dual	The dual link rasters.
Stereo	The stereoscopy rasters (only applicable to GFX / SDI).

**Pulldown button** Enable to remove 3:2 pulldown from Film-to-video transferred material. See [Removing Pulldown when Capturing](#) (page 2306).

**Full Range button** Enable to configure Lustre to capture the full video signal from the video board. If disabled, Lustre captures only the legal portion of the video signal.

**Sync Mode list** Select one of the sync modes.

Select:	To:
InternalSync	Set the sync mode to a free running internal sync (SD and HD).
ExternalSync	Genlock to an analog sync connected to the sync input (SD only).
TrilevelSync	Genlock to a trilevel sync connected to the sync input (HD only).

**Video Capture Format list** Select a video capture format to set file type, colour space, and bit depth of the captured material.

Select:	To capture only:
Dpx 10Bit RGB	DPX files with an RGB colour space at a bit depth of 10-bit.
Tiff 8Bit RGB	TIFF files with an RGB colour space at a bit depth of 8-bit.
AVI 8Bit RGB	AVI files with an RGB colour space at a bit depth of 8-bit (available only on Windows workstations.)

**Audio File Type option box** Choose whether to save audio captured from a VTR/ATR, or imported from Wiretap as a Wave (.WAV) or AIFF (.AIF) file.

**Audio Sampling Rate/Bit Depth option box** Select to capture the audio tracks at a sampling rate of 48 kilohertz (kHz) and a bit depth of 16-bit, or 48 kHz and a bit depth of 24-bit.

**Single File Capture button** When enabled, all the selected audio tracks are saved in a single file. When disabled, each audio track is saved as an individual file. This option is enabled by default.

**Log panel** Displays status messages during capture.

**TC button** Initiates a capture from VTR using timecode in and out points. See [Capturing from Timecode](#) (page 2308).

**EDL button** Initiates a capture from VTR using an EDL. See [Auto-conforming an EDL](#) (page 2314).

---

**NOTE** EDL Capture is video only; audio events are ignored.

---

**Capture TC Break button** Initiates a capture from VTR using the timecode in and out points, regardless of the number of timecode breaks. See [Capturing Media with Timecode Breaks](#) (page 2311).

**Timecode In Point field** Enter the start timecode. Press Set next to the field to set the current timecode (read from the VTR) as the in point.

**Timecode Out Point field** Enter the end timecode. Press Set next to the field to set the current timecode (read from the VTR) as the out point.

**EDL Log Add button** Logs the In and Out timecode points as an EDL for capture. See [Logging and Batch Digitizing](#) (page 2312).

---

**NOTE** Only video events are supported for EDL logging.

---

**Handle button** Enable to capture heads and tails. This feature is used when capturing from an EDL or from timecode.

---

**NOTE** You must enable the Handle button in order to use the Handle slider.

---

**Handle slider** Set the number of head and tail frames to capture.

**V button** Enable to capture the video track when capturing from a video source. Disable to capture audio only.

**A1 - A16 buttons** Enable the audio track(s) (A1-A16) to capture from an audio source.

**VTR Status panel** Displays the VTR status messages when Lustre is connected to a VTR.

**Audio Track Selection option box** Used in correlation with the A1-A16 buttons. Toggle to determine whether tracks 1-8 or 9-16 are visible. Tracks 9-16 are only available with embedded AJA audio. If only eight audio tracks are available, this option is disabled (greyed out).

**Audio Input option box** Toggle to specify the source of the captured audio.

Select:	To specify the connection to the audio source:
Embedded	The SDI connection.
AES	The XLR connections on the DVS/AJA breakout box.

**Video Delay field** Enter a frame number to delay the video capture for that number of fields. For example, if you set the field to 10, the capture begins 10 frames after the In point. If you set the field to -10, capture begins 10 frames before the In point.

**Audio Delay field** Enter a frame number to delay the audio capture for that number of fields. For example, if you set the field to 10, the audio capture begins 10 frames after the In point.

---

**NOTE** The Video and Audio Delay fields compensate for the frame delays that may exist when capturing to Lustre.

---

**Capture Error status** Displays a message when an error has occurred while capturing from a VTR.

**Pulldown Field buttons** Enable a Pulldown Field button to select the frame used for the 3:2 pulldown. Only available when Pulldown is enabled. See [About 3:2 Pulldown](#) (page 2338).

**Standby Off button** Removes the VTR heads from the tape.

**Eject button** Ejects the tape in the VTR.

**Home field** Displays the project home directory. This is the destination path for captured footage. You cannot change this value without modifying your project settings.

**Scene field** Displays the current scene you are working in during capture. You cannot change this value without modifying your project settings.

**Capture field** Enter the name of the folder where video media is saved.

**Tape field** Displays the tape name. When capturing in TC mode, enter a tape name. When capturing from an EDL, the default tape name is determined by that EDL. If you capture an EDL with multiple tapes, a folder structure (<tape>/<resolution>/) is created for each tape (e.g., 0001/1920x1080).

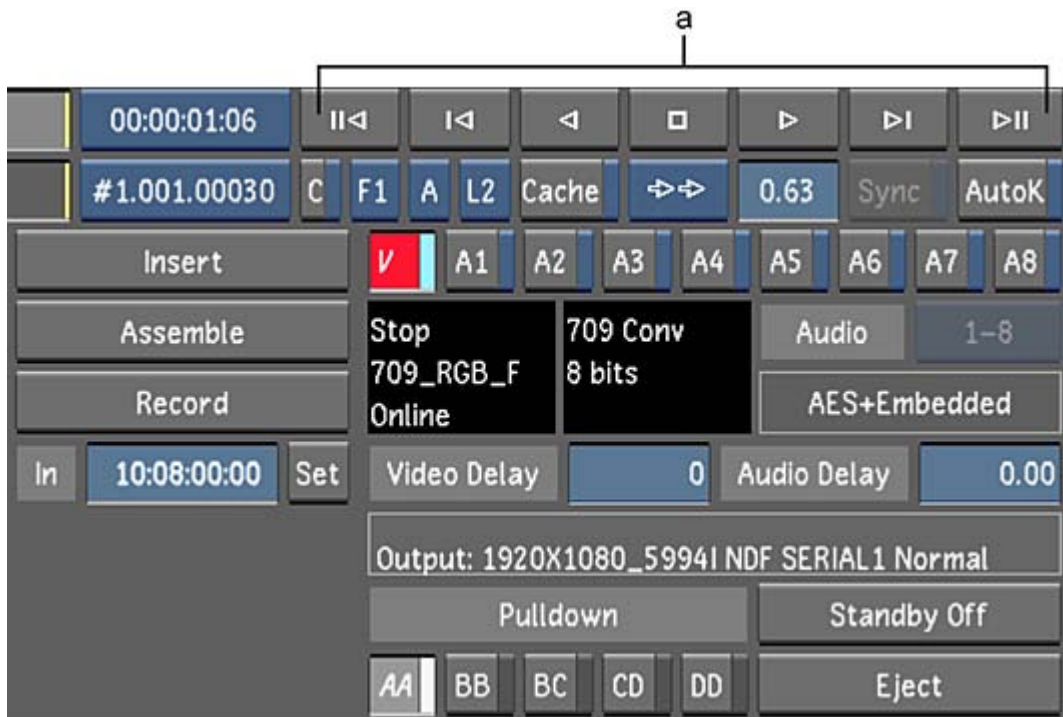

**Resolution field** Defaults to the resolution of the captured files, and is used in the folder structure. Do not change this field.

**File field** Displays the filename, which is the frame offset value based on the source timecode (e.g., 84600.dpx is 1:00:00:00 at 24 fps). <NUM7> defines the amount of padding for the file name (for example, 084600.dpx reflects six digits of padding before the extension). You can add a prefix before the <NUM7> number, but to ensure consistent frame counting, do not erase the <NUM7> number (e.g., Mymovietitle.084600.dpx).

## Controlling the VTR

When working with a VTR, you can use the VTR transport controls to play through the video tape and locate your footage. As you find your footage, you can capture it immediately, or add shots to a list that you can batch digitize all at once.

You can also use the transport controls to cue up a VTR to the record in point when playing out to the VTR.

(a) VTR transport controls

**NOTE** To control the VTR remotely, you must connect a 9-pin RS-422 cable between the VTR and Lustre. For information, refer to the *Autodesk Lustre Software Installation Guide* for your platform.

#### To control the VTR:

- 1 Do one of the following:
  - If performing capture operations in the Capture menu, click the Source Timecode field. The capture controls turn blue to indicate that you can use them as VTR transport controls.
  - If performing playout operations in the Playout menu, click the Source Timecode field. The playback controls turn blue to indicate that you can use them as VTR transport controls.

**NOTE** In the Playout menu, you can toggle between the timeline and VTR by clicking on the Source Timecode field. If the Source Timecode field is blue, the controls can be used as VTR transport controls. If the controls are white, they are timeline controls.

(a) Source Timecode field

The transport controls are as follows.

Click:	To:
	Fast rewind.

Click:	To:
	Cue to TC In. Right-click to jog back one frame.
	Play in reverse.
	Stop the VTR.
	Play forward.
	Cue to TC Out. Right-click to jog ahead one frame.
	Fast forward.

2 To eject the tape in the VTR, click Eject in the Capture menu.

**NOTE** You can also control the VTR from the Playout menu. See [Playing Out to a VTR](#) (page 2321).

## Capturing Material

Use the Capture menu to digitize material from an external source. You can digitize in any one of the following ways:

- Digitize one event at a time by capturing from timecode values. See [Capturing from Timecode](#) (page 2308).
- Digitize events from an external source that has various timecode breaks. See [Capturing Media with Timecode Breaks](#) (page 2311).
- Batch digitize from a Log file. See [Logging and Batch Digitizing](#) (page 2312).
- Batch digitize from an imported EDL. See [Auto-conforming an EDL](#) (page 2314).
- Perform a live capture from non-controlled sources. See [Performing a Live Capture from a Non-Controlled Source](#) (page 2317).

For certain video formats, you can remove pulldown when capturing. See [Removing Pulldown when Capturing](#) (page 2306).

## Selecting a Raster for Capture

Whenever capturing material, you must select a raster. For a list of the supported rasters, see [Supported Video SDI and GFX SDI Rasters](#) (page 2339).

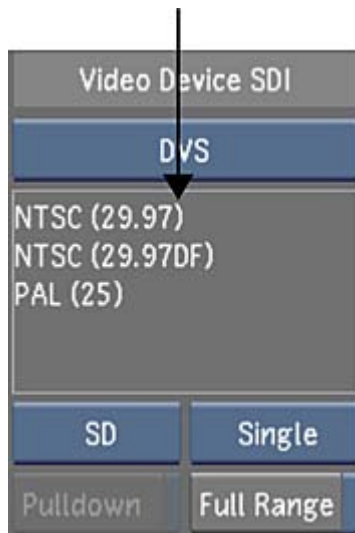

---

**NOTE** When you select a drop frame (DF) video format, the timecodes are calculated in Drop Frame mode.

---

**To select a raster for capture:**

- 1 In the Video Device SDI group, toggle the Video/Graphics option box to display your video card (AVIO). See [Capture Menu Options](#) (page 2299).
- 2 Select an option from the Link Type box. Select Single for a 4:2:2 video signal, and Dual for a 4:4:4 video signal.
- 3 Toggle the Format option box to the required raster format (SD, HD, Film, or Audio).
- 4 In the Raster list, select the raster that matches the material to capture.

**NOTE** If clicking on a raster in the Raster list does not select the item, that format is not available for capture on that system.

- 5 (Optional) Remove 3:2 pulldown frames on capture. See [Removing Pulldown when Capturing](#) (page 2306).

## Removing Pulldown when Capturing

Depending on the type of source material you are working from, you may need to remove 3:2 pulldown frames at capture time. For more information about 3:2 pulldown, see [About 3:2 Pulldown](#) (page 2338).

---

**NOTE** Inconstant cadence material (i.e., re-edited material) may produce jittery results.

---

**To remove 3:2 pulldown during capture:**

- 1 Click Pull down.
- 2 Use the VTR to shuttle to the first frame you want to capture.

(a) Pulldown Field buttons

- 3 Enable the Pulldown Field button that matches the field composition of that frame.

## Setting In and Out Points

You can set in and out points to select the material to capture from an external video source.

**To set in and out points:**

- 1 Set the in point. Use one of the following techniques:
  - Enter the in point timecode by typing the value directly in the In field.
  - Navigate to the in point using the VTR transport controls, and then, in the Capture from group, click Set next to the In field.

- 2 Set the out point. Use one of the following techniques:
  - Enter the out point timecode by typing the value directly in the Out field.
  - Use the VTR transport controls to navigate to the out point, and then, in the Capture from group, click Set next to the Out field.

## Capturing from Timecode

In capturing from timecode mode, you capture one shot by marking the length of the shot with in and out timecode values. You can either enter the timecode values manually or scrub the VTR to the in and out points. You also have the option of capturing video only, audio only, or audio along with the video.

**To capture from timecode:**

- 1 Click Editing, and then click Capture.  
The Capture menu appears.
- 2 In the Naming group, enter values in Capture and Tape. See [Capture Menu Options](#) (page 2299).

Naming	
Home	C:\Footage\New\Projects\Project
Scene	scene01
Capture	capture
Tape	<TAPE>
Resolution	<RES>
File	<NUM7>.dpx

- 3 Select a raster for capture. See [Selecting a Raster for Capture](#) (page 2305).
- 4 In the Sync Mode list, select a synchronization option. See [Capture Menu Options](#) (page 2299).
- 5 In the Video Capture Format list, select a file format. See [Capture Menu Options](#) (page 2299).

Video Capture Format	
Dpx 10Bit RGB	
Tiff 8Bit RGB	
AVI 8Bit RGB	
Audio Capture Format	
Wave	48kHz/24bit
Single File Capture	

**NOTE** The AVI format is only available on Windows workstations.

- 6 Select the audio file type, bit depth, and determine if you want to capture the audio tracks as a single or multiple files. Single File Capture is enabled by default. For more information about capturing audio, see [Capturing an Audio File](#) (page 2350).
- 7 (Optional) Set video and audio capture delays. See [Capture Menu Options](#) (page 2299).
- 8 Select the video and audio tracks to capture. See [Capture Menu Options](#) (page 2299).
- 9 Set the in and out points. See [Setting In and Out Points](#) (page 2307).
- 10 In the Capture from group, click TC. When the button turns red, click it again to confirm the action.

The capture starts. The VTR shuttles back to the in point and begins capturing. The VTR's current timecode and remaining timecode are displayed in a field located to the left of the playback controls. While capturing, both timecodes update and appear in red.

(a) VTR timecode remaining (b) Current VTR timecode

During capture, the message "Capturing from tape..." appears in the Player, and progress bars display shot, tape, and overall progress. There is no video displayed in the Player during capture.

(a) Shot progress (b) Tape progress (c) Overall progress

- 11 (Optional) To pause the capture process to access additional capture options, press `ESC`, and then do one of the following:
- Press `ESC` to abort the capture.
  - Press `E` to restart the capture.
  - Press `S` to skip the current tape.

## Capturing Media with Timecode Breaks

The Capture with Timecode Breaks feature allows you to capture all the content of a tape, regardless of the number of timecode breaks. When you use this option, Lustre begins capturing from the given in point until the duration point has been reached. A file sequence is created for each continuous timecode section.

To use this feature properly, you need to make sure you are entering the correct values for the in and out point. The in point is the source timecode of where you want the capture to begin. In the following procedure, the in point is set at 10:00:00:00 (as an example). The out point is used to compute the duration of capture. In the procedure, the out point is set at 10:10:00:00. This represents that ten minutes of footage will be captured, regardless of the number of timecode breaks within this time frame.

---

**NOTE** The pulldown removal option and audio capture feature are not supported when capturing with timecode breaks.

---

### To capture media that contains timecode breaks:

- 1 Click Editing, and then click Capture to display the Capture menu.
- 2 Enable the Capture TC break button.

- 3 Make sure the video track button is enabled.
- 4 In the timecode in point field, enter the point of where you want the capture to begin (e.g., 10:00:00:00).
- 5 In the timecode out point field, enter a timecode that is used to compute the duration of the capture (e.g., 10:10:00:00, to represent ten minutes of capture).

- 6 Click TC. When the button turns red, click it again to confirm the action. The capture starts.

## Logging and Batch Digitizing

You can log shots and batch digitize them. To do this, you shuttle through the tape, mark in and out points that correspond to the sections you want to digitize, and then add those sections to a list of shots to digitize all at once.

---

**NOTE** This operation only logs and captures video.

---

### To batch digitize shots from a video tape:

- 1 Click Editing, and then click Capture.  
The Capture menu appears.
- 2 Select a raster for capture. See [Selecting a Raster for Capture](#) (page 2305).
- 3 In the Video Capture Format list, select the file format that you want to create during the capture operation.
- 4 In the Naming group, enter values in the Capture and Tape fields. See [Capture Menu Options](#) (page 2299).

**WARNING** It is important that you enter a tape name to avoid overwriting previously captured files.

- 5 Set the in and out points. See [Setting In and Out Points](#) (page 2307).
- 6 In the EDL Log group, click Add to add the selected material to the events list.

- 7 To view the events list, click Editing, and then Assemble.

You need to mark the captures before returning to the Capture menu: click in the Event column to select an entry, or click Select All, and then click Mark for Capture. The entries marked for batch digitization appear in the Assemble menu.

- 8 Continue adding entries to the events list as needed.
- 9 (Optional) To delete an entry from the events list, select it from the Assemble window and click Delete Selected. Click it a second time to confirm the action. To clear the list, click Delete All.

- 10 When you are ready to digitize, return to the Capture menu.
- 11 In the Capture from group, click EDL once and then confirm the action by clicking EDL a second time.

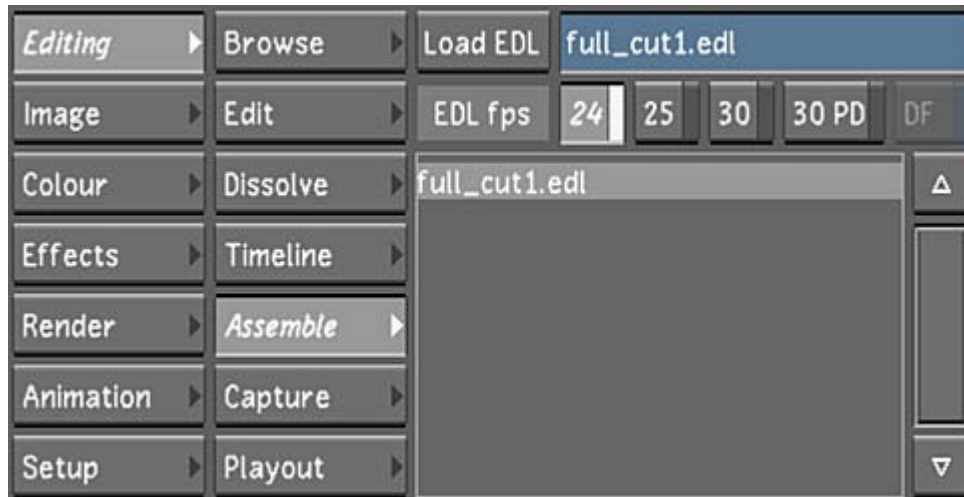

## Auto-conforming an EDL

You can automatically digitize material using instructions contained in an EDL, and then assemble the digitized events into a cut which appears in the Storyboard and the timeline.

You can batch digitize from an EDL that has been placed in the current scene's Library directory. This directory is located under *<HOME>\<scenename>\*.

**To capture from an EDL:**

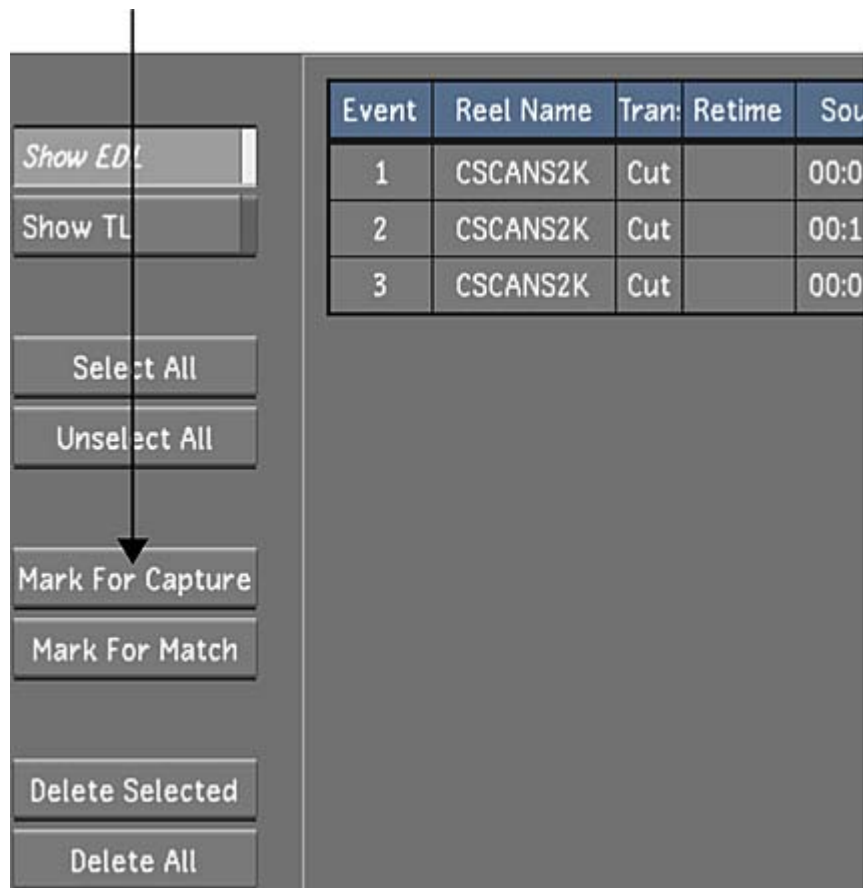

- 1 Make sure your EDL file is in the scene's Library directory.  
**NOTE** If the file is in the wrong location, it will not show up in the EDL list.
- 2 Click Editing, and then click Capture.
- 3 Select a raster for capture. See [Selecting a Raster for Capture](#) (page 2305).
- 4 Click Assemble to access the Assemble window.

- 5 Select an EDL file from the EDL list. **Ctrl**-click the EDL list to refresh it.

- 6 Click Load EDL to display the EDL contents in the Assemble menu.
- 7 Select individual events to capture (**Ctrl**+click), a group of events (**Shift**+click), or click Select All.
- 8 Click Mark for Capture.

The selected events are marked as Need Capture under the Media column of the EDL events.

- 9 Click Capture.
- 10 In the Video Capture Format list, select the file format that you want to create during the capture operation. See [Capture Menu Options](#) (page 2299).
- 11 In the Naming group, enter values in the Capture and Tape fields. See [Capture Menu Options](#) (page 2299).
- 12 Click EDL once, and then confirm the action by clicking EDL a second time.

The Capture starts.

- 13 When capture is completed, add the new shots to the Library. See [Loading Clips to the Library](#) (page 1917).
- 14 Go back to the Assemble menu and assemble the EDL. See [Assembling an EDL](#) (page 1941).
- 15 Click Browse to display the Browse menu.
- 16 Enter the name for the new cut in the Cut name field.
- 17 Click New.

The new cut is saved and named after the captured EDL.

## Performing a Live Capture from a Non-Controlled Source

You can capture live from any non-controlled source. A non-controlled source is any source with an SDI Out, such as another Lustre workstation, or a Smoke or Flame workstation. For example, you have footage residing on a Flame workstation that you need. You can connect to that workstation and input the footage directly, without going through tape output and input.

**To perform a live capture from a non-controlled source:**

- 1 Connect the SDI Out of the non-controlled source to the SDI In on the video card of the Lustre workstation.
- 2 Click Editing, and then click Capture.
- 3 Select a raster for capture. See [Selecting a Raster for Capture](#) (page 2305).
- 4 In the Capture from group, enter in and out points in the In and Out fields.

This is done in order to set the duration of the capture. The values can be anything, as long as they reflect the desired duration.

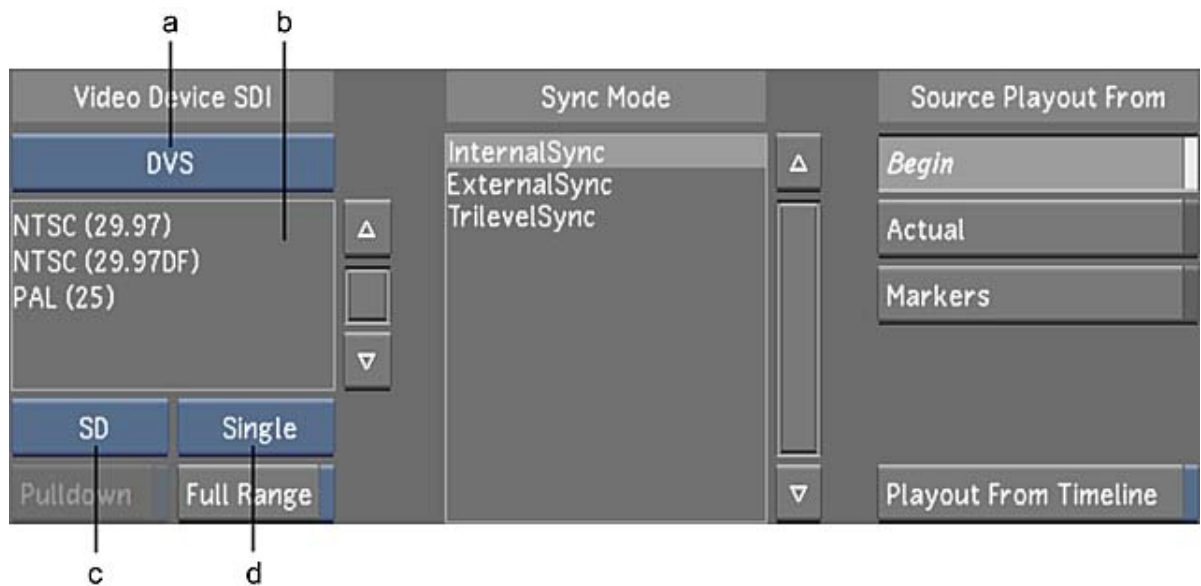

- 5 To start the capture, **Ctrl**+double-click TC.

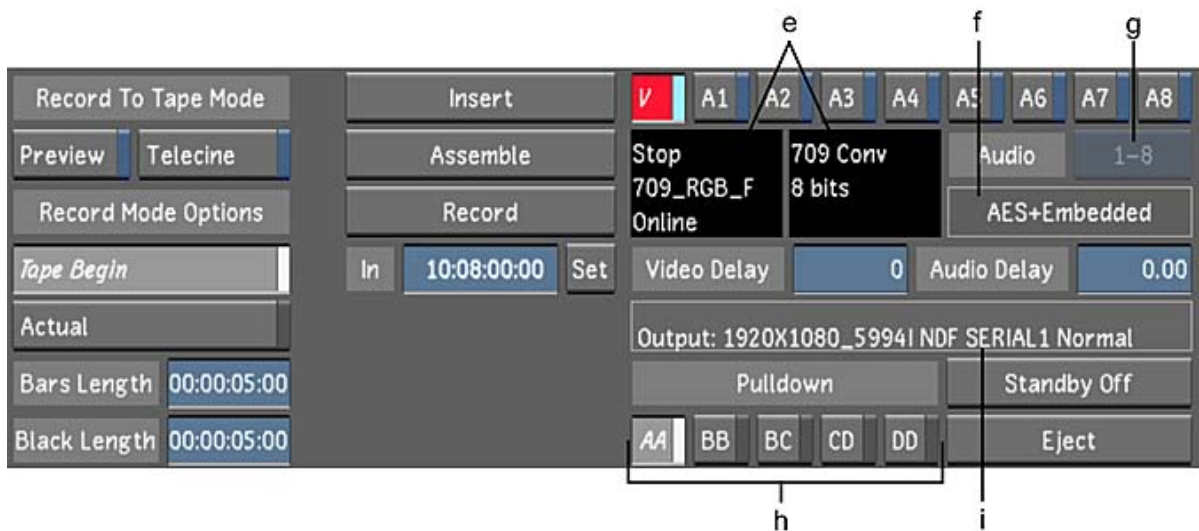

## Playout Menu Options

Use the Playout menu to play out media to a VTR.

The following two graphics represent the Playout menu.

**(a)** Video/Graphics Raster option box **(b)** Raster list **(c)** Format option box **(d)** Link Type option box **(e)** VTR Status panel **(f)** Audio Output status **(g)** Audio Track Selection option box **(h)** Pulldown Field buttons **(i)** Playout Error status

**Video/Graphics option box** Toggle between the video card (AVIO) and the graphics card (GFX/SDI). The Raster list is then populated with rasters for the selected card.

**Raster list** With a video card selected in the Video option box (AVIO), select one of the listed rasters to set the resolution and timing for capture. See [Supported Video SDI and GFX SDI Rasters](#) (page 2339).

**Format option box** Toggle to display only rasters belonging to a particular footage format in the Raster list.

Select:	To display:
SD	Standard definition rasters.
HD	High-definition rasters.
Film	Film rasters.
Audio	Audio rasters (only applicable to GFX/SDI).

**Link Type option box** Toggle to display only rasters belonging to a particular link type in the Raster list.

Select:	To display:
Single	The single-link (4:2:2 signal) rasters.
Dual	The dual-link (4:4:4 signal) rasters.
Stereo	The stereoscopy rasters (only applicable to GFX/SDI).

**Pulldown button** Enable to configure Lustre to add a pulldown frame when playing out. See [About 3:2 Pulldown](#) (page 2338).

**Full Range button** Enable to configure Lustre to play out the full video signal from the video board. If disabled, Lustre plays out only the legal portion of the video signal.

**Sync Mode list** Select one of the sync modes.

Select:	To:
InternalSync	Set the sync mode to a free-running internal sync (SD and HD).
ExternalSync	Genlock to an analog sync connected to the sync input (SD only).
TrilevelSync	Genlock to a trilevel sync connected to the sync input (HD only).

**Source Playout From buttons** Select a starting point for the playout.

Enable:	To select:
Begin	The start of the timeline as the starting point for playing out to tape.
Actual	The current position of the positioner as the starting point for playing out to tape.
Markers	The marker position as the starting point for playing out to tape.

**NOTE** Markers are In/Out marks that you can set to define the playout operation. See [Defining In and Out Markers when Playing Out to Tape](#) (page 2323).

**Playout From Timeline button** When enabled it allows you to play out source material containing secondary grading without having to perform a render first. See [Playout from Timeline with GPU Acceleration](#) (page 2336).

**Record To Tape Mode buttons** Allow you to configure Lustre to display what the edited footage would look like without recording to VTR or to play out the current timeline and send the source timecode to the VTR.

Enable:	To:
Preview	Preview the footage that will be recorded without recording to tape.
Telecine	Record the footage to tape along with its original source timecode and black media between shots. See <a href="#">Writing Telecine-Style Tape</a> (page 2331).

**Record Mode Options buttons** Define where on the tape Lustre begins recording when using the Record playout mode. For more information about Record Mode options, see [Playing Out to a VTR](#) (page 2321).

Enable:	To begin recording:
Tape Begin	At the beginning of the tape.
Actual	At the position of the current frame on the tape.

**Bars Length field** Defines the duration (in seconds) of the colour bars recorded to the video tape before the recorded footage begins.

**Black Length field** Defines the duration (in seconds) of the leader black recorded to the video tape before the recorded footage begins.

**Insert button** Initiates recording when inserting video and/or audio onto a tape that already contains material.

**Assemble button** Initiates recording of both video and audio signals on all tracks to a tape when you need to record beyond the point where the valid control track ends.

**Record button** Initiates recording of both video and audio signals on all tracks when recording an entire cut to tape.

---

**NOTE** Use the Record button to write to a new tape with no content. When you record in Record mode, Lustre writes bars and black media before the payout.

---

**In Point field** Enter the timecode of the tape where the recording will begin.

---

**NOTE** When you configure the in point, the out point is automatically set to the timecode that equals to sum of the clip duration added to the in point.

---

**In Point Set button** Sets the current timecode of the tape as the in point.

**V button** Enable to play out the video track when playing out to a video source. Disable to play out audio only.

**A1 - A16 buttons** Enable the audio tracks (A1-A16) for payout.

---

**NOTE** You can only specify specific video and audio tracks to play out if you are in Insert mode.

---

**VTR Status panel** Displays VTR status messages when Lustre is connected to a VTR.

**Audio Track Selection option box** Used in correlation with the A1-A16 buttons. Toggle to determine whether tracks 1-8 or 9-16 are visible. Tracks 9-16 are only available with embedded AJA audio. If only eight audio tracks are available, this option is disabled (greyed out).

**Audio Output status** Audio is always outputted to both AES and Embedded audio.

**Video Delay field** Enter a frame number to delay the video payout for that number of fields. For example, if you set the field to 10, payout begins 10 frames after the in point. If you set the field to -10, payout begins 10 frames before the in point.

**Audio Delay field** Enter a frame number to delay the audio payout for that number of fields. For example, if you set the field to 10, audio payout begins 10 frames after the in point. If you set the field to -10, audio payout begins 10 frames before the in point.

---

**NOTE** The Video and Audio Delay fields compensate for frame delays that may exist while transferring shots from Lustre to the output device.

---

**Payout Error status** Displays a message if an error occurs while performing a payout.

**Pulldown Field buttons** Enable a Pulldown Field button to select the frame used for the 3:2 pulldown. Only available when Pulldown is enabled. See [About 3:2 Pulldown](#) (page 2338).

**Standby Off button** Removes the VTR heads from the tape.

**Eject button** Ejects the tape in the VTR.

## Playing Out to a VTR

Use the Payout tool to play out frames from Lustre so that they can be recorded to an external device.

---

**NOTE** If you play out Telecine-style to tape, you can only play out in Assemble mode.

---

In the majority of cases, you will play out rendered frames to a VTR. See [Rendering Shots](#) (page 2259). There are exceptions:

- The creation of real-time deliverables using source material. See [Creating Real-Time Deliverables from the Timeline or Rendered Material](#) (page 2332).
- GPU playout from the timeline. See [Playout from Timeline with GPU Acceleration](#) (page 2336).

There are three modes for playing out to a VTR:

- In Insert mode, you record video only, audio only, or a combination of both, to a tape that already contains material (either pre-striped with black or actual video material with a valid control track).
- In Assemble mode, you can add video to the end of previously-recorded material.
- In Record mode, you can play out video to a blank tape or a tape that contains existing material. Everything on the tape is overwritten when recording.

For some video formats, you can add 3:2 pulldown during the playout operation. See [About 3:2 Pulldown](#) (page 2338).

## Playout Workflow

The recommended steps for playing out video to a VTR are as follows.

Step:	Refer to:
1. Render the timeline in the appropriate resolution for the VTR to which you want to play out.	<a href="#">Rendering Shots</a> (page 2259).
2. Use the transport controls to cue up the VTR to the in point.	<a href="#">Controlling the VTR</a> (page 2303).
3. (Optional) Cue up the timeline.	<a href="#">Navigating through Shots</a> (page 2018).
4. Select a playout mode.	<a href="#">Playing Out to a VTR</a> (page 2321).

## Selecting a Raster for Playout

When playing out to an external device, you must select a raster. See [Supported Video SDI and GFX SDI Rasters](#) (page 2339).

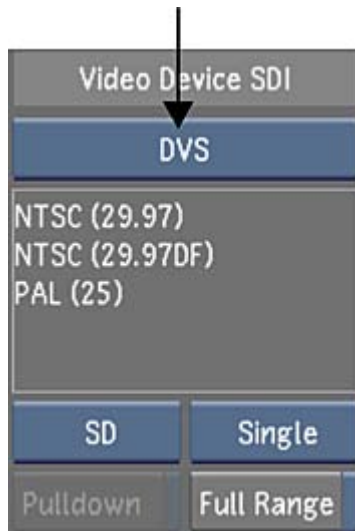

---

**NOTE** When you select a drop frame (DF) video format, the timecodes are calculated in Drop Frame mode.

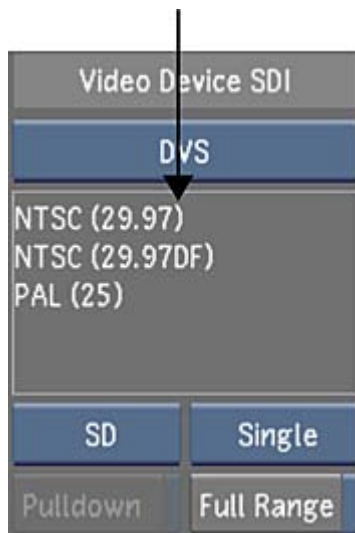

---

**To select a raster for playout:**

- 1 In the Video Device SDI group, toggle the Video/Graphics raster option box to display your video card (AVIO). See [Playout Menu Options](#) (page 2318).

- 2 Select an option from the Link Type box. Select Single for a 4:2:2 video signal, and Dual for a 4:4:4 video signal.
- 3 Toggle the Format option box to the required raster format (SD, HD, Film, or Audio).
- 4 In the Raster list, select the raster for playout.

**NOTE** If clicking on a raster in the Raster list does not select the item, that format is not available for capture on that system.

- 5 (Optional) If you need to add 3:2 pulldown frames when playing out, enable Pulldown.  
The pulldown is added to the played out video. The first frame played out becomes the AA frame in the pulldown sequence. See [About 3:2 Pulldown](#) (page 2338).

## Defining In and Out Markers when Playing Out to Tape

Users can create a video tape from a specific segment of the timeline by setting in and out points for playing out to tape. This is done using the same hot keys as for setting in and out points for playing shots in the

Player. A new option has been added to the Editing > Payout menu that lets you select the marked section for payout to tape.

**To define in and out markers when playing out to tape:**

- 1 Go to the start and end frame and mark the in and out points.

Press:	To:
Shift+I	Mark an in point.
Shift+O	Mark an out point.
Shift+L	Clear in and out points.

- 2 Click Editing, and then click Payout to display the Payout menu.
- 3 Click Markers.

**NOTE** If you enable an in point only, payout begins at that point and goes to the end of the timeline. If you enable an out point only, payout begins at the start of the timeline and ends at the out point.

## Recording in Insert Mode

Use Insert mode when you want to insert video only, audio only, or both video and audio onto a tape that already contains material. The entire area to which you are recording must have a valid, continuous control track, as this mode only plays out the video (existing timecode and audio are not affected).

**NOTE** When recording to tape, you can only configure specific video and audio tracks to play out if you are in Insert mode.

**To record in Insert mode:**

- 1 Set the VTR to Regen timecode.
- 2 Before you can play out to a VTR, you must render the timeline at the appropriate video resolution. See [Rendering Shots](#) (page 2259) and [Payout Workflow](#) (page 2322).
- 3 Click Editing, and then click Payout to display the Payout menu.
- 4 Select a raster for payout. See [Selecting a Raster for Payout](#) (page 2322).
- 5 In the Sync Mode list, select the synchronization mode. See [Payout Menu Options](#) (page 2318).
- 6 (Optional) To record only a portion of the timeline, use markers to define where, in the timeline, you wish to start and stop recording to tape. See [Defining In and Out Markers when Playing Out to Tape](#) (page 2323).

- 7 In the Source Payout From group, determine where the playout operation starts.

Click:	To start the playout:
Begin	From the start of the current timeline.
Actual	At the current frame.
Markers	At the in marker in the timeline, and stop at the out marker.

- 8 In the In field, enter the tape timecode where the video is to be inserted.

**TIP** To find the desired timecode more quickly, click the Source Timecode field next to the playback controls while still in the Playout menu. The playback controls and Source Timecode field turns blue to indicate that they can be used to control the VTR. Scrub to the desired timecode, then enter it in the In field.

- 9 (Optional) In the Record To Tape Mode group, enable Preview.

With Preview enabled, your footage is played out in the Player, but nothing is written to tape. The Insert button turns green after the first click to show that the action is non-destructive.

- 10 (Optional) Configure video and audio record delay. See [Playout Menu Options](#) (page 2318).
- 11 Configure Lustre to record specific video and audio tracks to tape. See [Playout Menu Options](#) (page 2318).
- 12 Click Insert, and then click it again to confirm the action.

**TIP** To record a single shot as opposed to the entire timeline, select the shot you want to play out and hold down **SHIFT** while clicking Insert.

The playout operation begins.

## Recording in Assemble Mode

Use Assemble mode when recording on a tape that contains a valid control track up until a certain point, but you need to record beyond that point. In Assemble mode, you are attaching video and audio to existing material. For example, yesterday you played out your work onto a blank tape using Record mode. Today, you have completed additional work and would like to add it to the end of the tape. In this case, you cue the tape to the in point (at a point where there is a valid control track) and begin playing out in Assemble mode. The timecode is continued from the previously recorded material.

---

**NOTE** When recording to tape, you can only configure specific video and audio tracks to play out if you are in Insert mode.

---

### To record in Assemble mode:

- 1 Set the VTR to Regen timecode.
- 2 Before you can play out to a VTR, you must render the timeline at the appropriate video resolution. See [Rendering Shots](#) (page 2259) and [Playout Workflow](#) (page 2322).
- 3 Click Editing, and then click Playout to display the Playout menu.
- 4 Select a raster for playout. See [Selecting a Raster for Playout](#) (page 2322).
- 5 In the Sync Mode list, select the synchronization mode. See [Playout Menu Options](#) (page 2318).
- 6 (Optional) To record only a portion of the timeline, use markers to define where, in the timeline, you wish to start and stop recording to tape. See [Defining In and Out Markers when Playing Out to Tape](#) (page 2323).
- 7 In the Source Playout From group, determine where the playout operation starts.

Click:	To start the playout:
Begin	From the start of the current timeline.
Actual	At the current frame.
Markers	At the in marker in the timeline, and stop at the out marker.

- 8 In the In field, enter the tape timecode where the video is to be edited.

**TIP** To find the desired timecode more quickly, click the Source Timecode field next to the playback controls while still in the Playout menu. The playback controls and Source Timecode field turns blue to indicate that they can be used to control the VTR. Scrub to the desired timecode, then enter it in the Tape Rec IN field.

- 9 (Optional) In the Record To Tape Mode group, enable Preview.

With Preview enabled, your footage is played out in the Player, but nothing is written to tape. The Insert button turns green after the first click to show that the action is non-destructive.

- 10 (Optional) Enable Telecine. See [Writing Telecine-Style Tape](#) (page 2331).
- 11 (Optional) Configure video and audio record delay. See [Playout Menu Options](#) (page 2318).
- 12 Click Assemble, then confirm the action.

**TIP** To record a single shot as opposed to the entire timeline, select the shot you want to play out and hold down **SHIFT** while clicking Assemble.

The playout operation begins.

## Recording in Record Mode

Use Record mode to record an entire cut to a VTR. Record mode overwrites the entire contents of the tape (including timecode). To use Record mode, you must set the VTR timecode to Preset or Auto timecode.

You do not have to pre-stripe the tape with timecode when using Record mode.

You have the option of specifying a start timecode value, and including leader black and colour bars. Leader black and colour bars are added to the start of the program (on tape).

---

**NOTE** In Record mode, it is not possible to record a subset of the total available tracks to tape; all tracks are recorded to tape in this mode.

---

At least 10 seconds of black are always recorded to the video tape before the footage. Also, footage always starts on the minute. Lustre pads the leader with additional black and colour bars to ensure that the video always begins on the minute. The following examples illustrate how this is calculated.

### Example 1

- Start Timecode: 00:59:00:00
- Min Colourbar Length: 15 seconds
- Black Length: 15 seconds

To begin, Lustre always records 10 seconds of black from 00:59:00:00 to 00:59:10:00 (this length is locked and is always recorded).

After the initial black, colour bars are recorded from 00:59:10:00 to 00:59:45:00 (the Minimum Colourbar Length of 15 seconds is surpassed).

Finally, black is recorded from 00:59:45:00 to 01:00:00:00 (the Black Length value of 15 seconds must be respected) and the video material begins exactly at 01:00:00:00.

### Example 2

- Start Timecode: 00:59:30:00
- Min Colourbar Length: 20 seconds
- Black Length: 10 seconds

To begin, Lustre always records 10 seconds of black from 00:59:30:00 to 00:59:40:00 (this length is locked and is always recorded).

After the initial black, colour bars are recorded from 00:59:40:00 to 01:00:50:00 (the Minimum Colourbar Length of 20 seconds is surpassed).

Finally, black is recorded from 01:00:50:00 to 01:01:00:00 (the Black Length value of 10 seconds must be respected) and the video material begins exactly at 01:01:00:00.

In this case, the Minimum Colourbar Length and the Black Length (which combine to add up to 30 seconds) does not fit into the gap between 00:59:40:00 and 01:00:00:00 (20 seconds). Because video must always start on the minute, additional colour bars are added so that the material starts at the next minute.

### To record to a VTR in Record mode:

- 1 Before you can play out to a VTR, you must render the timeline at the appropriate video resolution. See [Rendering Shots](#) (page 2259) and [Playout Workflow](#) (page 2322).
- 2 Click Editing, and then click Playout to display the Playout menu.
- 3 Select a raster for playout. See [Selecting a Raster for Playout](#) (page 2322).

- 4 In the Sync Mode list, select the synchronization mode. See [Playout Menu Options](#) (page 2318).
- 5 (Optional) To record only a portion of the timeline, use markers to define where, in the timeline, you wish to start and stop recording to tape. See [Defining In and Out Markers when Playing Out to Tape](#) (page 2323).
- 6 In the Source Playout From group, determine where the playout operation starts.

Click:	To start the playout:
Begin	From the start of the current timeline.
Actual	At the current frame.
Markers	At the in marker in the timeline, and stop at the out marker.

- 7 (Optional) In the Record To Tape Mode group, enable Preview.

With Preview enabled, your footage is played out in the Player, but nothing is written to tape.

- 8 In the Record Mode Options group, determine where on the video tape you want to record to:
  - Enable Tape Begin to rewind to the start of the tape, and then begin the playout.
  - Enable Actual to start the playout operation at the current frame of the tape.

- 9 Enter the start timecode in the In field.

- 10 Enter the minimum colour bar length and the minimum Black length in the Bars Length and Black Length fields, respectively.

- 11 (Optional) Configure the video and audio record delay. See [Playout Menu Options](#) (page 2318).
- 12 Click Record, and then click it again to confirm the action.

The playout operation begins.

## VTR Emulation

When configured to emulate a VTR, Lustre can be controlled, using an RS-422 interface, by a third-party application or device. You control Lustre VTR emulation from the application or device that treats Lustre as a VTR device. Lustre supports SD and HD emulators.

The RS-422 commands that you can use for VTR emulation are summarized as follows:

- |                       |                 |                        |
|-----------------------|-----------------|------------------------|
| ■ Play                | ■ Reset TC IN   | ■ TC IN+               |
| ■ Stop                | ■ Reset TC OUT  | ■ TC IN-               |
| ■ REW                 | ■ Mark TC IN    | ■ TC OUT+              |
| ■ FF                  | ■ Mark TC OUT   | ■ TC OUT-              |
| ■ PREROLL             | ■ Set TC IN     | ■ CUE to (given) TC    |
| ■ PREROLL TIME PRESET | ■ Set TC OUT    | ■ CUE to TC OUT        |
| ■ SHUTTLE             | ■ AUTO mode ON  | ■ EDIT channels preset |
| ■ JOG                 | ■ AUTO mode OFF | ■ Eject                |
| ■ VARPLAY             |                 |                        |

---

**NOTE** Unless otherwise configured by the controller device, the pre-roll time on the Lustre VTR emulator defaults to seven seconds with each video initialization.

---

**To operate Lustre as a VTR:**

- 1 Connect Lustre to the breakout box by doing one of the following:
  - If Lustre is running on the IBM® IntelliStation® Z Pro 6223 or the HP® xw8400, connect to the B port on the DVS Centaurus breakout box.
  - If Lustre is running on the HP xw8600, connect to the B port on the AJA breakout box.
- 2 Connect the master application or device to Lustre on the patch panel using a straight pin-to-pin serial cable. A cross-cable will not work.

**WARNING** Save your grade before editing your project, or you will lose any unsaved work.

- 3 Launch Lustre and navigate to the Engineering page of the Project Management settings (See [Engineering Settings](#) (page 1795)).
- 4 Enable VTR Emulator.
- 5 Use the Offset in Frames slider to set the number of frames you wish to shift ahead as footage is transferred from the controlling device to Lustre. Enter a negative number of frames to shift the clip backwards.
- 6 Click Save Project.
- 7 Click Editing, and then click Playout to display the Playout menu.
- 8 Select a raster for playout. See [Selecting a Raster for Playout](#) (page 2322).
- 9 Prior to playout from the VTR emulator, perform the following tasks:
  - Add a header of at least five seconds to the start of the Storyboard.
  - Verify that the start Timecode begins at the end of the header, and not at 00:00:00:00. This is necessary because the Lustre VTR emulation does not provide a pre-roll outside of the boundaries of the existing Storyboard.

**To disable VTR emulation:**

- 1 Click Eject.

- 2 To re-initialize, either switch between the Editing Capture and Playout menus, or re-select the DVS raster.

## Writing Telecine-Style Tape

The Telecine feature allows you to emulate grading with telecine tape. The original source timecodes are written to tape, and each shot is separated by a black sequence of duration equal to Black Length value field.

Before you can use the Telecine feature, you must configure the VTR and the breakout box.

### To configure the VTR:

- 1 Set the VTR's timecode configuration to:
  - Record run.
  - Preset Timecode Generation.

**NOTE** The timecode data is transferred through the RS-422 connection.

### To output telecine-style tape:

- 1 Enable Telecine prior to starting the playout operation.

- 2 Sort the timeline in C mode (with or without Head/Tail) using the C-Mode option found in the Editing > Assemble > Sort Modes menu.
- 3 (Optional) To resize *rendered* 2K or HD content to NTSC or PAL resolutions:
  - Select an NTSC or PAL raster.
  - Enable the Pulldown option.
- 4 Click Assemble once, and then a second time to confirm the action.

## Playout and GPU Acceleration

It is possible to play out real-time content to tape without having to first process by using the power of the graphical processing unit, or GPU.

- Use Real-time deliverables. See [Creating Real-Time Deliverables from the Timeline or Rendered Material](#) (page 2332).
- Playout from the timeline. See [Playout from Timeline with GPU Acceleration](#) (page 2336).

## Creating Real-Time Deliverables from the Timeline or Rendered Material

You can record 10-bit, multi-format video deliverables to tape from existing source or rendered footage without having to perform additional render passes. These deliverables are processed in real time and are subject to high-quality resizing.

---

**NOTE** Support for real-time deliverables depends on the version of the graphics card installed on your system.

---

Real-time deliverables can include specific primary grading (excluding curves), most reposition types, and hardware LUTs. Animation on primary grading, and on panning and scanning is also available and is performed in real time during output to tape. Modifications for real-time deliverables are displayed in Deliverable (D) view and do not affect the master version's Output view or rendered version's Print view. When playing out, you can use either source or rendered material.

---

**NOTE** Real-time deliverables playout cannot include output primary grading, secondary grading, or rotations. These types of modifications must be rendered or copied to the real-time deliverables module prior to playout. See [Sharing Modifications Between Setups and Grades](#) (page 2336).

---

For example, you could use 2K rendered footage to create an HD tape and a DVD version without having to render again. Alternately, you could use source material and apply primary grading and repositioning that only affects the real-time deliverable, and does not require a render pass prior to playing out.

### Creating Setups for Real-Time Deliverables

After you switch to Real-Time Deliverables mode, the work you perform on your shot is no longer saved to the grade. Instead, it is saved to a real-time deliverables setup file. This file contains grading and reposition information that is separate from the grade file. The setup file is an XML-based grade file, which allows you to use it with other systems.

**NOTE** You can share grading between real-time deliverables setups and grade files. See [Sharing Modifications Between Setups and Grades](#) (page 2336).

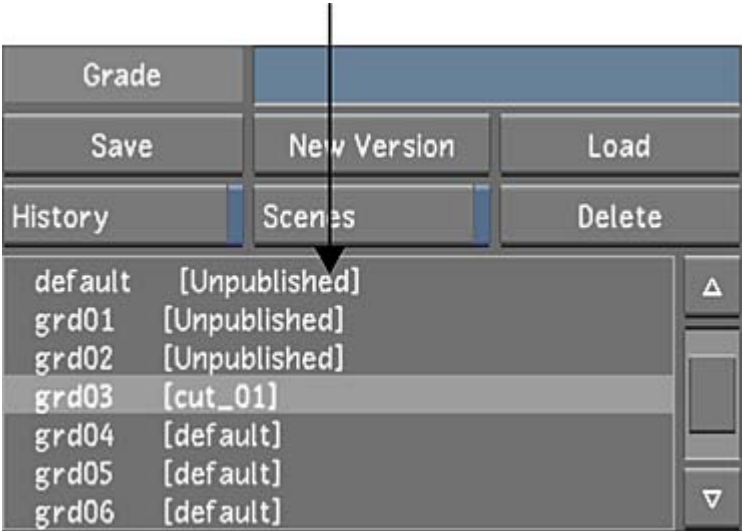

Although real-time deliverables setups are linked to the grade file, you can apply a setup to a grade linked with a different cut.

After the setup has been created and loaded to a grade, you can switch back to the Playout menu and play out to tape in either Insert or Assemble mode.

**TIP** Enabling the D button also allows you to send a 10-bit buffer to the SDI output.

**To create a real-time deliverables setup:**

- 1 In the Main menu, click Setup, and then click Grade.  
The Grade menu appears.
- 2 From the Grade list, load the grade from which you want to create a real-time deliverables setup.

- 3 Click D.

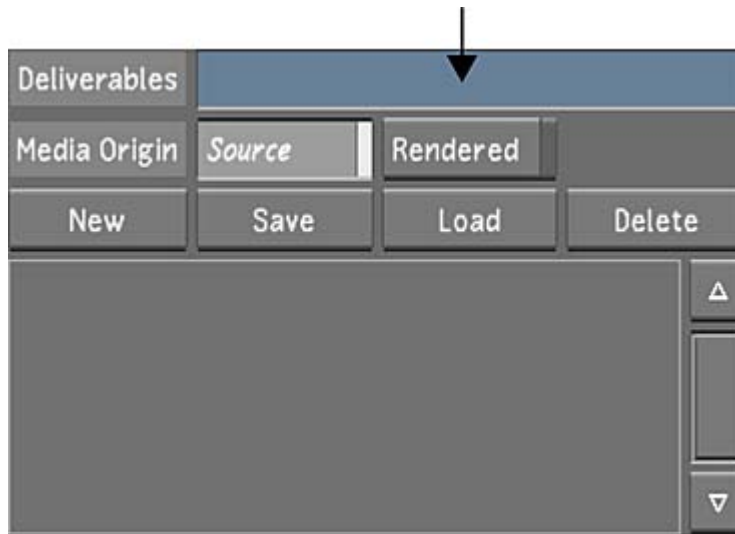

The button automatically switches you to Real-Time Deliverables view mode, and enables GPU processing. See [GPU Acceleration](#) (page 2086).

**NOTE** If the screen shows a red X instead of an image, the enabled Media Origin contains no media. The following step tells you what to do.

- 4 Select the media origin to be used during playout. Enable Source for original, unrendered material. Enable Rendered for rendered material.

**NOTE** Unrendered changes made to source material will not be applied to setups. Also, when you select Source (O scans) as the media origin, Grade file settings are bypassed.

- 5 In the Deliverables field, enter a name for the setup.

- 6 Click New. The setup name is added to the list of setups for the grade.
- 7 (Optional) Perform reposition modifications such as panning and scanning, resizing, and repositioning. See [Repositioning Images](#) (page 2059).

**NOTE** Rotations cannot be included in real-time deliverables setups.

- 8 (Optional) Perform input primary colour grading. See [Primary Colour Grading](#) (page 2101).

**NOTE** Only input primary grading is permitted for real-time deliverables setups.

- 9 (Optional) Apply a HW LUT, using a grade file to store it. Real-time deliverables do not save Print Lut reference. See [Applying LUTs for Viewing \(Print LUTs\)](#) (page 1899).

**NOTE** When creating real-time deliverables setups, you can only apply a HW LUT to the main monitor. In other words, you can only enable the button labelled 1.

- 10 Return to the Setup Grade menu.

- 11 Click Save to save the setup.

The setup is saved to the scene's Library folder as an XML file. The file uses the real-time deliverables setup name, preceded by the name of the grade on which it is based. For example, if the grade name is *grd01*, and the setup name is *My\_HD*, the XML grade file is *[grd01]My\_HD.deliv.xml*.

**TIP** You can save different versions of the same setup according to your mastering requirements.

Once a setup exists, it can either be loaded to the grade for which it was created, or loaded to a different grade.

**To load a setup to the grade for which it was created:**

- 1 In the Deliverables section of the Grade menu, select a setup from the list and click Load.  
This loads both the grade and the setup.

**To load a setup to a different grade:**

- 1 In the Grade menu, load the grade on which you want to apply the existing deliverables.
- 2 Select a setup from the list, and press **Ctrl** while clicking Load.  
This loads the setup to the grade.

**To rename a setup:**

- 1 Middle-click the setup name.
- 2 Enter the new name, and then press **Enter**.

**To delete a setup:**

- 1 Select a setup from the list, and click Delete.

**Resizing Shots Prior to Playing Out**

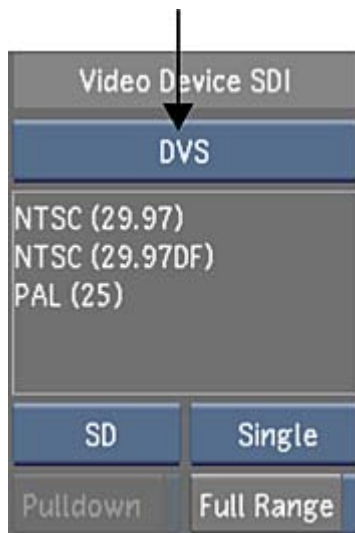

Before you play out real-time deliverables, resize your shots to ensure that they properly conform to the destination output format. See [Resizing Shots](#) (page 2261).

**Playing Out Real-Time Deliverables to Tape**

After a setup has been created and loaded to the desired grade, and resizing has been performed, you are ready to play out to tape.

**To play out real-time deliverables to tape:**

- 1 In the Main menu, click Editing, and then click Payout.  
The Payout menu appears.
- 2 Toggle the Video/Graphics raster option box to display the graphics card (GFX/SDI).

- 3 Toggle the Link Type option box to the required link type (Single or Dual).

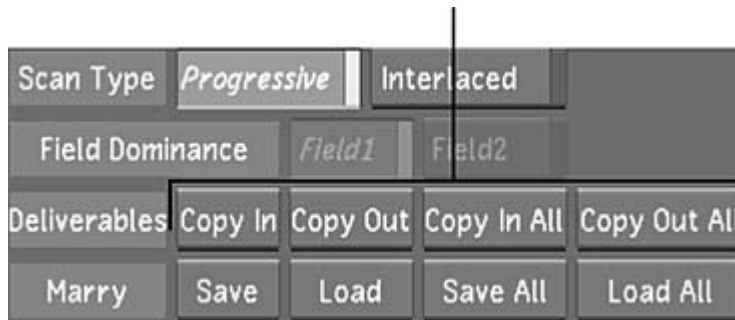

- 4 Toggle the Format option box to the required raster format (SD, HD, Film, or Audio).
- 5 In the Raster list, select a raster.
- 6 Play out to tape in either Insert or Assemble mode. See [Recording in Insert Mode](#) (page 2324) and [Recording in Assemble Mode](#) (page 2326).

## Sharing Modifications Between Setups and Grades

By default, unrendered changes to a grade file are not applied to real-time deliverables setups, and modifications made to a setup are not copied back to the grade. However, you can force changes to be copied back and forth either on a shot-by-shot basis or for the entire scene.

To share modifications between setups and grades:

- 1 In the Grade menu, click one of the Deliverables buttons.

Click:	To transfer:
Copy In	Modifications made to the current shot from the grade to the setup.
Copy In All	Modifications made to the scene from the grade to the setup.
Copy Out	Modifications made to the current shot from the setup to the grade.
Copy Out All	Modifications made to the scene from the setup to the grade.

## Playout from Timeline with GPU Acceleration

**NOTE** When playing out from source, playback performance may be impacted depending on the grading applied to the current shot. If frames are dropped during play out, Lustre recues the VTR to the last known frame laid down to tape.

You can now use GPU acceleration to play out source material in real time with Print LUT, primary and secondary grading, and GPU-accelerated plugins applied. While Real-Time Deliverables mode allows you to play out directly to tape, it only permits primary grading, resizing, pan and scan, and LUT processing. The Playout From Timeline option lets you play out source material containing secondary grading without having to first perform a rendering pass.

By enabling the Playout From Timeline function in the project settings or the Playout menu, and by enabling GPU acceleration, you can play out from Output view mode and use all features currently supported by enhanced GPU acceleration.

---

**NOTE** If you enable the **Playout From Timeline** function in project settings, playing out from the **Output** view is the default for this project. If you enable the **Playout From Timeline** function from within the **Playout** menu, this setting applies only for the current session.

---

- For more information about GPU acceleration, see [GPU Acceleration](#) (page 2086).
- For more information about **Output** view mode, see [Setting Image View Options](#) (page 2016).

If you want to play out at a different resolution than your timeline, use the real-time deliverable solution. But if you want to play out content with complex grading, use **Play out from Timeline**, in which case you are limited to using the same resolution as the source.

**To play out source material to tape with all features supported by GPU acceleration mode:**

- 1 Enable the **Playout From Timeline** setting by doing one of the following:
  - In your project settings, enable **Playout from Timeline** in the **Engineering** menu. See [Engineering Settings](#) (page 1795).
  - In the **Playout** menu, enable **Playout from Timeline**. See [Playout Menu Options](#) (page 2318).

**NOTE** When you define settings in **Project Management**, these settings become the default settings whenever this project is loaded. When you define settings in the application (that is, not in the project settings), **Lustre** reverts to the project setting defaults upon reboot.

- 2 Set the **Player** to the **O** view by clicking **O**.

**NOTE** You must set the **Player** to the **O** view to be able to record unrendered media to tape and to use GPU acceleration.

- 3 Enable GPU acceleration by clicking **GPU** or by pressing **Y** on your keyboard.
- 4 Play out to the **VTR**. See [Playing Out to a VTR](#) (page 2321).

### Expected Performance

Real-time playback is not guaranteed when you play out directly to tape with GPU acceleration. The playback speed indicator in the GUI is a good indicator of what to expect when you lay down the timeline to tape. If frames are dropped when you play back your timeline on the SDI monitor, the same is likely to occur when you play out to tape.

You can expect good playback with no dropped frames when you ensure the following:

- HD or SD format is used for both capture and output (no resize applied).
- Up to four secondaries with keys are used, with a maximum of one geometry per secondary.
- A 3D Mesh LUT is enabled.
- **GFX/SDI** is enabled in the **Playout** menu.

Regardless of whether or not you conform to all conditions stated above, some animations may not play back in real time.

---

**NOTE** Support for direct playout to tape from GPU acceleration depends on the version of the graphics card installed on your system.

---

## About 3:2 Pulldown

When capturing from or playing out to a VTR, you may want to convert footage using a 3:2 pulldown raster if the incoming video is NTSC or 1080i HD.

When film, which plays at 24 fps, is telecined to either NTSC or 1080i HD video, which plays at 29.97 fps, an extra 'pulldown frame' is added for every four film frames. This is because a straight 1:1 playback of film frames at NTSC or interlaced HD speeds results in a faster than appropriate playback. The telecine machine used to transfer film to video adds the pulldown frame by taking four consecutive film frames (A, B, C, and D) and performing a telecine to five interlaced video frames (A1A2, B1B2, B1C2, C1D2, and D1D2). Consequently, the pulldown insertion process creates two hybrid frames (B1C2 and C1D2), as shown in the following diagram.

---

**NOTE** The '1' and '2' suffixes after the frame letters denote the field number in each interlaced frame of NTSC or 1080i HD video. They do not represent a sequence over time.

---

When you capture NTSC or 1080i HD video previously telecined from film, you may want to conform with 24 fps progressive footage. In this case, you should capture the NTSC footage and simultaneously remove the 3:2 pulldown frame. When a 3:2 video SDI raster is selected, you can select the first pulldown field in the footage by clicking on the appropriate Pulldown Field button in the Capture menu. Then, the five interlaced NTSC frames are reconfigured into four progressive frames.

When you are ready to record to a VTR, you might need to record to NTSC or 1080i HD video. If your cut runs at 24 fps, you need to configure Lustre to add a 3:2 pulldown frame to bring the framerate up to 29.97 fps. In this case, use the Pulldown Field button in the Playout menu to specify which of the five pulldown fields will be the first in the sequence to be recorded to tape. Lustre will add the additional 3:2 pulldown frame for every four frames starting at the specified field.

## Converting Logarithmic to Linear

You can output your film scans to video once you have completed the film grading. There are two general workflows you can use to convert logarithmic images to linear ones:

- Using the Render Viewing option
- Creating manually a Log-to-Lin conversion LUT

### To convert logarithmic images to linear ones using the Render Viewing option:

- 1 Use the same project and the same source footage.
  - 2 Switch to Lin mode. See [Setting Logarithmic or Linear Mode](#) (page 1831).
  - 3 Colour grade the footage for video.
  - 4 In the Render > Local menu, enable Viewing in the Rendering group, and then adjust the black, white, and gamma as needed.
  - 5 Render the files in the correct video resolution. See [Rendering Shots](#) (page 2259).
- NOTE** When Render Viewing is ON, the output render format is set automatically to 8-bit BMP files.
- 6 Play out the rendered frames to record them on an appropriate VTR.

### To convert logarithmic images to linear ones by manually creating a Log-to-Lin conversion LUT:

- 1 Use the same project and the same source footage.
- 2 Switch to Lin mode. See [Setting Logarithmic or Linear Mode](#) (page 1831).  
When you switch to Lin mode, a Log-to-Lin conversion LUT is applied to the images automatically.
- 3 If needed, access the Input LUT menu and adjust the parameters of the default Log-to-Lin conversion.
- 4 Switch off monitor calibration (since the final render will also be seen on a monitor) and turn off any Print LUTs.
- 5 Use the Render Output menu to adjust the white, black, and gamma as needed.
- 6 Colour grade the footage for video.
- 7 Render the files in the correct video resolution. See [Rendering Shots](#) (page 2259).
- 8 Play out the rendered frames to record them on an appropriate VTR.

## Supported Video SDI and GFX SDI Rasters

When capturing from or recording to a VTR, you must select the appropriate raster. The raster defines the video capture/playout SDI timing and the graphic SDI timing. Lustre supports many DVS and AJA video SDI rasters and GFX SDI graphics rasters. See [Video SDI Rasters](#) (page 2339) and [GFX SDI Rasters](#) (page 2342).

In past releases of Lustre, you had to define a colour conversion matrix in a configuration file. You no longer need to do this. The correct conversion matrix is automatically configured when you select a video SDI raster. The matrix name will be displayed in the VTR status box located in the Editing > Capture and Editing > Playout menus.

---

**NOTE** You cannot enable both a GFX and a Video raster, except when working with audio, when you can use a DVS/AJA raster for audio, and a GFX for graphics.

---

### Video SDI Rasters

The following table lists the video SDI rasters that are available for capture and playout in Lustre.

**NOTE** The Lustre HD Station does not support bit depths greater than 10-bit, input resolutions greater than 2K, or output resolutions greater than 1920x1080.

Video Type:	Pulldown:	Link Type:	Video Signal:
NTSC (29.97)	No	Single	29.97 fps, 59.94 Hz, interlaced, 720x486, NDF timecode, YUV 4:2:2 data.
NTSC (29.97)	Yes	Single	29.97 fps, 59.94 Hz, interlaced, 720x486, pulldown insert on playout and removal on capture, NDF timecode, YUV 4:2:2 data.
NTSC (29.97DF)	Yes	Single	29.97 fps, 59.94 Hz, interlaced, 720x486, DF timecode, YUV 4:2:2 data.
NTSC (29.97DF)	No	Single	29.97 fps, 59.94 Hz, interlaced, 720x486, pulldown insert on playout and removal on capture, DF timecode, YUV 4:2:2 data.
PAL (25)	No	Single	25 fps, 50 Hz, interlaced, 720x576, YUV 4:2:2 data.
720p (50)	No	Single	50 fps, progressive, 1280x720, YUV 4:2:2 data.
720p (50)	No	Dual	50 fps, progressive, 1280x720, RGB 4:4:4 data.
720p (59.94)	No	Single	59.94 fps, progressive, 1280x720, NDF timecode, YUV 4:2:2 data.
720p (59.94DF)	No	Single	59.94 fps, progressive, 1280x720, DF timecode, YUV 4:2:2 data.
720p (59.94)	No	Dual	59.94 fps, progressive, 1280x720, NDF timecode, RGB 4:4:4 data.
720p (59.94DF)	No	Dual	59.94 fps, progressive, 1280x720, DF timecode, RGB 4:4:4 data.
720p (60)	No	Single	60 fps, progressive, 1280x720, YUV 4:2:2 data.
720p (60)	No	Dual	60 fps, progressive, 1280x720, RGB 4:4:4 data.
1080PsF (23.98)	No	Single	23.98 fps, 72 Hz, segmented frames, 1920x1080, YUV 4:2:2 data.
1080PsF (23.98)	No	Dual	23.98 fps, 72 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080p (23.98)	No	Single	23.98 fps, progressive, 1920x1080, YUV 4:2:2 data

Video Type:	Pulldown:	Link Type:	Video Signal:
1080p (23.98)	No	Dual	23.98 fps, progressive, 1920x1080, RGB 4:4:4 data
1080PsF (24)	No	Single	24 fps, 48 Hz, segmented frames, 1920x1080, YUV 4:2:2 data.
1080PsF (24)	No	Dual	24 fps, 48 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080p (25)	No	Single	25 fps, progressive, 1920x1080, YUV 4:2:2 data
1080p (25)	No	Dual	25 fps, progressive, 1920x1080, RGB 4:4:4 data
1080p (29.97)	No	Single	29.97 fps, progressive, 1920x1080, NDF timecode, YUV 4:2:2 data
1080p (29.97)	No	Dual	29.97 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data
1080p (29.97DF)	No	Single	29.97 fps, progressive, 1920x1080, DF timecode, YUV 4:2:2 data
1080p (29.97DF)	No	Dual	29.97 fps, progressive, 1920x1080, DF timecode, RGB 4:4:4 data
1080p (30)	No	Single	30 fps, progressive, 1920x1080, NDF timecode, YUV 4:2:2 data
1080p (30)	No	Dual	30 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data
1080i (25)	No	Single	25 fps, 50 Hz, interlaced, 1920x1080, YUV 4:2:2 data.
1080i (25)	No	Dual	25 fps, 50 Hz, interlaced, 1920x1080, RGB 4:4:4 data, RGB 4:4:4 data.
1080i (29.97)	No	Single	29.97 fps, 59.94 Hz, interlaced, 1920x1080, NDF timecode, YUV 4:2:2 data.
1080i (29.97)	No	Dual	29.97 fps, 59.94 Hz, interlaced, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080i (29.97DF)	No	Single	29.97 fps, 59.94 Hz, interlaced, 1920x1080, DF timecode, YUV 4:2:2 data.
1080i (29.97DF)	No	Dual	29.97 fps, 59.94 Hz, interlaced, 1920x1080, DF timecode, RGB 4:4:4 data.

Video Type:	Pulldown:	Link Type:	Video Signal:
1080i (29.97)	Yes	Single	29.97 fps, 59.94 Hz, interlaced, 1920x1080, pull-down insert on playout and removal on capture, NDF timecode, YUV 4:2:2 data.
1080i (29.97)	Yes	Dual	29.97 fps, 59.94 Hz, interlaced, 1920x1080, pull-down insert on playout and removal on capture, NDF timecode, RGB 4:4:4 data.
1080i (29.97DF)	Yes	Single	29.97 fps, 59.94 Hz, interlaced, 1920x1080, pull-down insert on playout and removal on capture, DF timecode, YUV 4:2:2 data.
1080i (29.97DF)	Yes	Dual	29.97 fps, 59.94 Hz, interlaced, 1920x1080, pull-down insert on playout and removal on capture, DF timecode, RGB 4:4:4 data.
1080i (30)	No	Single	30 fps, 60 Hz, interlaced, 1920x1080, NDF timecode, YUV 4:2:2 data.
1080i (30)	No	Dual	30 fps, 60 Hz, interlaced, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080i (30)	Yes	Single	30 fps, 60 Hz, interlaced, 1920x1080, pulldown insert on playout and removal on capture, NDF timecode, YUV 4:2:2 data.
1080i (30)	Yes	Dual	30 fps, 60 Hz, interlaced, 1920x1080, pulldown insert on playout and removal on capture, NDF timecode, RGB 4:4:4 data.
1556PsF (14/HSDL)	No	Single	14 fps, segmented frame, 2048x1556, allows HSDL transfer, YUV 4:2:2 data.
1556PsF (15/HSDL)	No	Single	15 fps, segmented frame, 2048x1556, allows HSDL transfer, YUV 4:2:2 data.
1556PsF (14/HSDL)	No	Dual	14 fps, segmented frame, 2048x1556, allows HSDL transfer, RGB 4:4:4 data.
1556PsF (15/HSDL)	No	Dual	15 fps, segmented frame, 2048x1556, allows HSDL transfer, RGB 4:4:4 data.

## GFX SDI Rasters

The following table lists the GFX SDI rasters that are available for capture and playout in Lustre.

**NOTE** The Lustre HD Station does not support bit depths greater than 10-bit, input resolutions greater than 2K, or output resolutions greater than 1920x1080.

Video Type:	Pulldown:	Link Type:	Stereo:	Video Signal:
NTSC (29.97)	No	Single	No	29.97 fps, 59.94 Hz, interlaced, 720x486, NDF timecode, YUV 4:2:2 data.
NTSC (29.97)	Yes	Single	No	29.97 fps, 59.94 Hz, interlaced, 720x486, pulldown insert on playout and removal on capture, NDF timecode, YUV 4:2:2 data.
PAL (25)	No	Single	No	25 fps, 50 Hz, interlaced, 720x576, YUV 4:2:2 data.
720p (60)	No	Single	No	60 fps, progressive, 1280x720, YUV 4:2:2 data.
720p (60)	No	Dual	No	60 fps, progressive, 1280x720, RGB 4:4:4 data.
720p (59.94)	No	Single	No	59.94 fps, progressive, 1280x720, NDF timecode, YUV 4:2:2 data.
720p (59.94)	No	Dual	No	59.94 fps, progressive, 1280x720, NDF timecode, RGB 4:4:4 data.
1080PsF (23.98)	No	Single	No	23.98 fps, 72 Hz, segmented frames, 1920x1080, YUV 4:2:2 data.
1080PsF (23.98)	No	Dual	No	23.98 fps, 72 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080PsF (23.98)	No	Dual	Yes	23.98 fps, 72 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080PsF (24)	No	Single	No	24 fps, 48 Hz, segmented frames, 1920x1080, YUV 4:2:2 data.
1080PsF (24)	No	Dual	No	24 fps, 48 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080PsF (24)	No	Dual	Yes	24 fps, 48 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080PsF (25)	No	Dual	Yes	25 fps, 48 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.

Video Type:	Pulldown:	Link Type:	Stereo:	Video Signal:
1080PsF (30)	No	Dual	Yes	30 fps, 48 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080p (23.98)	No	Dual	Yes	23.98 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080p (24)	No	Single	No	24 fps, progressive, 1920x1080, NDF timecode, YUV 4:2:2 data.
1080p (24)	No	Dual	No	24 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080p (24)	No	Dual	Yes	24 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080p (25)	No	Dual	Yes	25 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080p (29.97)	No	Dual	Yes	29.97 fps, progressive, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080PsF (25)	No	Single	No	25 fps, 50 Hz, segmented frames, 1920x1080, YUV 4:2:2 data.
1080PsF (25)	No	Dual	No	25 fps, 50 Hz, segmented frames, 1920x1080, RGB 4:4:4 data.
1080i (25)	No	Single	No	25 fps, 50 Hz, interlaced, 1920x1080, YUV 4:2:2 data.
1080i (25)	No	Dual	No	25 fps, 50 Hz, interlaced, 1920x1080, RGB 4:4:4 data, RGB 4:4:4 data.
1080i (25)	No	Dual	Yes	25 fps, 50 Hz, interlaced, 1920x1080, RGB 4:4:4 data, RGB 4:4:4 data.
1080p (29.97)	No	Single	No	29.97 fps, progressive, 1920x1080, NDF timecode, YUV 4:2:2 data.
1080p (29.97)	No	Dual	No	29.97 fps, progressive, 1920x1080, NDF timecode, YUV 4:2:2 data.
1080i (29.97)	No	Single	No	29.97 fps, 59.94 Hz, interlaced, 1920x1080, NDF timecode, YUV 4:2:2 data.

Video Type:	Pulldown:	Link Type:	Stereo:	Video Signal:
1080i (29.97)	No	Dual	No	29.97 fps, 59.94 Hz, interlaced, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080i (29.97)	No	Dual	Yes	29.97 fps, 59.94 Hz, interlaced, 1920x1080, NDF timecode, RGB 4:4:4 data.
1080i (29.97)	Yes	Single	No	29.97 fps, 59.94 Hz, interlaced, 1920x1080, pulldown insert on playout and removal on capture, NDF timecode, YUV 4:2:2 data.
1080i (29.97)	Yes	Dual	No	29.97 fps, 59.94 Hz, interlaced, 1920x1080, pulldown insert on playout and removal on capture, NDF timecode, RGB 4:4:4 data.
1080i (30)	No	Dual	Yes	30 fps, 59.94 Hz, interlaced, 1920x1080, NDF timecode, RGB 4:4:4 data.

## Audio

There are a few ways you can hear audio during a timeline playback:

- You can import audio files to the system.
- You can capture audio from a video tape recorder (VTR) or audio tape recorder (ATR).
- You can have an external device chase the audio timecode by using the longitudinal timecode (LTC) chase option.

The audio signal is captured and played back from the DVS or AJA breakout box (BOB). For information on connecting the external audio devices, refer to your hardware guide. When you are capturing, playing back, or playing out audio tracks, you can select up to 16 tracks (eight tracks of DVS/AJA AES audio, or 16 tracks of embedded AJA audio) from the track selector at a sampling rate of 48 kHz (16-bit or 24-bit). See [Capture Menu Options](#) (page 2299) or [Playout Menu Options](#) (page 2318).

**NOTE** To monitor the audio from the DVS/AJA BOB, the AES audio needs to be converted to an analog audio signal. To do this, use a digital audio mixer or a digital to analog converter (e.g., the Lucid converter). Refer to your hardware guide for information about the Lucid converter.

## Audio Workflow

Use the following typical workflow to add audio to your video playback.

Step:	Refer to:
1. Import or capture the audio file.	<a href="#">Importing an Audio File</a> (page 2347), <a href="#">Importing Audio From Wiretap</a> (page 2349), or <a href="#">Capturing an Audio File</a> (page 2350).
2. Playback the selected audio file/tracks with the video.	<a href="#">Playing Back Audio with the Timeline</a> (page 2351) or <a href="#">Playback Using the LTC Chase Option</a> (page 2354).
3. Playing out the audio file/tracks with the video.	<a href="#">Playout of Audio and Video</a> (page 2356).

## Importing an Audio File

Lustre can use the audio files that you import into the scene's *Library\audio* directory or embedded in media imported from the Wiretap or Wiretap Gateway server.

**NOTE** The audio folder is automatically created when you create a scene.

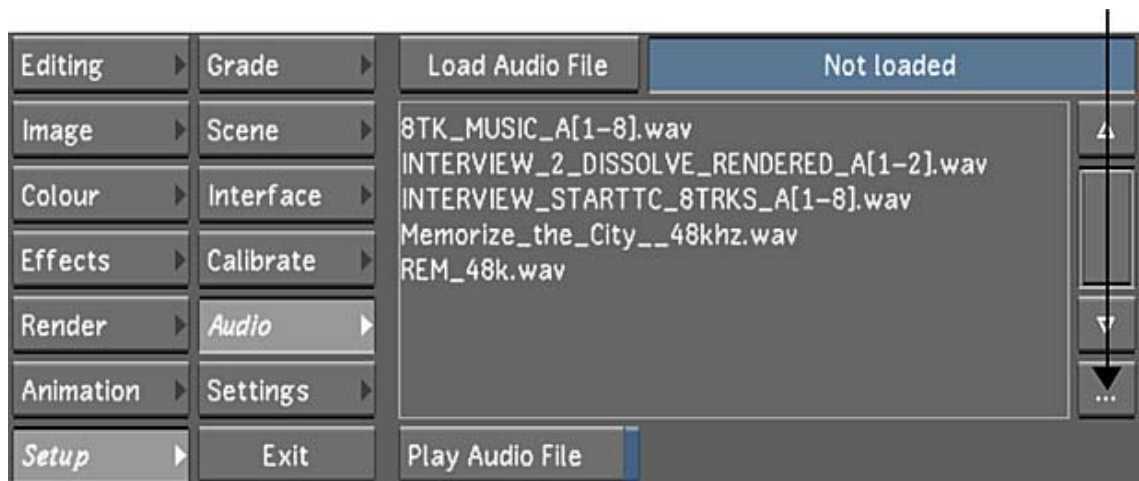

An imported audio file can comprise of a single track or up to 16 interleaved tracks.

There are three ways to import audio into Lustre:

- Outside of Lustre, copy WAV or AIFF files manually to the scene's *Audio* folder.
- Within Lustre, import copies of audio files using the Import file browser.
- Within Lustre, import audio through the Wiretap server and Wiretap Gateway server.

To import an audio WAV or AIFF file while in Lustre:

- 1 Click Setup in the Main menu, and then click Audio.
- 2 In the audio file list, click the Browse button.

The Import file browser appears.

- 3 Navigate to the appropriate source folder and select one or more audio files (You can also use [bookmarks](#) (page 1915) to retain a list of folder locations). Traditional methods of multi-selecting (Shift-click, Ctrl-click) are enabled.

- 4 Click Import.

A copy of the audio file is imported into the *Audio* folder, and appears in the audio file list.

---

**NOTE** If you add audio files to the scene's *Audio* folder after launching Lustre, press **Ctrl+R** to refresh the audio file list.

---

## Importing Audio From Wiretap

You have the option of including audio tracks when you import content containing audio from the Wiretap server. Since the content contains raw audio, you can import the audio tracks as a WAV (including multi-channel WAVE Extensible files) or AIFF file (the bit depth of the file is preserved and the Single File Capture option is not applicable). To set audio file type, see [Capture Menu Options](#) (page 2299).

You can also import audio embedded in compressed media files from the Wiretap Gateway server as a WAV or AIFF file. When importing multiple files, only the audio track(s) for one of these files can be used within Lustre since Lustre is limited to a single audio file (or group of files) per grade.

---

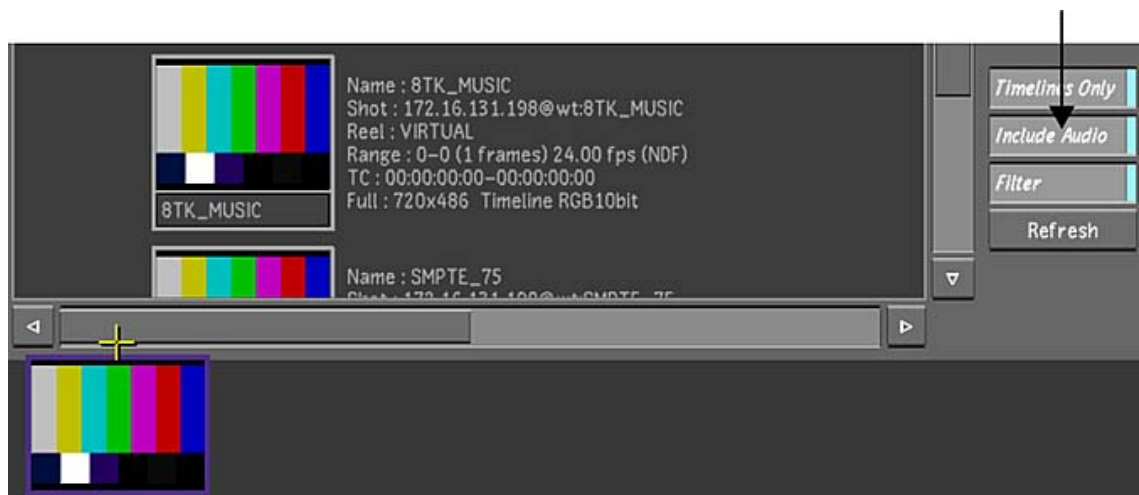

**NOTE** You cannot import audio only clips.

---

### To import audio files using Wiretap:

**TIP** All audio Timeline FX and dissolves must be rendered on a Visual Effects and Finishing application prior to being imported into Lustre.

- 1 Click Editing in the Main menu, and then click Browse.
- 2 Complete one of the following:
  - In the file browser, use the Wiretap server to navigate to a library containing a timeline with audio tracks.
  - In the file browser, use the Wiretap Gateway server to navigate to a media file that contains embedded audio tracks.
- 3 Make sure Include Audio is enabled, then select the file and drag it to the Storyboard.

- 4 Click Setup in the Main menu, and then click Audio.

The audio file from the Wiretap media has been imported and is automatically loaded and ready to play. If multiple tracks were imported, the tracks are grouped together under the same file name. For example, if the name of the media is **8TK\_MUSIC**, Lustre displays the file as **8TK\_MUSIC\_A[1-8].wav** (where [1-8] represents the number of tracks within the file).

8TK\_MUSIC\_A[1-8].wav

---

**NOTE** You can only import audio tracks from the Wiretap server and Wiretap Gateway server. The audio tracks cannot be rendered back.

---

## Capturing an Audio File

You can capture an audio signal of up to 16 tracks as a single 48 kHz (16-bit or 24-bit), interleaved WAV or AIFF file. The audio is saved in the scene's *Audio* folder. If using the Linux version of Lustre, the filename uses forward slashes.

---

**NOTE** The audio folder is automatically created when you create a scene.

---

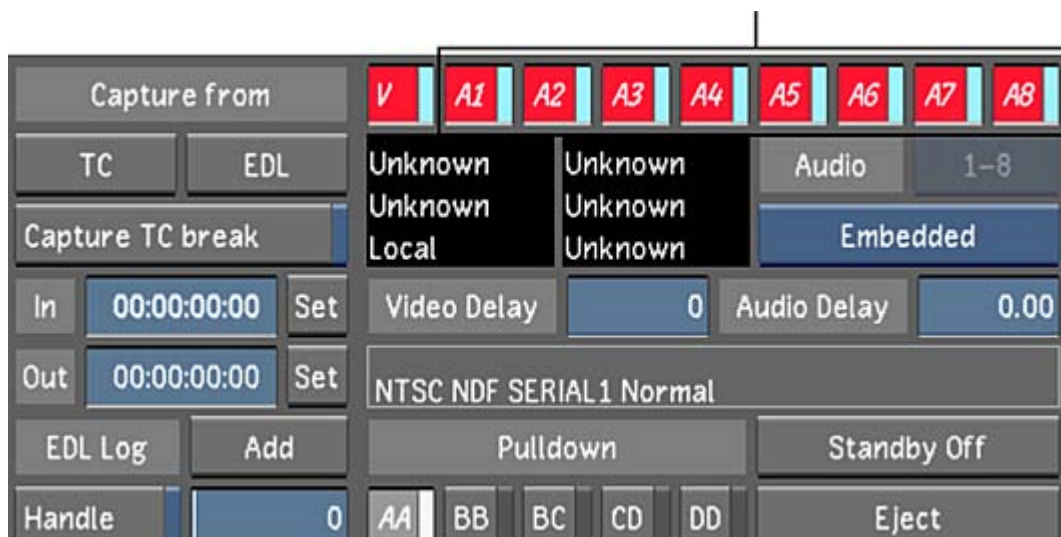

To capture an audio WAV or AIFF file:

- 1 Click Editing in the main menu, and then click Capture.
- 2 Select the appropriate raster. See [Selecting a Raster for Capture](#) (page 2305).
- 3 Select the audio file type, bit depth, and determine if you want to capture the audio tracks as a single or multiple files. Single File Capture is enabled by default.

- 4 Enable the audio track(s) you want to capture.

**NOTE** You have the option of capturing the video along with the audio. See [Capturing from Timecode](#) (page 2308).

- 5 Click the TC button to start the capture.

If the audio you are capturing is on numerous tracks and the Single File Capture option is enabled, Lustre groups all the tracks with the same name and displays them as a single file (e.g., **file\_name.wav**). If Single File Capture is disabled, each track is saved separately but grouped together in the audio file list. For example, the audio file name will be **file\_name\_A[#-#].wav**, where the numbers within the brackets represent the number of tracks within the file.

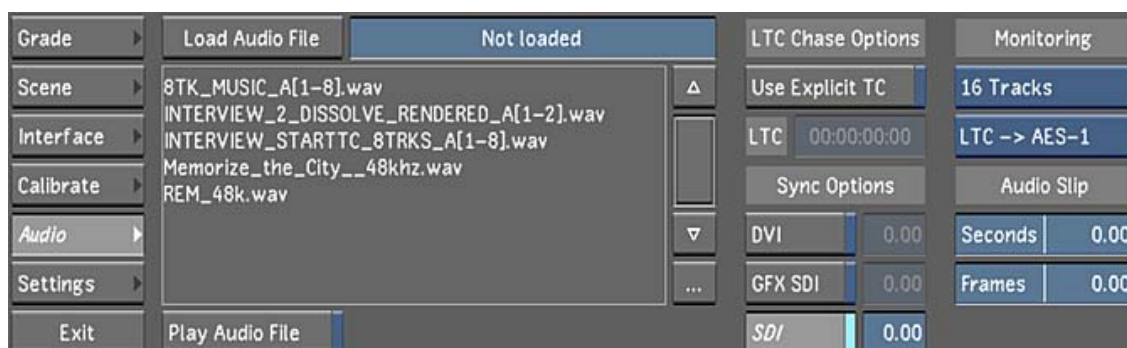

**NOTE** When you capture a broken selection (e.g., tracks A1, A3, and A5) and Single File Capture is enabled, the resulting single audio file contains three tracks. Therefore, in the Playout menu, tracks A1, A2, and A3 are enabled. If Single File Capture is disabled, the three tracks are saved as three separate files and in the Playout menu, tracks A1, A3, and A5 are enabled.

## Playing Back Audio with the Timeline

Once the audio file is in the audio folder, you can play it back at the same time as your timeline.

**To play back an imported audio file with the timeline:**

- 1 Click Setup in the Main menu, and then click Audio.  
The Audio menu is displayed.

- 2 (Optional) Import an audio file into the audio file list. See [Importing an Audio File](#) (page 2347).
- 3 Select a file from the audio file list.

**NOTE** Only one audio file can be associated with the timeline.

- 4 Click Load Audio File.  
The selected audio file is displayed in the audio file field and the Play Audio File button is automatically enabled.

**NOTE** When you capture an audio file, it is automatically loaded.

- 5 Select a Monitoring option. See [Audio Monitoring Options](#) (page 2352).  
6 (Optional) Set an audio offset if the audio is to begin at a certain time before, or after, the video has begun. See [Offsetting the Audio File](#) (page 2353).  
7 (Optional) Select a Sync option. See [Sync Options](#) (page 2353).  
Now when you play the timeline, the audio file is played as well.

**TIP** Disable the Play Audio File button if you do not want to hear the audio during playback.

While the audio file is playing back, you can scrub the audio.

Press:	To:
Alt+click location in the shot/scene timebar	Scrub the audio to the location you selected.
Ctrl+Alt+drag in the shot/scene timebar	Scrub the audio forward or backward quickly.

## Audio Monitoring Options

When you are playing back audio with your video, you need to make sure your playback settings correspond to your audio configuration. Typically, each track is played through a corresponding port (e.g., track 1 passes through port 1, track 2 passes through port 2, etc.), but your system might be configured to have multiple tracks going through a single port (e.g., tracks 1, 3, and 5 pass through port 1). The Monitoring option allows you to set how the tracks are played back.

**NOTE** If you disable any audio tracks in the Playout menu, it will not be heard during playback.

To select a monitoring option, click the Monitoring option box to select the monitoring option you want.

Select:	Audio Device:	When:
Stereo Downmix	DVS or AJA	There are only two audio tracks that are supported on the audio monitoring device. All the odd numbered tracks (e.g., 1, 3, 5, etc.) go through port 1 and all the even numbered tracks go through port 2.

Select:	Audio Device:	When:
4-Track Downmix	DVS or AJA	There are only four audio tracks that are supported on the audio monitoring device.
8 Tracks	DVS only	There are up to eight tracks and each track is supported on the audio monitoring device.
8-Track Downmix	AJA only	There are only eight tracks that are supported on the audio monitoring device.
16 Tracks	AJA only	There are up to 16 tracks and each track is supported on the audio monitoring device.

**NOTE** The audio monitoring option can also be set within the Engineering settings tab of the project configuration settings. See [Engineering Settings](#) (page 1795).

## Offsetting the Audio File

When you playback the audio with the timeline, both the audio and video begin at the same time. If you want your audio to play before, or after, the video has begun, you need to enter an offset for the audio file. Use the Audio Slip option to offset the audio file. For example, if the audio file starts two seconds after the start of the timeline, create a two second offset.

**To offset the audio:**

- Do one of the following:
  - Click and drag the Audio Slip sliders to offset the audio. If the audio starts before the video, drag right to set a positive offset. If the audio starts after the video, drag left to set a negative offset. You can use one or both sliders to set the duration of the offset.
  - Right-click within the slider to display the calculator and enter the frames and/or seconds offset to align your audio and video.

## Sync Options

Depending upon the output device you are using to view the timeline, the audio and video might not be in sync. Use the Sync Options feature to sync the audio and video. When you enable a sync option, a pre-calculated default is already applied. You only need to enter a value if the audio and video are still not in sync.

**DVI** Syncs the audio to the video that is displayed on the monitor (DVI).

**GFX SDI** Syncs the audio to the video that is displayed on an external device (e.g., projector, broadcast monitor, etc.).

**SDI** Syncs the audio to the video that is displayed on an external device connected to the DVS/AJA BOB.

**To sync the audio and video:**

- 1 In the Audio menu enable the Sync Options button corresponding to your output viewing device.  
**NOTE** Your system can be connected to multiple viewing outputs, but the sync is only applied to the option that is enabled.
- 2 (Optional) Click within the field and drag the mouse left or right to set the frame value for the sync. Enter a negative number if the audio plays after the video has begun and enter a positive number if the audio plays before the video has begun.

## Playback Using the LTC Chase Option

The LTC Chase Options allow you to send the timeline's timecode through the DVS or AJA BOB to an audio device that can chase the LTC timecode. By default, the LTC timecode is the same as the record time (REC TC). For example, if the start timecode for the timeline is 10:00:00:00, the LTC will be 10:00:00:00. When you move the shot positioner to a further position in the timeline and press play, the LTC value is also updated so it is in sync with the record timecode. If the Telecine option is enabled in the Editing>Playout menu, the LTC timecode is the same as the source timecode.

---

**NOTE** Your LTC Chase Option settings are saved in the *context.config* file.

---

**To play back the audio track using the LTC Chase Options:**

- 1 Click Editing in the Main menu, and then click Capture.
- 2 Select the appropriate raster to observe the audio and video files together. See [Selecting a Raster for Playout](#) (page 2322). Refer to “Selecting a Raster for Playout” in the “Video Capture and Video Playout” chapter of the Luster user guide.
- 3 (Optional) Click Setup in the Main menu, and then Audio to display the Audio menu. If you are using the AJA BOB, select an audio channel from the LTC Track Selector that is to represent the LTC channel.

(a) LTC Track Selector option box

**NOTE** Since the AJA BOB does not have a designated LTC channel, you must assign one of the audio channels to be the LTC channel. Refer to the Hardware Guide for information on how to setup the AJA BOB for the LTC Chase Option.

- 4 Make sure the audio device is set to chase.  
Now when you play back the timeline, the audio track is played at the same time.

## Use Explicit Timecode

If the audio device has a different timecode than the timeline, you can set a different timecode by enabling the Use Explicit TC button. For example, if your source timecode starts at 10:00:00:00 and your audio timecode begins at 11:00:00:00, you can enable the Use Explicit TC option and create an offset of 1:00:00:00.

**To play back an audio track with a different timecode:**

- 1 Click Editing in the Main menu, and then click Capture.
- 2 Select the appropriate raster. See [Selecting a Raster for Playout](#) (page 2322). Refer to “Selecting a Raster for Playout” in the “Video Capture and Video Playout” chapter of the Lustre User Guide.
- 3 Click Setup in the Main menu, and then Audio to display the Audio menu.
- 4 (Optional) If you are using the AJA BOB, select an audio channel from the LTC Track Selector that is to represent the LTC channel.

(a) LTC Track Selector option box

**NOTE** Since the AJA BOB does not have a designated LTC channel, you must assign one of the audio channels to be the LTC channel. Refer to the Hardware Guide for information on how to setup the AJA BOB for the LTC Chase Option.

- 5 Enable Use Explicit TC.
- 6 In the timecode field, enter the timecode of when you want the audio track to begin.

Now when you move the shot positioner, the audio and video are in sync.

## Playout of Audio and Video

Once you have verified the playback of your audio file/track(s) and timeline, you can play out the timeline to tape. See [Playing Out to a VTR](#) (page 2321).

## Working with Wiretap

Wiretap is Autodesk's cross-platform client-server interoperability framework, providing Lustre with high-performance access to remote media and metadata. With Wiretap, you can work with material from Autodesk Visual Effects and Finishing applications, without duplicating media. Import timelines directly from the host application, and read/write clips and frames on remote FS and Standard FS storage devices with the same ease as you would local media. In addition, Wiretap allows you work with multi-layer and stereoscopic timelines.

Lustre gains access to the remote media and metadata via Wiretap servers running on the host workstations. A Wiretap server is installed by default with most Visual Effects and Finishing applications, and runs independently of the application. By default, Lustre automatically detects all the Wiretap servers running on the Wiretap network. You can then browse for footage on the remote filesystem and load it into the Shot bin or timeline, just as if it were locally attached storage.

## Working with Wiretap Timelines

Lustre can interpret a Visual Effects and Finishing timeline as a single one-sequence clip, or as an imported timeline. When you reference a Wiretap timeline in Lustre, the dissolve and splice transitions are maintained. The Wiretap timeline appears on the Lustre Storyboard as a series of shots and transitions. Each shot comprising the timeline is added separately to the Library. Working with remote timelines containing soft-imported clips is equally possible.

Lustre can import a multi-layer timeline from a Visual Effects and Finishing application and export it to the Wiretap server (only available with Wiretap 2010 Extension 1 or higher). When gaps are imported from a multi-layer timeline, they are seen as black media for Layer 1 and appear transparent for the layers above Layer 1.

## Wiretap Timelines and Soft-Imported Media

Recall that in Autodesk Visual Effects and Finishing products, clips using soft-imported media contain only links to the media at its original location, so that no media is actually imported and duplicated in the Autodesk managed storage.

When importing a Wiretap timeline containing soft-imported media into Lustre, there is an additional advantage. Lustre recognizes the clips as soft-imports, and reads the associated media by way of the Wiretap

Gateway server, allowing you to modify the associated input parameters. That is, you are not bound by the resolution used in the originating application, and can work in Lustre at the resolution of your choice.

For example, suppose a Smoke timeline contains soft-imported RED media at HD resolution. When importing the timeline into Lustre via Wiretap, the soft-imported media is accessed directly, via the Wiretap Gateway. You thus have access to all the RED transcoding options for the *source* material, and can work with it at any available resolution, such as SD, HD, 2K or higher.

---

**NOTE** This discussion applies to media soft-imported to a Smoke or Flame project created in a Standard FS only. If the media has been soft-imported to Stone FS, Lustre will interpret this as media as “Stone” instead of RED.

---

## Wiretap Timelines and Wiretap Gateway Media

Autodesk Visual Effects and Finishing applications can import a wide variety of media formats from the Wiretap Gateway. It is important to note that Lustre can read all these formats, when you import a Wiretap timeline where they are used.

In particular, when a Visual Effects and Finishing application imports RED media files via the Wiretap Gateway server, the artist sets the debayering, colour, gain and curve settings to adjust the look and size of the imported media. When Lustre imports a timeline that includes RED media, it automatically makes use of the Wiretap Gateway server to gain direct access to the original footage. You thus have access to all the RED transcoding options for the *source* material, and can work with it at any available resolution, such as SD, HD, 2K or higher.

## Wiretap Playback Speed

Regarding clip playback speed, network bandwidth and traffic play the expected role. On an optimized GigE network, for example, you can achieve up to 80 MB/sec throughput. This is enough for real-time playback of SD clips, or about 1/4 real-time for 2K material. Better results can be achieved using InfiniBand or 10 GigE. Note that the Visual Effects and Finishing application on the Wiretap server host workstation can also affect performance. Visual Effects and Finishing applications have guaranteed access to the 'local' framestores—remote access by Lustre over Wiretap is at a lower priority. If you notice playback is suffering, consider generating local proxies for the remote material.

---

**NOTE** To improve real-time playback of RED media, the Wiretap Gateway can spawn multiple slave processes that increase performance without requiring additional licenses. See the *Wiretap Gateway Installation Guide*.

---

## Rendering to Wiretap

Once you are finished grading the material from the Stone FS or Standard FS, there are different rendering possibilities. As with any Lustre grading project, you can render to the local storage array. Under Wiretap it is also possible to render back to the Stone FS or Standard FS, and to publish soft-import links to rendered media.

## Before You Begin

This section presents important points to consider before beginning to work with Wiretap.

## Timeline Considerations and Restrictions

When creating a Visual Effects and Finishing timeline for use in Lustre, please note the following.

- **Drop Frame and Non-Drop Frame:** Lustre now supports a timeline with a mix of media that has drop frame and non-drop frame. Instead of using only the timeline frame code mode, it now also uses the source clips' frame code mode.
- **BatchFX** must be rendered prior to importing your timeline in Lustre. They will be seen as regular clips in the Lustre timeline.
- **Supported Timeline Elements:** Colour sources, soft-effects, timeline gaps, dissolve transitions, and fade-ins and fade-outs are supported in Lustre.
- **Dissolves:** These are regenerated in Lustre, along with the animation curve. This is only supported by Wiretap server 2010 and higher.
- **Unsupported Transition Types:** Wipe and Axis transitions are unsupported. These are displayed as dissolves in Lustre and can be recognized by a special icon.
- **Focus Point and Saving:** In a Visual Effects and Finishing application timeline, the positioner's focus point indicates the layer of interest for edits and other operations. It also determines what appears when you import the timeline into Lustre. When saving the timeline for use in Lustre, ensure the focus point is on the top-most layer you want included in the Lustre timeline. For example, if the Visual Effects and Finishing timeline contains four layers and the focus point is on the third layer when it is saved, only three layers are included in the Lustre timeline.

## Wiretap Limitations

It is important to note the following limitations:

- **Fade-Ins:** Avoid having a timeline starting with a fade-in at record timecode 00:00:00:00.
- **Tape Names:** Avoid using different shots that have the same timecode and tape name.
- **Hard-Committing:** Hard-committing a selection of shots creates a new clip with a tape name of *COMMIT*, and a source timecode obtained from the record timecode. There is no need to add this information to the shot manually. Hard-committing a single shot preserves the original tape name and timecode.
- **Start Timecode:** The Start timecode of the timeline should not be negative. Also, avoid using a timeline that begins with a fade-in and has a start timecode of 00:00:00:00.
- **Saving to a Clip Library:** Once you have added a clip to a clip library, make sure to switch to a different clip library. This both saves the clip library, and allows Wiretap to broadcast the updated information about the timeline and clips.
- **Dual Library View:** In Visual Effects and Finishing applications, the Dual Library View mode displays the contents of two clip libraries simultaneously, each in its own panel. When you switch from Dual Library View back to Single View, the newly-hidden library remains selected by the application, and is read-only to Wiretap. Lustre will be unable to render media to the clip library until it is deselected.

## Wiretap Gateway Limitations

When ingesting media using the Wiretap Gateway, please note the following:

- **OpenEXR:** Lustre supports ingest of OpenEXR in 16-bit float RGB format only. Files with other channels cannot be read in Lustre.
- **RED Rocket Board:** The RED Rocket board allows real-time decoding and debayering of RED media. For Lustre, it is supported in one configuration only. This is with Lustre installed on an HP Z800 workstation running Linux, and the Wiretap Gateway installed on a Mac OS workstation containing the

RED Rocket board. The board must be installed in a PCI-E x16 slot. The network connection must be 10 GigE.

## Incinerator Limitations

Incinerator provides in-line processing by several computers for Lustre, dramatically increasing the power of real-time playback. The following Wiretap and Wiretap Gateway features are not supported when an Incinerator cluster is connected:

- Stereoscopy
- Accessing media located on a Stone FS or Standard FS through Wiretap. Note: Timelines consisting of soft-imported media that has been “published” are supported.
- Real-time playback of media accessed through Wiretap Gateway.

## Wiretap Backwards Compatibility

You can view and write back to projects created in any current Visual Effects and Finishing application. However, if a project was created using an earlier version of the software, Lustre has read-only access to it. Similar considerations apply to the Wiretap server. That is, Lustre has read/write access to media via any current Wiretap server. Earlier Wiretap servers may provide read-only access. The version of the Wiretap server is shown in the Lustre browser.

## Networking

Lustre and Visual Effects and Finishing applications communicate through Wiretap over a network connection. The network infrastructure can be GigE or InfiniBand. A GigE connection is sufficient for SD and HD 8-bit workflows. An InfiniBand connection is recommended for high-resolution projects like HD 10-bit, 2K, and beyond.

See [Configuring Wiretap and Lustre](#) (page 2370) and the *Autodesk Visual Effects and Finishing Installation and Configuration Guide*.

## Supported Filesystems and Media Types

From the perspective of the Lustre user, there are no operational differences between accessing media on a Stone FS and a Standard FS for colour grading. However, there may be differences in performance. Performance varies when using Standard FS, depending on the configuration. Refer to “Standard FS Performance Expectations” in the *Autodesk Visual Effects and Finishing Installation and Configuration Guide*.

## MXF

Format	Extension	Import	Export	Depth
AVC-Intra 50	.mxf	yes	yes	
	NOTE Panasonic P2			
AVC-Intra 100	.mxf	yes	yes	
	NOTE Panasonic P2. Import includes support for 1080/60p.			
AVC-Intra 200	.mxf	yes	—	
DNxHD	.mxf	yes	yes	
	NOTE Includes support for formats: 36, 60, 75, 90, 90x, 110, 110x, 115, 145, 175, 175x, 185, 185x, 220, 220x.			

Format	Extension	Import	Export	Depth
DV 25	.mxf	yes	—	
	NOTE Panasonic P2			
DVCPRO	.mxf	yes	yes	
	NOTE Panasonic P2			
DVCPRO 50	.mxf	yes	yes	
	NOTE Panasonic P2 (PAL & NTSC)			
DVCPRO HD	.mxf	yes	yes	
	NOTE Panasonic P2. Available in 1080p@25/50, 1080p@24/30/60, 720p@25/50, and 720p@24/30/60.			
SonyRAW	.mxf	yes	—	
	NOTE Includes support for Sony F65, F55, and F5 camera outputs.			
XAVC	.mxf	yes	—	
	NOTE Includes support for Sony F55 and F5 camera outputs.			
XDCAM	.mxf	yes	—	
	NOTE MPEG-2 IMX 30, 40, and 50			
XDCAM HD	.mxf	yes	yes	
	NOTE MPEG-2 long-GOP. Import supports 4:2:0 and 4:2:2. Export: 4:2:2.			

**NOTE** Flame Premium exports MXF as OP-1a files (including the timecode). The is audio encoded as PCM, 16-Bit or 24-Bit. Avid applications support OP-Atom MXF files: use the AMA MXF plug-in to bring the OP-1a files into an Avid application.

## MP4

Format	Extension	Import	Export	Depth
H.264	.mp4	yes	—	
XDCAM EX	.mp4	yes	—	

Format	Extension	Import	Export	Depth
	<b>NOTE</b> MPEG-2 long-GOP			

### Other Streaming Codecs

Format	Extension	Import	Export	Depth
AVCHD	.mts or .m2ts	<b>yes</b>	—	
	<b>NOTE</b> Only linear PCM audio is supported. Some cameras can record AC-3 audio, but this format is not supported. Only the video portion of AVCHD media with AC-3 audio content is accessible from Flame Premium.			
R3D	.r3d	<b>yes</b>	—	RAW
	Supports REDCODE RAW 2 and 3, RED SDK version 4.4, including MONOCHROME R3D media. Starting with Flame 2013 20th Anniversary Edition Extension Extension 2 Service Pack3, changes to the RED SDK affected how the DRX setting was computed for all R3D clips. If you are using clips imported with a earlier version, review the clips DRX setting.			

### Audio File Formats

Format	Extension	Import	Export	Depth
AIFF	.aiff	yes	yes	16 or 24
AIFF-C	.aifc	yes	yes	16, 24, 32 (float)
Audio Visual Research	.avr	yes	yes	16
Berkeley/IR-CAM/CARL Sound (BISCF)	.bsf	yes	yes	16
MP3	.mp3	yes	yes	16
Nextsnd	.au	yes	yes	16, 24, 32 (float)
WAVE	.wav	yes		16, 24, 32 (float)
WAVE - Broadcast	.wav	yes	yes	16, 24, 32 (float)
	<b>NOTE</b> Includes support for RF64 files (BWF-compatible format that supports files larger than 4 GB).			
WAVE - Extensible	.wav	yes	—	16, 24, 32 (float)

Format	Extension	Import	Export	Depth
	<div><b>NOTE</b> Audio tracks are imported as regular audio tracks, without mapping the channels to spatial locations.</div>			
<b>NOTE</b> Files of any sample rate can be imported, but they are all resampled to 48 kHz.				

## Soft-Imported Media

In a Visual Effects and Finishing application, soft-importing creates a clip that references unmanaged media. Unmanaged media typically resides on shared network storage, such as a SAN or NAS, where numerous applications can have equal access to it, avoiding data duplication. If soft-imported media is overwritten, the clip referencing it is updated accordingly. If soft-imported media is deleted, the clip referencing it displays a checkerboard pattern indicating that the media files can't be found. Inversely if, in the Effects or Finishing application, all clips referencing media are deleted, the source media remains unaffected. Basically, soft-imported media is unmanaged, whereas imported media is managed.

## Published Media

Publishing consists of exposing managed or unmanaged media to a location accessible by other applications. Once published, the media is still being referenced in a clip library, just like any other clip, but automatically becomes soft-imported and unmanaged media. If the publish destination resides on the same volume and if the format of the published files is the same as the original file format, hard links to the managed media can be created as an option. This media is accessible to Lustre and unmanaged by the Effects and Finishing application.

If you are accessing media residing on a direct attached storage over a slow network connection via Wiretap, you may choose to publish your media to a shared network storage, which allows Lustre to access the media through a fast network storage connection. See [Sample Workflows](#) (page 2368).

## About QuickTime ProRes Support

On Smoke, which runs on Mac OS X, Apple QuickTime ProRes imports and exports are supported natively.

For all Linux-based application, exports using the Quicktime ProRes format requires connecting to a Wiretap Gateway running on a Mac OS X workstation.

Native ProRes import is supported in the following Linux applications:

- Flame
- Flame Premium
- Flame Premium - Grading
- Flare (when working with a Flame or Flame Premium project)

The following services can also decode clips using ProRes media imported by one of the above products:

- Burn
- Lustre Burn and Lustre ShotReactor
- Wiretap Central

Other Linux-based products can import ProRes by connecting to a Wiretap Gateway running on a Mac OS X workstation.

## Mixed Media Support

A 'mixed' clip or timeline contains media of different storage formats. Typically, this kind of timeline contains both media from a Stone FS framestore and media soft-imported from a Standard FS framestore. In earlier versions, these clips could not easily be used by Wiretap clients without an explicit *stonifize* or publish from within the Visual Effects and Finishing application. As a result of server-side video media conversion, this is no longer necessary.

---

**NOTE** One limitation is that the frames within a given shot must be the same format throughout the shot. For example, a shot must have all Stone FS media or all .DPX media.

---

## Proxy Media

A Lustre user can see proxy media on a Wiretap server by enabling the Half resolution button in the player. It is also possible to generate local proxies for Wiretap content. See [Project Menu Settings](#) (page 2374) and [Viewing Local Proxies for Wiretap Media](#) (page 2375). Lustre can create proxies as you are rendering the hires content to the Wiretap server by enabling the Proxy Rendering button within Network Rendering of the user configuration settings. See [Network Rendering Menu Settings](#) (page 2374).

## Sample Workflows

The ability to access remote footage makes it possible for Lustre to share footage with other Autodesk products. The example workflows provided below offer high-level descriptions of how Lustre could be integrated into different post-production pipelines.

---

**NOTE** While Smoke is used in the examples, other applications such as Flame are equally applicable.

---

### Workflow #1: Importing One-Sequence Clips

In the one-sequence workflow, you work with a single clip representing the timeline coming from Wiretap. In this case, files are first imported into Smoke from the Stone FS and assembled into a timeline created especially for Lustre. The timeline does not contain any splices or soft transitions. Lustre then accesses the timeline as a one-sequence clip by way of Wiretap. This workflow is particularly useful as a guide for a confidence check or scene detection.

---

**NOTE** A one-sequence clip appears as a single shot on the Lustre timeline and in the Library. You can perform a scene detection on the clip in order to break it down to its component shots. See [Using Scene Detection](#) (page 2010).

---

In Lustre, you create local proxies, grade them, and then render the source clips back to the Stone FS using any of the standard Render mode controls in the Render Local menu. See [Specifying the Destination for Local Render Files](#) (page 2263). The graded material is imported into Smoke to create an updated timeline to which finishing touches are applied prior to rendering the final clip.

## Workflow #2: Importing Timeline

Importing a Timeline allows you to work with an editorial sequence that contains shots and soft transitions (such as dissolves). In this case, timelines are created in a Visual Effects and Finishing application and Lustre gains access to the timeline by way of Wiretap. This is a useful workflow for shot-to-shot grading.

---

**NOTE** The timeline includes information for all the segments in a clip, including the head and tail information for dissolve and splice events. When you load a Timeline clip, it auto-assembles, allowing you to bypass the conform step.

---

Lustre renders the final clip to local storage using one of the four rendering options in the Render Local menu. See [Specifying the Destination for Local Render Files](#) (page 2263).

## Workflow #3: Smoke Renders Final Version

Smoke and Lustre users each access the same files from the external SAN or NAS, and work on them simultaneously. The Smoke user assembles the files and creates a multi-layer timeline while grading is performed on the one-sequence clip in Lustre. At any time during the process, Smoke can be made to publish metadata to reflect editorial changes. Lustre can then be used to re-conform and create a new version of the timeline based on updates performed in Smoke. When grading is complete, the source clips are rendered by Lustre to the external storage using any of the standard Render Place controls in the Render Local menu. See [Specifying the Destination for Local Render Files](#) (page 2263). The timeline can then be updated in Smoke by soft-importing the graded sources. Finishing touches are applied to the timeline in Smoke prior to rendering the final clip.

---

**NOTE** As an alternative to rendering to the SAN or NAS, Lustre could render to the Stone FS in order to allow Smoke users to bypass the soft-import step.

---

## Workflow #4: Lustre Renders Final Version

As in the previous example, files are soft-imported into Smoke and Lustre in order to be worked on at the same time. The only differences are: instead of referencing the timeline as a one-sequence clip, it is referenced as an timeline; Lustre renders the final version of the timeline, instead of Smoke.

## Workflow #5: Simple Source Grading

The following procedure illustrates a possible workflow for source grading for complex projects that include multi-layer timelines with numerous effects, transitions, etc. Since Wiretap flattens the timelines it imports from a Visual Effects and Finishing application, for complex projects, it is worthwhile creating a new single-layer timeline in the Visual Effects and Finishing application. In this way, all the material needed by the Effects and Finishing artists can be made available.

### Workflow for simple source grading

- 1 In Smoke, capture and import media from the off-line editor as a timeline.  
For greatest flexibility in the colour grading process, capture the material in A-mode or C-mode—that is, in ascending timecode sequence.
- 2 Create a timeline in Smoke that is especially for grading in Lustre, containing all the clips in a single video layer.

This can be accomplished most easily by selecting all the source clips needed in the clip library reel and performing a Load and Join operation.

- 3 In Lustre, use Wiretap to import the timeline created in the above steps.
- 4 Grade the sources in the imported timeline, then render it back, via Wiretap.  
The rendered clips contain the updated grading but the same tape name and timecode information as the original clips.
- 5 In Smoke, create a copy of the multi-layer timeline—that is, the *destination* timeline.
- 6 Save the unlinked timeline to the clip library where Lustre has rendered the media, and relink.  
The multi-layer timeline now contains the graded clips.

## Preparing the Wiretap Timeline for Lustre

Before you can read a Visual Effects and Finishing timeline using Wiretap, the Visual Effects and Finishing artist must prepare the timeline.

**To save a Wiretap timeline to a Visual Effects and Finishing clip library:**

- 1 Process Timeline FX and transitions (see your Visual Effects and Finishing application's User Guide).
- 2 Save the timeline to the Clip Library.  
  
**NOTE** When saving a timeline to the Clip Library for use in Lustre, the position of the focus point is important. See [Timeline Considerations and Restrictions](#) (page 2358).
- 3 Exit the library by changing to a different clip library.  
Exiting the library updates the information in the Visual Effects and Finishing database, making it available to Wiretap, and frees up the directory for read/write activity in Lustre.

## Configuring Wiretap and Lustre

Before you begin using Wiretap with Lustre, some one-time configuration is required. Depending on how you will be using Wiretap, the following items might require configuration:

- Dual network support
- Wiretap server auto-detection
- Access to a shared storage mount point
- Soft-imported timelines

## Configuring Dual Network Support

If your facility has both a GigE network and an InfiniBand network, you can configure Wiretap to use both. The Wiretap server will then make use of the high-bandwidth network for moving media, greatly improving network performance and increasing reliability. The behaviour is transparent to end-users.

**To configure the Wiretap server to use InfiniBand for media transfers:**

- 1 On the workstation hosting the Wiretap server, open the Wiretap configuration file, *wiretapd.cfg*, using a text editor.  
The file is located in the following directory:

**/usr/discreet/sw/cfg**

- 2 Scroll down to the **[Server]** section.

This section lists the IP addresses of the network interfaces used by Wiretap, in the order in which the connections are attempted.

- 3 In the case of a facility with both a GigE and an InfiniBand network, the IP address of the InfiniBand network must be first in the list, at **IP0**.

In the following example, the InfiniBand network IP address is **10.10.11.213**, and the GigE network IP address is **192.168.129.3**:

**[Server]**

**IP0=10.10.11.213**

**IP1=192.168.129.3**

- 4 Make the appropriate entries for your own networks, then save and close the file.
- 5 You must restart the Wiretap server for your changes to take effect:

**/usr/discreet/sw/sw\_restart**

## Configuring Lustre to Work with Wiretap

When starting Lustre, Visual Effects and Finishing systems running Wiretap servers on the same network are detected and displayed in the Browser by default. The Wiretap Server can be identified by its host name or IP address, depending on how the workstation's network settings have been configured. You can edit the *init.config* file to configure Lustre to restrict what is displayed to a specified selection of Wiretap servers if you want to limit access.

### The Configuration File

All Wiretap-related items are located in the *init.config* file, located in the following directories:

- *C:\Program Files\Autodesk\Lustre <version>* (Windows)
- */usr/autodesk/lustre\_<version>* (Linux)

To display a specified selection of Wiretap servers:

- 1 Open the *init.config* file in a text editor.
- 2 In the **<Wiretap>** section, change the Wiretap server auto-detection state to 'Off'.  
**<ServerAuto state="Off">**

**NOTE** Settings in the *init.config* file are case-sensitive. You must use a capital 'O' when setting the auto-detection state to Off.

- 3 In the **<WiretapServerGroup>** subsection of the **<Wiretap>** section, add each Wiretap server's IP address or host ID to a separate **<WiretapServer String>** line.

**NOTE** The Wiretap server string lines must be inside the open and close comment tags of the **<WiretapServerGroup>** example.

For example, if your network uses DNS:

**<WiretapServer string="berlin"/>**

Otherwise:

**<WiretapServer string="192.168.0.1"/>**

You can add as many workstations as you need in this list. Just add one WiretapServer line for each workstation.

- 4 Save the *init.config* file and start Lustre.

## Configuring the Wiretap Server to use a Shared Storage Mount Point

By default, Wiretap enables access to Visual Effects and Finishing media by way of the Wiretap server. However, if the applications share a storage mount point, Lustre can gain access to the media directly, while reading the metadata off the Wiretap server. You configure this behaviour by adding entries to the Wiretap *path translation file*.

Recall that the Linux and Windows operating systems present file path names using different syntaxes. For example, the path to network storage on a SAN that appears to a Windows workstation as **F:\SAN** might appear on Linux as **/SAN**. The path translation file ensures the path names are translated correctly as information moves between each application.

There are two main steps. First, determine how the shared mount point is seen by each system. Next, create a new translation rule-pair for each mount point in the Wiretap *path translation file*. In this way, you ensure that the Standard FS media used by a Visual Effects and Finishing timeline is directly read/write accessible in Lustre.

Note the following:

- The mount point/mapped network drives must already be set up in their respective operating systems before you refer to them in the path translation file.
- You can create translation rules on a host-by-host basis (most common), or on a per-platform basis. In situations where several hosts see their mount points in the same way, you can simplify the file by creating groups of hosts.
- Place each rule in the rule-pair on a separate line.
- Wiretap applies the rules in the order in which they appear in the file.

For complete information, see the *Autodesk Visual Effects and Finishing Installation and Configuration Guide*.

To configure the Wiretap path translation file:

- 1 On the workstation hosting the Wiretap server, open the Wiretap path translation configuration file, *wiretap\_path\_translation\_db.xml*, using a text editor.

The file is located in the following directory:

**/usr/discreet/wiretap/cfg**

- 2 Scroll down to the section of interest, for example, the **Translation between two operating systems** section.
- 3 Copy and modify an existing entry, or enter your own rule-pair.

For example, the following rule-pair enables Lustre to read and write a shared mount point seen by the Linux workstation as **/SAN**, and by the Windows workstation as **F:\SAN**:

```
<map src_os="WindowsNT" src_path="F:\SAN" dst_os="Linux" dst_path="/SAN" />
```

```
<map src_os="Linux" src_path="/SAN" dst_os="WindowsNT" dst_path="F:\SAN" />
```

- 4 Save the *wiretap\_path\_translation\_db.xml* file and restart the Wiretap server:

**/usr/discreet/sw/sw\_restart**

Restarting the server is not essential, since the Wiretap server regularly polls the path translation file for changes. However, by restarting the server, you force it to be parsed. This is a good way to test the file for any XML syntax errors. Access to the mount points themselves is not tested during this phase.

## Configuring for Soft-Imported Timelines

If you will be working with timelines containing soft-imported media, there are two configuration details to take care of. First, you must configure the Wiretap path translation table to permit the use of a shared storage mount point (as indicated in [Configuring the Wiretap Server to use a Shared Storage Mount Point](#) (page 2372)). Next, you must correctly set up the directory structure on the shared storage mount point, as indicated in the following procedure.

**To configure projects to access soft-imported timelines over Wiretap:**

- 1 On the shared network storage system, such as a SAN or NAS, ensure that files to be soft-imported into the Visual Effects and Finishing application are all located in the same directory structure.

For example, the directory on the shared network storage system could be configured as follows:

*/SAN/lustre/scans\_full/2k/images/2048x1556/*

Such a configuration is necessary in order for you to be able to render locally with Lustre.

- 2 On the Visual Effects and Finishing workstation where the Wiretap server is running, ensure the Wiretap path translation file contains entries to translate the paths to the shared mount points from one operating system to another.

This is necessary so that Lustre can have access to soft-imported media in Wiretap timelines.

See [Configuring the Wiretap Server to use a Shared Storage Mount Point](#) (page 2372).

- 3 In the Lustre Project Management menu, ensure that the Scans Full Home path points to the Windows drive configured in the Wiretap path translation file (S:\), for example:

*S:\lustre\scans\_full\2k\images\2048x1556\*

All other project setup fields can be configured as usual.

- 4 The shared network storage system, such as the SAN or NAS, must be mounted and accessible (writeable) from both the Wiretap server host and Lustre workstation.

You are now ready to import soft-imported timelines by way of Wiretap.

**TIP** You can tell whether or not the directory has been properly translated by checking to see if the <Home> prefix appears as part of the shot information in the Library. See [Viewing Media File Information](#) (page 1913).

## Setting Up the Lustre Wiretap Project

Lustre projects that make use of Wiretap must be configured differently than regular Lustre projects. The choices you make depend upon several factors. These factors include whether you will render locally or to a SAN or NAS (as can be the case in non-Wiretap setups), or use Wiretap to render to a Stone FS or Standard FS. In addition, you need to decide whether you will generate local proxies for the clips, or make use of proxies that might already exist on the Stone FS or Standard FS. If your project will make use of soft-imported media, additional considerations apply.

This section describes the settings for Lustre projects that make use of Wiretap, for all configurations other than those that use soft-imported media. For Wiretap projects that also make use of soft-imported media, see [Working with Soft-Imported Media](#) (page 2380). For general considerations on setting up projects, see [Project Management](#) (page 1765).

## Project Menu Settings

The following table explains the criteria to consider for each of the fields in the Project menu related to Wiretap projects.

Field	Criteria
<i>Scans Full Home</i>	<ul style="list-style-type: none"><li>■ To access a Stone FS or Standard FS, this field should have the same path as <i>Project Home</i>.</li><li>■ To access 'published', unmanaged media (also called soft-imported media), populate this field with the path to the media residing on the shared network storage (for example, a SAN or NAS). For example, if the media is located in <i>F:/SAN/Project/001</i>, the <i>Scans Full Home</i> path should be <i>F:/SAN</i>.</li></ul>
<i>Scans Half Home</i>	<ul style="list-style-type: none"><li>■ To use proxies coming from a Stone FS or Standard FS, this field should have the same path as <i>Project Home</i>.</li></ul>
<i>Renders Full Home</i>	<ul style="list-style-type: none"><li>■ To render media to a Stone FS or Standard FS, browse to a clip library destination. This automatically sets the Wiretap render path.</li><li>■ To render media to a shared network storage device (for example, a SAN or NAS), browse to a shared network destination. See <a href="#">Rendering Shots</a> (page 2382).</li></ul>
<i>Renders Half Home</i>	<ul style="list-style-type: none"><li>■ To render proxy media to a Stone FS or Standard FS, browse to a clip library destination. This automatically sets the Wiretap render path.</li><li>■ To generate local proxies from media coming from a Stone FS or Standard FS, populate this field with the path to your local storage array.</li><li>■ To generate local proxies from Published content, populate this field with the path to the local storage array or shared storage network.</li></ul>

## Rendering Menu Settings

If you are rendering to a Stone FS or Standard FS, enable the *Same Format As Scans* button. If you plan to render to shared storage, select the file format to be used (DPX, TIFF, etc.). Make sure the format you select is supported by the Wiretap server. See [Supported Media File Formats](#) (page 69).

## Network Rendering Menu Settings

To improve interoperability of projects used by Lustre and a Visual Effects and Finishing application, enable the *Proxy Rendering* button. Proxies are automatically generated when you render the timeline. This makes it efficient to load clips in a Visual Effects and Finishing application as you no longer have to render proxies first.

## Viewing Local Proxies for Wiretap Media

As with non-Wiretap Lustre projects, proxy generation reduces processing time and can be helpful when working with large image formats. Wiretap projects will make use of Visual Effects and Finishing proxies, if available. This, nevertheless, involves transferring the proxies across the network. It can be advantageous to generate *local* proxies, regardless of proxy availability on the Visual Effects and Finishing side. Note that you can generate the local proxies at 100% of the original resolution. This allows you to work with high-resolution material on the local Lustre storage, avoiding network traffic without sacrificing image quality.

To view local proxies generated from the Wiretap media, enable the *Local Proxy* button in the Network Rendering menu (see [Network Rendering Settings](#) (page 1799)). When this button is disabled, you will be able to see the original Visual Effects and Finishing proxies using the network connection, upon import. Note that this will not work for clips already imported when the button was disabled.

## Browsing for Remote Footage

Wiretap servers are displayed in the Lustre file browser as an IP address or server workstation name, followed by the Wiretap server version. When you manually open the Wiretap server entry in the browser, both Stone FS and Standard FS filesystems are visible.

▼ chorley	Autodesk IFFFS 2009.0.0
▶ stonefs	Free: 652.59GB Total: 1.59TB
▶ stonefs3	Free: 120.61GB Total: 144.64GB

(a) Wiretap server workstation name (b) Stone FS volume (c) Standard FS volume

For details on using the file browser, see [Accessing the File Browser](#) (page 1909).

**NOTE** If you are unable to browse the remote filesystem, ensure the Wiretap service is functioning. See [Verifying Connectivity between Lustre and the Wiretap Server](#) (page 2386).

## Viewing the Volume Hierarchy

Expanding a Wiretap volume presents its contents as a hierarchy.

▼ chorley	Autodesk IIFFS 2009.0.0.beta6
▼ stonefs	Free: 658.26GB Total: 1.59TB
▶ DELETE	
▶ DJ_WIRETAP	
▼ HD_Proxy_On	
▶ 16-bit	
▶ Default	(Read-Only)
▶ RENDERS	
▶ SD_SOFT	
▶ HD_v2008	
▶ HD_v2008_12bU	
▶ HD_v2009	

(a) Wiretap server (b) Free space on the file system (c) Read-Only indicator (d) Total space on the file system

The following information is presented:

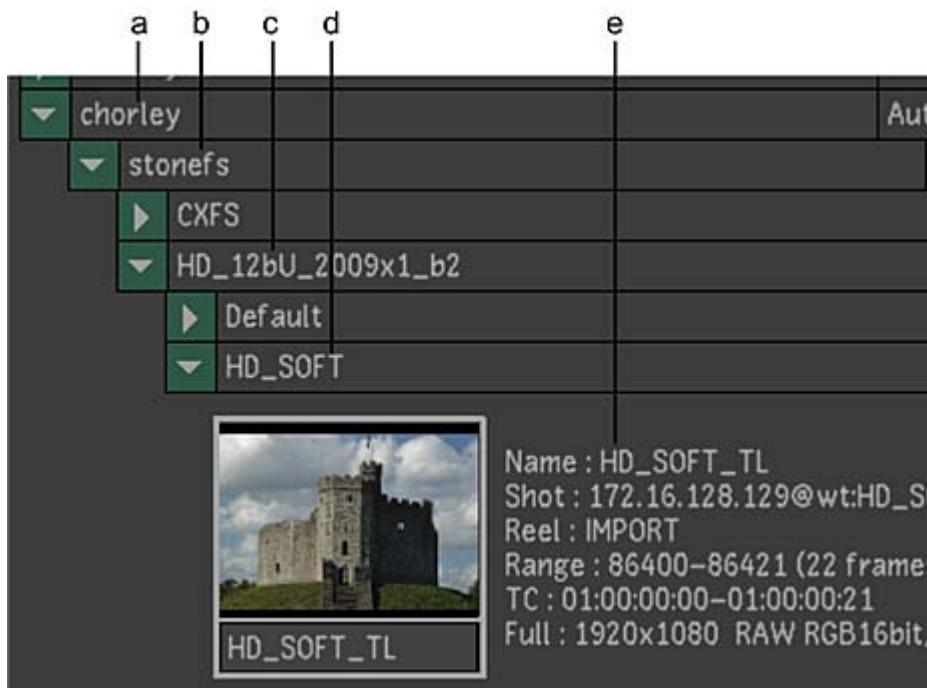

- Wiretap server
- Volume
- Project
- Library
- Reel (optional)
- Clip (in libraries and reels)

Note the following additional points:

- When you access a Wiretap server's volume in the file browser, the remaining space and the total space of the file server on the storage device is also displayed.
- *Read-Only* indicates the library is locked and new clips cannot be written to it. This is the case when a Visual Effects and Finishing artist is browsing the library, for example.
- In the browser, click Refresh to refresh the view of your filesystem.

## Viewing Volume and Clip Details

Expanding the volume presents additional details.

**(a) Wiretap server (b) Volume (c) Project (d) Library (e) Clip and Clip Metadata**

A detailed view of a Wiretap clip is represented in the Library and in the file browser with the following information:

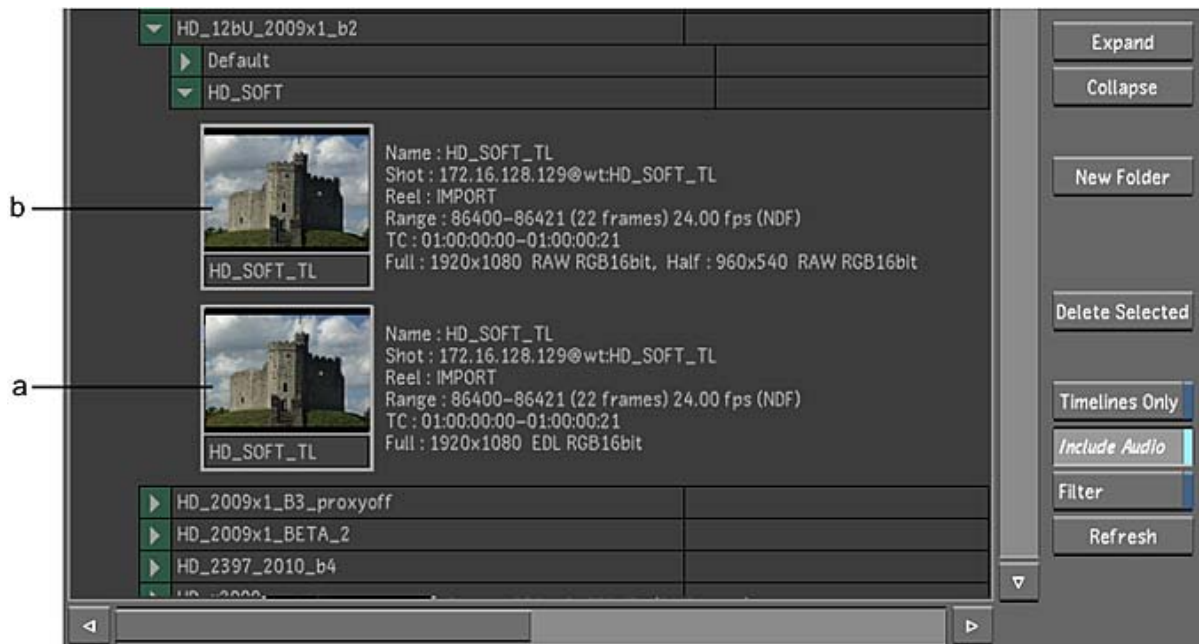

- Clip name
- Shot location
- Frame range and timecode start/end
- Full and proxy resolutions
- Media type

For more information about viewing clip metadata, see [Viewing Media File Information](#) (page 1913).

## One-Sequence and Timeline Views

By default, the Timelines Only button in the Browser is enabled, which allows Wiretap content to be presented in a timeline form. You can also choose to display the one-sequence representation of the Wiretap timeline by disabling the Timelines Only button, in which case both the one-sequence and timeline versions are displayed at the same time.

(a) Timeline version (b) One-sequence version

The difference between the two is as follows:

- One-sequence: a sequence of files is presented to Lustre with clip metadata as opposed to timeline metadata and you can still see transitions as 'read-only'. This is useful, for example, when manually comparing the contents of the timeline against a digital cut captured directly from an offline video tape. See [Performing a Confidence Check](#) (page 2008).
- Timeline: a sequence of shots that contains source clip metadata (for example, shot name, source timecode), dissolve, and cut transitions. This allows you to recreate the timeline that you had in your Visual Effects and Finishing application (in a single-layer format) when you import the Wiretap timeline. You can then grade each shot and render back either a single-sequence clip or render with the timeline structure intact.

Additionally, you can choose to display the clip thumbnails with or without details about the clips by enabling Details for a detailed view or Proxies for thumbnail-only view. For more information about the Browser, see [Accessing the File Browser](#) (page 1909).

## Importing the Wiretap Timeline

Please note the following points about importing footage from the browser:

- To maintain the editorial structure and transitions of the Wiretap timeline, it is recommended that you import the Wiretap timeline by dragging and dropping from the browser directly to the empty Storyboard area.
- If the Storyboard already contains a timeline, the new timeline is added as a layer above the existing layer(s). It is added at its record timecode position (not at the drop point), which contains the new timeline content.
- If the Storyboard or timeline is empty, importing a timeline from Wiretap automatically creates a cut. The name of the cut is the same as the name of the timeline.
- Source clips containing long tape names (more than seven characters) are supported.
- For long timelines, consider creating a new cut before dragging and dropping a clip from Wiretap. See [Creating a New Cut](#) (page 1819).

- It is possible to load multiple timelines from Wiretap into different Lustre timeline layers (this is only applicable if you are using a Wiretap server version older than 2010 Extension 1). This is useful to create a timeline as it appears in the Visual Effects and Finishing application. In this case, the Visual Effects and Finishing artist must create multiple timelines, one for each layer. In Lustre, you manually load these into the current timeline. Lustre adds each layer based on the record timecode of the Wiretap timeline.
- Once the Wiretap timeline is regenerated as a Lustre timeline in the Storyboard, the source clips are automatically added to the Library.
- If you drag and drop the Wiretap timeline directly into the Library (as you would for local footage), only the source clips are imported into the Library. The timeline is not created in Lustre.
- By default, audio tracks are imported along with the timeline it is associated with. If you do not wish to import any audio over Wiretap, disable the Include Audio button. For more information about importing and playing back audio from Wiretap, see [Importing Audio From Wiretap](#) (page 2349).
- Once shots are loaded into the Storyboard, information about the selected shot is displayed in the Shot Info field.

(a) Location of the Wiretap clip (b) Resolution of the clip (c) File format (d) Bit depth per channel (RGB)

## Dust Bust and Marry Grade

It is possible to perform dust removal on media imported via Wiretap. However, since media stored on a Stone FS or Standard FS filesystem cannot be replaced by Lustre, you can create dust metadata for use when rendering media only.

---

**NOTE** The render options within the Image>Dust menu are inactive when media is imported from the Wiretap server or Wiretap Gateway. You can only render by using the Dust option within the Render>Local menu.

---

Media imported by Wiretap can also be used to generate Marry Grade data. However, since it is not possible to write Marry Grade files to Stone FS or Standard FS filesystems, the Marry Grade files are stored in the project's Full or Half Scan location. In the Marry Grade folder, a WT (Wiretap) folder is automatically created. Within it, a hierarchy of folders contain the Marry Grade data.

## Working with Half Float Media

OpenEXR is a high-dynamic range (HDR) media format supporting multi-resolutions and an arbitrary number of channels and channel types, such as specular, diffuse, alpha, RGB, normals, in a single file. Lustre supports OpenEXR 16-bit RGB only (files with other channels cannot be read). This format is sometimes referred to as "16-bit half float".

Lustre can obtain 16-bit floating point media in two distinct ways. First, it can acquire the media by way of a Wiretap server. That is to say, by browsing the clip libraries and associated framestores of Visual Effects and Editing applications. Second, it can acquire the media directly, by importing OpenEXR media using a Wiretap Gateway server. In both cases, you need to tell Lustre how to work with the half float media.

As indicated, OpenEXR represents pixels as floating-point numbers. Internally, Lustre uses a 16-bit integer format. Thus, before you can grade OpenEXR media, it must be converted from floating point to integer.

This is done by setting a floating point conversion LUT for the project. See [Applying an Existing Input LUT](#) (page 2072).

Two special floating point conversion LUTs and one output LUT have been provided for this purpose. Before working with OpenEXR media, select the conversion LUT corresponding to the colour space defined for the project.

LUT	Description
lin_default	The default linear colour space input LUT, generally reserved for video images.
log_default	The default logarithmic colour space input LUT, generally reserved for film images.
identityExtended	An output LUT designed to preserve the floating point media.

When rendering to Wiretap as part of an interoperability workflow with an Autodesk Visual Effects and Finishing application, apply the inverse LUT, *identityExtended*, during the render, to restore the original colour space. If interoperability is not the goal, specify an output format and render as usual, without applying an output LUT. See [Rendering Shots](#) (page 2259).

**NOTE** It is not possible to output in the OpenEXR format.

## Working with Soft-Imported Media

This section presents the considerations that apply when working with timelines or clips containing soft-imported media. When using soft-imported media, be aware that you have no control if another user modifies the original media files. All soft-imported clips that refer to the modified media files are updated to reflect the change. Ensure that all users accessing the same media are aware of these implications.

## Creating Soft-Imported Links to Rendered Media

You can create soft-imported clips from rendered material and write the generated timeline back to the Wiretap Clip Library. The rendered results reside in the destination specified in the project settings, and a soft-import link is created on the Stone FS or Standard FS.

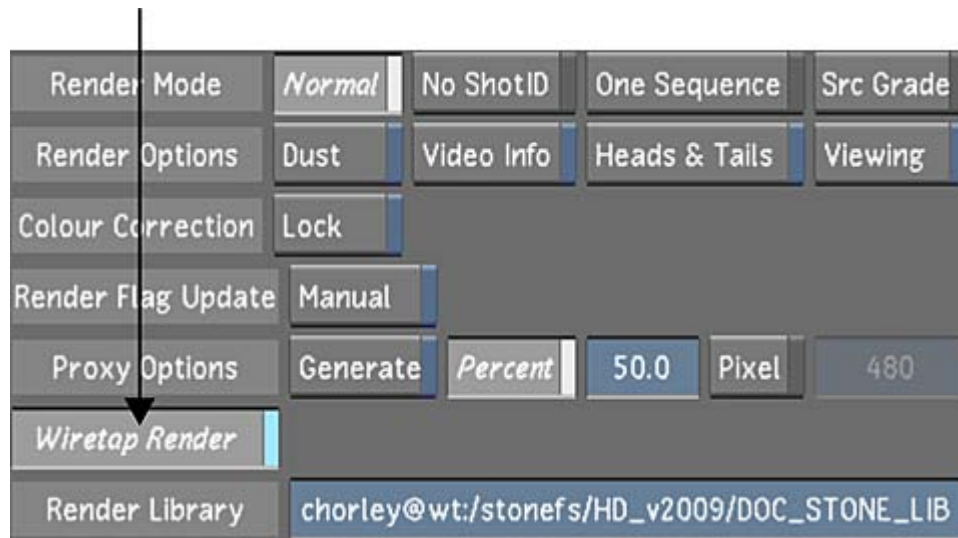

**To create a soft-imported link to your graded renders in the Wiretap Clip Library:**

- 1 Click Setup, and then click Project to display the Project menu.
- 2 In the Renders Full Home field, enter the path for the graded files to be rendered to.  
For example, if your Windows drive is mapped to the network storage as S:\, then the renders full home path should be S:/SAN/lustre\_renders.

**NOTE** The shared storage network (i.e., SAN or NAS) must be mounted and accessible from both the Wiretap Linux host and the Lustre workstation.

- 3 Click Render, and then click Local to display the Local menu.
- 4 Select one of the following render options:
  - Normal
  - No ShotID
  - One Sequence
  - Src Grade

- 5 Enter the path for the location of the soft-imported clip in the Render Library field.  
For example, *10.145.43.31@wt:/stonefs/project/library*.  
Note that you can set a default value for the Render Library field when configuring the project, as described in the next procedure.
- 6 Enable the Wiretap Render button.

- 7 Click Start.  
This renders the files to the specific path of the shared network storage, and publishes the soft-import links to your rendered files in the destination Wiretap clip library. A new scene grade reel containing the soft-imported clips and/or timeline is created in the location specified by the Render Library field.

#### To set the Render Library path as a project setting:

- 1 From the Main menu, click Setup, and then Settings. Select the project to edit, and then click Edit in the Project group.
- 2 On the Network Rendering menu, enter the desired path in the Render Library field in either of the following ways:
  - Navigate to the directory using the navigation aid button and browser.
  - Enter the desired path directly in the Render Library field, in the following format:  
`<Wiretap_server>@wt:<volume>/<project_name>/<library>`  
 For example:  
*rishikesh@wt:/stonefs/HD\_project/lustresmoke*
- 3 Save the settings for the project by clicking Save Project.
- 4 Click Exit Project.
- 5 To verify the path shows up as expected, from the Main menu, click Render, and then Local.  
The path appears in the Render Library field.

## Working with Stereoscopic Wiretap Timelines

Importing a stereoscopic Wiretap timeline follows all the principles and restrictions outlined for non-stereo Wiretap timelines (see [Importing the Wiretap Timeline](#) (page 2378)). Similarly, once in Lustre, it is indistinguishable from a “local” stereoscopic timeline. Under specific circumstances, however, when rendered

back to the Wiretap server, the timeline will lose its stereo status in the originating application. The status can easily be regained.

Recall that in an Autodesk Visual Effects and Finishing application, such as Smoke or Flame, the metadata must always be identical between the left and right eye layers. The layers must share the same resolution, bit-depth and framerate. They must also be of the same duration, and have the same number of edits, in the same places. If the metadata falls out of sync, the timeline loses its stereo status.

However, in Lustre it is sometimes necessary to apply processing to just one layer of a stereo timeline. For example, applying a cut and animating the brightness channel can be a convenient technique for correcting a shot that becomes increasingly bright as it progresses. A cut applied to one layer but not the other puts the metadata out of sync, and the shot is no longer recognized as a stereo timeline, once rendered back to the Autodesk Visual Effects and Finishing application. It appears as a timeline with two layers, but without any of the stereo features or interface components.

When this arises, simply select the shot that caused the metadata to fall out of sync, and adjust it. Often this can be done in the originating application. In the case of an added cut, for example, you can “hard commit” the two shots involved. This renders the frames and eliminates the cut, “re-synchronizing” the metadata.

For other information on the Stereoscopy feature, see [Stereoscopy](#) (page 2247).

## Rendering Shots

When you have finished grading the imagery from the filesystem, you can render to the local storage array, or write back to the Stone FS via Wiretap.

---

**NOTE** Audio tracks that were imported through the Wiretap server cannot be rendered back to Wiretap.

---

If working with soft-imported clips, you must also set up the directory structure on the SAN or the NAS in such a way that Lustre can recognize it. See [Setting Up the Lustre Wiretap Project](#) (page 2373). You render clips from a local storage the same way as you would for any other clip. See [Rendering](#) (page 2258).

Rendering clips back to Wiretap requires that the render destination be specified in the project setup. See [Setting Up the Lustre Wiretap Project](#) (page 2373). The render destination you specify in the project setup will determine the location of the reel in which the rendered clip will be placed. See [Rendering with Wiretap](#) (page 2383).

---

**NOTE** The clip’s long tape name metadata is also rendered back through Wiretap.

---

You can use the Render menus to render your work. You can render selected shots, all shots in a cut, a specific layer in the Timeline, or the flattened result of a multi-layer timeline. To prepare for rendering, do the following.

### Rendering workflow:

- 1 Specify the layer to be rendered.
- 2 Set the resolution of the render files.
- 3 Set resize options, as needed.
- 4 Specify the destination for the render files.
- 5 Specify the output file format (if different than the original footage).
- 6 (Optional) Change the output colour space or specify an output LUT.
- 7 Set other options such as timecode burn-in and rendering with a viewing LUT.

## Rendering with Wiretap

When rendering with Wiretap, a new reel (based on the scene name, grade, and timeline name) will be created in the destination Clip Library that was defined when the project was created. See [Project Management](#) (page 1765).

This is the syntax to use when rendering to Wiretap, or publishing soft-import links to your graded sources:

```
<IP address or hostname>@wt:/<volume>/<project_name>/<library>
```

In the above sample, `<IP address or hostname>` is the IP address or host name of the Wiretap server. For a Stone FS, the volume is specified as *stonefs*. For a Standard FS, it is specified as *stonefs<#>*—for example, *stonefs2*.

If, for example, *10.145.43.31@wt:/stonefs/HD\_project/rendered\_grades* was entered in the Renders Full Home field, the rendered clip will be placed in:

```
/stonefs/HD_project/rendered_grades/<scene>_<grade>_<timeline_name>
```

You can specify how you want render files to be organized in the Wiretap Clip Library using the Render Place controls in the Render Local menu.

### Normal Rendering Mode

A Normal render creates source clips (with or without head and tail frames) and a timeline. The extension of the timeline is the grade that the timeline is associated with (e.g., `<cut/timeline_name>_grd<number>`). In this mode, dissolves are rendered, and cannot be further modified in the Visual Effects and Finishing application.

For shots rendered to a Wiretap Clip Library, a new reel (based on the scene name, grade, and timeline name) is generated in the Clip Library that was defined when the project was created. This is where the rendered material is placed.

For example, if *10.145.43.31@wt:/stonefs/tutor/lustregrades* was entered in the Renders Full Home field, the graded rendered shots are placed in *10.145.43.31@wt:/stonefs/tutor/lustregrades*. These shots contain the clip name, grade name, and the shot's unique ID.

```
<clip_name>_<grade>_<unique_id> (example:shot1_grd14_AB3E9770000053)
```

An additional clip with a `_grd<number>` suffix is also generated containing the cut or timeline name. For example, if the grade name is *grd14* from the timeline called "interior\_003", the additional file is:

```
interior_003_grd14
```

The graded timeline is generated based on the new rendered source files.

### No ShotID Rendering Mode

As outlined in the Normal mode description above, when rendering clips to Wiretap, a new reel (based on the scene name, grade, and timeline name) is created in the Wiretap Clip Library and all rendered material is placed there. The additional clip with the `_grd<number>` suffix is also generated.

### One-Sequence Rendering Mode

As with Normal and No ShotID mode, when rendering clips to Wiretap, a new reel (based on the scene name, grade, and timeline name) is created in the Wiretap Clip Library and all rendered material is placed there.

One-Sequence mode generates one clip of the graded sequence containing the Lustre cut or timeline name and the grade number. If, in Lustre, your scene is named *interior\_003*, the timeline is named *FINAL\_CUT*, and the grade file is named *grd14*, the new reel in the Wiretap Clip Library will be called:

/stonefs/HD\_project/rendered\_grades/interior\_003\_FINAL\_CUT\_grd14/

The rendered, one-sequence clip will contain the grade name: *FINAL\_CUT\_grd14*

### Source Grade Rendering Mode

Src Grade mode renders the complete timeline back to Wiretap with Lustre grading applied, but dissolves and retimes are rendered as soft effects with modifiable values. This is the most convenient rendering mode for regenerating source clips for relinking in the Visual Effects and Finishing application, in a “simple source grading” workflow.

For shots rendered to Wiretap, a new reel (based on the scene name, grade, and timeline name) is generated in the library that was defined when the project was created. This is where the rendered material is placed.

For example, if *10.145.43.31@wt:/stonefs/tutor/lustregrades* was entered in the Renders Full Home field, the graded rendered shots are placed in *10.145.43.31@wt:/stonefs/tutor/lustregrades/scene\_grade*. These shots contain the clip name, grade name, and the shot's unique ID.

<clip\_name>\_<grade>\_<unique\_id> (example: *shot1\_grd14\_AB3E9770000053*)

An additional clip with a *\_grd<number>* suffix is also generated containing the cut or timeline name. For example, if the grade name is *grd14* from the timeline called “interior\_003”, the additional file is:

*interior\_003\_grd14*

The graded timeline is generated based on the new rendered source files.

Rendered graded source files are renamed according to the grade number and the clip's unique ID. For example: *grd01\_4323B1F4*.

## Rendering Wiretap Clips to Local or Network Storage

The render directory structure for Wiretap clips is different from how local scans are rendered to the local or networked storage. The location and structure of the *scene* or *grd* directory depends on whether your shots are written on the Stone FS, or soft-imported into the Stone FS, and is based on your project directory structure. See [Setting Up the Lustre Wiretap Project](#) (page 2373).

You can specify how you want render files to be organized under the *grd* or *scene* directory using the Render Place controls in the Render Local menu. These controls affect the location where they are saved and the naming scheme of the render files.

---

**NOTE** There is currently no difference between Normal and No ShotID renders.

---

### To set how render files are organized:

- 1 Enable Normal, No ShotID, One Sequence, or Src Grade.

---

**NOTE** Soloing and Muting rules for Wiretap rendering are the same as those for local rendering. See [Specifying the Destination for Local Render Files](#) (page 2263).

---

### Normal Rendering Mode

Clips are rendered to sub-directories of a directory based on the scene name, which Lustre creates automatically when you first render shots. From there, they are rendered with each shot in its own *grd\_UID* directory, creating the final name by combining the grade name with the scene name.

For example:

Stone-based clips are rendered as:

<Home>/<scene>/grd/<grdXX\_UID>/<resolution>/<scene\_grdXX.xxxx>.dpx

Soft-imported clips are rendered to a directory called *grd*. With this *grd* directory, all the shots are rendered to a single directory based on the source location of the soft-imports (let's call it the source reel) and the grade name. From there, the final name is created based on the source filename and Lustre grade name.

For example:

Soft-imported clips are rendered as:

<HOME>/grd/<sourcereel\_grdXX\_UID>/<resolution>/<origfilename\_grdXX\_UID.xxxx>.dpx

If a source clip called *shot13* has been soft-imported into the Effects or Finishing application from this location:

/SAN/lustre/scans\_full/2k/reel23/2046x1556/

Lustre then imports this soft-imported clip via Wiretap, saves the grade as *grd01*, and renders it to the local or networked storage array. Lustre will take the name of the shot directory preceding the resolution directory, in this case, *reel23*.

For example:

Soft-imported clips are rendered as:

<HOME>/grd/reel23\_grd02\_AB3E9770000053/2046x1556/shot13\_grd01\_4323B1F4.0001.dpx

### No ShotID Rendering Mode

As with Normal renders, Stone-based clips are rendered to sub-directories based on the scene name, which Lustre creates automatically when you first render shots. From there, they are rendered with each shot in its own *grd\_UID* directory, creating the final name by combining the grade name with the scene name.

For example:

Stone-based clips are rendered as:

<HOME>/<scene>/grd/<grdXX\_UID>/<resolution>/<scene\_grdXX.xxxx>.dpx

As with Normal renders, soft-imported clips are rendered to a directory called *grd*. With this *grd* directory, all the shots are rendered to a single directory based on the source location of the soft-imports (let's call it the source reel) and the grade name. From there, the final name is created based on the source filename and Lustre grade name.

For example:

Soft-imported clips are rendered as:

<HOME>/grd/<sourcereel\_grdXX\_UID>/<resolution>/<origfilename\_grdXX\_UID.xxxx>.dpx

### One Sequence Rendering Mode

As with Normal and No ShotID renders, clips are rendered to sub-directories of a directory based on the scene name, which Lustre creates automatically when you first render shots. From there, under the sub-directory called *grd*, the shots are rendered as a single sequence to a directory based on the *grd* name. The filenames consist of the scene name, the grade name, and a sequential number. There are no UUIDs in the directory naming scheme.

Soft-imported clips are rendered to sub-directories based on the scene name, which Lustre creates automatically when you first render shots. From there, under the sub-directory called *grd*, the shots are rendered as a single sequence to the sub-directory based on the *grd* name. The filenames consist of the scene name, the grade name, and a sequential number. There are no UUIDs in the directory naming scheme.

For example:

Stone-based clips are rendered as:

```
<HOME>/<scene>/grd/<grdXX>/<resolution>/<scene_grdXX.xxxx>.dpx
```

Soft-imported clips are rendered as:

```
<HOME>/<scene>/grd/<grdXX>/<resolution>/<scene_grdXX.xxxx>.dpx
```

### Source Grade Rendering Mode

As with Normal and No ShotID renders, clips are rendered to sub-directories based on the scene name, which Lustre creates automatically when you first render shots. From there, they are rendered with each shot in its own *grd\_UID* directory, creating the final name by combining the grade name with the scene name. In addition, Src Grade excludes dissolves and retimes and renders the files with their pre-dissolve and pre-ptime handles.

Stone-based clips are rendered as:

```
<HOME>/<scene>/grd/<grdXX_UID>/<resolution>/<scene_grdXX.xxxx>.dpx
```

As with Normal and No ShotID renders, soft-imported clips are rendered to a directory called *grd*. With this *grd* directory, all the shots are rendered to a single directory based on the source location of the soft-imports (let's call it the source reel) and the grade name. From there, the final name is created based on the source filename and Lustre grade name. In addition, Src Grade excludes dissolves and retimes and renders the files with their pre-dissolve and pre-ptime handles.

Soft-imported clips are rendered as:

```
<HOME>/<grd/<sourcereel_grdXX_UID>/<resolution>/<origfilename_grdXX_UID.xxxx>.dpx
```

## Troubleshooting

This section presents a few helpful procedures relating to the Wiretap server and Lustre-server connectivity.

### Verifying Connectivity between Lustre and the Wiretap Server

Verify that you have proper connectivity over the network.

To verify connectivity (Windows):

- 1 On your Lustre workstation, click the Start button, and then click Run.
- 2 In the Run dialog box, type:

**cmd**

A command console is displayed.

- 3 In the command console, type:

**ping** <IP address of Wiretap host or Wiretap host workstation name>

---

#### Example system response

```
ping computer
```

```
Reply from 172.16.128.129: bytes=32 time=3ms TTL=63
```

```
Reply from 172.16.128.129: bytes=32 time=3ms TTL=63
```

```
Reply from 172.16.128.129: bytes=32 time=3ms TTL=63
```

A system response with ping times similar to the example, above, indicates that your Lustre workstation can see the remote Wiretap host workstation.

#### To verify connectivity (Linux):

- 1 On your Lustre workstation, open a shell and type:

**ping** <IP address of Wiretap host or Wiretap host workstation name>

---

#### Example system response

ping computer

Reply from 172.16.128.129: bytes=32 time=3ms TTL=63

Reply from 172.16.128.129: bytes=32 time=3ms TTL=63

Reply from 172.16.128.129: bytes=32 time=3ms TTL=63

A system response with ping times similar to the example, above, indicates that your Lustre workstation can see the remote Wiretap host workstation.

## Starting and Stopping the Wiretap Server

The following utilities have been provided for starting, stopping, and restarting the Wiretap server.

Utility	Description
<i>sw_start</i>	Starts the Wiretap server
<i>sw_stop</i>	Stops the server
<i>sw_restart</i>	Stops then restarts the server

The utilities are located in the following directory:

**/usr/discreet/sw**

## Verifying that the Wiretap Server is Running

#### To verify a Wiretap server is running:

- 1 On the Wiretap server, open a shell and type:

**ps -ef |grep wiretap**

---

#### Example system response

root 19579 10 May14 ? 00:00:00 /bin/sh /usr/discreet/sw/sw\_wiretapd

root 19588 195790 May14 ?00:01:51 /usr/discreet/wiretap/<version\_number>/ifffsWiretapServer -c /usr/discreet/wiretap/cfg/wiretapd.cfg

---

### Example system response

```
root27965 277280 10:02 pts/5 00:00:00 grep wiretap
```

In the above output, the line `/usr/discreet/wiretap/<version_number>/ifffsWiretapServer -c /usr/discreet/wiretap/cfg/wiretapd.cfg` indicates the version number of Wiretap that is running. If you do not see information similar to this, restart the Wiretap server.

## Hotkeys

### Storyboard Navigation

Use these hotkeys to navigate in the Storyboard and shot timebars.

Press:	To:
Up Arrow	Play forward.
Down Arrow	Play backward.
Left Arrow	Go to the first frame of the previous shot.
Right Arrow	Go to the first frame of the next shot.
Spacebar	Toggle Play/Stop.
Shift+Spacebar	Switch to Render View mode, switch off the user interface, and start playback.
Right Ctrl	Step one frame forward.
Right Alt	Step one frame backward.
Shift+I	Mark an in point for loop play on the Scene timebar.
Shift+O	Mark an out point for loop play on the Scene timebar.
Shift+L	Clear in and out points from the Scene timebar.
. (decimal point on the numeric keypad)	Cycles through the play modes (loop sequence, loop shot, and loop in and out points).
Tab	Toggle the Storyboard on/off. In the Editing menus, the Storyboard is always on.
Q	Switch between Storyboard viewing modes (regular and large Storyboard view). Not applicable to the Editing menu.

Press:	To:
Shift+1	Enable or disable the Update Storyboard feature. When enabled, the Storyboard thumbnails are automatically updated as you make changes to your shot.
. (period)	Update the shot's thumbnail according to the colour correction applied on the current frame.
Shift+. (period)	Regenerates multiple Storyboard thumbnails consecutively, starting from the current shot onwards.
Spacebar	Stop the multiple Storyboard thumbnail regenerating procedure.
Middle-drag	Pans the Storyboard.
F	Toggle between the collapsed Storyboard and the original.

## View Modes

Use these hotkeys to switch between the different view modes.

Press:	To:
P	Switch to Render View mode.
Shift+P	Switch to Render View mode and have Lustre re-detect and reparse the rendered files. This is useful when the files are not found automatically, for example, when they are not rendered from the application itself, but using the command line render.
Shift+ Spacebar	Switch to Render View mode, switch off the user interface, and start play. (This hotkey cannot be used in any of the Editing menus.)
O	Switch to Result view (this is the default).
I	Switch to Primary view. In this mode, only primary correction appears (secondaries or plugins are turned off).
Middle-drag	Pans the image in any direction.
Middle-right-drag	Zoom in/out of the image.
L	Show the framestore image.
K	Save the current image to the framestore.
Shift+K	Load only one reference image. You must define this image in the Lustre configuration file (with its full path).

Press:	To:
Ctrl+F	Enable or disable the filtering option. When enabled, it softens the shot so when you zoom in, the pixels are not as sharp or obvious.
Enter	Switch on/off the user interface.
~	Switch between the Player and a graphical schematic view of the axis hierarchy.
Shift+~	Switch the background colour between the selected colour and full black.
B	Toggle the Library or file browser's viewing mode: Proxies, List, or Details.
V	Toggle the Ratio button in the Grade menu to set the display aspect ratio. When you enable the Ratio button, the aspect ratio that appears in the Ratio field is used.
W	Toggle on/off the shot name text on the image.
Alt+1	Toggle on/off the RGB waveform monitor.
Alt+2	Toggle on/off the RGB histogram.
Alt+3	Toggle on/off the luminance waveform monitor.
Alt+4	Toggle on/off the vectorscope.
' (apostrophe)	Switch on/off monitor sub-region calculating.
F1	Display Playhead A.
F2	Display Playhead B.
Ctrl+F1	Cycle through the different colour view selections (i.e., colour, red, green, blue, and luminance channels).
Shift+Ctrl+F1	Return to the previous colour view selection.
F3	Cycle through the different viewers (i.e., Single, Dual, or Multi view).
Shift+F3	Return to the previous viewer option.
F4	Cycle through the Playhead A and B Dual view modes (i.e., 2-up, horizontal wipe, and vertical wipe).
Shift+F4	Return to the previous Playhead A and B Dual view mode.

Press:	To:
Ctrl+F4	Cycle through the Stereo Dual view modes (i.e., 2-up, horizontal wipe, vertical wipe, and blend).
Shift+Alt+F4	Return to the previous Stereo Dual view mode.
F5	Toggle between the current view options and the Single view (default).
Ctrl+F5	Cycle through the Multi view modes (i.e., 2, 4, 9, and 16).
Shift+Ctrl+F5	Return to the previous Multi view mode.
F6	Refresh the images in Multi view.
F7	Displays the timeline, Player, grading tools, and keyer (HLS or Diamond) and puts the mouse cursor and secondaries handling in the GFX SDI output.
F8	Toggle on/off the user interface update during playback.
F9	Switch between full and half resolution.
F10	Switch between the 1x and 2x zoom.
F11	Show the matte on the current secondary. Press F11 once to view the matte in Secondary view if Mask Type is set to Overlay. Press F11 twice to view the matte in Matte view if Mask Type is set to Greyscale.
F12	Show the result.
E	Show the selected colour's numbering type (code value, F-stop, or HDR).
Z	Show or hide the dust removal boxes.
H	Show or hide the selected overlay.
J	Switch on/off video preview.

## Timeline Sort Modes

Use the following hotkeys to sort the shots in your timeline.

Press:	To:
Alt+F9	Sort the shots using A-mode sort and enable heads and tails.
Alt+F10	Sort the shots using A-mode sort and disable heads and tails.

<b>Press:</b>	<b>To:</b>
Alt+F11	C-mode sort by EDL reel name and enable heads and tails.
Alt+F12	C-mode sort by EDL reel name and disable heads and tails.
Ctrl+Alt+F11	C-mode sort by folder name and enable heads and tails.
Ctrl+Alt+F12	C-mode sort by folder name and disable heads and tails.
Ctrl+Alt+Shift+F11	C-mode sort by DPX reel name and enable heads and tails.
Ctrl+Alt+Shift+F12	C-mode sort by DPX reel name and disable heads and tails.
Alt+F8	Disable sort mode.

## Notes

You can use any of the following standard text editor functions when drafting notes in the Notes window.

<b>Press:</b>	<b>To:</b>
cursor arrows	Move up, down, left or right.
Ctrl+A	Select all text.
Backspace, Delete	Delete text.
Home	Jump to the start of the current line.
Ctrl+Home	Jump to the start of the text.
End	Jump to the end of the current line.
Ctrl+End	Jump to the end of the text.
Page Up	Jump one text screen up.
Page Down	Jump one text screen down.
Shift+cursor arrow or left mouse button-drag	Select text.
Ctrl+A	Select all text.
Enter	Add an empty line.

Press:	To:
Esc or click outside the text editor	Disable the text editor.

## Calculators

The following hotkeys can be used with the standard calculator and the timecode calculator.

Press:	To:
Backspace	Erase the last digit in the calculator's numeric field.
Delete	Reset the calculator's numeric field to zero.
Page Down	Change the sign of the value in the calculator's numeric field.
Up cursor arrow	Add the current calculator value to the field or slider value.
Down cursor arrow	Subtract the current calculator value from the field or slider value.
Enter or click the calculator's active numeric field	For the standard calculator: calculate the value, apply it to the field or slider, and close the calculator. For the timecode calculator: jump to the frame number that corresponds with the value entered in the calculator's numeric field.
Enter or click the calculator's = (equals) button	Calculate the value and display the result without applying it to the field or slider. Applicable to the standard calculator only.
Ctrl+Enter or right-click the calculator's = (equals) button	Calculate the value, display the result, and apply it to the field or slider. Applicable to the standard calculator only.
Esc or click outside the calculator	Close the calculator and leave the field or slider value unchanged. Applicable to the standard calculator only.

## Dust Removal

Use these hotkeys when working in the Dust menu.

Press:	To:
Shift-click	Place a special "red pixel" repair box, which can repair a one-point scanned error.
Z	Show or hide the dust removal boxes.
, (comma)	Show or hide the dust removal boxes.
Backspace	Delete the active dust frame.

Press:	To:
Shift-click (Shot button)	Render dust removal results in all shots in the timeline that have been modified (rather than the current shot only).

## Grain Removal

Use these hotkeys when working in the Degrain menu.

Press:	To:
Z	Show or hide the degrain analysis sub-region boxes.
, (comma)	Show or hide the degrain analysis sub-region boxes.
Backspace	Delete the active degrain analysis sub-region boxes.
Right-click	Select or de-select multiple degrain analysis sub-region boxes.

## Editing

Certain editing hotkeys are available from any menu, whereas the rest are available exclusively from the Edit menu.

### Global Editing Hotkeys

When you enable the Editing While Grading button in the System & Menu page of the user configuration, you can access the following editing hotkeys from any Lustre menu (except the Colourist Timeline).

Press:	To:
Shift+C	Cut the shot in two at the current frame.
Shift+J	Join the current shot with the previous shot if they are from the same source.
Shift+T	Start interactive visual trimming.
Shift+R	Start interactive visual sliding between the current and the previous Shot.
Shift+S	Start a scene detection.

### Edit Menu Hotkeys

Use these hotkeys in the Edit menu.

For numeric keypad hotkeys that pertain to editing, see [Editing Menu—Edit](#) (page 2405).

Press:	To:
Shift+D	Delete the current shot.
Shift+Q	Locate and select the shot in the Library that corresponds to the selected shot in the Storyboard.
Alt-click	Locates and places a red border around the shot in the Storyboard and moves the positioner to the element in the Timeline that corresponds to the shot you Alt-click in the Library.
Esc	Exit visual interactive trimming, interactive slipping, and scene detection.
Backspace	Delete the last digit of the typed timecode number.
Shift+click-drag	Replace the shot.
Shift+hold-drag	Replace the shot with an offset.
Enter (on numeric keypad)	Confirm and exit Shot Replace mode.

## Timeline Menu Hotkeys

Use these hotkeys in the Timeline menu when your cursor is on the Timeline canvas.

Press:	To:
Up Arrow	Move focus up.
Down Arrow	Move focus down.
Left Arrow	Go to the first frame of the previous shot.
Right Arrow	Go to the first frame of the next shot.
Spacebar	Toggles play and stop.
Right Ctrl	Step one frame forward.
Right Alt	Step one frame backward.
Shift+Q	Locate and select the shot in the Library that the positioner is placed on.
Shift+I	Mark an in point on the Scene timebar for loop play.

Press:	To:
Shift+O	Mark an out point on the Scene timebar for loop play.
Shift+L	Clear all in and out points.
. (period) on numeric keypad	Toggles through the play modes (loop timeline, loop shot, and loop in and out points).
F1	Go to Playhead A.
F2	Go to Playhead B.
Shift+M	To mute or unmute the track on the focus layer.
T	To enable or disable Trim mode.
Enter	Toggles between the Player, file browser, and full-screen player.
Alt+S	Enable or disable Solo mode.
Alt+C	To turn on or turn off copy element(s) and grade.
Shift-drag	Copy the selected shot and constrain.
Shift+C	To make a cut in the element.
Shift+J	To join/remove splice on selected element.
Shift+D	Delete element(s) from the Timeline.
, (comma)	Enable or disable the Slip mode.
Ctrl-right-click	Timeline home view.
Alt+H	Zooms into the selected shot(s).
Middle-click-drag	Pans the Timeline left or right.
Right-click-drag	Zooms in and out of the Timeline.
Shift-click	To select multiple elements in a continuous order.
Ctrl-click	To select multiple elements that are not in a continuous order.
Shift+N	Copies the focus element to a new layer.

Press:	To:
S	Save a cut file and the associated grade files. If a grade file has not been created, a default grade file is saved.
Shift+R	Toggles the Ripple mode (Off/Start/End).
[	Zooms out of the Timeline. Zoom is centred on the playhead.
]	Zooms in on the Timeline. Zoom is centered on the playhead.
D	Adds a dissolve according to the focus and the positioner.
Shift+\	Applies/removes priority to/from the shot with focus.
Shift+right-click	Applies/removes priority to/from the selected shot.

## Capture Menu Hotkeys

Use these hotkeys during the capture process.

For numeric keypad hotkeys that pertain to editing, see [Editing Menus—Capture and Playout](#) (page 2406).

Press:	To:
Esc	Pause the capture. Press again to abort the capture.
E	Restart the capture.
S	Skip the current tape.
Backspace	Delete the last digit of the current timecode value.

## Playout Menu Hotkeys

Use these hotkeys during the playout process.

For numeric keypad hotkeys that pertain to editing, see [Editing Menus—Capture and Playout](#) (page 2406).

Press:	To:
Shift+click Insert button	Record a single shot to a tape that already contains material. This mode plays out the video and/or audio (the existing timecode is not affected).
Shift+click Assemble button	Record a single shot to a tape that already contains material. This mode plays out the video (and/or audio) and timecode to tape.

# Colour Grading

Use colour grading hotkeys to perform colour grading operations carried out in the Grading, Curves, and Secondaries menus.

For numeric keypad hotkeys that pertain to colour grading, see [Colour Menus — Grading and Secondaries](#) (page 2403).

## Global Colour Grading Hotkeys

Use these hotkeys in any of the Colour menus.

Press:	To:
C	Copy the parameters in the Selector tool from the current shot to the selected shot(s).
RR	Reset all the current shot's parameters to the default setting.
U	Undo the last action.
S	Save the current grade files and cut. If a grade file has not been created, a default grade file is saved.
G	Switch between Gang and Solo mode when in Group mode.
Y	Enable/disable GPU acceleration.
Ctrl (left)+H	To hide or show the selected geometry.
Page Up (Secondaries menu)	Increase the Hue Rotator value.
Page Down (Secondaries menu)	Decrease the Hue Rotator value.
Page Up (other menus)	Go to the Saturation curve in the Curves menu.
Insert	Go to the Hue curve in the Curves menu.
Home (Secondaries menu)	Increase the saturation of a secondary when a layer is enabled, or of the entire image when either the Input or Output button is enabled.
Home (other menus)	Go to the Lightness curve in the Curves menu.
End (Secondaries menu)	Decrease the saturation.
Ctrl+click Delete button	Delete a grade setup.
Print Scrn	Go to the Grading menu.

Press:	To:
Scroll Lock	Go to the Secondaries menu. Press it again to go to the next secondary.
Right-click menu	Display the preset menu for grading curves or secondaries.
/ (slash)	Auto-grade with the Balance Input Primaries for the selected colour. The master (brightness or lift/gain) is not modified. You can auto-grade the master as well by <code>Ctrl</code> -clicking the image.
Click	Pick the colour at the current position. <b>NOTE</b> The Show button must be disabled for this to work.
Shift-drag	Drag an area to calculate this area's mean colour, and show it in the colour picker. In monitoring view, this defines the sub-region as well. If you picked a colour, you can then perform colour matching. <b>NOTE</b> The Show button must be disabled for this to work.
Alt-click	Sample an individual pixel and set the Brightness Balance wheel to match the reference sample. You can drag through the image until you locate the pixel you want to sample, then <code>Alt</code> -click.
Ctrl-click	Sample an individual pixel and set the Brightness Balance wheel and Brightness slider to match the reference sample. You can drag through the image until you locate the pixel you want to sample, then <code>Ctrl</code> -click.

## Grade Bin Hotkeys

Use these hotkeys for the Grade bin.

Press:	To:
Shift+- (hyphen)	Cycle between Grade bin locations (cursor must be outside file browser or expanded Grade bin).
Double-click	Load all the settings for the selected preset thumbnail to the current shot only.
Right-click	Save the stored image to the framestore.
Shift-double-click	Load all the settings for the selected preset thumbnail to selected shots.
Ctrl-double-click	Load current menu settings for the selected preset thumbnail to the current shot only.
Ctrl+Shift-double-click	Load current menu settings for the selected preset thumbnail to a selection of shots.
Alt-double-click	Load specified parameters in the Selector to the current shot only.

Press:	To:
Alt+Shift-double-click	Load specified parameters in the Selector to a selection of shots.

## Expanded Grade Bin Hotkeys

Use these hotkeys for the expanded Grade bin.

Press:	To:
Right-click	Edit a note in the List view.
Shift+- (hyphen)	Cycle between expanded Grade bin locations (cursor must be over file browser or expanded Grade bin).
Shift-click	Select contiguous grade files.
Ctrl-click	Select multiple grade files.
Ctrl-drag	Copy a grade file to a Grade bin storage container.
Shift-double-click	Load all the settings for the selected grade file to selected shots.
Ctrl-double-click	Load current menu settings for the selected grade file to the current shot only.
Ctrl+Shift-double-click	Load current menu settings for the selected grade file to a selection of shots.
Alt-double-click	Load specified parameters in the Selector to the current shot only.
Alt+Shift-double-click	Load specified parameters in the Selector to a selection of shots.

## Secondary Layers Hotkeys

Use these hotkeys when working with the secondary layer panel.

Press:	To:
1, 2, 3, 4, 5, 6, 7, 8, 9, 0, -, =	Select a secondary layer (1-12, 13-24, 25-36, or 37-48).
\	Activate/deactivate the selected secondary layer.
Ctrl+(1, 2, 3, or 4)	Select the secondary layers page 1, 2, 3, or 4.
Scroll Lock	Cycle through all the activated secondary layers.

Press:	To:
Ctrl-click secondary layer button	Copy the grading information from the current menu (e.g., Grading, Curves, or Secondaries) to the selected secondary layer.
Shift-click secondary layer button	Copy all the colour grading information to the selected secondary layer.

## Curves Menu Hotkeys

Use these hotkeys in the Curves menu.

Press:	To:
A	Add a vertex to the mouse position in the current curve.
Shift+A	Lock the curve in place while adding a vertex.
D	Delete the selected vertex from the current curve.
R	Reset the current shot's curve parameters to the default setting.
Right-drag	Zoom in or out.
Middle-drag	Pan the curve.
Alt-drag	Zoom in on a curve using rectangle zoom.
Alt-right-drag	Zoom in on a curve using proportional zoom.
Ctrl (right)-left-click	Reset the curve zoom in/out properties to the default setting.
Ctrl (right)-right-click	Reset the curve viewer.
Shift-drag	Restrict movement of selected vertices to the Y axis.
Shift+Alt-drag	Restrict movement of selected vertices to the X axis.

## Secondaries Menu Hotkeys

Use these hotkeys in the Secondaries menu.

Press:	To:
, (comma)	Show or hide a geometry.
R	Reset all secondary colour correction parameters for the current shot.

Press:	To:
Shift+D	Enable Del Geom, and then delete a geometry.
A	Enable Add Pts, and then add vertices to a geometry.
D	Enable Del Pts, and then delete vertices from a geometry.
Z	Enable the Rotate button, and then click on the geometry's axis to rotate.
Right-click-drag	Rotate the geometry when you right-click its axis and drag.
Click-drag (on Z-axis)	Proportional scale left.
T	Enable the Move button, and then move a geometry's axis, vertex, or tangent.
X	Enable the Scale button, and then scale a geometry. You can scale a geometry along the X-axis, Y-axis, or you can scale it proportionally using the Global Scaling axis.
Backspace (tracking)	Delete the latest tracked position.
Right-click (basic geometry)	Convert a basic geometry to a free-form geometry.
Ctrl-click (free-form geometry)	Break or repair a tangent handle when you click one of the geometry's vertices.
Alt-right-click	Offset the axis.

## Timeline Menu Hotkeys

Use these hotkeys in the colour grading Timeline menu.

Press:	To:
Shift+C	To make a cut in an element.
Alt+S	Enable or disable Solo mode.
Up Arrow	Move the focus up.
Down Arrow	Move the focus down.
F7	Displays the timeline, Player, grading tools, and keyer (HLS or Diamond). Also activates the SDI out if the GFX SDI is enabled.
Ctrl+drag+drop	Drag and drop the grade from one shot to another.

Press:	To:
Ctrl+Shift+drag+drop	Drag and drop the grade from one shot to a selection of shots.
Ctrl+Alt+drag+drop	Drag and drop the Selector parameters to one shot.
Ctrl+Alt+Shift+drag+drop	Drag and drop the Selector parameters to a selection of shots.

## Numeric Keypad

The numeric keypad hotkeys vary depending on the menu. The following section includes hotkey tables for the following menus:

- Colour—Grading and Secondaries menus
- Editing—Edit menu
- Editing—Capture and Playout menus

### Colour Menus — Grading and Secondaries

Refer to the following table for numeric keypad hotkey functions when working in the Grading and Secondaries menus.

Press:	To:
1	Decrease cyan brightness by 1 point.
Shift+1	Decrease cyan brightness by 1/2 point.
2	Decrease magenta brightness by 1 point.
Shift+2	Decrease magenta brightness by 1/2 point.
3	Decrease yellow brightness by 1 point.
Shift+3	Decrease yellow brightness by 1/2 point.
4	Increase cyan brightness by 1 point.
Shift+4	Increase cyan brightness by 1/2 point.
5	Increase magenta brightness by 1 point.
Shift+5	Increase magenta brightness by 1/2 point.
6	Increase yellow brightness by 1 point.

Press:	To:
Shift+6	Increase yellow brightness by 1/2 point.
7	Decrease red brightness by 1 point.
Shift+7	Decrease red brightness by 1/2 point.
8	Decrease green brightness by 1 point.
Shift+8	Decrease green brightness by 1/2 point.
9	Decrease blue brightness by 1 point.
Shift+9	Decrease blue brightness by 1/2 point.
0	Copy the same type setting from the previous shot.
Enter	Decrease master brightness by 1 point.
Shift+Enter	Decrease master brightness by 1/2 point.
+ (add)	Increase master brightness by 1 point.
Shift+'+' (add)	Increase master brightness by 1/2 point.
- (subtract)	Reset brightness.
/ (divide)	Increase green brightness by 1 point.
Shift+/ (divide)	Increase green brightness by 1/2 point.
* (multiply)	Increase blue brightness by 1 point.
Shift+* (multiply)	Increase blue brightness by 1/2 point.
NumLock	Increase red brightness by 1 point.
Shift+NumLock	Increase red brightness by 1/2 point.

## Curves Menu — Hue, Lightness, Saturation and Luminance

Refer to the following table for numeric keypad hotkey functions when working on the Hue, Lightness, Saturation or Luminance values in the Curves menu.

Press:	To:
1	Decrease the cyan point's hue, lightness, saturation, or luminance value.
2	Decrease the magenta point's hue, lightness, saturation, or luminance value.
3	Decrease the yellow point's hue, lightness, saturation, or luminance value.
4	Increase the cyan point's hue, lightness, saturation, or luminance value.
5	Increase the magenta point's hue, lightness, saturation, or luminance value.
6	Increase the yellow point's hue, lightness, saturation, or luminance value.
7	Decrease the red point's hue, lightness, saturation, or luminance value.
8	Decrease the green point's hue, lightness, saturation, or luminance value.
9	Decrease the blue point's hue, lightness, saturation, or luminance value.
Enter	Decrease all points' hue, lightness, saturation, or luminance value.
+ (add)	Increase all points' hue, lightness, saturation, or luminance value.
/ (divide)	Increase the green points' hue, lightness, saturation, or luminance value.
* (multiply)	Increase the blue points' hue, lightness, saturation, or luminance value.
– (subtract)	Reset the current curve.
NumLock	Increase the red point's hue, lightness, saturation, or luminance value.

## Editing Menu—Edit

Refer to the following table for numeric keypad hotkey functions when working in the Edit menu.

Press:	To:
1	Enter 1 in the timecode field.
2	Enter 2 in the timecode field.

Press:	To:
3	Enter 3 in the timecode field.
4	Enter 4 in the timecode field.
5	Enter 5 in the timecode field.
6	Enter 6 in the timecode field.
7	Enter 7 in the timecode field.
8	Enter 8 in the timecode field.
9	Enter 9 in the timecode field.
0	Enter 0 in the timecode field.
. (decimal)	Enter 00 in the timecode field.
+ (add)	Set the edit operation to “plus.”
/ (divide)	Reset the current timecode.
* (multiply)	Switch between the trim in, trim out, slide and default editing modes.
– (subtract)	Set the edit operation to “minus.”

## Editing Menus—Capture and Playout

Refer to the following table for numeric keypad hotkey functions when working in the Capture and Playout menus.

Press:	To:
1	Enter 1 in the timecode field.
2	Enter 2 in the timecode field.
3	Enter 3 in the timecode field.
4	Enter 4 in the timecode field.
5	Enter 5 in the timecode field.
6	Enter 6 in the timecode field.

Press:	To:
7	Enter 7 in the timecode field.
8	Enter 8 in the timecode field.
9	Enter 9 in the timecode field.
0	Enter 0 in the timecode field.
. (decimal)	Enter 00 in the timecode field.
/ (divide)	Reset the current timecode.
* (multiply)	Switch the timecode typing focus to the in timecode.
– (subtract)	Switch the timecode typing focus to the out timecode.

## Stereoscopy

Use these hotkeys when the Stereoscopy feature is enabled.

Press:	To:
Alt+L	Assigns the layer the focus point is positioned on as the Left Eye.
Alt+R	Assigns the layer the focus point is positioned on as the Right Eye.
; (semicolon)	Toggles the Player to display the Left Eye or Right Eye footage.
Ctrl+F4	Cycle through the Stereo Dual View modes (i.e., 2-up, Blend, Horizontal Wipe, and Vertical Wipe).
Shift+Alt+F4	Return to the previous Stereo Dual View mode.

## Animation

Use these hotkeys in the Animation menu.

Press:	To:
Alt+A	Enable/disable Autokey.
Delete	Delete the selected keyframe.
Drag	Draw a selection box.

<b>Press:</b>	<b>To:</b>
Right-drag	Zoom in or out.
Middle-drag	Pan the view.
Backspace	Delete last tracked position.
Ctrl (left)+C	Copy keyframe(s).
Ctrl (left)+V	Paste keyframe(s).
Alt+C	Toggle between 'One Fr' and All Fr' copy modes.

## Miscellaneous Functions

These hotkeys are for assorted tasks (e.g., text editing, toggling render settings, and manipulating geometries).

<b>Press:</b>	<b>To:</b>
Right-click	Scroll through the option box options in reverse order. For example, refer to the Filter option box within Image > Transcode > Format settings.
Shift+Insert	Exit Lustre without confirmation.
Shift+Esc	Cancel Burn buffer preallocation.
Shift+F1	Access Lustre help system.
Shift-drag	Quickly increase/decrease the value of colour wheels and certain sliders. Use this hotkey to allow you to surpass the minimum/maximum value restricted by using the user interface.
Alt-drag	Slowly increase/decrease the value of colour wheels and certain sliders. Use this hotkey to allow you to surpass the minimum/maximum value restricted by using the user interface.
Tab	Move the focus to the next text field in the current menu if a text field has focus.
Ctrl+C	Copy selected text.
Ctrl+V	Paste copied text into the current text field.
Ctrl-click	Reset a parameter when you click the parameter's user interface element.
Shift+B	Bypass all menu parameters.

Press:	To:
R	Resets the current menu.
Ctrl+R	Refresh the displayed list to show any changes you have made. You can press Ctrl+R to refresh the Cutlist, EDL list, Audio list, overlay list, LUT list and Presets list.
Ctrl+Backspace (Presets menu)	Delete the active preset.
Ctrl+Backspace (Gang tool)	Delete the active gang.
M	Start result caching.
N	Switch off the result cache.
[ (left bracket)	Switch off the render flag of the current shot.
] (right bracket)	Switch on the render flag of the current shot.
{ (left brace)	Switch off the render flag of all the shots.
} (right brace)	Switch on the render flag of all the shots.
X	Switch on/off background rendering.
Shift+W	Switch on/off Incinerator.
Ctrl+Z	Undo the last operation.
Ctrl+Alt+Z	Reverse the last 'Undo' operation.

## XML in Lustre

Lustre's XML-based files are stored as plain text on disk so that you may view, generate, and, in certain cases, modify them. The three types of XML-based files are:

- CUT (*\*.cut.xml*)
- CLIP (*\*.clip.xml*)
- GRADENOTES (*\*.desc.xml*)

The XML files are generated by Lustre and should be modified sparingly and with caution, as errors can cause serious malfunctions. An example of a modification you could safely make would be to change the Note field in the DESC file. The Note field contains a shot's note text. See [Assigning Notes to Shots](#) (page 1852).

## Limitations

Lustre's XML-based files have the following limitations:

- Certain functions have not been implemented.
- You can only include hard returns in the structure tags. You must include all other tags and their contents (opening tag, value, and closing tag) in a single line.
- You can use XML features that are included in the predefined tag list only. This is to ensure optimized performance.
- The Lustre XML parser ignores tags that you use to store additional information.

## CUT File Tags

The CUT file is located in the Library directory and contains the following shot information:

- Physical location of files, trims, and additional metadata information (such as EDL and keycode data).
- Clip information (such as timecode and keycode data).
- Timeline information (such as framerate and video tracks).
- Transcode information, if relevant.
- Retime effect parameters.
- Dissolve parameters.

The CUT file is built from the sequence of shots, and its order determines the order of shots on the Lustre Timeline.

When modifying the CUT file, you are restricted to the following tags.

**NOTE** Items in the Children row are occasionally marked with a + (plus sign) or \* (asterisk). The + indicates that the parent tag can contain more than one instance of this element. The \* indicates that the element is mandatory.

Cut	
Description	The root tag that contains opening and closing tags. It is a structure tag and as such can include hard returns.
Parameters	For the current release the only parameter allowed is <b>Ver="3.0"</b>
Parents	N/A
Children	+*Shot
Shot	
Description	A single shot (uninterrupted sequence of images). It is a structure tag and as such can include hard returns. The parent cut tag can contain any number of shots.
Parameters	N/A
Parents	Cut

<b>Shot</b>	
Children	+Seq, +AliasName, +EData
<b>Seq</b>	
Description	The image sequence location. For example: <b>[HOME]/scene1/1828x1332/%05d.dpx*7751.</b>
Parameters	N/A
Parents	Shot
Children	N/A
<b>AliasName</b>	
Description	The shot's short name. An asterisk (*) indicates a previous wedge number. You can make the alias name appear in the Library and the browser by pressing <b>w</b> on the keyboard.
Parameters	N/A
Parents	Shot
Children	N/A
<b>EData</b>	
Description	The structure for storing editing metadata.
Parameters	N/A
Parents	Shot
Children	+Uniqueld, +SrcFullStart, +SrcFullLength, +SrcTrimStart, +SrcTrimLength, +ResStart, +ResLength, FadeType, FadeStartFromEnd, FadeSize, FadeCurve, RetimeRefFrame, RetimeSpeed, RetimeRemain, EDLEvent, EDLFadeDur, EDLFrameRate, EDLReelName, EDLFadeType, EDLSrcTcIn, EDLSrcTcOut, EDLRecTcIn, EDLRecTcOut, EDLFadeDur, EDLRetimeSpeed, EDLRetimeRef, EDLFadeUID, EDLKeyCodeStart, EDLKeyCodeEnd, DLEDLRes, DLEDLStartTc, DLEDLFrameIdList, DLEDLClipName, MediaUnlinked, MediaPtr, MediaDef, MediaLinkData, DPXTimeCodeStart, DPXTimeCodeEnd, DPXKeyCodeStart, DPXKeyCodeEnd, DPXFrameRate, DPXCodeRes, DPXKeyCodeType
<b>Uniqueld</b>	
Description	A shot's unique identification string. If generated internally, do not modify. This would result in grade loss since shots and grades are linked by the unique ID. If the CUT file

<b>Uniqueld</b>	
	was generated externally, the ID must respect the following conditions: it must be unique within the cutlist, and the data type must be a 64-bit integer in a hexadecimal format. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData
Children	N/A
<b>SrcFullStart</b>	
Description	The first frame of the original image sequence. The frame number is converted and displayed as timecode.
Parameters	N/A
Parents	EData
Children	N/A
<b>SrcFullLength</b>	
Description	The shot's number of frames.
Parameters	N/A
Parents	EData
Children	N/A
<b>SrcTrimStart</b>	
Description	The trim start frame. This value should be greater than the SrcFullStart value and smaller than the sum of SrcFullStart plus SrcFullLength.
Parameters	N/A
Parents	EData

<b>SrcTrimStart</b>	
Children	N/A
<b>SrcTrimLength</b>	
Description	The trimmed shot length. The sum of SrcTrimStart plus SrcTrimLength should always be smaller than the sum of SrcFullStart plus SrcFullLength.
Parameters	N/A
Parents	EData
Children	N/A
<b>ResStart</b>	
Description	The start record frame. The frame number can be converted to timecode if required.
Parameters	N/A
Parents	EData
Children	N/A
<b>ResLength</b>	
Description	The record length in frames.
Parameters	N/A
Parents	EData
Children	N/A
<b>FadeType</b>	
Description	The transition type. Type 1 is a dissolve, and type 0 is a cut.
Parameters	N/A
Parents	EData

<b>FadeType</b>	
Children	N/A
<b>FadeStartFromEnd</b>	
Description	The starting frame of the transition, counting from the end of the current shot.
Parameters	N/A
Parents	EData
Children	N/A
<b>FadeSize</b>	
Description	Length of the transition in frames.
Parameters	N/A
Parents	EData
Children	N/A
<b>FadeCurve</b>	
Description	Container for transition curves. There are two types of transition curves: InChannel and OutChannel. The InChannel transition curve determines the transparency of the current shot, whereas the OutChannel transition curve determines the transparency of the overlapped shot.
Parameters	N/A
Parents	EData
Children	+InChannel, +OutChannel
<b>InChannel</b>	
Description	The transition curve that determines the transparency of the current shot.
Parameters	N/A
Parents	EData

<b>InChannel</b>	
Children	+*Point
<b>OutChannel</b>	
Description	The transition curve that determines the transparency of the overlapped shot.
Parameters	N/A
Parents	EData
Children	+*Point
<b>Point</b>	
Description	One control point on a curve. For dissolves, the curve calculation is based on Hermite interpolation, and all values are normalized to a 0-65535 range.
Parameters	N/A
Parents	InChannel, OutChannel
Children	+X, +Y, +TangentX, +TangentY
<b>X</b>	
Description	X coordinate of a control point.
Parameters	N/A
Parents	Point
Children	N/A
<b>Y</b>	
Description	Y coordinate of a control point.
Parameters	N/A
Parents	Point

<b>Y</b>	
Children	N/A
<b>Tangent X</b>	
Description	The absolute X position of the tangent point. This is unrelated to the tangent angle.
Parameters	N/A
Parents	Point
Children	N/A
<b>Tangent Y</b>	
Description	The absolute Y position of the tangent point. This is unrelated to the tangent angle.
Parameters	N/A
Parents	Point
Children	N/A
<b>RetimeRefFrame</b>	
Description	The retime's base point in frames. This is usually equivalent to the SrcTrimStart.
Parameters	N/A
Parents	EData
Children	N/A
<b>RetimeSpeed</b>	
Description	Speed change rate. Supported data type is long float ("lf", aka double). For example, normal speed is 1.0, half speed is 0.5, double speed is 2.0, -1.0 is normal speed reverse play, -0.5 is half speed reverse play, and -2.0 is double speed reverse play.
Parameters	Type
Parents	EData

<b>RetimeSpeed</b>	
Children	N/A
<b>RetimeRemain</b>	
Description	Value for compensating rounding errors. This tag is used only if a retimed shot was retrimmed. Otherwise its value is zero. Supported data type is long float ("lf", aka double).
Parameters	Type
Parents	EData
Children	N/A
<b>EDLEvent</b>	
Description	EDL event number.
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLFadeDur</b>	
Description	EDL fade duration in frames.
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLFrameRate</b>	
Description	EDL framerate. This tag's parameter is the float data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData

<b>EDLFrameRate</b>	
Children	N/A
<b>EDLReelName</b>	
Description	EDL reel name. The tag's parameter is the string data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData
Children	N/A
<b>EDLFadeType</b>	
Description	The EDL fade type. Legal values include: -1= cut -2=dissolve >=SMPTE wipe type number
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLSrcTcln</b>	
Description	EDL source in timecode. This tag's parameter is the timecode data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData
Children	N/A
<b>EDLSrcTcOut</b>	
Description	EDL source out timecode. This tag's parameter is the timecode data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData

<b>EDLSrcTcOut</b>	
Children	N/A
<b>EDLRecTcIn</b>	
Description	EDL record in timecode. This tag's parameter is the timecode data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData
Children	N/A
<b>EDLRecTcOut</b>	
Description	EDL record out timecode. This tag's parameter is the timecode data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	Type
Parents	EData
Children	N/A
<b>EDLFadeDur</b>	
Description	EDL fade duration in frames.
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLRetimeSpeed</b>	
Description	EDL retime as a percentage value.
Parameters	N/A
Parents	EData

<b>EDLRetimeSpeed</b>	
Children	N/A
<b>EDLRetimeRef</b>	
Description	The retime's base point in frames. This is usually equivalent to the SrcTrimStart.
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLFadeUID</b>	
Description	Unique ID of the second shot in the dissolve.
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLKeyCodeStart</b>	
Description	EDL keycode start. This tag's parameter is the keycode data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	N/A
Parents	EData
Children	N/A
<b>EDLKeyCodeEnd</b>	
Description	EDL keycode end. This tag's parameter is the keycode data type. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	N/A
Parents	EData

<b>EDLKeyCodeEnd</b>	
Children	N/A
<b>DLEDLRes</b>	
Description	String from the DLEDL that describes the image format.
Parameters	N/A
Parents	EData
Children	N/A
<b>DLEDLStartTc</b>	
Description	Start timecode from the DLEDL.
Parameters	N/A
Parents	EData
Children	N/A
<b>DLEDLFrameIdList</b>	
Description	Pointer to the frame ID list, which is used by the system to locate frames on the Stone filesystem. Supported data type is integer. See <a href="#">CUT File Data Types</a> (page 2423).
Parameters	N/A
Parents	EData
Children	N/A
<b>DLEDLClipName</b>	
Description	DLEDL clip name.
Parameters	N/A
Parents	EData

<b>DLEDLClipName</b>	
Children	N/A
<b>DPXTimeCodeStart</b>	
Description	DPX header timecode start.
Parameters	N/A
Parents	EData
Children	N/A
<b>DPXTimeCodeEnd</b>	
Description	DPX header timecode end.
Parameters	N/A
Parents	EData
Children	N/A
<b>DPXKeyCodeStart</b>	
Description	DPX header keycode start.
Parameters	N/A
Parents	EData
Children	N/A
<b>DPXKeyCodeEnd</b>	
Description	DPX header keycode end.
Parameters	N/A
Parents	EData

<b>DPXKeyCodeEnd</b>	
Children	N/A
<b>DPXFrameRate</b>	
Description	DPX header frame rate.
Parameters	N/A
Parents	EData
Children	N/A
<b>DPXCodeRes</b>	
Description	The resolution of the DPX header origin (full or half).
Parameters	N/A
Parents	EData
Children	N/A
<b>DPXKeyCodeType</b>	
Description	The number of frames stored on one foot of film.
Parameters	N/A
Parents	EData
Children	N/A

## CUT File Data Types

The following data types are supported in CUT file tags.

<b>Data Type</b>	<b>Description</b>
f	Floating point number. These can be always expressed as a fraction of two integers. For example: -147.244
s	Sequence of ASCII characters. These can include both letters and numbers. For example: abcdef_12345-ABCDEF

Data Type	Description
tc	Encoded timing format. Format: "hh:mm:ss:ff" where hh=hours, mm=minutes, ss=seconds, and ff=frames. For example: 01:23:45:23
kk	Film-based timing format. Format: "TT PPPP FFFF+OO" where TT=film type, PPPP=prefix, FFFF=feet frames, and OO=offset. For example: KI 120863 7624+07
u	Unsigned integer. These are the positive numbers, and are usually stored in 32-bit. For example: 1
i64	64-bit integer. These can be positive or negative numbers, and are usually stored in 64-bit. For example: -7846238974878347

If you want to use an integer, do not specify a data type.

## CUT File Example

The following is an example of an XML-based CUT file.

```

<Timeline_Ver="1.0">
<TimelineName_Type="s">PAL_sample_cut</TimelineName>
<StereoEnabled>0</StereoEnabled>
<TimelineFrameRate_Type="f">25</TimelineFrameRate>
<TimelineDropMode_Type="s">0</TimelineDropMode>

## Tangent Element Control Surface

The Tangent Element control surface is designed to improve interactivity when colour grading film and video footage. You can accomplish all of the main grading tasks you do in the Lustre user interface using the Tangent Element control surface.

## The Modes

The basic Tangent Element workflow is mode based. This means that you set the appropriate mode for the grading tasks you wish to accomplish and the knob, button and trackball functions are dynamically updated. Each mode consists of multiple pages of parameters that can be cycled through.

To select a mode, press the appropriate button on the MF module, as indicated on the module's screen.

The following modes are supported by the Tangent Element Control Surface:

### **Grading Mode (Linear and Logarithmic)**

The available functions in this mode correspond to those in the Colour/Grading menu in the application. By default, the control surface is in Grade Mode (Linear or Logarithmic, according to your project settings).

### **Curves Mode**

The available functions in this mode correspond to those in the Colour/Grading menu in the application.

### **Geometry Mode**

The available functions in this mode correspond to those in the Colour/Secondaries menu in the application.

### **Pan & Scan Mode**

The available functions in this mode correspond to those in the Image/Reposition menu in the application.

### **HLS Keyer Mode**

The available functions in this mode correspond to the HLS Keyer functions in the Colour/Secondaries menu in the application.

### **Diamond Keyer Mode**

The available functions in this mode correspond to the Diamond Keyer functions in the Colour/Secondaries menu in the application.

### **Editing Mode**

The available functions in this mode correspond to those in the Editing/Timeline menu in the application.

### **Preferences Mode**

The Preferences mode groups together various user set preferences.

## **Using the Modules**

The Tangent Element Control Surface is composed of four modules.

The layout of the displays of each module mirrors the functions of the knobs/buttons of each module.

---

**BEST PRACTICE** It is recommended to add a second BT module to display and access commonly used functions at all times, otherwise only available the second and third pages of the MF module.

---

## KB module (Knobs)

The KB module is a knob-based interface for user input parameters.

The values of each parameter assigned to the knobs can be reset by pressing the knob.

**A button:** Cycle through the different pages of functions mapped to the module.

**B button:** Enable either Precise Mode or Turbo Mode, based on your user settings.

## TK module (Trackballs)

The TK module is also an interface for user input parameters. The trackballs and rings provide an intuitive way of precisely modifying parameters and are especially well suited for grading, among other things.

Moving the trackball from left to right / right to left has the same effect as moving them up and down / down and up.

Turning the ring from left to right increases the value of the assigned parameter, whereas turning the ring from right to left decreases the value.

The values of each parameter assigned to each trackball and ring can be reset by pressing the Reset button above them.

**A button:** Cycle through the different pages of functions mapped to the module.

**B button:** Enable either Precise Mode or Turbo Mode, according to your user settings, for all knobs, trackballs and rings.

## MF module (Multi-Function)

The MF module enables you to select the mode you want to work in and provides a transport section, which allows navigation via the trackball and ring as well.

The values of each parameter assigned to each trackball and ring can be reset by pressing the Reset button above them.

**A button:** Cycle through the different pages of functions mapped to the module.

**B button:** Enable alternate functionality of the buttons, trackball and ring.

**Trackball:** The trackball's default behavior is scrub. By holding the B button, the behavior changes to pan.

**Ring:** The ring's default behavior is jog. By holding the B button, the behavior changes to zoom.

---

**NOTE** You can press the B button twice and lock Alt mode.

---

### Button sequences for alternate functions on the MF module

- **Forward Play button + B Button:** Cycle forward through the grades applied to succeeding shots and temporarily apply them to the current shot. Pressing Enter permanently applies the selected grade to the current shot.
- **Backward Play button + B Button:** Cycle through the grades applied to previous shots and temporarily apply them to the current shot. Pressing Enter permanently applies the selected grade to the current shot.
- **Next Clip Button + B Button:** Move the positioner forward to the next keyframe in your timeline .
- **Previous Clip Button + B Button:** Move the positioner backward to the previous keyframe in your timeline.
- **Stop Button + Forward Play button:** Move the positioner forward by one frame in your timeline.
- **Stop Button + Backward Play button:** Move the positioner backward by one frame in your timeline.

## BT (1) module (Buttons)

The BT module is dedicated to providing quick access to the secondaries and the Grade Bin. It is available in all modes, except Preferences Mode. The buttons mirror the position of the secondaries and of saved grades in the Grade Bin.

**A button:** allows you to enable/disable Grade Bin access.

**B button:** allows you to cycle through the four pages of secondaries, giving you access to all 48 secondaries.

## BT (2) module (Buttons)

The second BT module is recommended. It enables you access at all times to View Modes and commonly used functions such as setting keyframes, copying and saving, among others.

**A button:** The A button on this module is not mapped. Pressing it will have no effect.

**B button:** Enable alternate functionality of the buttons, trackball and ring.

# Installing the Control Surface

The first time you connect the Tangent Element Control Surface to your Lustre station, it automatically connects to your software and populates all the menus.

If the Control Surface does not automatically connect, see the [Troubleshooting](#) (page 2467) section.

Once it is connected, you must access the User Preferences and select whether you want the behavior of the B button on the KB and TK panels to be Precise Mode, which increases and decreases the parameter values in smaller increments, giving you more precision. Or Turbo Mode, which increases and decreases the parameter values in larger increments, enabling you to set your values quickly.

---

**TIP** You can create a user for each mode and select one or the other based on whether you want to work with Precise Mode or Turbo Mode.

---

## To set the behavior of the B button

- 1 Access the Setup/Settings menu.
- 2 Press Edit, next to the User Settings.
- 3 Select the System & Menu tab.
- 4 Press the Alt-Precise/Alt-Turbo button to the right of the Tangent Setup Folder field to select either Precise or Turbo Mode.

# Control Surface Layouts

## Linear Grading Layout

Module 1 (KB) - Page 1 of 2

- **Hue:** Modify the hue value.

**NOTE** The hue can only be modified on secondaries.

- **R Lift:** Modify the lift of the red channel.
- **G Lift:** Modify the lift of the green channel.
- **B Lift:** Modify the lift of the blue channel.
- **Contrast:** Modify contrast value.
- **R Gamma:** Modify the gamma of the red channel.
- **G Gamma:** Modify the gamma of the green channel.
- **B Gamma:** Modify the gamma of the blue channel.
- **Saturation:** Modify the saturation value.
- **R Gain:** Modify the gain of the red channel.
- **G Gain:** Modify the gain of the green channel.
- **B Gain:** Modify the gain of the blue channel.

- **Black Clip:** Modify the black clip value.
- **White Clip:** Modify the white clip value.
- **Black Ref:** Modify the black reference value.
- **White Ref:** Modify the white reference value.
- **LiftCtOff:** Modify the lift cutoff value.
- **GammaCtOff:** Modify the gamma cutoff value.
- **GainCtOff:** Modify the gain cutoff value.

---

**NOTE** The Grade mode functions are always available, even when not in Grading mode. To access the Grading functions while in other modes, press the A button to cycle through the Grading pages. Pressing the A button twice brings you back to the first page of the current mode.

---

- **Lift:** Move the trackball right or left (x axis) to modify the lift in the low, mid and high range colour values (Master).
- **Lift:** Move the trackball up or down (y axis) to modify the lift in the low, mid and high range colour values (Master).
- **Lift:** Move the ring left or right to modify the lift of the luminance channel.
- **Gamma:** Move the trackball right or left (x axis) to modify the gamma in the low, mid and high range colour values (Master).
- **Gamma:** Move the trackball up or down (y axis) to modify the gamma in the low, mid and high range colour values (Master).
- **Gamma:** Move the ring left or right to modify the gamma of the luminance channel.
- **Gain:** Move the trackball right or left (x axis) to modify the gain in the low, mid and high range colour values (Master).
- **Gain:** Move the trackball up or down (y axis) to modify the gain in the low, mid and high range colour values (Master).
- **Gain:** Move the ring left or right to modify the gain of the luminance channel.

- **Low Lift:** Move the trackball right or left (x axis) to modify the lift in the low range colour values.
- **Low Lift:** Move the trackball up or down (y axis) to modify the lift in the low range colour values.
- **Low Lift:** Move the ring left or right to modify the lift of the luminance channel in the low range colour values.
- **Low Gamma:** Move the trackball right or left (x axis) to modify the gamma in the low range colour values.
- **Low Gamma:** Move the trackball up or down (y axis) to modify the gamma in the low range colour values.
- **Low Gamma:** Move the ring left or right to modify the gamma of the luminance channel in the low range colour values.
- **Low Gain:** Move the trackball right or left (x axis) to modify the gain in the low range colour values.
- **Low Gain:** Move the trackball up or down (y axis) to modify the gain in the low range colour values.
- **Low Gain:** Move the ring left or right to modify the gain of the luminance channel in the low range colour values.

- **Mid Lift:** Move the trackball right or left (x axis) to modify the lift in the mid range colour values.
- **Mid Lift:** Move the trackball up or down (y axis) to modify the lift in the mid range colour values.
- **Mid Lift:** Move the ring left or right to modify the lift of the luminance channel in the mid range colour values.
- **Mid Gamma:** Move the trackball right or left (x axis) to modify the gamma in the mid range colour values.
- **Mid Gamma:** Move the trackball up or down (y axis) to modify the gamma in the mid range colour values.
- **Mid Gamma:** Move the ring left or right to modify the gamma of the luminance channel in the mid range colour values.
- **Mid Gain:** Move the trackball right or left (x axis) to modify the gain in the mid range colour values.
- **Mid Gain:** Move the trackball up or down (y axis) to modify the gain in the mid range colour values.
- **Mid Gain:** Move the ring left or right to modify the gain of the luminance channel in the mid range colour values.

- **High Lift:** Move the trackball right or left (x axis) to modify the lift in the high range colour values.
- **High Lift:** Move the trackball up or down (y axis) to modify the lift in the high range colour values.
- **High Lift:** Move the ring left or right to modify the lift of the luminance channel in the high range colour values.
- **High Gamma:** Move the trackball right or left (x axis) to modify the gamma in the high range colour values.
- **High Gamma:** Move the trackball up or down (y axis) to modify the gamma in the high range colour values.
- **High Gamma:** Move the ring left or right to modify the gamma of the luminance channel in the high range colour values.
- **High Gain:** Move the trackball right or left (x axis) to modify the gain in the high range colour values.
- **High Gain:** Move the trackball up or down (y axis) to modify the gain in the high range colour values.
- **High Gain:** Move the ring left or right to modify the gain of the luminance channel in the high range colour values.

- **InPrimary:** Enable input primary grading mode.
- **OutPrimary:** Enable output primary grading mode.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.  
  
**NOTE** Inside grading is enabled by default.
- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Once enabled, single-press to select outside grading, to edit your grade.
- **Grade:** Access the Colour/Grade menu.
- **PanScan:** Access the Image/Reposition menu.
- **Geometry:** Enable the draw geometry mode in the Secondaries menu. The fourth row of functions on the module is dynamically updated to display the rectangle, circle and wipe options. Pressing the corresponding button enables you to add the desired geometry.
- **Prefs:** Access the preferences functions.
- **Curves:** Access the Colour/Curves menu.
- **Keyer:** Enable the keyer in the secondaries menu. The default behavior is to enable the HLS keyer. Pressing Keyer again enables the diamond keyer.
- **Editing:** Access the Editing/Timeline menu.
- **Undo:** Undo the last operation performed. Pressing the B button changes the function of the Undo button to Redo. The panel display is be updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).

InPrimary	Grade	Curves
OutPrimary	PanScan	Keyer
Inside	Geometry	Editing
Outside	Prefs	Redo

- **Confirm:** When the Lustre UI prompts you to confirm an operation, the Undo button is automatically updated to display Confirm. Press to confirm the operation.

InPrimary	Grade	Curves
OutPrimary	PanScan	Keyer
Inside	Geometry	Editing
Outside	Prefs	Confirm

### Module 3 (MF) - Page 2 of 3

- **InPrimary:** Enable input primary grading mode.
- **OutPrimary:** Enable output primary grading mode.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.

**NOTE** Inside grading is enabled by default.

- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Once enabled, single-press to select outside grading, to edit your grade.
- **O/P/M:** Toggle between output, print and matte views.
- **Autokey:** Enable/disable Autokey.
- **Reset:** Press once to reset the currently selected grading tool. Press twice to reset all grading tools.
- **SetKey:** Set a keyframe at the current position on the currently selected channel. Pressing the B button changes the function of the SetKey button to SetKey All. The panel display is updated.

InPrimary	O/P/M	A/B
OutPrimary	Autokey	SingleView
Inside	Reset	Bypass
Outside	SetKeyAll	Undo

- **SetKeyAll:** Set a keyframe at the current position on all channels.
- **A/B:** Toggle A/B playheads.
- **SingleView:** Toggle between single, dual and multi views, as defined under the Preferences.
- **Bypass:** Press once to bypass the currently selected grading tool. Press twice to bypass all grading tools.
- **Undo:** Undo the last operation performed. Pressing the B button will change the function of the Undo button to Redo. The panel display is updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).

InPrimary	O/P/M	A/B
OutPrimary	Autokey	SingleView
Inside	Reset	Bypass
Outside	SetKey	Redo

### Module 3 (MF) - Page 3 of 3

- **InPrimary:** Enable input primary grading mode.
- **OutPrimary:** Enable output primary grading mode.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.

**NOTE** Inside grading is enabled by default.

- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Once enabled, single-press to select outside grading, to edit your grade.
- **Stereo:** Enable stereoscopy.
- **L/R:** Toggle between tight eye view and left eye view modes (when working with stereoscopic footage).

- **MultiCopy:** Enter multi copy mode. When in multi copy mode, turn the ring to cycle your shots forward or backwards to copy the selected grade to your current shot. When you release the ring, the Undo button is automatically updated to display Apply. Press Apply to confirm and repeat the process for other shots as needed. To exit multi copy mode, press the MultiCopy button again.

InPrimary	Stereo	Sync
OutPrimary	L/R	Cursor
Inside	MultiCopy	Copy
Outside	Save All	Apply

- **SaveAll:** Save your current cut and grade.
- **Sync:** Sync your left and right eyes when working with stereoscopic footage. When in sync, any operation performed on the left eye is also applied to the right eye.
- **Cursor:** Enable cursor mode. When cursor mode is enabled, the trackball is used to move the cursor in the UI. In cursor mode, the Reset Trackball button acts as the left mouse button and the Reset Ring button acts as the right mouse button.
- **Copy:** Enter copy mode. When in copy mode, turn the ring to cycle your shots forward or backwards to copy the selected grade to your current shot. When you release the ring, the Undo button is automatically updated to display Apply. Press Apply to confirm the copy operation. Once the copy operation confirmed, you automatically exit copy mode.

InPrimary	Stereo	Sync
OutPrimary	L/R	Cursor
Inside	MultiCopy	Copy
Outside	Save All	Apply

- **Undo:** Undo the last operation performed. Pressing the B button will change the function of the Undo button to Redo. The panel display will be updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).

InPrimary	Stereo	Sync
OutPrimary	L/R	Cursor
Inside	MultiCopy	Copy

#### Module 4 (BT) - Page 1 of 6

Secondaries List (4 pages, 12 secondaries per page).

## Module 4 (BT) - Page 5 of 6

## Grade Bin - Load

The BT Panel also controls your Grade Bin for saving and loading grades. The buttons mirror the position of saved grades in the Grade Bin.

- **A Button:** Exit the Grade Bin.
- **B Button:** Toggle between load mode and save mode in the Grade Bin.

**NOTE** The trackball of the MF module navigates the Grade Bin when in Grade Bin mode.

**Module 4 (BT) - Page 6 of 6**

Grade Bin - Save

- **A Button:** Exit the Grade Bin.
- **B Button:** Toggle between load mode and save mode in the Grade Bin.

---

**NOTE** The trackball of the MF module navigates the Grade Bin when in Grade Bin mode.

---

**Optional 2nd BT Module - Page 1 of 1**

It is recommended to attach a second BT module, which is mapped to give you access to many of the most used functions at all times. These functions correspond to the second and third page of the MF module.

- **SingleView:** Toggle between single, dual and multi views, as defined under the Preferences.
- **A/B:** Toggle A/B playheads. Pressing Alt (B key) will change the function of the A/B button to L/R. The panel display is updated.

- **L/R:** Toggle between right eye view and left eye view modes (when working with stereoscopic footage).
- **Bypass:** Press once to bypass the currently selected grading tool. Press twice to bypass all grading tools.
- **Reset:** Press once to reset the currently selected grading tool. Press twice to reset all grading tools.
- **Multi 2:** Toggle the number of active viewports when in multi view. Options are:
  - 2
  - 4
  - 9
  - 16
- **Matte:** Enable/disable matte view.
- **Autokey:** Enable/disable Autokey.
- **Copy:** Enter copy mode. When in copy mode, turn the ring on the MF module to cycle your shots forward or backwards to copy the selected grade to your current shot. When you release the ring, the Undo button on the MF module is automatically updated to display Apply. Press Apply to confirm. Once the copy operation confirmed, you automatically exit copy mode. Pressing the B button changes the function of the Copy button to MultiCopy. The panel display is updated.

SingleView	Multi 2	2-Up
A/B	Matte	O/P
Bypass	Autokey	SetKey
Reset	MultiCopy	Save All

- **MultiCopy:** When in multi copy mode, turn the ring on the MF module to cycle your shots forward or backwards to copy the selected grade to your current shot. When you release the ring, the Undo button on the MF module is automatically updated to display Apply. Press Apply to confirm and repeat the process for other shots as needed. To exit multi copy mode, press the MultiCopy button again.
- **2-up:** Toggle the display mode when in dual view. Options are:

**For A/B**

- 2-up
- HorizWipe
- VertWipe

**For L/R**

- 2-up
- HorizWipe
- VertWipe
- Blend

- **O/P:** Toggle between output and print views.
- **SetKey:** Set a keyframe at the current position on the currently selected channel. Pressing the B button will change the function of the SetKey button to SetKeyAll. The panel display is updated.

SingleView	Multi 2	2-Up
A/B	Matte	O/P
Bypass	Autokey	SetKeyAll
Reset	Copy	Save All

- **SetKeyAll:** Set a keyframe at the current position on all channels.
- **Save All:** Save your current cut and grade.

# Logarithmic Grading Layout

## Module 1 (KB) - Page 1 of 2

- **Contrast:** Modify the global contrast value.
- **R Bright:** Modify the brightness of the red channel.
- **R Cntrast:** Modify the contrast of the red channel.
- **Brightness:** Modify the global brightness value.
- **Hue:** Modify global hue value.

**NOTE** The hue can only be modified on secondaries.

- **G Bright:** Modify the brightness of the green channel.
- **G Cntrast:** Modify the contrast of the green channel.
- **Saturation:** Modify the global saturation value.
- **Pivot:** Modify the pivot value.
- **B Bright:** Modify the brightness of the blue channel.
- **B Cntrast:** Modify the contrast of the blue channel.

## Module 1 (KB) - Page 2 of 2

- **Shadow:** Modify the luminance of the low range colour values.
- **CtOffSha:** Set the cutoff value for the shadows.
- **Midtones:** Modify the luminance of the mid range colour values.
- **CtOffMid:** Set the cutoff value for the midtones.
- **Highlights:** Modify the luminance of the high range colour values.
- **CtOffHi:** Set the cutoff value for the highlights.

## Module 2 (TK) - Page 1 of 2

---

**NOTE** The Grade mode functions are always available, even when not in Grade mode. To access the grading functions while in other modes, press the A button to cycle through the grading pages. Pressing the A button twice brings you back to the first page of the current mode.

---

- **Shadow:** Move the trackball right or left (x axis) to add colour to the low range colour values.
- **Shadow:** Move the trackball up or down (y axis) to add colour to the low range colour values.
- **Shadow:** Move the ring left or right to modify the luminance of the low range colour values.
- **Contrast:** Move the trackball right or left (x axis) to add colour to the contrast ratio.
- **Contrast:** Move the trackball up or down (y axis) to add colour to the contrast ratio.
- **Contrast:** Move the ring left or right to modify the luminance of the contrast ratio.
- **Brightness:** Move the trackball right or left (x axis) to add colour to the brightness channel.
- **Brightness:** Move the trackball up or down (y axis) to add colour to the brightness channel.
- **Brightness:** Move the ring left or right to modify the luminance of the brightness channel.

- **Shadow:** Move the trackball right or left (x axis) to add colour to the low range colour values.
- **Shadow:** Move the trackball up or down (y axis) to add colour to the low range colour values.
- **Shadow:** Move the ring left or right to modify the luminance of the low range colour values.
- **Midtones:** Move the trackball right or left (x axis) to add colour to the mid range colour values.
- **Midtones:** Move the trackball up or down (y axis) to add colour to the mid range colour values.
- **Midtones:** Move the ring left or right to modify the luminance of the mid range colour values.
- **Highlights:** Move the trackball right or left (x axis) to add colour to the high range colour values.
- **Highlights:** Move the trackball up or down (y axis) to add colour to the high range colour values.
- **Highlights:** Move the ring left or right to modify the luminance of the mid range colour values.

- **InPrimary:** Toggle input primary grading mode.
- **OutPrimary:** Enable output primary grading mode.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.  
  
**NOTE** Inside grading is enabled by default.
- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Once enabled, single-press to select outside grading, to edit your grade.
- **Grade:** Access the Colour/Grade menu.
- **PanScan:** Access the Image/Reposition menu.
- **Geometry:** Enable the draw geometry mode in the secondaries menu. The fourth row of functions on the module is dynamically updated to display the rectangle, circle and wipe options. Pressing the corresponding button enables you to add the desired geometry.
- **Prefs:** Access the preferences functions.
- **Curves:** Access the Colour/Curves menu.
- **Keyer:** Enable the keyer in the secondaries menu. The default behavior is to enable the HLS keyer. Pressing Keyer again enables the diamond keyer.
- **Editing:** Access the Editing/Timeline menu.
- **Undo:** Undo the last operation performed. Pressing the B button changes the function of the Undo button to Redo. The panel display is be updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).

InPrimary	Grade	Curves
OutPrimary	PanScan	Keyer
Inside	Geometry	Editing
Outside	Prefs	Redo

- **Confirm:** When the Lustre UI prompts you to confirm an operation, the Undo button is automatically updated to display Confirm. Press to confirm the operation.

InPrimary	Grade	Curves
OutPrimary	PanScan	Keyer
Inside	Geometry	Editing
Outside	Prefs	Confirm

### Module 3 (MF) - Page 2 of 3

- **InPrimary:** Enable input primary grading mode.
- **OutPrimary:** Enable output primary grading mode.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select Inside Grading and edit your grade.

**NOTE** Inside grading is enabled by default.

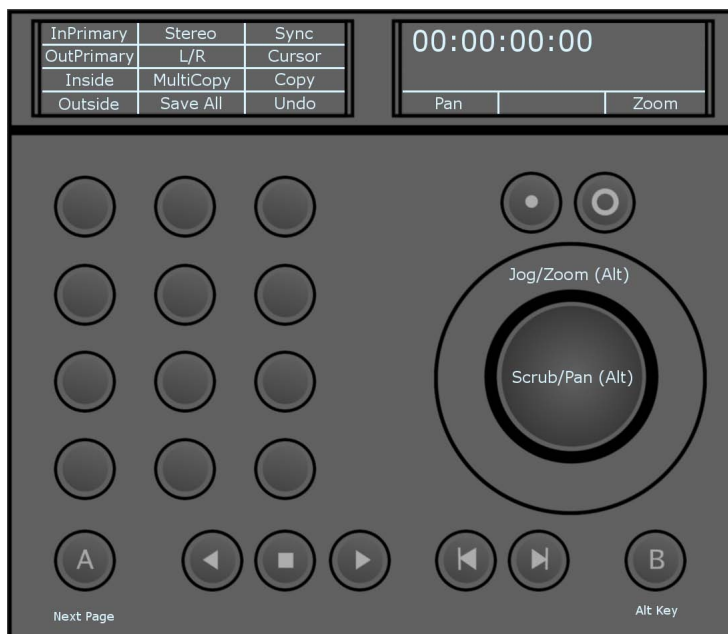

- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.
- **O/P/M:** Toggle between output, print and matte views.
- **Autokey:** Enable/disable Autokey.
- **Reset:** Press once to reset the currently selected grading tool. Press twice to reset all grading tools.
- **SetKey:** Set a keyframe at the current position on the currently selected channel. Pressing the B button changes the function of the SetKey button to SetKey All. The panel display is updated.

InPrimary	O/P/M	A/B
OutPrimary	Autokey	SingleView
Inside	Reset	Bypass
Outside	SetKeyAll	Undo

- **SetKeyAll:** Set a keyframe at the current position on all channels.
- **A/B:** Toggle A/B playheads.
- **SingleView:** Toggle between single, dual and multi views, as defined under the preferences.
- **Bypass:** Press once to bypass the currently selected grading tool. Press twice to bypass all grading tools.
- **Undo:** Undo the last operation performed. Pressing the B button will change the function of the Undo button to Redo. The panel display is updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).

#### Module 4 (BT) - Page 1 of 6

Secondaries List (4 pages, 12 secondaries per page).

## Module 4 (BT) - Page 5 of 6

## Grade Bin - Load

The BT Panel also controls your Grade Bin for saving and loading grades. The buttons mirror the position of saved grades in the Grade Bin.

- **A Button:** Exit the Grade Bin.
- **B Button:** Toggle between load mode and save mode in the Grade Bin.

**NOTE** The trackball of the MF module navigates the Grade Bin when in Grade Bin mode.

**Module 4 (BT) - Page 6 of 6**

Grade Bin - Save

- **A Button:** Exit the Grade Bin.
- **B Button:** Toggle between load mode and save mode in the Grade Bin.

---

**NOTE** The trackball of the MF Module navigates the Grade Bin when in Grade Bin mode.

---

**Optional 2nd BT Module - Page 1 of 1**

It is recommended to attach a second BT module, which is mapped to give you access to many of the most used functions at all times. These functions correspond to the second and third page of the MF module.

- **SingleView:** Toggle between single, dual and multi views, as defined under the preferences.
- **A/B:** Toggle A/B playheads. Pressing the B button will change the function of the A/B button to L/R. The panel display is updated.

- **L/R:** Toggle between right eye view and left eye view modes (when working with stereoscopic footage).
- **Bypass:** Press once to bypass the currently selected grading tool. Press twice to bypass all grading tools.
- **Reset:** Press once to reset the currently selected grading tool. Press twice to reset all grading tools.
- **Multi 2:** Toggle the number of active viewports when in Multi View. Options are:
  - 2
  - 4
  - 9
  - 16
- **Matte:** Enable/disable matte view.
- **Autokey:** Enable/disable Autokey.
- **Copy:** Enter copy mode. When in copy mode, turn the ring on the MF module to cycle your shots forward or backwards to copy the selected grade to your current shot. When you release the ring, the Undo button on the MF module is automatically updated to display Apply. Press Apply to confirm. Once the copy operation confirmed, you automatically exit copy mode. Pressing the B button changes the function of the Copy button to MultiCopy. The panel display is updated.

SingleView	Multi 2	2-Up
A/B	Matte	O/P
Bypass	Autokey	SetKey
Reset	MultiCopy	Save All

- **MultiCopy:** When in multi copy mode, turn the ring on the MF module to cycle your shots forward or backwards to copy the selected grade to your current shot. When you release the ring, the Undo button on the MF module is automatically updated to display Apply. Press Apply to confirm and repeat the process for other shots as needed. To exit multi copy mode, press the MultiCopy button again.
- **2-up:** Toggle the display mode when in dual view. Options are:

**For A/B**

- 2-up
- HorizWipe
- VertWipe

**For L/R**

- 2-up
- HorizWipe
- VertWipe
- Blend

- **O/P:** Toggle between output and print views.
- **SetKey:** Set a keyframe at the current position on the currently selected channel. Pressing the B button will change the function of the SetKey button to SetKeyAll. The panel display is updated.

SingleView	Multi 2	2-Up
A/B	Matte	O/P
Bypass	Autokey	SetKeyAll
Reset	Copy	Save All

- **SetKeyAll:** Set a keyframe at the current position on all channels.
- **Save All:** Save your current cut and grade.
- **B Button:** Enable alternate functionality for specified buttons.

## Curves Layout

### Module 1 (KB) - Page 1 of 2

- **Hue:** Press on the knob to enable the hue curve. Turning the knob left or right will raise or lower the Hue across the entire spectrum.
- **Lightness:** Press on the knob to enable the lightness curve. Turning the knob left or right will raise or lower the lightness across the entire spectrum.
- **Saturation:** Press on the knob to enable the saturation curve. Turning the knob will raise or lower the saturation across the entire spectrum.
- **L/S:** Press on the knob to enable the lightness - saturation curve. Turning the knob left or right will raise or lower the lightness - saturation across the entire spectrum.
- **Red:** Adjust the red point on the hue, lightness or saturation curve, according to the selected curve.
- **Green:** Adjust the green point on the hue, lightness or saturation curve, according to the selected curve.
- **Blue:** Adjust the blue point on the hue, lightness or saturation curve, according to the selected curve.
- **Cyan:** Adjust the cyan point on the hue, lightness or saturation curve, according to the selected curve.
- **Magenta:** Adjust the magenta point on the hue, lightness or saturation curve, according to the selected curve.
- **Yellow:** Adjust the yellow point on the hue, lightness or saturation curve, according to the selected curve.

## Pan & Scan Layout

### Module 1 (KB) - Page 1 of 2

Pan & Scan mode accesses the Image/Reposition menu.

- **Pos X:** Move your image on the X axis.
- **Pos Y:** Move your image on the Y axis.
- **Rotate :** Rotate your image.
- **Flip:** Press the knob to enable/disable Flip.
- **Flop:** Press the knob to enable/disable Flop.
- **Scale:** Scale your image proportionally.
- **Aspect:** Scale your image in X.

- **Pos X:** Move the trackball left or right to move your image on the X axis.
- **Pos Y:** Move the trackball left or right to move your image on the Y axis.
- **Rotate:** Turn the ring to rotate your image.
- **Aspect:** Move the trackball left or right to scale your image in X.
- **Scale:** Turn the ring to scale your image proportionally.

## Geometry Layout

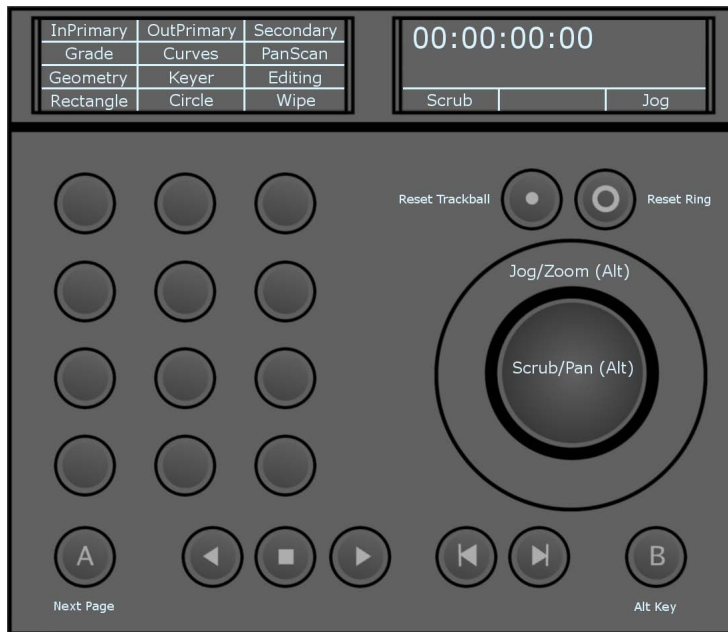

### Module 1 (KB) - Page 1 of 2

- **Pos X:** Move your geometry on the X axis.
- **Pos Y:** Move your geometry on the Y axis.
- **Rotation:** Rotate your geometry.
- **Scale X:** Scale your geometry in X.
- **Scale Y:** Scale your geometry in Y.
- **Scale Prop:** Scale your geometry proportionally.
- **Invert:** Press the knob to invert your geometry.
- **Mask Blur:** Set the level of mask blur.
- **Mask Clr:** Set the level of mask colour.
- **Mask Opac:** Set the level of mask opacity.
- **Mask Soft:** Set the level of mask softness.

- **Pos X:** Move the trackball left or right to move your geometry on the X axis.
- **Pos Y:** Move the trackball left or right to move your geometry on the Y axis.
- **Mask Soft:** Turn the ring to add/remove softness to your mask.
- **Rotate:** Turn the ring to rotate your geometry.
- **Scale X:** Move the trackball left or right to scale your geometry in X.
- **Scale Y:** Move the trackball left or right to scale your geometry in Y.
- **ScaleProp:** Turn the ring to scale your geometry proportionally.

**NOTE** The bottom row functions of the MF module in Geometry mode (Rectangle, Circle, Wipe) appear when you press the Geometry button. Once you press either Rectangle, Circle or Wipe to add the desired shape or start editing an existing shape, the bottom row reverts back to its default functions (Prefs, Undo, Enter). To add another shape, press Geometry again and press the button corresponding to the shape you want to add.

- **InPrimary:** Toggle input primary and output primary grading modes.
- **Grade:** Access the Colour/Grade menu.
- **Geometry:** Enable the draw geometry mode in the Secondaries menu. The fourth row of functions on the module is dynamically updated to display the rectangle, circle and wipe options. Pressing the corresponding button enables you to add the desired geometry.
- **Rectangle:** Add a default rectangle.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.
- **Curves:** Access the Colour/Curves menu.
- **Keyer:** Enable the keyer in the secondaries menu. The default behavior is to enable the HLS keyer. Pressing Keyer again enables the diamond keyer.
- **Circle:** Add a default circle.
- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Single-press to select outside grading, to edit your grade.
- **PanScan:** Access the Image/Reposition menu.
- **Editing:** Access the Editing/Timeline menu.
- **Wipe:** Add a default wipe.

# HLS Keyer Layout

## Module 1 (KB) - Page 1 of 2

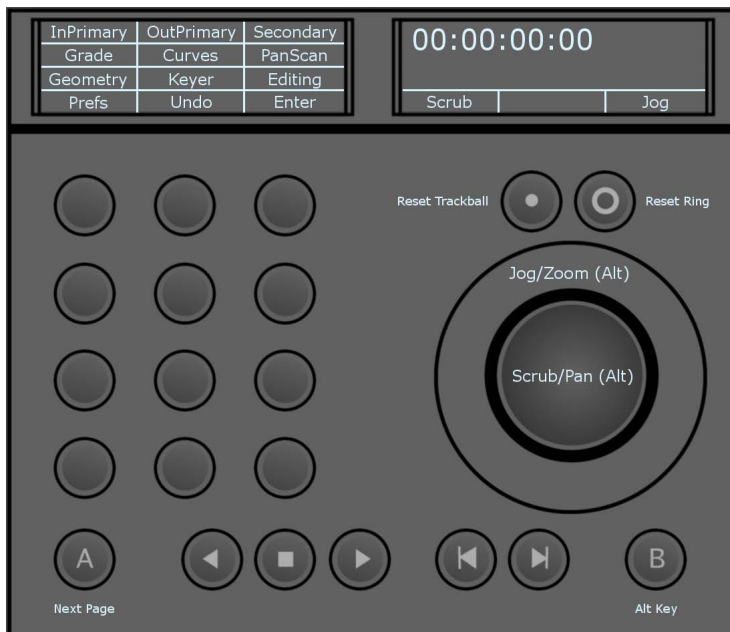

- **TolAll:** Set the global tolerance for your key (hue, luminance and saturation channels).
- **TolHue:** Set the tolerance for the hue channel.
- **TolLum:** Set the tolerance for the luminance channel.
- **TolSat:** Set the tolerance for the saturation channel.
- **SoftAll:** Set the global softness for your key (hue, luminance and saturation channels).
- **SoftHue:** Set the softness for the hue channel.
- **SoftLum:** Set the softness for the luminance channel.
- **SoftSat:** Set the softness for the saturation channel.
- **Range Hue:** Offset the tolerance range for the hue channel.
- **Range Lum:** Offset the tolerance range for the luminance channel.
- **Range Sat:** Offset the tolerance range for the saturation channel.

## Module 1 (KB) - Page 2 of 2

- **MatInvert:** Press the knob to invert your matte.
- **MatClean:** Set the matte cleanup value.
- **MatShrink:** Set the matte shrink value.
- **MatteBlur:** Set the matte blur value.

## Module 3 (MF) - Page 1 of 4

- **InPrimary:** Toggle input primary and output Primary grading modes.
- **Grade:** Access the Colour/Grade menu.

- **Geometry:** Enable the draw geometry mode in the Secondaries menu. The fourth row of functions on the module is dynamically updated to display the rectangle, circle and wipe options. Pressing the corresponding button enables you to add the desired geometry.
- **Prefs:** Access the preferences functions.
- **Inside:** Double press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single press to select inside grading and edit your grade.
- **Curves:** Access the Colour/Curves menu.
- **Keyer:** Enable the keyer in the Secondaries menu. The default behavior is to enable the HLS keyer. Pressing Keyer again enables the diamond keyer.
- **Undo:** Undo the last operation performed. Pressing the B button will change the function of the Undo button to Redo. The panel display will be updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).
- **Outside:** Double press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Single press to select outside grading, to edit your grade.
- **PanScan:** Access the Image/Reposition menu.
- **Editing:** Access the Editing/Timeline menu.
- **Enter:** Confirm operations.

## Diamond Keyer Layout

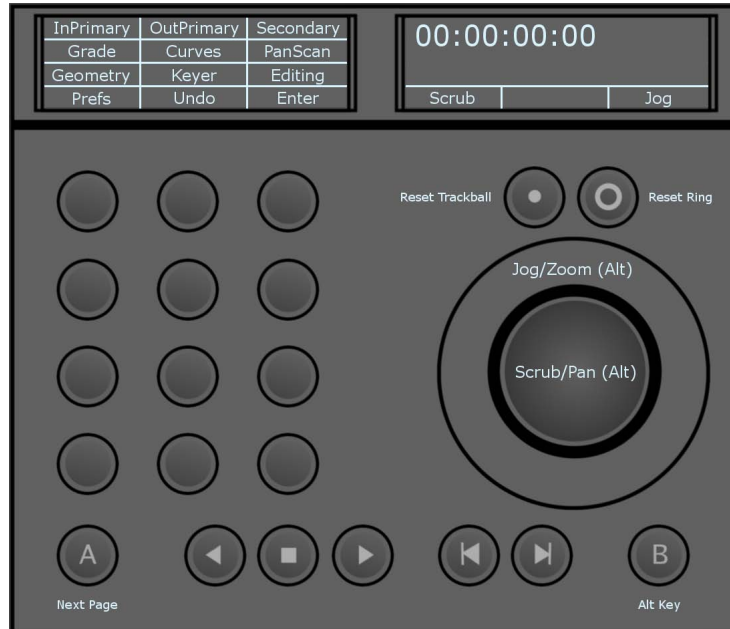

### Module 1 (KB) - Page 1 of 2

- **TolScale:** Set the tolerance scale value.
- **TolSkew:** Set the horizontal tolerance skew value.
- **TolPos:** Set the tolerance position value.
- **TolLum:** Set the tolerance luminance value.
- **SoftScale:** Set the softness scale value.

- **SoftSkew:** Set the horizontal softness skew value.
- **SoftPos:** Set the softness position value.
- **SoftLum:** Set the softness luminance value.
- **MattSharp:** Set the matte sharpness value.
- **MattClean:** Set the matte cleanup value.
- **MatShrink:** Set the matte shrink value.
- **MatteBlur:** Set the matte blur value.

### Module 3 (MF) - Page 1 of 4

- **InPrimary:** Toggle input primary and output primary grading modes.
- **Grade:** Access the Colour/Grade menu.
- **Geometry:** Enable the draw geometry mode in the secondaries menu. The fourth row of functions on the module is dynamically updated to display the rectangle, circle and wipe options. Pressing the corresponding button enables you to add the desired geometry.
- **Prefs:** Access the preferences functions.
- **Inside:** Double-press to enable inside grading in secondary mode (grading affects the inside of your shape) for the currently selected shape. Inside grading is enabled by default. Single-press to select inside grading and edit your grade.
- **Curves:** Access the Colour/Curves menu.
- **Keyer:** Enable the keyer in the secondaries menu. The default behavior is to enable the HLS keyer. Pressing Keyer again enables the HLS keyer.
- **Undo:** Undo the last operation performed. Pressing the B button will change the function of the Undo button to Redo. The panel display will be updated. Pressing the B button and Redo will redo the last operation (if you previously undid it).
- **Outside:** Double-press to enable outside grading in secondary mode (grading affects the outside of your shape) for the currently selected shape. Single-press to select outside grading, and edit your grade.
- **PanScan:** Access the Image/Reposition menu.
- **Editing:** Access the Editing/Timeline menu.

- **Enter:** Confirm operations.

## Editing Layout

### Module 4 (BT) - Page 1 of 1

- **Solo:** Solo the currently selected track/layer.
- **Cut:** Insert a cut at the current location of the positioner.
- **AModeSort:** Enable A-mode timeline Sort.
- **AModeHdls:** Enable A-mode timeline Sort with handles.
- **Trim:** Enable trim mode.
- **Join:** Join the timeline segment on which the positioner is parked with the segment immediately succeeding it.
- **CModeSort:** Enable C-mode timeline Sort.
- **CModeHdls:** Enable C-mode timeline Sort with handles.
- **Ripple:** Toggle between ripple off, ripple start and ripple end modes.
- **Delete:** Delete the timeline segment on which the positioner is parked.

---

#### NOTE

- When in Editing mode, pressing the B button and turning the ring on the MF panel enables timeline zoom in and out.
  - Pressing the B button and moving the trackball enables you to move the timeline positioner's focus point up or down.
-

# Preferences Layout

## Module 4 (BT) - Page 1

- **Storybrd:** Enable/disable the storyboard.
- **GUI:** Enable/disable onscreen GUI hiding.
- **Multi 2:** Toggle the number of active viewports when in multi view. Options are:
  - 2
  - 4
  - 9
  - 16
- **Histogram:** View/hide the histogram.
- **Thumbnail:** Enable/disable auto thumbnail refresh.
- **Play All:** Toggle play modes. Options are:
  - Play All (plays full timeline).
  - Play Shot (plays current shot).
  - PlayInOut (plays the interval between the In and Out marks).
- **Dual A/B:** Toggle the active sources displayed when in dual view. Options are: A/B or L/R.
- **Waveform:** Display/hide the waveforms in the audio tracks.
- **Label:** Enable/disable the image label.
- **Clr View:** Toggle single channel views. Options are:
  - Colour (all channels)
  - Red
  - Green
  - Blue
  - Luminance

- **2-up:** Toggle the display mode when in dual view. Options are:

**For A/B**

- 2-up
- HorizWipe
- VertWipe

**For L/R**

- 2-up
- HorizWipe
- VertWipe
- Blend

- **Vectorscp:** Display/hide the vectorscope.

## Troubleshooting

In the event that one or more of your panel modules are not recognized by Lustre, restarting the background service that manages the interactions between Lustre and the Tangent Element Control Surface can resolve the issue.

**To restart the background service:**

- 1 Exit Lustre.
- 2 Open a shell on your Linux machine.
- 3 Login as root.
- 4 Type: */etc/init.d/tangenthub restart*
- 5 Launch Lustre.

All of your module panels should now be recognized.

If the above procedure does not resolve the issue, you can manually connect the Control Surface to your software. To do this, you must define each module's unique ID number in the panel-list.xml file within the Lustre filesystem for the panel to be recognized.

**To manually install the panel:**

- 1 Plug and connect the four or five modules (depending on your setup) of your Tangent Element Control Panel to a power outlet and to your USB hub.
- 2 Once the modules are booted up and are displaying the Tangent logo, hit the A button on each module to display its unique ID number.

- 3 On your Linux machine, log in as root and use kEdit to edit the panel-list.xml file:  
*kedit /var/opt/Tangent/Hub/panel-list.xml*

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<TangentWave fileType="PanelList" fileVersion="3.0">
 <Panel type="Element-Mf" number="1" serial="30"/>
 <Panel type="Element-Bt" number="1" serial="68"/>
 <Panel type="Element-Bt" number="2" serial="77"/>
 <Panel type="Element-Kb" number="1" serial="53"/>
 <Panel type="Element-Tk" number="1" serial="13"/>
 <Panel type="Wave"/>
 <Options>
 <DHCP enabled="true"/>
 </Options>
</TangentWave>
```

- 4 Add the corresponding ID numbers to the panel-list.xml file.

**NOTE** In a four module setup, the line <Panel type= "Element-BT" number="2" serial="00"/> should be left blank.

- 5 Save the file.

The Tangent Element Control Surface should be now recognized by Lustre.

## The Autodesk Control Surface

The Autodesk® control surface provides improved interactivity when colour grading film and video footage. You can perform many of the same tasks you do in the Autodesk Lustre® user interface using the control surface. The modular design of the control surface also allows you to work on different grading stages simultaneously. For example, you can perform curves grading while modifying the image lift.

The Autodesk control surface consists of three panels. Although licensed separately, they are designed to work together.

## Connecting the Autodesk Control Surface

For information on connecting the control surface, refer to the *Autodesk Lustre Installation and Configuration Guide* for your operating system.

## Autodesk Control Surface Technical Information

For technical information about the Autodesk control surface, see [http://www.tangentdevices.co.uk/downloads\\_documents.asp](http://www.tangentdevices.co.uk/downloads_documents.asp). For those who wish to mount the Autodesk control surface in a desk, this link provides the precise dimensions of the panels in millimeters.

Consult the following table for the power consumption requirements of the Autodesk control surface.

Component	Quantity	Amps (120v)	Amps (240v)	Watts
Autodesk control surface panel	1	1.0	.5	120

# Connecting the Autodesk Control Surface to a Lustre Workstation

The Autodesk Control Surface consists of three panels connected to the workstation's on-board GigE port 1 by way of the supplied network switch. The central panel requires an additional connection to the remote unit of the USB extender kit.

This section provides information on making the physical connections needed to operate the Autodesk Control Surface. For information on using the Control Surface, see the [Autodesk Control Surface User Guide](#).

---

## NOTE

The illustration shows the central panel only (the Colour Grading panel). This panel is easily identified, since it has both an Ethernet network port and a USB connector. It is also the panel with the built-in tablet.

---

### To connect the Autodesk Control Surface:

- 1 Connect each panel to a power supply using the AC power adapter cables.
- 2 Use network cables to connect each panel to the available ports in the network switch.
- 3 Connect the Colour Grading panel to the remote unit of the USB extender kit.
- 4 Use a network cable to connect an available port on the Netgear network switch to the workstation, as illustrated.

### Assigning an IP Address to the Autodesk Control Surface

You must assign an IP address and subnet mask to the Autodesk Control Surface.

Assign the network port connected to the control surface with a static IP address that does not interfere with any of the IP addresses on your network.

### To configure the Autodesk Control Surface:

- 1 Type:  
**nedit /etc/sysconfig/network-scripts/ifcfg-eth<port#>**
- 2 Modify the IPADDR and NETMASK values. For example:

```
IPADDR=192.168.125.10
NETMASK=255.255.255.0
```

## Configuring Lustre to Connect to the Autodesk Control Surface

To configure Lustre to use the Autodesk control surface:

- 1 Turn the power on to each of the modules and look at the top display panel on the module. It should display the panel name and ID.
- 2 After you install Lustre, open the `init.config` file located in `/usr/autodesk/<lustre_version>` with a text editor.
- 3 In the `ControlSurface` section of the `init.config` file of your project, enter the panel IDs for each panel.

```
ControlSurface
AutodeskPanels state="On"
PanelIDs function="<panel_ID>" grading="<panel_ID>" navigation="<panel_ID>"
```

- 4 Start Lustre. The following message should appear in each Console:

```
Panel #<panel_ID> is detected
```

This confirms that the Autodesk Control Surface is enabled.

## Control Surface Panel Descriptions

Each of the three control surface panels are designed to perform different functions.

The following image shows the Navigation panel.

Use the Navigation panel to:

- Select menus. Pressing one of the menu buttons along the top of the panel activates a menu. For example, pressing the Grade button activates grading functionality.
- Reset or bypass the currently selected menu.
- Cache memory.
- Navigate the Storyboard.
- Pan and zoom the image.
- Copy grades.
- Activate mouse functionality.
- Add keyframes.
- Revert and compare grades.
- Toggle playback mode between Storyboard and clip loop.
- Switch playheads.
- Scroll shots.
- Undo and redo actions.
- Perform actions with the Grade bin.

- Adjust printer lights.
- Jump to specified frame number or timecode on the Storyboard.
- Show or hide user interface elements.
- Adjust the appearance of the panels.

The following image shows the Function panel.

Use the Function panel to work in the menu you activated in the Navigation panel. For example, if you pressed the Key menu button in the Navigation panel, the functions for pulling a key are activated in the Function panel. The features available on the Function panel depend entirely on the menu selected in the Navigation panel. You can use the digital display at the top of the panel as a guide for understanding how functionality is distributed when a given menu is active.

You can also use the Function panel to set viewing modes. Some of the viewing functions included in the Function panel include Multi view, Dual view in 2-up mode, Dual view in Wipe mode, proxy view, output view, and print view.

The following image shows the Colour Grading panel.

Use the Colour Grading panel for most grading functions. Colour grading functionality is split between the Colour Grading and the Function panels. The Colour Grading panel is always in grading mode. Depending on the colour space selected in the Setup Project menu, either Linear or Logarithmic functionality is available.

The Colour Grading panel also contains the tablet.

## Navigating the Storyboard

You can use the Navigation panel to:

- Scrub the Storyboard.
- Scroll through the shots in the Storyboard.
- Toggle between the regular and large Storyboard viewing modes.
- Jump to a specified frame or timecode on the Storyboard.
- Jump ahead or back a frame at a time, or a shot at a time.
- Play forwards or backwards.

**To scrub the Storyboard:**

- 1 Use the ring portion of the trackball.

**To scroll through shots on the Storyboard:**

- 1 Press the Scroll button.
- 2 Use the ring portion of the trackball.
- 3 Press the Scroll or Do button to confirm the move.

**To switch between regular and large Storyboard viewing modes:**

- 1 Press the top More button on the Navigation panel.

The Label, Thumbnails, and GUI options appear in the digital display at the top of the panel. The location of each option in the digital display reflects their button position on the panel.

- 2 If the Storyboard option does not appear, press the button for Thumbnails (the P&S button) to display Storyboard thumbnails. This makes the Storyboard option appear in the digital display.

- 3 Press the button for Storyboard (the Key button). This switches Storyboard thumbnails to the large Storyboard option.

**NOTE** This is equivalent to using the **Q** hotkey.

#### To jump to a specified frame on the Storyboard:

- 1 Press the Enter button.
- 2 Do one of the following:
  - To jump ahead, enter the frame number using the numeric pad on the right side of the panel.
  - To jump back, press the +/- button on the numeric pad and then enter the frame number.
- 3 Press the Enter button to jump to the specified frame.

#### To jump to a specified timecode on the Storyboard:

- 1 Press the Enter button.
- 2 Enter a timecode using the numeric pad on the right side of the panel.
- 3 Press the Enter button to jump to the specified timecode.

#### To jump back or ahead a frame at a time:

- 1 To jump back a frame, do one of the following:
  - Press the Frame Back button (left arrow button to the left of the trackball).
  - Simultaneously press the Shot Back button (below the Redo button) and the Play button (below the Do button).
- 2 To jump ahead a frame, do one of the following:
  - Press the Frame Forward button (right arrow button to the right of the trackball).
  - Simultaneously press the Shot Forward button (below the Undo button) and the Play button (below the Do button).

#### To jump to the beginning or end of a shot:

- 1 To jump to the first frame of the shot, press either of the two Shot Back buttons. One button is located to the left of the trackball, and the other is below the Redo button.
- 2 To jump to the last frame of the shot, press either of the two Shot Forward buttons. One button is located to the right of the trackball, and the other is below the Do button.

### To play forwards or backwards:

- 1 To play the Storyboard forward, do one of the following:
  - Press the Play Forward button (above the trackball).
  - Press the Spacebar-style Play button (below the Undo button). This button operates like the Spacebar on the keyboard, in that you use it both to start and stop playback.
- 2 To play the Storyboard backwards, press the Play Backwards button (above the trackball).
- 3 To stop playback, do one of the following:
  - Press the Stop button (above the trackball).
  - Press the Spacebar-style Play button.

## Toggling Play Modes

You can toggle the playback mode between looping a shot or looping the entire Storyboard.

### To toggle play modes:

- 1 Press the Clip button on the Navigation panel.

This button corresponds to the Play Mode button in the user interface.

## Activating Mouse Functionality

You can enable mouse functionality on the Navigation panel.

### To activate mouse functionality:

- 1 Press the Cursor button on the Navigation panel.

2 Use the panel's features as follows.

Use the:	As the:
Trackball	Mouse.
Backward play button	Left mouse button.
Stop button	Middle mouse button.
Forward play button	Right mouse button.

## Panning and Zooming the Image

You can use the Navigation panel to pan and zoom the image.

To zoom the image:

- 1 Hold down the ALT button on the Navigation panel and use the ring on the trackball to zoom in and out.

To pan the image:

- 1 Hold down the ALT button on the Navigation panel and use the jog ball on the trackball to pan the image.

## Resetting Zoom and Pan

You can now reset the zoom and pan.

To reset the zoom and pan:

- 1 Hold down the ALT button on the Navigation panel and press the Reset button.

**NOTE** The zoom and pan are always reset together.

## Customizing the View

There are options for customizing the view on both the Navigation panel and the Function panel.

When working with secondaries, users can use the Function panel to view them in Saturated Mask view or Matte view. Saturated Mask view displays the range of colours you define through a greyscale image. The unselected colours remain grey. Matte view displays a black and white template indicating which parts of the image are transparent (black), and which are opaque and selected (white).

To access view options available on the Navigation panel:

- 1 Press the top MORE button on the Navigation panel.

The View, Panel, Storyboard, Label, Thumbs, and GUI options appear in the digital display at the top of the panel. The location of each option in the digital display reflects their button position on the panel.

- 2 Select one of the following options.

Press:	To:
GRADE	Select the viewing options. <a href="#">Player Viewing Options</a> (page 2485).
CURVES	Adjust the panel sensitivity. See <a href="#">Customizing the Panel Sensitivity</a> (page 2482).
KEY	Toggle the Storyboard on or off.
GEOM	Toggle the shot name on or off the image.
P&S	Toggle the Storyboard thumbnails on or off.
MISC	Toggle the full-screen Player on or off.

**To access view options available on the Function panel:**

- 1 Use the viewport options to change the view as you work on your grades. For example, press PROXY to view a proxy version of your shot in the Player.

Viewport options

Viewport option	Description
MULTI	Cycles through the Multi view modes. You can view 2, 4, 9, or 16 shots within the Player.
WIPE	Cycles through the horizontal wipe, vertical wipe, and blend (for a stereoscopic project only).
SPLIT	Toggles between the current view options and the Single view (default).
PROXY	Toggles between the full-resolution and half-resolution (proxy) version of your shot in the Player. If you have not rendered a proxy, an X appears in the Player.
MATTE	Toggles between secondary grading view and result view.
O/P	Toggles between a rendered version of your shot (P) and the pre-rendered version with grading applied (O). If you have not rendered the shot, an X appears in the

Viewport option	Description
	Player when in P mode. Press the ALT and O/P buttons simultaneously to toggle to I mode (this displays the image with colour corrections made in the Grading and Curves menus only).
STILL	Displays the stored reference image. Press the ALT and Still buttons simultaneously to store the current frame in the reference buffer.

**NOTE** You can also access the SHOW button in the Function panel. This button shows or hides the geometry wireframe for the current secondary layer.

**NOTE** There is no functionality assigned to the Function panel's ALT button for this release.

**To change fonts in the digital display:**

- 1 On the keyboard, press `Shift+F` until you obtain the desired font.

**NOTE** The change is only maintained for the current session.

**To toggle between “O” view and Matte view:**

- 1 Press the MATTE button on the Function panel.

- 2 Hold down the ALT button on the Function panel while pressing MATTE again to switch between Saturated Mask view and black and white Matte view.

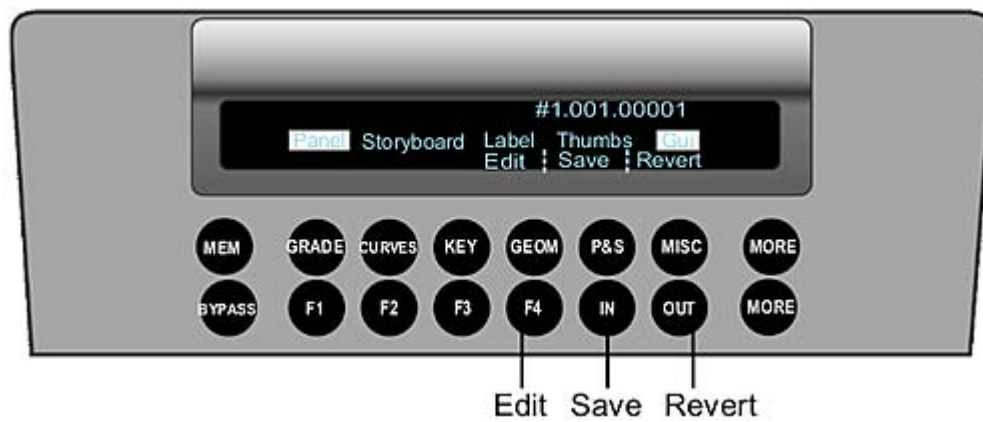

**TIP** You can go directly to Saturated Mask view mode from another mode, e.g. Output, by holding down the ALT button and pressing MATTE.

## Customizing the Panel Sensitivity

When you enable the Edit function, you can modify the sensitivity of any modifier (e.g., knobs, wheels, and rings). These items include the Grading, Curves, Key, Geom, P&S, and Misc menu.

**To edit the sensitivity of the Autodesk Control Surface panels:**

- 1 On the Navigation panel, press the top MORE button.
- 2 Press the CURVES button to enter the Panel menu.

In the Panel menu you can Edit (F4 button), Save (IN button), and Revert (OUT button) your panel sensitivity changes.

- 3 Press the F4 button to enable the Edit mode.
- 4 Touch any modifier you want to change its sensitivity on the panel. Turn the modifier clockwise to increase the sensitivity or counter-clockwise to decrease the sensitivity.

**NOTE** The Function panel displays the Grade menu by default. To change the sensitivity of the Curves, Geometry, Keyer, or Reposition menu, you must enable the menu you want to modify first before entering the panel sensitivity option.

When a control is selected, its name and sensitivity are displayed on all the LCD panels. The last line of the LCD displays the control you are modifying, its value, and the enabled Edit mode.

**NOTE** Some control names are long and therefore are truncated on the Navigation panel LCD. The Function and Grading panels display the full name and value.

- 5 Press the F4 button again to disable the Edit mode. You can now test out the new sensitivity value.

**NOTE** Pressing F4 does not exit you from the Panel menu.

**NOTE** You need to save the rules file in order to commit your modification. If you do not save the modification, you will lose the modified value(s) when you quit Lustre.

## Saving the Sensitivity Modifications

When you have completed making modifications to the sensitivity of your Autodesk control surface panel and tested the sensitivity, you must save your changes.

**To save the modifications to your Autodesk Control Surface panel:**

- 1 Press the IN button. The Save option is selected and the LCD displays “Confirm Save”.

**NOTE** If you do not want to confirm the save, press the F1 button to exit the Save menu. The display returns to the Panel menu.

- 2 Press the IN button again. The LCD displays “Saving Panel File”.  
The changes are saved and the display returns to the top level menu.

## Reverting the Panel Modifications

If you have made modifications to the panel control values and have not saved the changes, you can revert back to the previous saved values.

**To revert the saved panel modifications:**

- 1 Press the OUT button to select the Revert option.

The LCD displays “Confirm Revert”.

**NOTE** If you do not want to confirm the revert, press the F1 button to cancel the revert. The display returns to the Panel menu.

- 2 Press the OUT button again to confirm the revert. The LCD displays “Reverting Panel File” and then returns to the top level menu.

## Selective Backlighting of Active and Available Buttons

In order to make it easier to determine which functions are currently available on the Autodesk control surface panels, you can select Mid from amongst the options accessible from the Navigation panel.

The Mid option highlights active buttons and available buttons.

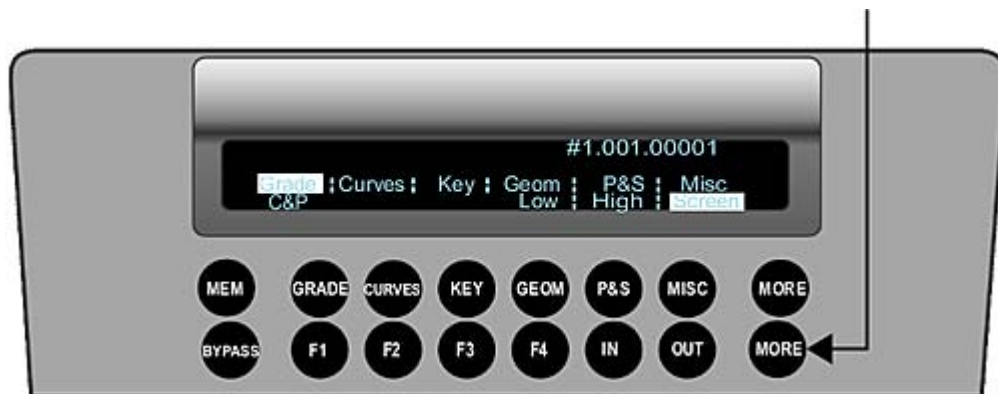

An active button is one that has been enabled by the user. For example, if you enable secondary two for Inside grading, the 2 button on the numeric keypad and the Inside button are backlit on the Navigation panel.

An available button is one that has been enabled by the system based on a feature that you selected. For example, if you switch from the Geom menu to the Reposition menu, the backlighting on the Function panel changes to show which buttons are available for performing repositioning tasks.

**To enable backlighting for active and available buttons:**

- 1 Press the bottom MORE button on the Navigation panel.

The Low, Mid, High, and Screen options appear in the digital display.

- 2 Press the F4 button.  
Active and available buttons are now backlit.

**NOTE** The Low option is now accessible by pressing the F3 button.

## Toggling Playheads

You can toggle between the images assigned to Playhead A and B.

To toggle playheads:

- 1 Press the A/B button on the Navigation panel.

## Player Viewing Options

There are several ways you can view the shots within the Player. You can choose to display the shot(s) in a Single, Dual, or Multi view. These viewing options are accessible through the Navigation panel.

To access the viewing options:

- 1 Press the top MORE button on the Navigation panel.
- 2 Press GRADE to access the viewing options.
- 3 Use the following controls.

Press:	To:
F1	Cycle through the different colour view selections (i.e., colour, red, green, blue, and luminance channels).
F2	Cycle through the different viewers (i.e., Single, Dual, or Multi view).
F3	Toggle between Playheads A and B (A/B) or Left Eye and Right Eye (L/R). This is only applicable for Dual view.
F4	Cycle through the Dual view modes (i.e., 2-up, horizontal wipe, vertical wipe, or blend). Blend is only available if you have L/R selected. Cycle through the Multi view modes (i.e., 2-up, 4-up, 9-up, or 16-up).

**NOTE** To revert to the previous selection, press ALT on the Navigation panel and the corresponding F1, F2, F3, or F4 button.

- 4 (Optional) If you have selected a wipe or blend, you can adjust the position of the wipe or the opacity of the blend by holding ENTER on the Navigation panel and rotating the ring portion of the trackball.

## Using the Undo List

You can access the undo list from the Navigation panel. The undo list works differently than it does in the user interface. When you use the panel, you must save your changes to the undo list using the Do button. Undo lists are saved on a shot-by-shot basis.

**To save a change to the undo list:**

- 1 Press the DO button.

**To go through the undo list:**

- 1 Press the UNDO or REDO button.

## Reverting to Previous Grades

You can use the Navigation panel to toggle between the grade that was applied to a shot when you first selected it in the Storyboard and the current grade.

**To revert to previous grades:**

- 1 Press the REVERT button on the Navigation panel.

**To save the reverted stage to the undo list:**

- 1 Press the DO button on the Navigation panel.

## Comparing Grades

You can compare the current image with the grade you last committed to the undo list.

To toggle between the current image and the grade you last committed to the undo list:

- 1 Press the COMP button on the Navigation panel.

## Working with the Grade Bin

You can use the Navigation panel to access Grade bin functionality.

## Saving a Grade to the Grade Bin

Use Grade Save mode to save one or more grades to the Grade bin.

To save a grade to the Grade bin:

- 1 On the Storyboard, use the ring to navigate to the shot with the grade you want to save.  
**TIP** This step can also be performed after you enter Grade Save mode.
- 2 Press the Grade button on the Navigation panel.  
This activates Grade Save mode.
- 3 To select a storage container in the Grade bin, do one of the following:
  - Use the jog ball on the trackball.
  - Press the keypad number button that corresponds to the desired Grade bin container position.
- 4 To save the shot's grade to the storage container, double-press the keypad number button that corresponds to the desired Grade bin container.  
After the grade is saved, you are still in Grade Save mode and can save other grades. Use the trackball ring to navigate to other shots.
- 5 To exit Grade Save mode, press Grade.

## Loading a Grade From the Grade Bin

Use Grade Load-Recall mode to load grades from the Grade bin to one or more shots on the Storyboard.

**To load a grade from the Grade bin:**

- 1 On the Storyboard, navigate to the shot to which you want to load one or more grades.  
**TIP** This step can also be performed after you enter Grade Load-Recall mode.
- 2 Press the Recall button on the Navigation panel.  
This activates Grade Load-Recall mode.
- 3 To select a grade in the Grade bin, do one of the following:
  - Use the jog ball on the trackball to navigate the Grade bin.
  - Press the keypad number button corresponding to the desired Grade bin container position once to jump to it.
- 4 To load the grade to the current selected shot on the Storyboard, double-press the appropriate number button twice.  
After the grade is loaded to the shot, you are still in Grade Load-Recall mode and can load other grades from the Grade bin to the shot. Use the trackball ring to navigate to other shots.
- 5 To exit Grade Load-Recall mode, press Recall.

## Saving the Current Grade

You can use the Navigation panel to save the current grade file and cut.

---

**NOTE** If a grade file has not been created, a default grade file is saved.

---

**To save the current grade file and cut:**

- 1 Press ALT and DO on the Navigation panel.

## Adjusting Printer Lights

You can adjust printer lights on the Navigation panel. Printer light values are displayed in the Colour Grading panel's digital display.

---

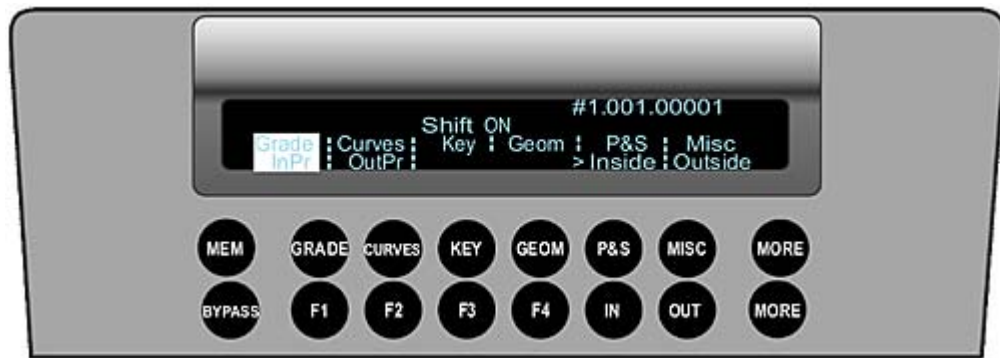

**NOTE** You can also adjust printer lights on the Function panel when the Grade menu is enabled. See [Grading in Logarithmic Mode Using the Function Panel](#) (page 2502).

---

**To adjust printer lights:**

- 1 On the Navigation panel, double-press the ALT button.  
The words "Shift ON" appear in the digital display.

- 2 Use the following buttons on the keypad to make printer light adjustments to the image.

Press:	To:
7	Increase red brightness by one step.
4	Decrease red brightness by one step.
8	Increase green brightness by one step.
5	Decrease green brightness by one step.
9	Increase blue brightness by one step.
6	Decrease blue brightness by one step.
1	Increase cyan brightness by one step.
- (minus sign)	Decrease cyan brightness by one step.
2	Increase magenta brightness by one step.
0	Decrease magenta brightness by one step.
3	Increase yellow brightness by one step.
. (period)	Decrease yellow brightness by one step.

## Copying Grades

You can temporarily or permanently copy a grade to the current shot from another shot in the Storyboard.

**To copy a grade to the current shot from another shot in the Storyboard:**

- 1 Scroll to the shot you would like to copy grades to by performing one of the following two actions:
  - Hold down the ALT button on the Navigation panel and then press the Frame Forward or Frame Back button to temporarily apply the grade from the previous or next shot to the current shot.

**NOTE** Each time you press ALT and Frame Forward or Frame Back, you move one shot at a time through possible sources to copy back to the current Storyboard position. For example, if you hold down ALT and press Frame Forward three times, you see a preview of the current Storyboard position with the grade from three shots ahead applied.

- Press Offset on the Navigation panel and then scroll through the shots by pressing the Scroll button and using the ring portion of the trackball.

- 2 Press Do to permanently copy the grade from the shot outlined in blue to the current shot.
- 3 Press the ALT button to cancel the operation.

## Adding Keyframes

When you animate parameters, you can set keyframes using the Mark button.

**To add keyframes:**

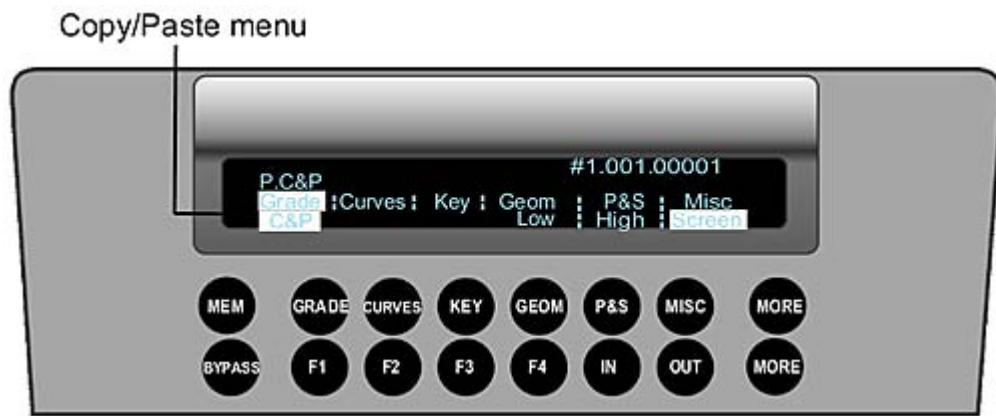

- 1 Go to the frame where you want to add the keyframe.
- 2 Press Mark.
- 3 Modify the parameters.
- 4 Repeat the above steps as required.

## Copying and Pasting Keyframes

You can copy and paste keyframes using the Navigation and Function panels of the Autodesk control surface panel.

**To copy and paste keyframes:**

- 1 On the Navigation panel, press the bottom MORE button.
- 2 Press the F1 button to enable the P. C & P menu.  
The Permanent Copy/Paste (P. C & P) menu is displayed.

- 3 On the Function panel, press the appropriate button (F1-F8) to perform your choice of copy and paste operation.

**NOTE** When you press one of these buttons, the corresponding button is automatically pressed in the Channel hierarchy and the corresponding menu command is highlighted in the Function panel display. For example, when you press F1 to add a keyframe, the Add button is pressed and the Add command is highlighted.

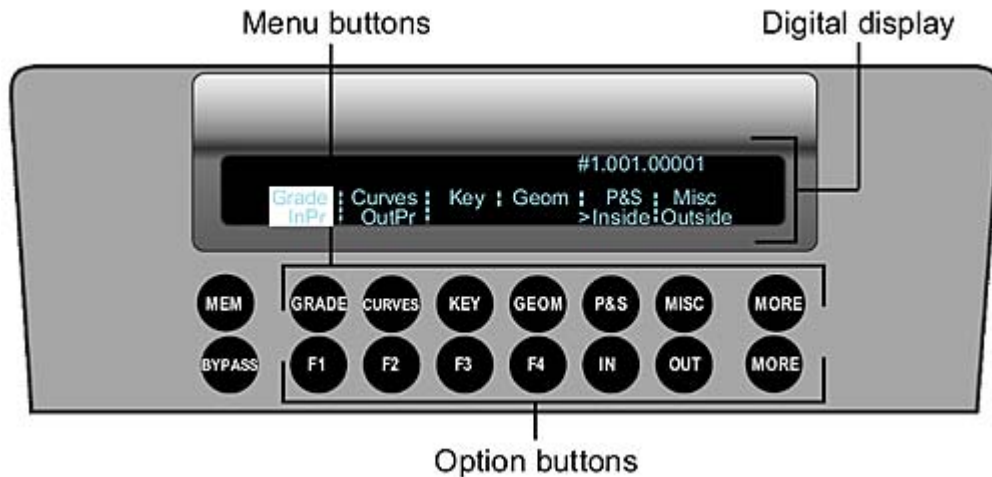

Copy/Paste Keyframe functions

Copy/Paste Keyframe option	Function
F1	Add keyframe
F2	Copy
F3	Remove keyframe
F4	One frame
F5	Next keyframe
F6	All frames
F7	Previous keyframe

Copy/Paste Keyframe option	Function
F8	Paste

## Selecting Menus

Selecting a menu from the first row of buttons on the Navigation panel determines which options are available in the second row of buttons. What you select in the Navigation panel also determines the features available on the Function panel.

You can see which options are available by checking the digital display. For example, in the following illustration the Grade menu has been selected and the InPr, OutPr, Inside, and Outside options appear in the digital display. The location of these options in the digital display is the same as their location amongst the option buttons.

To select a menu:

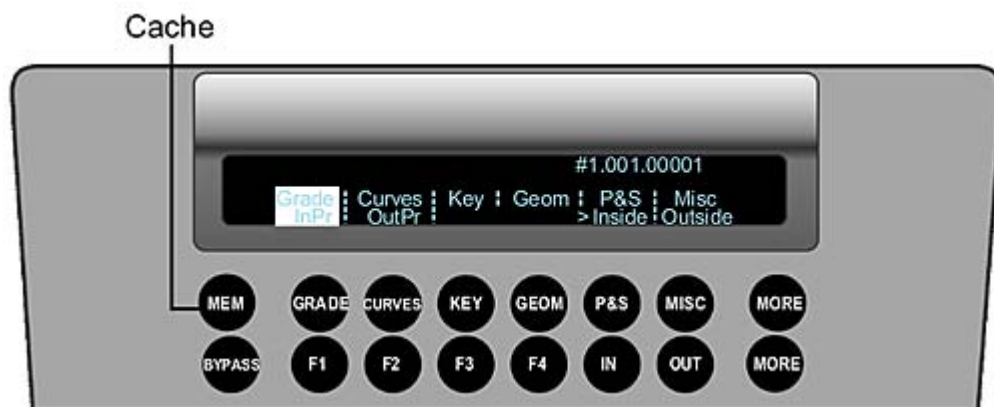

- 1 Choose one of the following.

Press:	To:
Grade	Enable the In Primary, Out Primary, Inside, and Outside options, and activate Logarithmic or Linear grading in the Function panel. See <a href="#">Performing Colour Grading</a> (page 2499).
Curves	Enable the In Primary, Out Primary, Hue, and RGB options, and activate curves grading in the Function panel. See <a href="#">Performing Curves Grading</a> (page 2510).
Key	Enable the Key menu, and activate keying functionality in the Function panel. See <a href="#">Extracting Keys using the HLS Keyer</a> (page 2515) and <a href="#">Extracting Keys using the Diamond Keyer</a> (page 2520).
Geom	Enable the Rectangle, Circle, Wipe (in Dual view), Bezier (free-form geometry), Inside, and Outside options, and activate geometry grading in the Function panel. See <a href="#">Creating and Grading Geometries</a> (page 2525).
P&S	Activate repositioning functionality in the Function panel. When this function is selected, no additional options are activated in the Navigation panel. See <a href="#">Repositioning Shots</a> (page 2497).
More (upper)	Access the following additional options: Label, Thumbnails, and GUI. These options pertain to elements in the user interface. See <a href="#">Customizing the View</a> (page 2478).
More (lower)	Access the following additional options: Low, High, and Screen. These options pertain to the control surface appearance. See <a href="#">Modifying the Appearance of the Autodesk Control Surface</a> (page 2531).

**NOTE** There is no functionality assigned to the Misc button for this release.

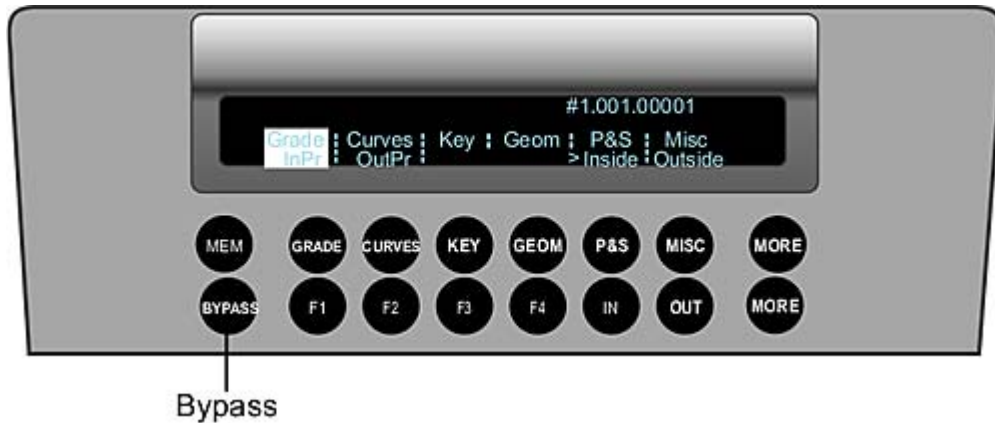

## Caching Memory

When a shot does not play back in real time, you can cache the frames into memory using the Mem button.

## Bypassing Functions

Use the Bypass button on the Navigation panel to bypass the currently selected menu.

## Resetting Functions

Use the Reset button on the Navigation panel to reset parameters for the current menu only, or to reset all parameters on the currently selected shot.

**To reset parameters for the current menu only:**

- 1 Press the Reset button once.

**To reset all parameters on the shot:**

- 1 Double-press the Reset button.

---

**TIP** You can reset individual parameters by pressing its assigned Reset button. These buttons are indicated throughout this chapter.

---

## Repositioning Shots

You can reposition a shot by:

- Scaling
- Panning vertically and horizontally
- Rotating
- Changing the aspect ratio
- Flipping and flopping

When Sync mode is enabled in a stereoscopic project, you can use the Convergence tool to pan and scale both eyes at the same time in opposite directions.

**To reposition a shot:**

- 1 Press the P&S button on the Navigation panel.

- 2 On the Function panel, use the following controls.

Use:	To:
Wheels	Reposition the image. Wheel 1=Pan X Wheel 2=Pan Y Wheel 3=Scale Wheel 4=Rotate To reset a wheel, press the button above it.
Knob at right	Change the image's aspect ratio. To reset, press the button below it.
First row of buttons at bottom right	Flip or flop the image. F1=Flip F3=Flop Toggle the state of the Convergence Tool. F5=Toggle Convergence
SHOW button	Toggle the geometry wireframe on or off.

# Performing Colour Grading

You can use the Autodesk control surface to perform input and output grading in Logarithmic or Linear mode.

As with other menus, you select the Grade menu from the Navigation panel. This activates colour grading functionality on the Function panel. The Colour Grading panel is enabled regardless of which menu is active in the Function panel. The features available on these panels depend on whether you are in Logarithmic or Linear mode. You specify the colour architecture in the Setup Grade menu in the user interface.

## Logarithmic Mode

When Log is enabled in the Setup Grade menu, the Colour Grading panel and the Function panel are activated with logarithmic colour grading functionality.

### Grading in Logarithmic Mode Using the Colour Grading Panel

Use the Colour Grading panel to:

- Adjust brightness balance and contrast balance for the entire image or for a range of colours.
- Adjust brightness in the shadows, midtones, and highlights.

There are two available setups for the Colour Grading panel. You can switch between setups by pressing the F9 button.

The default setup allows you to modify contrast, overall brightness, and brightness in the shadows, midtones, and highlights. Adjusting brightness in the shadows, midtones, and highlights requires that you switch the functionality of the first trackball among the three. You use the second and third trackballs to adjust contrast and brightness in the overall image.

The alternate setup distributes brightness controls for the shadows, midtones, and highlights amongst the three trackballs. This allows you to balance the values without having to constantly switch the functionality of a single trackball.

**To colour grade using the Colour Grading panel default setup:**

- 1 On the Colour Grading panel, use the following controls.

Use:	To:
First ring	Adjust brightness in the shadows, midtones, or highlights for the overall image. To reset, press F1.
First jog ball	Adjust brightness in the shadows, midtones, or highlights for a range of colours. To reset, press F2.
F3 button	Switch functionality for the first trackball between shadows, midtones, or highlights.
Second ring	Adjust contrast/pivot in the overall image. To reset, press F4.
Second jog ball	Adjust contrast/pivot in a range of colours. To reset, press F5.
F6 button	Toggle functionality for the second trackball between contrast and pivot.
Third ring	Adjust brightness in the overall image. To reset, press F7.
Third jog ball	Adjust brightness in a range of colours. To reset, press F8.

To colour grade using the Colour Grading panel alternate setup:

- 1 Press the F9 button to switch to the alternate setup.
- 2 On the Colour Grading panel, use the following controls.

Use:	To:
First ring	Adjust overall brightness in the shadows. To reset, press F1.
First jog ball	Adjust brightness in the shadows for a range of colours. To reset, press F2.
Second ring	Adjust overall brightness in the midtones. To reset, press F4.
Second jog ball	Adjust brightness in the midtones for a range of colours. To reset, press F5.
Third ring	Adjust overall brightness in the highlights. To reset, press F7.
Third jog ball	Adjust brightness in the highlights for a range of colours. To reset, press F8.

Use:	To:
F9 button	Toggle between the panel default and alternate setup.

### Grading in Logarithmic Mode Using the Function Panel

When the Grade menu is enabled, you can use the Function panel to:

- Adjust overall hue, brightness, and saturation.
- Balance brightness and contrast in the red, green, and blue channels.
- Balance brightness of colours in the shadows, midtones, and highlights.
- Adjust cutoff values.
- Increase or decrease printer light settings.

#### To colour grade in Logarithmic mode using the Function panel:

- 1 Press the Grade button on the Navigation panel.  
The In Primary, Out Primary, Inside, and Outside options are activated.

- 2 Do one of the following:
  - Press the F1 option button to work on the initial primary grade.
  - Press the F2 option button to work on final curve modifications.
  - If you are colour grading a secondary, either a key or a geometry, use the numeric keys on the Navigation panel to select and activate a secondary layer. See [Adding Secondary Layers](#) (page 2513).
- 3 If you are accessing the Grade menu after having created a geometry or key, do one of the following:
  - Press the IN option button to grade inside the secondary.
  - Press the OUT option button to grade outside the secondary.
- 4 On the Function panel, use the following controls.

Use:	To:
Wheels	Modify overall hue, brightness/contrast, and saturation. Wheel 1=Hue Wheel 3=Brightness/contrast Wheel 4=Saturation To reset a wheel, press the button above it.
Knobs at top left	Balance brightness or contrast in the RGB channels. Knob 1=Red brightness/contrast Knob 2=Green brightness/contrast Knob 3=Blue brightness/contrast To toggle knob functionality, press the F1 button in the centre column. To reset a channel, press the button below it.
Knobs at top right	Balance S/M/H brightness of the colours, or adjust cutoff values. Knob 4=Brightness in shadows/cutoff values Knob 5=Brightness in midtones/cutoff values Knob 6=Brightness in highlights To toggle knob functionality, press the F4 button in the centre column. To reset a knob, press the button below it.

Use:	To:
First row of buttons at bottom right	Increase printer light values. F1=Red F3=Blue F5=Green F7=Overall
Second row of buttons at bottom right	Decrease printer light values. F2=Red F4=Blue F6=Green F8=Overall Press ALT for half point adjustments.
SHOW button	Toggle the geometry wireframe on or off.

## Linear Mode

When Lin is enabled in the Setup Grade menu, the Colour Grading panel and the Function panel are activated with linear colour grading functionality.

### Grading in Linear Mode Using the Colour Grading Panel

Use the Colour Grading panel to modify lift, gain, and gamma in the low, mid, and high levels of the image, or across the entire image.

**To colour grade in Linear mode using the Colour Grading panel:**

- 1 On the Colour Grading panel, use the following controls.

Use:	To:
First ring	Modify lift in the overall image. To reset, press the F1 button.
First jog ball	Modify lift in a range of colours. To reset, press the F2 button.
Second ring	Modify gain in the overall image. To reset, press the F4 button.
Second jog ball	Modify gain in a range of colours. To reset, press the F5 button.
Third ring	Modify gamma in the overall image. To reset, press the F7 button.
Third jog ball	Modify gamma in a range of colours. To reset, press the F8 button.
F3 button	Toggle between Master and Low levels.

Use:	To:
F6 button	Toggle between Master and Mid levels.
F9 button	Toggle between Master and High levels.

### Grading in Linear Mode Using the Function Panel

When the Grade menu is enabled, you can use the Function panel to:

- Modify hue, contrast, gain, and saturation values.
- Balance lift, gamma, and gain values for the red, green, and blue channels.
- Set black and white clip and reference values.

#### To colour grade in Linear mode using the Function panel:

- 1 Press the Grade button on the Navigation panel.  
The In Primary, Out Primary, Inside, and Outside options are activated.

- 2 Do one of the following:
  - Press the F1 option button to work on the initial primary grade.
  - Press the F2 option button to work on final curve modifications.
  - If you are colour grading a secondary, either a key or a geometry, use the numeric keys on the Navigation panel to select and enable a secondary layer. See [Adding Secondary Layers](#) (page 2513).
- 3 If you are accessing the Grade menu after having created a geometry or key, do one of the following:
  - Press the IN option button to grade inside the secondary.
  - Press the OUT option button to grade outside the secondary.
- 4 On the Function panel, use the following controls.

Use:	To:
Wheels	Modify overall hue, contrast, gain, and saturation. Wheel 1=Hue Wheel 2=Contrast Wheel 3=Gain Wheel 4=Saturation To reset a wheel, press the button above it.
Knobs at top left	Balance the RGB channels. Knob 1=Red Knob 2=Green Knob 3=Blue To reset a knob, press the button below it.
Buttons in left centre column	Toggle the type of value to be adjusted in the RGB channels (Knobs 1-3). F1=Lift F2=Gamma F3=Gain

Use:	To:
Knobs at top right	Define values to clamp minimum and maximum luminance. Knob 4=Black Knob 5=White
Buttons in right centre column	Toggle the type of black and white values to be adjusted (Knobs 4-5). F4=Clip F5=Reference
SHOW button	Toggle the geometry wireframe on or off.

## Performing Curves Grading

When the Curves menu is enabled, you can use the Function panel to:

- Modify Hue and RGB curves either after the initial primary colour grade, or after the addition of any Lustre Sparks® effects.
- Adjust the Hue, Lightness, Saturation, and Luminance curves separately.
- Modify the entire curve uniformly or modify individual vertices for RGBCMY channels (red, green, blue, cyan, magenta, and yellow).

**To modify Hue and RGB curves:**

- 1 Press Curves on the Navigation panel.  
The In Primary, Out Primary, Hue, and RGB options are activated.

- 2 Do one of the following:
  - Press the F1 option button to indicate that you are working on the initial primary grade.
  - Press the F2 option button to indicate that you are working on final curve modifications.
- 3 Do one of the following:
  - Press the F3 option button to work on Hue curves.
  - Press the F4 option button to work on RGB curves.
- 4 On the Function panel, use the following controls.

Use:	To:
	F3=Saturation If you press the F1 button when working with RGB curves, you are toggled to Hue curves.
First row of buttons at bottom right	Select the low point, mid point, high point, or all for the L-S curve. F1=Low F3=Mid F5=High F7=Master
SHOW button	Toggle the geometry wireframe on or off.

## Adding Secondary Layers

Secondary layers are used to colour grade specific hues and areas within an image. You can create up to 48 secondary layers for each shot within your project. Secondary layers can be added to your shot by accessing the numerical buttons on the Navigation panel. You can add layers to your shot from the Grade, Curves, Key, or Geometry menu. Once a secondary layer has been created, it can be modified by generating keys and geometries, removing grain, or by adding Lustre Sparks Effects.

Press:	To:
0-9, -, or C	<p>Select, activate, or deactivate a layer. The buttons on the Navigation panel correspond to the position of the secondary layer on the user interface, and not to the actual numbers. For example, press 7 for layer 1.</p> <p>Press the button once to select a layer.</p> <p>Press the button twice to activate/deactivate a layer.</p>
+/-	<p>Cycle through the four pages of secondary layers. Each page consists of 12 secondary layers (e.g., P1 displays layers 1-12, P2 displays layers 13-24, etc.).</p>

## Extracting Keys

Lustre provides two separate keyers for extracting keys. When the Key menu is enabled, you can use the Function panel to work with:

- The Hue, Luminance, and Saturation (HLS) Keyer. See [Extracting Keys using the HLS Keyer](#) (page 2515).
- The Diamond Keyer. See [Extracting Keys using the Diamond Keyer](#) (page 2520).

**NOTE** The keyer default is set in the Lustre user interface. See the Tools Settings section in the Project Management chapter of the *Autodesk Lustre User Guide*.

## Extracting Keys using the HLS Keyer

Use the Navigation panel to:

- Enable the HLS Keyer.
- Select a secondary layer.
- Sample the image.
- Extract a key.

Use the Function panel to adjust the key by setting softness and tolerance ranges, modify key edges, invert the key, and link layers.

To enable the HLS Keyer in the Navigation panel:

- 1 Press the Key button once to activate the Key menu, and then press F1 to enable the HLS Keyer. The HLS Keyer and Inside are enabled.

**To select a secondary layer in the Navigation panel:**

- 1 Use the numeric keys to select and enable a secondary layer. Press the number key once to select the layer, and then double-press it to enable it. To enable layer 10, press the minus button (-). To enable layer 11, press 0. To enable layer 12, press the C button.

**To sample the image in the Navigation panel:**

- 1 Press F3 (pick). The trackball on the Navigation panel is activated as a picker, allowing you to move through the image. Press F3 again to pick the current pixel for the sample. To sample an area of the image, hold down the ALT button while in picker mode and draw, with the trackball, a rectangular area of the image, and then release the ALT button.

**To extract a key in the Navigation panel:**

- 1 To extract a key after input primary grading has been performed, press F4. To switch back to the primary-graded result, press F4 again.

**To adjust a key in the Function panel:**

- 1 Use the following controls listed in the table below to adjust the key for the sampled colour.

Use:	To:
Wheels	Adjust the tolerance and softness around the picked colour. Wheel 1=Tolerance Wheel 2=Softness
Knobs at top left	Adjust minimum/maximum tolerance, centre tolerance, and minimum/maximum softness. Knob 1=Minimum/maximum tolerance Knob 2=Centre Knob 3=Minimum/maximum softness
Upper left F1 and F4 buttons	Enable either minimum or maximum tolerance (Knob 1) adjustments. F1=Minimum F4=Maximum
Upper left F3 and F6 buttons	Enable either minimum or maximum softness (Knob 3) adjustments. F3=Minimum

Use:	To:
	F6=Maximum
Buttons in centre column	Adjust tolerance, centre, and softness values separately for each of the channels forming the basis of the key. F1=Hue F2=Luminance F3=Saturation
Knobs at top right	Modify key edges and remove stray pixels from a key. Knob 4=Cleanup Knob 5=Shrink Knob 6=Blur
Buttons at top right	Press F1 to enable cleanup (Key-out), shrink, and blur. Press F4 to enable soften (Key-in filter). F1=Cleanup F2=Shrink F3=Blur F4=Soften Single press F2 and F3 to reset shrink and blur, respectively. Double-press F1 and F4 to reset cleanup and soften, respectively.
Upper right F6 button	Invert the key.
First row of buttons at bottom right	Press F1 to cycle through add, intersect, subtract, or link layers. F1=Add, intersect, subtract, or link F3=Invert link F5=Log to Lin F7=GPU compatibility
Second row of buttons at bottom right	Add or subtract tolerance and softness from the key. F2=Tolerance F4=Softness F6=Add softness/tolerance F8=Subtract softness/tolerance Press F3 on the Navigation panel to change the cursor into a picker prior to using any of the above buttons. When done defining tolerance and softness, press F3 again.
SHOW button	Toggle the geometry wireframe on or off.

## Toggling the Keyer Button and Keyer Channels On and Off

Users can toggle the on or off status of the Keyer button visible on the Navigation panel. Users can also enable or disable any or all of the Hue, Luminance, or Saturation channels on the Function panel.

To make the HLS Keyer status visible on the Navigation panel:

- 1 Press the Key button once to activate the Key menu, and then press F1 to enable the HLS Keyer channel and activate backlighting to show its enabled status.
- 2 Double-press the F1 button to disable the HLS Keyer channel.  
The HLS Keyer is disabled in the Lustre application.

To enable or disable the Hue, Luminance, or Saturation channels on the Function panel:

- 1 Double-press F1, F2, or F3.

## Extracting Keys using the Diamond Keyer

Use the Navigation panel to:

- Enable the Diamond Keyer.
- Select a secondary layer.
- Sample the image.
- Extract a key.

Use the Function panel to adjust the key by setting softness and tolerance ranges, modify key edges, invert the key, and link layers.

**To enable the Diamond Keyer in the Navigation panel:**

- 1 Press the Key button once to activate the Key menu, and then press F2 to select the Diamond Keyer.

The Diamond Keyer is enabled.

**NOTE** To hide/show the hue cube, press Alt+Show.

**To select a secondary layer in the Navigation panel:**

- 1 Use the numeric keys to select and enable a secondary layer. Press the number key once to select the layer, and then double-press to enable it. To enable layer 10, press the minus button (-). To enable layer 11, press 0. To enable layer 12, press the C button.

**To sample the image in the Navigation panel:**

- 1 Press F3 (pick). The trackball on the Navigation panel is activated as a picker, allowing you to move through the image. Press F3 again to pick the current pixel for the sample. To sample an area of the image, hold down the ALT button while in picker mode and draw, with the trackball, a rectangular area of the image, and then release the ALT button.

**To extract a key in the Navigation panel:**

- 1 To extract a key after input primary grading has been performed and the input LUT has been applied, press F4. To switch back to the primary-graded result, press F4 again.

**To adjust a key in the Function panel:**

- 1 Use the following controls listed in the table below to adjust the key for the sampled colour.

Use:	To:
Wheels	Adjust tolerance, softness, and sharpness around the picked colour. Zoom in (left) and zoom out (right). Wheel 1= Tolerance Wheel 2= Softness Wheel 3= Sharpness Wheel 4= Zoom in/out

Use:	To:
Knobs at top left	Scale, skew, or translate (move) the chrominance Softness and chrominance Tolerance Diamonds. Knob 1=Scale Knob 2=Skew Knob 3=Translate
Upper left F2 and F5 buttons	Skew the chrominance Tolerance or chrominance Softness Diamonds horizontally and vertically. F2=Horizontal skew F5=Vertical skew
Upper left F3 and F6 buttons	Move the Softness Diamond or Tolerance Diamond left or right, up or down. F3=X-axis (left or right) F6=Y-axis (up or down)
Buttons in centre column	Enable master luminance for tolerance and softness and minimum/maximum luminance levels for tolerance and softness. F1=Master luminance for tolerance F2=Minimum/maximum for luminance for tolerance F4=Master luminance for softness F5=Minimum/maximum luminance for softness
Knobs at top right	Modify key edges and remove stray pixels from a key. Reduce image grain and noise, and keep edges intact prior to keyer input processing. Knob 4=Cleanup/Soften toggle Knob 5=Shrink Knob 6=Blur
Upper right buttons	Press F1 to enable cleanup (Key-out filter), shrink, and blur. Press F4 to enable soften (Key-in filter). F1=Cleanup F2=Shrink F3=Blur F4=Soften Single-press F2 and F3 to reset shrink and blur, respectively. Double-press F1 and F4 to reset cleanup and soften, respectively.
Upper right F6 button	F6=Invert the key
First row of buttons at bottom right	Press F1 to cycle through add, intersect, subtract, or link layers. F1=Add, intersect, subtract, or link F3=Invert link F5=Log to Lin F7=GPU Compatibility (G/C)
Second row of buttons at bottom right	Add softness/tolerance and remove softness/tolerance. F2=Tolerance F4=Softness

Use:	To:
	F6=Add softness/tolerance F8=Remove softness/tolerance Press F3 on the Navigation panel to change the cursor into a picker prior to using any of the above buttons. When done defining tolerance and softness, press F3 again.
ALT+SHOW buttons	Toggle the hue cube on or off.

## Toggling the Diamond Keyer Button On and Off

Users can toggle the on or off status of the Diamond Keyer button visible on the Navigation panel.

**To make the Diamond Keyer status visible on the Navigation panel:**

- 1 Press the Key button once to activate the Key menu, and then press F1 to enable the Diamond Keyer and activate backlighting to show its enabled status.
- 2 Double-press the F1 button to disable the Diamond Keyer.  
The Diamond Keyer is disabled in the Lustre application.

## Creating and Grading Geometries

When the Geom menu is enabled, you can create and colour grade up to 12 secondaries by using the Function panel to:

- Select a geometry type.
- Modify geometries.
- Link secondary layers.
- Delete geometries.

After you have created geometries, you can use the Grade menu to colour grade them.

**To create geometries:**

- 1 Press the Geom button on the Navigation panel.  
The Rectangle, Circle, Wipe (in Dual view), and Bezier (free-form geometry) options are activated.

- 2 Use the numeric keys on the Navigation panel to select and enable a secondary layer. Press the number key once to select the layer, and then press it a second time to enable it. To enable layer 10, press the minus button (-). To enable layer 11, press 0. To enable layer 12, press the decimal button (.).
- 3 Do one of the following:
  - Press F1 to add a rectangle.
  - Press F2 to add a circle.
  - Press F3 to add a wipe.
  - Press F4 to add a Bezier shape using the pen or mouse.
- 4 Use the jog ball as a geometry mover and press the ALT and shot forward buttons to select the geometries on the current active secondary layer.
- 5 On the Function panel, use the following controls to adjust the geometry.

Use:	To:
Wheels	<p>Modify the geometry's blur, colour, opacity, and softness.</p> <p>Wheel 1=Blur</p> <p>Wheel 2=Colour</p> <p>Wheel 3=Opacity</p> <p>Wheel 4=Softness</p> <p>The direction for edge softness is inwards or outwards depending on the direction that you rotate the wheel. To reset a wheel, press the button above it.</p>
Knobs at top left	<p>Scale the geometry.</p> <p>Knob 1=Size X</p> <p>Knob 2=Size Y</p> <p>Knob 3=Master (scales in locked proportions)</p> <p>To reset a knob, press the button below it.</p>
Knobs at top right	<p>Move the geometry.</p> <p>Knob 1=Move X</p> <p>Knob 2=Move Y</p>

Use:	To:
	Knob 3=Rotate To reset a knob, press the button below it.
First row of buttons at bottom right	Link secondary layers. F1=Add F3=Intersect F5=Subtract F7=Invert link
Second row of buttons at bottom right	Further modify softness. F2=Apply softness inside mask border F4=Apply softness outside mask border F6=Apply variable softness F8=Change softness type
F1 button in centre column	Delete the currently active geometry.
SHOW button	Toggle the geometry wireframe on or off.

- 6 To colour grade the geometry, select either the Inside or Outside option button depending on whether colour grading should occur inside or outside the geometry. See [Performing Colour Grading](#) (page 2499).

## Geometry Invert Functionality

Users can invert geometries on the current secondary layer using the Autodesk control surface.

**To invert geometries using the Autodesk control surface:**

- 1 On the Function panel, press the F4 button in the centre column.

## Cycling Among Geometries

You can now move from one geometry to the next in the order of their creation.

To cycle among geometries:

- 1 With the Geom menu enabled, hold down the ALT button on the Navigation panel and then press the Shot Forward or Shot Back button to cycle forward or backwards.

## Working with Stereoscopic Projects

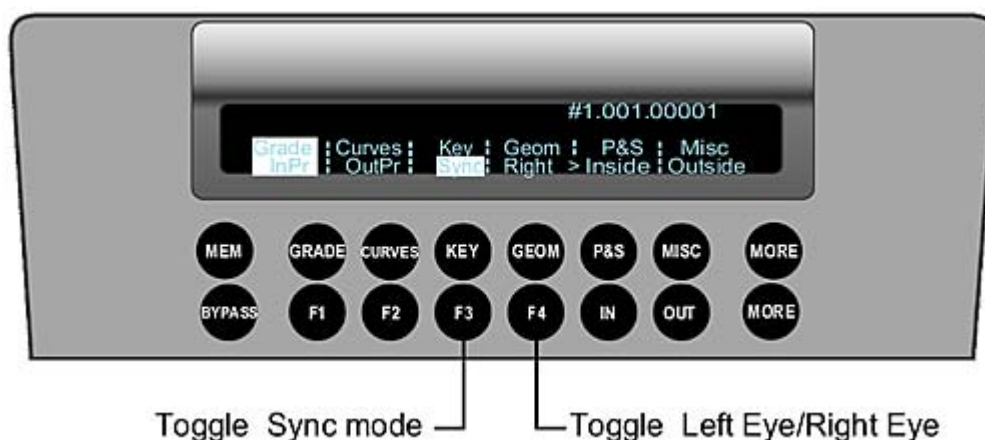

The Autodesk Control Surface panel accommodates common stereoscopic workflow operations. You must be in the Colour Grading or P&S menu to use these controls.

Using the Navigation panel, you can change the Sync mode state. You can also switch between the Left Eye and Right Eye.

When you are in Sync mode, you can use the Function panel to toggle the Convergence tool. See [Repositioning Shots](#) (page 2497).

To adjust stereoscopic features in the Navigation panel:

- 1 In the Navigation panel, enable the Grade or P&S menu.

- 2 You can use the following controls.

Press:	To:
F3	Toggle Sync mode.
F4	Toggle the assigned eye.

The Sync mode state and the assigned eye are displayed in the digital displays of the Navigation panel and Colour Grading panel. When Sync mode is enabled, the “L+R” appears in the digital display to indicate that grading affects both eyes.

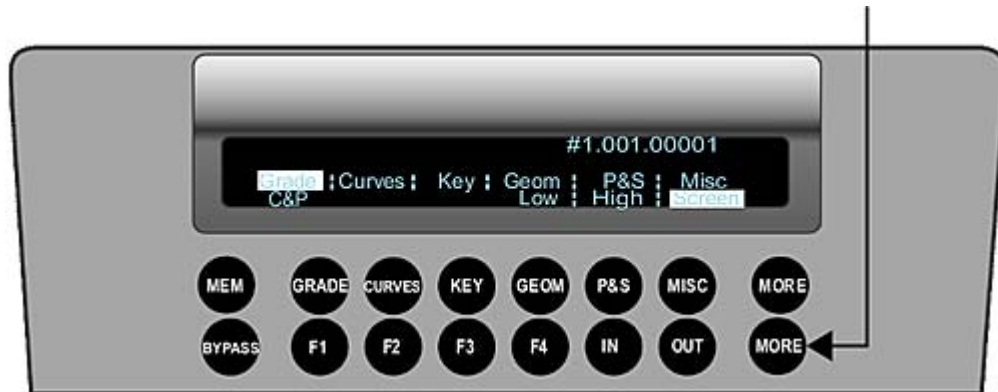

## Modifying the Appearance of the Autodesk Control Surface

You can customize the appearance of the control surface by accessing options from the bottom More button on the Navigation panel. Use these options to determine the brightness of:

- Backlighting for all buttons.
- Backlighting for a button being pressed.
- Backlighting for active and available buttons.
- The digital display.

To modify the appearance of the Autodesk control surface:

- 1 Press the bottom More button on the Navigation panel.

The Low, High, and Screen options appear in the digital display.

- 2 Press one of the following option buttons and use the ring portion of the trackball to increase or decrease brightness.

Press:	To change the brightness of:
F4	Backlighting for all buttons on the control surface. The change is visible as you modify with the ring.
IN	Backlighting for a button that is being pressed. The change is visible only when you press a button after having used the ring.
OUT	The digital display. The change is visible as you modify with the ring.

# ACS Hotkeys

Use these hotkeys on the Navigation panel.

Press:	To:
<div><div>ALT</div><div>+</div><div>MEM</div></div>	Enable the cache.
<div><div>ALT</div><div>+</div><div>BYPASS</div></div>	Bypass all menu parameters.
<div><div>ALT</div><div>+</div><div>RESET</div></div>	Reset the zoom and pan.
<div><div>ALT</div><div>+</div><div>MARK</div></div>	Add keyframes to all animation channels in the current frame.
<div><div>ALT</div><div>+</div><div>DO</div></div>	Save the current grade file and cut.

Press:	To:
 + 	Temporarily apply the grade from the previous shot to the current shot.
 + 	Temporarily apply the grade from the next shot to the current shot.
 + 	Cycle backward among the geometries (this is only applicable when the geometry menu is enabled).
 + 	Cycle forward among the geometries.

## The Tangent CP100 Control Surface

The Tangent CP100 control surface is designed to improve interactivity when colour grading film and video footage. You can accomplish many of the tasks you do in the Lustre user interface using the Tangent CP100 control surface.

The Tangent CP100 control surface is only supported on the Master Station.

You can do the following tasks with the control surface:

- Customize the view
- Toggle play mode
- Cache memory
- Navigate the Storyboard
- Undo and redo operations
- Copy grades from one shot to another
- Create and modify keyframes
- Reposition shots
- Perform primary colour grading
- Modify Hue curves
- Perform secondary colour grading

---

**TIP** While you learn how to do each of these tasks, show the user interface so that you can view the results in the menus.

---

Most buttons and dials on the control surface are labelled. For information on connecting the Tangent CP100 control surface, refer to the *Autodesk Lustre Software Installation Guide* for your platform.

#### To operate the control surface:

- 1 Do any of the following:
  - Press a button to select the displayed option.
  - Turn a dial to increase or decrease the value of the displayed channel or parameter. Turn clockwise to increase the value. Turn counter-clockwise to decrease it.
  - Use the Player controls to navigate the Storyboard.
  - Use the trackballs to modify the displayed parameter.

## Customizing the View

Use the controls on the lower right of the control surface to change the view as you work on your grades. For example, enable Half to view a half-resolution version of your shot in the Player.

You can select any of the following options.

Control Surface	Description	Hotkey or UI Option
GUI	Toggles the full-screen Player.	Enter
Geom UI	Shows or hides a geometry for the current secondary.	Show button in Secondaries menu
Matte	Switches between secondary view and result view.	F11 and F12
Split	Switches on and off split view in the Player. When you enable Split, you can press the PERFM button to enable multi-view and view up to 16 shots, or press the CUE button to switch between horizontal and vertical split view. These buttons are located on the upper right of the control surface.	F5, F3, and F4
Half	Switches between the full-resolution and half-resolution (proxy) version of your shot in the Player. If you have not rendered a proxy, an X appears in the Player.	F9
Zoom/Home	Switches between the 1x and 2x zoom.	F10
Render	Switches between a rendered version of your shot and output view. If you have not rendered the shot, an X appears in the Player.	P
Label	Toggles the shot name text on the image.	W
PRIM	Toggles the display of your shot. Displays your shot as it appears after modifications are made from the Grading or Curves menu, or as it currently appears (with the entire colour grade applied). You can use this option only after you have added secondaries.	I
Result	Displays the shot as it currently appears—with the grade applied.	O

**NOTE** Press the MORE button to view all the available options.

## Toggling Play Mode

You can loop play a shot or the entire Storyboard using the ClipPl button. This button corresponds to the Play Mode button in the user interface.

## Caching Memory

When a shot does not play back in real time, you can cache the frames into memory using the Cache button or by pressing M.

## Navigating the Storyboard

Use the Player controls on the lower right and the scrolling controls on the left to navigate the Storyboard.

Use the left dial (jog knob) and transport controls to play and scrub the Storyboard. You can also use the Alt button to switch between shots assigned to Playhead A and Playhead B.

### Player Controls

Use the right dial to scroll through the shots in the Storyboard. When you scroll, a yellow arrow in the Storyboard marks your position. You can then select the shot by pressing the button next to the dial.

---

**NOTE** If the shot is outlined in blue, you are in copy mode. See [Copying Grades](#) (page 2541).

---

You can show the Storyboard all the time or only when you scroll. To show the Storyboard all the time, press **Tab** on the keyboard. To show the Storyboard only when you scroll, first hide it by pressing **Tab**, and then scroll the Storyboard. In this mode, you hide the Storyboard again by pressing the button next to the scroll dial.

## Undo List

The undo list works differently on the control surface than it does in the user interface. Use the buttons on the lower right of the control surface to work with the undo list.

## Saving to the Undo List

When you use the control surface, you must save your changes to the undo list. Undo lists are saved on a shot-by-shot basis. To save a change to the undo list, press **Do**. You can then press **Undo** and **Redo** to go through the undo list.

## Reverting to Previous Grades

Use the Alt button on the lower right to toggle between the grade that was applied to a shot when you first selected it in the Storyboard and the current grade.

---

**TIP** To save the reverted stage to the undo list, press Do.

---

## Comparing Grades

You can compare the current image with the grade you last committed to the undo list. To toggle between these settings, use the Mix button.

## Resetting Parameters

On a shot-by-shot basis, you can reset the parameters set in some menus. You can also reset a single parameter.

**To reset a parameter:**

- 1 Press the Reset button associated with the dial or trackball.

To reset a menu:

- 1 Select the menu and then enable Reset. For example, select Geom, and then press Reset to clear all secondaries.

## Copying Grades

You can temporarily or permanently copy a grade from another shot in the Storyboard to the current shot.

### To copy grades:

- 1 Do one of the following:
  - Press Prev or Next to temporarily apply the grade from the previous or next shot to the current shot (outlined in red or magenta). Press Prev or Next multiple times to move through the shots in the Storyboard. The selected shot is outlined in blue.
  - Press Offset and then scroll through the shots. As you scroll, the grades are temporarily applied to the current shot (outlined in red or magenta). The selected shot is outlined in blue.

**TIP** Press the Offset button again to switch to scroll mode.

- 2 Press Do to permanently copy the grade from the shot outlined in blue to the current shot.

## Adding and Moving Keyframes

When you animate parameters, you can set keyframes using the Mark button. You can also adjust the timing of the first and last keyframes in the shot.

### To add a keyframe:

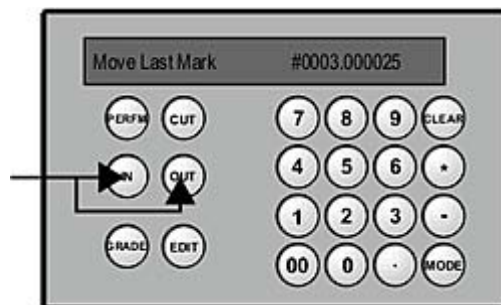

- 1 Go to the frame where you want to add the keyframe.

- 2 Press Mark.

To adjust the timing of an existing keyframe:

- 1 Do any of the following:
  - Press In and then use the right dial to move the first keyframe.
  - Press Out and then use the right dial to move the last keyframe.

## Repositioning Shots

You can reposition a shot by scaling it, or by panning it vertically and horizontally.

To reposition a shot:

- 1 Enable PanScn.

- 2 Use the following controls to reposition the shot.

## Primary Colour Grading

You can use the dials and trackballs in the centre of the control surface to perform primary colour grading. Primary colour grading can be done from the Grade menu.

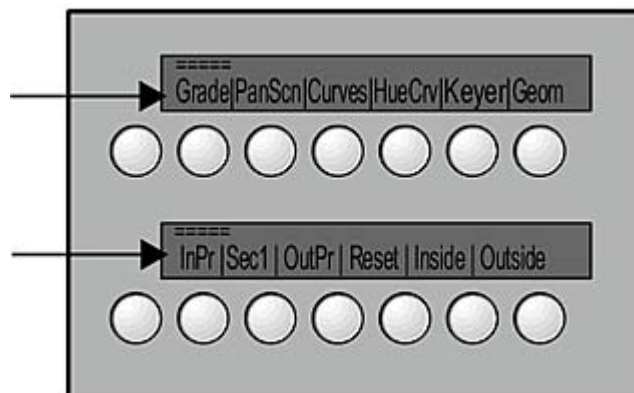

## Logarithmic Mode: Modifying Brightness and Contrast

You can modify brightness and contrast in several ways from the Grade menu. You can modify:

- Overall brightness and contrast of the red, green, and blue channels together.
- Overall brightness and contrast of the red, green, and blue channels separately.
- Brightness balance and contrast balance.
- Brightness in the shadows, midtones, and highlights.

To modify brightness and contrast:

- 1 Enable Grade and then do one of the following:
  - Enable InPr to modify the input primary values.
  - Enable OutPr to modify the output primary values.

- 2 Use the following controls to perform primary colour grading.

## Linear Mode: Modifying Gamma, Gain, and Lift

You can modify gamma, gain, and lift in several ways from the Grading menu. You can modify:

- Overall gamma, gain, and lift settings of the red, green, and blue channels together.
- Overall gamma, gain, and lift settings of the red, green, and blue channels separately.
- Gamma, gain, and lift balance settings.

To modify gamma, gain, and lift:

- 1 Enable Grade and then do one of the following:
  - Enable InPr to modify the input primary values.
  - Enable OutPr to modify the output primary values.

- 2 Use the following controls to perform primary colour grading.

## Modifying the Hue, Saturation, and Lightness Curves

You can modify the hue, saturation, and lightness curves that appear in the Curves menu. You can modify the entire curve uniformly or modify individual vertices for RGB/CMY channels (red, green, blue, cyan,

magenta, and yellow). You must toggle between controls that modify the position of the red, green, and blue vertices and those that modify the position of the cyan, magenta, and yellow vertices.

**To modify hue, saturation, and lightness curves:**

- 1 Enable HueCrv to access controls for the red, green, and blue vertices.

- 2 Use the following controls to modify the hue, saturation, and lightness curve at each displayed vertex.

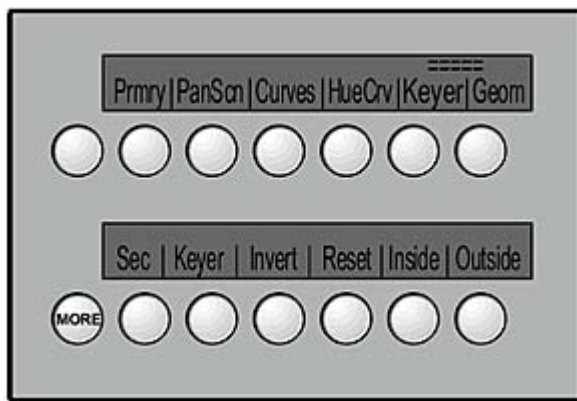

- 3 Press HueCrv again to access controls for the cyan, magenta, and yellow vertices, and then modify the curves.

## Secondary Colour Grading

You can colour grade up to eight secondaries from the control surface.

**To access a secondary:**

- 1 Enable Keyer.

The secondary controls for the first secondary appear. Once you enable and key a secondary, you can modify hue, gain, and saturation. You can also modify the brightness and contrast of the current secondary.

- 2 On the right side of the control surface, press Recall and then press a number between one and eight to go to that secondary. You can also press Selectv to toggle through the eight secondaries.

## Applying Secondaries to the Shot

Use the second row of buttons on the left side of the control surface to set basic parameters for secondaries.

Press:	To:
Sec	Switch on and off the current secondary.
Keyer	Switch on and off the Keyer for the current secondary.
Invert	Invert the key for the current secondary.
Reset	Reset the key for the current secondary.

Enable the Sec button to apply the displayed secondary to the shot.

## Creating Keys

Enable the Keyer button and then use the controls in the centre of the control surface to create a key.

**To create a key:**

- 1 Enable Keyer in the upper control surface menu, and then enable Keyer in the lower menu.
- 2 To sample initial softness and tolerance, press F1 on the control surface and then use the left trackball to position the colour picker over the image. Press F1 again to sample the image.

**NOTE** Sampling from the control surface works slightly differently than sampling from the Lustre user interface. When you sample from the control surface, the value and saturation channels are set to the maximum softness. When you sample from the user interface, the value and saturation channels are not set to maximum values.

- 3 Set the hue, brightness/gain, and saturation levels for the key. Each value is modified according to the original sample—you can adjust the centre tolerance value, as well as the softness and tolerance ranges.

- 4 Press More (lower left) to shrink, blur, or clean up the edges of the key.

The Cleanup, Shrink, and Blur controls appear.

## Creating Geometries

You can create and apply basic and free-form geometries to each secondary.

To create a geometry:

- 1 Enable Geom and then select the shape from the second row.

- 2 Use the controls in the centre of the control surface to modify the shape of the geometry, as well as its colour, opacity, and position on the image. You can also apply a blur.

- 3 To set softness, use the Geometry Softness dial.

- 4 To apply logical operations to the geometry, or invert the geometry, press the More button associated with the second row on the left.

## Moving Geometries

You can move geometries from the control surface.

### To move a geometry:

- 1 To select a geometry, press F1 on the control surface and then use the left trackball to position the cursor over the geometry. Press F1 again to select it. Alternatively, press F2 and F3 to move back and forth through the geometries (listed in the Axes list).
- 2 Use the left trackball to move the geometry.
